PREFACE

Elke KAHR

Mayor of the City of Graz

Welcome to Graz!

As the Mayor of the City of Graz, I am very pleased that the 30th anniversary of the REAL CORP conference is taking place here in Graz, allowing us to welcome world-renowned experts from the fields of spatial planning, geoinformation, and related disciplines.

As the second largest city in Austria – in fact the largest city in the country if you count our capital city Vienna as a federal state – Graz sees itself as a medium-sized agglomeration in global terms, with just over 300,000 inhabitants, even when considering the functional urban region around Graz. We are therefore all the more pleased that this year's REAL CORP is focusing specifically on the challenges and needs of medium-sized cities. Unlike large cities, metropolitan areas, or capital cities, the framework conditions of medium-sized cities and their urban regions are unique.

This begins with their financial capacity and extends to the provision of central functions and services of general interest for the whole region. Urban morphologies are also less dense, yet the challenge under growth conditions is to make sensible and efficient use of the limited urban space available and to allow developments that improve or at least do not reduce the local quality of life.

In Graz, great emphasis is placed on ensuring a high quality of life and that the benefits of the city are accessible to all its residents. Graz is a diverse and culturally appealing city. It is crucial that living and housing costs remain affordable for the population and that social cohesion is highly valued. This commitment to inclusivity and affordability helps maintain the city's vibrant community spirit and ensures that everyone can enjoy the advantages of living in Graz.

REAL CORP participants will be exchanging knowledge and ideas on precisely these kinds of topics for the 30th time this year here in Graz. Current developments from the global to the local level will be discussed, and new ideas, partnerships, and projects will be developed. As a central science and business location in southern Austria, Graz has traditionally acted as a bridge to southern and southeastern Europe. For this reason, we are particularly pleased about event formats such as REAL CORP, which allow us to look beyond our own horizons and provide us with inspiration.

I wish you a successful conference and would be delighted if you take home a positive image of our city – and maybe come again.

PREFACE

Judith SCHWENTNER

Deputy Mayor of the City of Graz

Actively meeting the challenges of climate change

Climate change affects us all and is fundamentally changing our lives. It is essential that we respond to it in both small and large ways. A front garden with bee-friendly flowers may be a small measure, but it is just as important as international cooperation. Medium-sized cities like Graz in particular play a key role: they may not be as big as metropolises, but their large number and combined expertise means that together they can have an enormous impact. The exchange of experience and knowledge between these cities makes it possible to spread sustainable solutions globally.

Of course, the framework conditions and challenges differ from city to city. Graz holds the title of UNESCO World Heritage Site and therefore has a special responsibility to preserve its historic centre. At the same time, the city is growing rapidly, bringing new challenges in the areas of climate and health-oriented urban development, environmentally friendly mobility and the clean energy transition. However, Graz is actively facing up to these challenges and is resolutely committed to the fight against the climate crisis.

I am therefore all the more pleased that REAL CORP 2025 is taking place in Graz this year. As hosts, we have the opportunity to present our achievements while also discussing upcoming challenges with international experts from administration, science and business. I am looking forward to an inspiring exchange that will provide valuable impulses for the sustainable future of our beautiful city.

PREFACE

Harald GRIESSER

Styrian Government
Head of Provincial and Regional Development

Welcome to Styria!

Since my student years the REAL CORP conference – at that time a small event at TU Wien – has been the meeting place for discussions related to the topic of digitalisation in spatial planning. Many years later, topics such as digital planning processes, artificial intelligence in planning and the actual use of digital instruments have become part of our daily working routine.

Since the beginning REAL CORP has remained, developed and internationalized as a platform for lively scientific debates and inspiring interactions with colleagues from all over the world. At this event, you can still get a feel for the state of the art in regional planning and urban development and get a glimpse into the future "hot topics" of digital planning.

It is a special honour and pleasure for our province that REAL CORP is stopping in Styria this year. We hope that all participants will spend some interesting days in Graz. Above all, however, we hope that these days will convey to all participants the Styrian wayof life – halfway between the Alps and the Adriatic – and that this will be a reason to return, both professionally and privately.

PREFACE

Manfred SCHRENK,

Conference Director,
President CORP – Competence Center of Urban and Regional Planning

WELCOME to REAL CORP 2025, the 30th International Conference on Urban & Regional Development and Spatial Planning in the Information Society Technologies at the University of Applied Sciences Joanneum in Graz, Styria!

Not only is the world's population constantly growing, many cities around the globe are also subject to permanent growth, even in countries and regions with constant or even shrinking population numbers. Global urbanisation is not only creating new challenges in terms of infrastructure, mobility, housing and spatial planning, but especially in climate mitigation and adoption, in technological change – especially digitisation, in resilience towards multiple natural and man-made challenges and in inclusion and accessibility to improve the quality of life even under adverse conditions.

In world's megacities, such challenges have to be tackled on a large scale – with all the technical, organisational, administrative hurdles that have to be dealt with. What about medium-sized and smaller cities? Can they be faster, more flexible, more efficient than the "big tankers" when it comes to innovations? Can they lead the way to a bright future? Can they take us to solutions that help us to boldly go where no cities have gone before, especially when it comes to the criteria of sustainability, resilience and especially quality of life for the whole society? Can solutions developed on a smaller scale be upscaled to metropolises on the one hand and even trickle down to small cities and rural regions? Can measures be easily scaled up and down or do they require completely different approaches?

Traditionally we are keeping the range of topics at REAL CORP conferences very broad – as we are convinced that it is advantageous and necessary to use the conference to hear about other topics, to get inspired by similar and maybe totally different approaches and very important: getting to know experts and personalities with the same and also different professional, organisational, cultural backgrounds and networking with them – to possibly develop new ideas and – by URBAN INNOVATION help cities TO BOLDLY GO WHERE NO CITIES HAVE GONE BEFORE.

The success of the REAL CORP conferences is – clearly without doubt – the result of the efforts of participants, reviewers, and the conference organising team. We would like to acknowledge the Reviewer Team and Programme Committee members for their valueable voluntary help with the review process. Our thanks go as well to all 200 participants and authors of the submitted papers from 31 countries worldwide. The programme of this year's conference contain around 160 scientific contributions; 98 of them were selected after a double-blind, double-stage (for both abstracts and full papers) peer-review process for publication and presentation at REAL CORP 2025. The non-reviewed papers were accepted by the programme committee after a double-blind abstract review.

Welcome to Graz! Welcome to Styria! Have a great conference!

1 ABSTRACT

The relationship between homelessness and urban security is a complex and multifaceted global issue. In many cities, visible homelessness can influence public perceptions of disorder and insecurity, perpetuating cycles of marginalization, criminalization, and social exclusion for those experiencing homelessness. At the same time, homelessness is often a direct consequence of insecurity, driven by factors such as violence, displacement, and economic instability. This study seeks to deepen the understanding of this intricate interplay by conducting a comprehensive bibliometric analysis of scholarly literature on homelessness and urban security. Utilizing the Scopus database and VOSviewer software, the research systematically investigates past, present, and emerging trends within this field. The analysis focuses on co-authorship networks, keyword co-occurrence patterns, and citation trajectories to achieve three primary objectives: (1) identify key research themes and trends, (2) map the intellectual structure of the field, and (3) pinpoint influential scholars and institutions shaping the discourse. The findings will offer critical insights into the current state of knowledge on homelessness and urban security, highlighting significant research gaps and underexplored areas. By uncovering the intellectual foundations and evolving priorities of this field, the study aims to inform future research directions and provide evidence-based recommendations for urban planning and policy development on a global scale. This work underscores the importance of addressing homelessness not merely as a social issue but as a critical component of urban security and sustainable urban development.

Keywords: homelessness, urban security, bibliometric analysis, Scopus database, urban planning

2 INTRODUCTION AND BACKGROUND

The relationship between homelessness and urban security is a complex and multifaceted global issue. In many cities, visible homelessness can influence public perceptions of disorder and insecurity, perpetuating cycles of marginalization, criminalization, and social exclusion for those experiencing homelessness. At the same time, homelessness is often a direct consequence of insecurity, driven by factors such as violence, displacement, and economic instability. This study seeks to deepen the understanding of this intricate interplay by conducting a comprehensive bibliometric analysis of scholarly literature on homelessness and urban security. Utilizing the Scopus database and VOSviewer software, the research systematically investigates past, present, and emerging trends within this field. The analysis focuses on co-authorship networks, keyword co-occurrence patterns, and citation trajectories to achieve three primary objectives: (1) identify key research themes and trends, (2) map the intellectual structure of the field, and (3) pinpoint influential scholars and institutions shaping the discourse. By uncovering the intellectual foundations and evolving priorities of this field, the study aims to inform future research directions and provide evidence-based recommendations for urban planning and policy development on a global scale.

This work underscores the importance of addressing homelessness not merely as a social issue but as a critical component of urban security and sustainable urban development. The significance of this study lies in its potential to provide critical insights into the intersection of homelessness and urban security, which remains an underexplored yet essential issue in contemporary urban research and policy-making. Homelessness is often perceived as a problem relegated to the margins of urban spaces, yet its impacts on both individuals and communities extend far beyond the personal hardships of those affected. By linking homelessness to urban security, this research brings attention to the broader socio-political and economic structures that contribute to urban vulnerability, marginalization, and exclusion. Furthermore, this paper aims to make a significant contribution to the field of homelessness and urban security by developing aconceptual

framework that deepens the understanding of the intricate and often underexplored relationship between these two critical urban issues.

3 GLOBAL PERSPECTIVES ON HOMELESSNESS AND URBAN SECURITY

Homelessness is a multi-dimensional problem that is deeply embedded within broader societal structures. It is often linked to issues such as poverty, unemployment, housing shortages, mental illness, substance abuse, and, crucially, urban policies that fail to address the needs of vulnerable populations (Fitzpatrick, 2018). In many cities, homelessness is seen through the lens of disorder and criminality, leading to stigmatization and the implementation of policies that criminalize homelessness rather than addressing its root causes. The dynamics of homelessness and urban security are shaped by multiple factors, including social, political, economic, and environmental influences, all of which contribute to the vulnerability and exclusion of homeless individuals (Sosin & Pollack, 2020).Globally, the challenge of homelessness is a pressing issue in both developed and developing nations. The United Nations has estimated that over 150 million people worldwide experience homelessness, with many more living in precarious housing situations (UN-Habitat, 2020). In cities across the globe, homelessness is a visible sign of urban inequality and insecurity, and it is often linked to rising levels of poverty, displacement, and conflict (Shinn & Khadduri, 2020). In the Global South, cities are grappling with rapid urbanization, slum development, and a lack of affordable housing, all of which contribute to high rates of homelessness (Afsar et al., 2020). Meanwhile, in the Global North, while homelessness rates may be lower, the visibility of homelessness in wealthy cities often exacerbates public concerns about disorder and crime, leading to more punitive measures against homeless populations (Chamberlain & MacKenzie, 2021).

For example, in the United States, homelessness is largely understood as a consequence of economic insecurity, with homelessness rates sharply rising during times of recession. The criminalization of homelessness is prevalent, with homeless individuals facing frequent arrests for “quality of life” offenses such as loitering or trespassing (Hopper, 2020). Similarly, in the United Kingdom, the rise in homelessness has been attributed to a combination of austerity policies, a lack of affordable housing, and cuts to social services (Pleace, 2019). The United Nations (2020) reports that homelessness is increasingly seen as a violation of human rights, with homeless people experiencing disproportionate levels of violence, abuse, and discrimination, further compounding their vulnerability in urban settings.In the Global South, the relationship between homelessness and urban security is particularly complex, with urban poverty and informal housing systems playing a central role. In African cities, the rapid growth of urban populations combined with inadequate urban planning has led to the proliferation of informal settlements and increased homelessness. In cities like Johannesburg and Nairobi, homelessness is often a direct result of economic displacement, lack of affordable housing, and the failure of governments to address the needs of marginalized populations (UN-Habitat, 2018). Informal settlements, which are characterized by inadequate housing, poor sanitation, and limited access to basic services, often become hotspots for insecurity and violence, further exacerbating the marginalization of homeless individuals (López-Morales, 2020).

Furthermore, in many African countries, economic instability and political violence have contributed to rising levels of displacement, both internally and across borders, creating a growing homeless population in urban centers (Hardoy et al., 2020). These conditions are compounded by the widespread criminalization of homelessness, as homeless individuals are often subjected to police harassment, forced eviction, and exclusion from public spaces, which only deepens their vulnerability (Lall, 2019). As a result, the intersection of homelessness and urban security in the Global South reflects a vicious cycle of marginalization, insecurity, and exclusion, which demands urgent attention from both policymakers and researchers. In South Africa, homelessness is a major urban challenge that reflects deep-rooted social and economic inequalities. The legacy of apartheid, which systematically excluded black South Africans from access to land, housing, and resources, has left a lasting impact on the urban landscape, particularly in major cities such as Johannesburg and Cape Town (Ntsimane, 2018). While South Africa has made significant strides in addressing housing needs through policies such as the Reconstruction and Development Programme (RDP), the country continues to face a growing homelessness crisis. This is largely due to factors such as rapid urbanization, inadequate public housing provision, and a rising unemployment rate (Statistics South Africa, 2020).

Homelessness in South African cities is also deeply intertwined with issues of urban security. In many urban areas, the presence of homeless individuals in public spaces is often viewed as a threat to security, leading to the criminalization and policing of homelessness (Olivier & Riemer, 2019). As public perceptions of insecurity rise, policymakers often resort to short-term, punitive measures such as the eviction of homeless people from public areas or the implementation of anti-loitering laws. These actions further contribute to the exclusion and stigmatization of homeless individuals, who are already vulnerable to violence and exploitation in urban spaces (Berg, 2021).Recent literature on homelessness and urban security highlights several key themes and emerging trends. One of the most prominent trends is the increasing recognition of homelessness as a human rights issue, with calls for policies that prioritize the dignity and well-being of homeless populations rather than focusing solely on criminalization (Fitzpatrick et al., 2013). Additionally, there is growing recognition of the role that urban planning and policy interventions can play in addressing homelessness, with researchers advocating for more inclusive and sustainable urban development models that prioritize affordable housing, public space access, and social services for marginalized communities (Turok, 2019).

However, despite these advancements, significant research gaps remain. There is a need for more studies that explore the relationship between homelessness and urban security in different geographical contexts, particularly in the Global South, where issues of displacement, informal settlements, and inadequate housing systems continue to drive homelessness. Moreover, the intersection of homelessness with other urban issues, such as crime, mental health, and substance abuse, remains underexplored and warrants further investigation.This is where this study intends to contribute.

4 METHODOLOGY

This study aims to deepen the understanding of the relationship between homelessness and urban security through a comprehensive bibliometric analysis of scholarly literature. The review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol to ensure a rigorous and transparent process for selecting and analyzing relevant publications. A comprehensive search was conducted in the Scopus database on 11 February 2025, focusing on peer-reviewed journal articles, books, and conference papers. The key search terms used was“homelessness AND urban security". The Scopus database was selected as the primary source for this study due to its extensive coverage of peer-reviewed literature across various disciplines, including urban planning, architecture, sociology, and cultural studies (Bass et al., 2020). The process followed is detailed in the diagram below:

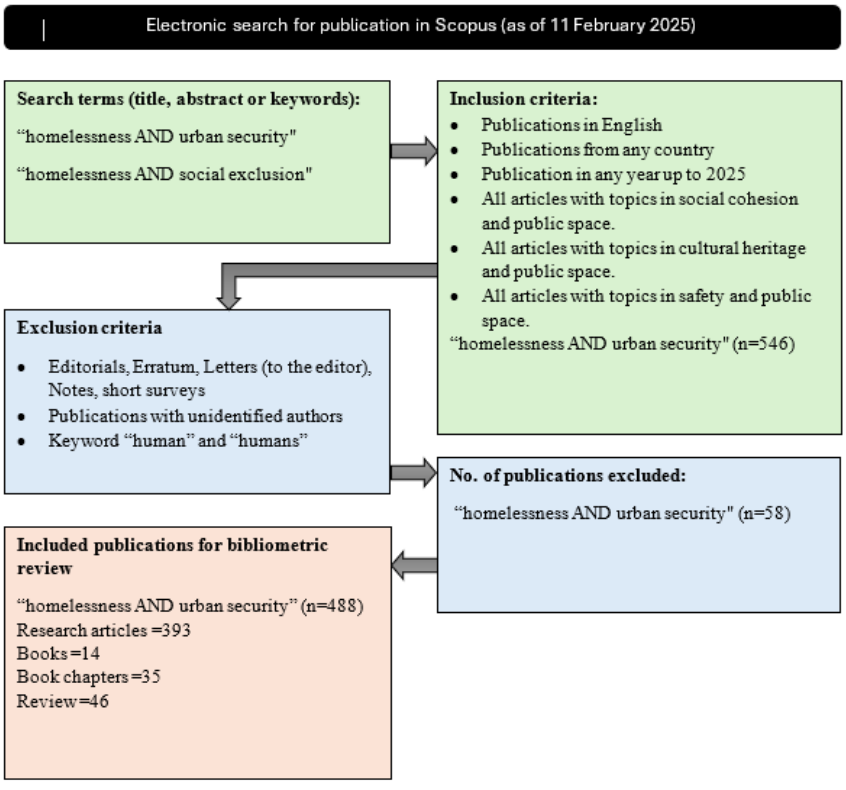

Figure 1: PRISMA flow diagram (Adapted from Moher et al. ,2016)

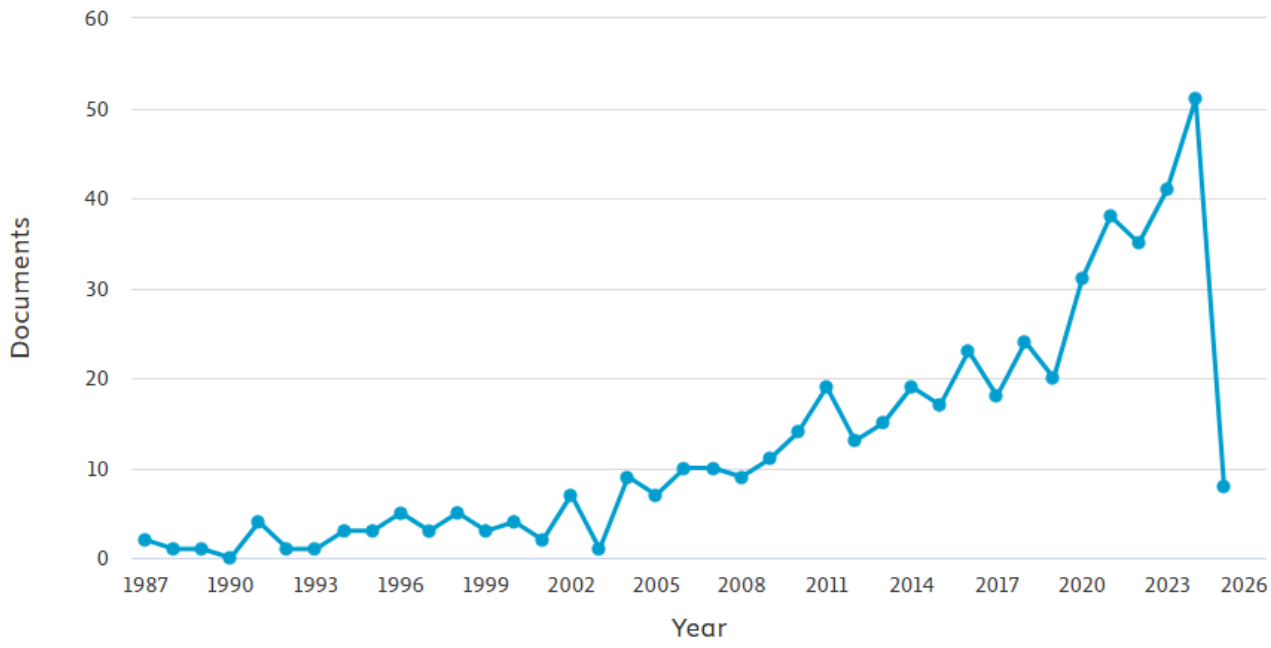
The initial searchyielded546publications on homelessness and urban security. After applyingtheinclusion and exclusion criteria, 58 publications were excluded, leaving a total of 488 eligible documents to beconsidered as part of the bibliometric analysis. VOSviewer was utilizedtoconductthebibliometricanalysis, as outlined in the figure below (Van Eck andWaltman, 2014).VOSvieweris a software tool that visually analyzes literature reviews, identifying trends, research foci, and key areas (Zhang et al., 2021). While other analysis tools like Citespace have been used in other studies, VOS viewer remains the preferred choice due to ist ability to handle large datasets and produce reliable results (Kalaoane et al., 2024).

5 RESULTS AND DISCUSSIONS OF THE BIBLIOMETRIC ANALYSIS

5.1 Publication trends

The graph representing publication trends on homelessness and urban security over nearly four decades reveals distinct fluctuations that warrant careful examination. From 1987 to the early 2000s, the number of publications in this field remained relatively low, indicating a nascent stage of research output. The early years of this period could reflect the challenges associated with the study of homelessness and urban security, both of which are complex, multifaceted issues often shaped by socio-economic, political, and cultural factors (Pritzker & Pascoe, 2020). During this time, homelessness was likely treated as a peripheral issue within urban studies, and research on the topic may not have been as prioritized or funded as other urban phenomena (United Nations, 2019).



However, from 2002 onwards, there is a notable surge in the number of publications, suggesting a significant shift in the research landscape. This escalation could be attributed to several factors. Firstly, an increase in research funding dedicated to urban studies and social issues, such as homelessness, likely played a significant role in this growth. Increased interest in urban security and homelessness can also be linked to technological advancements in data collection and analysis, which enabled researchers to study these issues more effectively (Fink & Freedman, 2022). For instance, the availability of satellite imagery, social media data, and geographic information systems (GIS) may have provided new insights into the spatial distribution of homelessness and urban safety, fueling academic interest (Fink & Freedman, 2022). Additionally, the early 2000s coincided with a heightened global awareness of social inequalities and urban poverty, which would have led to increased public and governmental interest in homelessness (Pritzker & Pascoe, 2020).

Moreover, international organizations such as the United Nations and the World Bank began publishing extensive reports on urbanization and poverty, contributing to a more focused academic and policy-driven dialogue on urban security and homelessness. This increased focus on policy relevance and the importance of addressing homelessness through systemic change likely spurred more researchers to engage with the

issue (United Nations, 2019). The significant rise in publications during this period is thus likely a result of a combination of institutional support, technological advancements, and a broader social agenda centered on poverty alleviation and social justice (Pritzker & Pascoe, 2020).The graph also reveals a plateau in publications after the initial surge, followed by a further escalation, reflecting the continued expansion of research in this area. This could point to an increased institutional recognition of the need for research on urban security as cities around the world faced growing challenges related to homelessness, particularly as urbanization rates soared. Researchers may have been spurred by the need for evidence-based policy solutions in the face of ongoing urbanization and the global housing crisis, as well as increasing concerns about social instability and security in metropolitan regions (Fink & Freedman, 2022).

Nevertheless, the most recent data point reveals a sharp decline in publications, which presents a critical opportunity for further inquiry into potential contributing factors. Several explanations can be posited for this downturn. One possible factor could be a shift in research priorities, where funding bodies and academic institutions may have reoriented their focus toward other pressing global issues, such as climate change, pandemics, or economic crises (Fink & Freedman, 2022). Moreover, the decline may reflect the limitations of existing funding sources, which could have been affected by global economic downturns, leading to fewer resources available for research on homelessness and urban security.A potential, albeit significant, factor in this decline could be the disruption caused by the COVID-19 pandemic. The pandemic caused widespread interruptions to academic research across all fields, with many research projects delayed, paused, or canceled entirely. Homelessness became an even more pressing issue during the pandemic as vulnerable populations were disproportionately affected by the virus, leading to an influx of governmental and NGO interventions. However, the pandemic may have also reshaped the research agenda, drawing attention away from long-standing issues and towards the immediate public health crisis, further compounding the decline in publications (Fink & Freedman, 2022).

5.2 Keyword Analysis

The network visualization presented provides a powerful tool for understanding the intricate relationships between key concepts related to homelessness and urban security. The map's structure, where nodes represent individual concepts and edges denote their co-occurrence, offers a snapshot of how these issues are interconnected. By identifying clusters of related themes, such as housing, food security, and demographic factors, the map facilitates a comprehensive view of the multifaceted nature of homelessness and urban security.

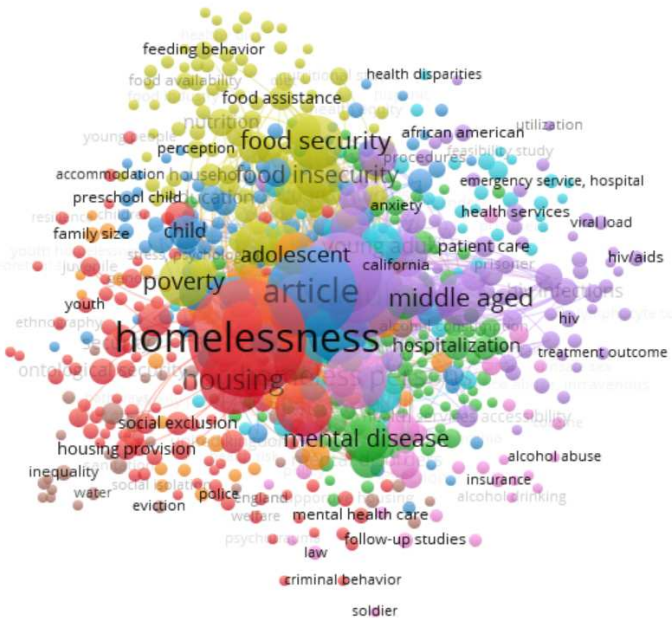


Figure 2: A co-occurrence network analysis of keywords on homelessness and urban security research.

The analysis emphasizes the prominence of central nodes such as "homelessness," "mental disease," "food security," and "poverty," noting their role as key themes that bridge multiple aspects of social vulnerability. These findings align with existing literature that highlights how homelessness, mental health issues, and

poverty form a cycle of disadvantage, reinforcing each other and exacerbating the challenges faced by vulnerable populations (Desmond & Shyr, 2014). The interconnections between these nodes are significant because they underscore the complexity of these issues. For instance, homelessness is not only a housing issue but is deeply entwined with mental health disorders and poverty, as individuals experiencing homelessness are more likely to suffer from mental health conditions and face greater barriers to economic mobility. While the centrality of these concepts is valid and reflective of current research, the network visualization may also oversimplify the intricate dynamics at play. It is crucial to consider that these relationships are not always linear or static. For example, the link between homelessness and mental health is well-established, but the nature of this relationship can vary depending on individual circumstances, such as the duration of homelessness, access to mental health services, and the presence of other social supports (Padgett et al., 2016). The visualization's inability to capture the directionality or causal pathways between nodes limits its ability to fully represent the complexity of these interactions.

The map's inclusion of food security as a central concept further illustrates the interconnectedness of social determinants. Research indicates that food insecurity is not only a consequence of poverty but also a driver of poor health outcomes, particularly for marginalized groups (Gundersen et al., 2018). The co-occurrence of food security with homelessness and mental health reflects this cyclical vulnerability, where inadequate access to nutritious food exacerbates both physical and mental health conditions, further entrenching poverty and homelessness. However, the visualization may not adequately account for the role of food assistance programs and social safety nets in mitigating these impacts. The connections in the map suggest a relationship between food security and food availability, but they do not offer insights into the effectiveness of interventions such as food banks or government programs in alleviating food insecurity. The presence of demographic factors, such as "African American," "adolescent," "child," and "middle-aged," is a critical aspect of the visualization, drawing attention to the disproportionate impact of these issues on specific populations. This aligns with extensive research on the social determinants of health, which highlights how race, age, and socio-economic status intersect to create unique vulnerabilities (Kawachi et al., 2017). For example, African Americans are more likely to experience homelessness and food insecurity, which can be attributed to historical and structural inequalities in access to resources and opportunities. The inclusion of these demographic factors is vital for informing targeted, equity-focused interventions, but the network map may not fully capture the intersectionality of these populations. A more nuanced approach might consider how overlapping identities – such as race, gender, and disability – shape individuals' experiences of homelessness and urban insecurity.

Furthermore, the visualization's focus on healthcare access and utilization is crucial for understanding how these social vulnerabilities impact health outcomes. As highlighted in the analysis, healthcare access is a key determinant of well-being for those experiencing homelessness or food insecurity. However, the map does not delve into the specific barriers to healthcare that these populations face, such as lack of insurance, transportation issues, or stigma. A more detailed examination of healthcare access could reveal important insights into how systemic barriers exacerbate health disparities among these vulnerable groups. From an urban planning perspective, this analysis is important as planners are tasked with addressing multifaceted issues, such as housing insecurity, poverty, food security, and healthcare access, all of which are interlinked and have profound implications for public health and social equity (Kawachi et al., 2017). By understanding these interconnections, planners can design more holistic and inclusive urban policies and infrastructure that address the root causes of homelessness and urban insecurity.

5.3 Top countries and scholars publishing research on homelessness and urban security

The analysis of publication trends on homelessness and urban security reveals significant variation across countries, with some nations exhibiting higher output and influence in this field. The United States stands as the dominant contributor, with 214 publications, 5243 citations, and the highest total link strength (26). This prominence can be attributed to the scale of homelessness in American cities, where the issue has been the focus of extensive academic and policy attention. The U.S. has numerous research institutions and a well-funded research environment, with government bodies like the U.S. Department of Housing and Urban Development (HUD) driving major studies on homelessness. Furthermore, the "Housing First" model has become a leading intervention, stimulating substantial academic and policy discourse (Padgett et al., 2016). Canada's rising output (78 publications, 2102 citations, and a total link strength of 19) also reflects a strong

policy focus on affordable housing, poverty reduction, and homelessness prevention. The Canadian government's National Housing Strategy, launched in 2017, further fueled interest in the issue, with scholars addressing the intersections of homelessness, mental health, and housing affordability, particularly among marginalized groups such as Indigenous communities (Gaetz et al., 2019).

Country	Documents	Citations	Total link strength
United States	214	5243	26
Canada	78	2102	19
Australia	66	749	13
United Kingdom	45	907	10
France	9	83	7
Netherlands	10	75	7
Ireland	11	65	6
Germany	7	27	5

Australia ranks third with 66 publications, 749 citations, and a total link strength of 13. In Australia, research on homelessness has gained momentum as urban areas such as Sydney and Melbourne have faced housing affordability crises. Researchers in Australia have focused on the resilience of urban areas, the impact of welfare systems, and the role of social safety nets in addressing homelessness. The increasing attention to climate change's impact on homelessness, particularly in Australian cities, has further propelled this research (Beer et al., 2011). The United Kingdom, with 45 publications, 907 citations, and a total link strength of 10, has similarly been a key player in the field. The UK's focus on housing instability, welfare reform, and austerity measures has led to significant academic contributions, exploring the link between housing policies, homelessness, and social exclusion (Pleace et al., 2019). Despite its lower citation count compared to the U.S. and Canada, the UK continues to influence international research on urban housing markets and homelessness prevention.Smaller contributors to the global research landscape include France, the Netherlands, Ireland, and Germany. France (9 publications, 83 citations, and a total link strength of 7) has a more centralized welfare approach, which may contribute to the lower visibility of homelessness in research. However, the issue has gained increasing attention in urban areas like Paris, with scholars investigating housing policies and the effectiveness of homelessness interventions (Baptista, 2015). The Netherlands (10 publications, 75 citations, and a total link strength of 7) also has a robust social safety net, leading to a relatively lower research output on homelessness, but a growing focus on housing issues in cities like Amsterdam is evident.

Similarly, Ireland's research on homelessness has intensified in response to the housing crisis, particularly following the 2008 financial crisis, which led to rising housing costs and increasing visibility of homelessness (Hennessy & Neri, 2019). Germany (7 publications, 27 citations, and a total link strength of 5) has comparatively low levels of visible homelessness due to its public housing system, but rising concerns over housing affordability in cities like Berlin have led to growing interest in urban housing and homelessness research (Wolch et al., 2014).The dominance of countries like the United States, Canada, and Australia in publications on homelessness and urban security is driven by the high visibility of homelessness in major urban centers, the scale of the problem, and significant funding directed toward social policy research. These countries are actively engaged in policy experimentation and international collaborations, contributing to the high citation counts. Conversely, countries such as France, the Netherlands, Ireland, and Germany, with lower publication outputs, have policies that have traditionally been more effective in mitigating homelessness, which may explain the more recent emergence of academic interest in these nations. However, the increasing citation counts in these countries signal a growing recognition of homelessness as a critical urban issue, and future research from these regions is expected to expand as urban vulnerabilities rise globally.

The analysis of top authors in publications on homelessness and urban security reveals diverse themes and research focuses that shape our understanding of the issue. The authors listed are contributing to the body of work that addresses the social, economic, and health-related aspects of homelessness, urban security, and vulnerability. Some of the key themes explored by these scholars include health outcomes, interventions, housing policies, and demographic disparities, all critical to urban planning and social policy.Catherine Hastings explores the social determinants of homelessness, particularly housing instability and its connection to public health, with a focus on race, gender, and economic status (Hastings, 2013). Stephen W. Hwang examines the health risks associated with homelessness, emphasizing mental health and chronic conditions, and advocating for integrated care models (Hwang, 2001). Thomas Kerr investigates policy interventions, especially housing-first strategies, and their effects on homelessness (Kerr et al., 2013), while Paula Mayock

addresses the gendered dimensions of homelessness, particularly for young people and women (Mayock et al., 2014). Cameron Parsell focuses on housing policy and the stigma surrounding homelessness, advocating for integrated services and public education (Parsell, 2018). Marc I. Rosen and Robert Rosenheck explore the relationship between homelessness, mental health, and substance abuse, with a particular focus on institutional and veteran-related issues (Rosen et al., 2012; Rosenheck et al., 2013). Chery Smith emphasizes the role of social determinants of health, including housing and healthcare access (Smith, 2010), while Wendy Stone examines the socio-legal aspects of homelessness, highlighting the importance of legal frameworks and protections for homeless individuals (Stone, 2015). These authors' work collectively informs policy and interventions aimed at addressing the multifaceted nature of homelessness.

Author	Documents	Citations
Catherine Hastings	4	19
Stephen W. Hwang	4	84
Thomas Kerr	5	135
Paula Mayock	4	14
Cameron Parsell	4	42
Marc I. Rosen	6	76
Robert Rosenheck	4	88
Chery Smith	5	199
Wendy Stone	4	27

6 CONCLUSION AND RECCOMENDATIONS: TOWARDS A HOMELESSNESS AND URBAN SECURITY CONCEPTUAL FRAMEWORK

Considering the key themes and research gaps from the bibliometric analysis. A conceptual framework is proposed in order to deepen the understanding of the intricate and often underexplored relationship between these two critical urban issues.The key components of the framework are:housing instability and security, social determinants of health and well-being, the role of policy interventions, intersectionality and vulnerable populations, urban safety and crime prevention and healthcare access and urban security. Homelessness and urban security are interconnected urban challenges that, though often studied separately, share overlapping factors. This framework explores the complex relationship between these issues, highlighting how housing instability, social determinants of health, policy interventions, and urban safety influence vulnerable populations. Housing instability is central, as inadequate housing and poor conditions contribute to both homelessness and urban insecurity (Hwang, 2001; Desmond, 2016). Social determinants like income inequality, access to healthcare, and social exclusion further exacerbate vulnerabilities, making homeless individuals more susceptible to crime and violence (Gundersen et al., 2018; Rosenheck, 2013).

Policy interventions, including housing-first models, are critical in addressing homelessness and improving security, while policies criminalizing homelessness can worsen urban insecurity (Kerr et al., 2013; Smith, 2010). Intersectionality is key in understanding how race, gender, and other factors shape experiences of homelessness and security, requiring tailored interventions for different vulnerable groups (Mayock et al., 2014; Rosenheck et al., 2013). Urban safety concerns, such as crime and stigmatization, are also intertwined with homelessness, necessitating a balanced approach that addresses both causes and effects (Rosen, 2012; Desmond & Shyr, 2014). Finally, improving healthcare access for the homeless, particularly mental health and substance abuse treatment, is essential for enhancing both individual well-being and urban security (Hwang, 2001). The framework presents these elements as interconnected components, with housing instability at the center, linked to social factors, policies, and public safety.

In conclusion, this study has explored the multifaceted nature of homelessness and urban security, proposing a comprehensive conceptual framework that incorporates various dimensions such as housing instability, mental health, poverty, policy interventions, and intersectionality. By integrating these factors, the framework highlights the complex, interconnected nature of homelessness and emphasizes the importance of a holistic, integrated approach to addressing this pressing urban issue. The findings from the bibliometric analysis underscore the critical role of health, policy, and social determinants in shaping homelessness outcomes, aligning well with the proposed framework. Furthermore, addressing homelessness requires more than just providing shelter; it demands a systemic approach that integrates housing solutions with healthcare, social services, and supportive policies. Urban planning must prioritize affordable housing, targeted interventions for vulnerable populations, and multi-agency collaboration to create supportive environments for the homeless. Research in this area should continue to explore the effectiveness of policy interventions and the lived experiences of marginalized groups to refine approaches that promote long-term solutions.By adopting the recommendations derived from this framework, cities can make meaningful strides in reducing homelessness, enhancing urban security, and ensuring that all residents have access to the resources they need for a dignified and secure life. This study contributes to a deeper understanding of the structural factors driving homelessness and offers actionable insights for both policy and practice, with the potential to influence urban planning and research directions in the future.

6.1 Practical applications of the bibliometric review and future directions

The bibliometric analysis of homelessness and urban security offers significant practical insights beyond fulfilling formal scientific publication criteria. By systematically mapping the evolution of research trends, thematic networks, and influential contributions, this analysis provides an empirical foundation for understanding the intellectual landscape of homelessness and urban security. Importantly, it highlights key knowledge gaps, emerging themes, and policy-relevant discussions that can inform future research, urban planning strategies, and governance frameworks. One of the primary contributions of this bibliometric analysis is its ability to trace the historical trajectory of research on homelessness and urban security. The identification of shifts in publication trends, particularly the surge in research output after 2002, underscores the growing recognition of homelessness as a critical urban issue influenced by policy shifts, technological advancements, and global socio-economic transformations (Pritzker & Pascoe, 2020; United Nations, 2019). These shifts are particularly relevant to urban planning, where historical insights help policymakers and planners understand how previous interventions have shaped contemporary urban challenges. For instance, neoliberal urban policies have played a crucial role in shaping homelessness through processes of gentrification, exclusionary zoning, and the privatization of public spaces (Smith, 2002; Lees, 2014). By demonstrating how these external factors shape scholarly attention, the analysis contributes to a deeper understanding of the interplay between research, policy, and urban governance. Furthermore, the observed decline in recent publications raises important questions about shifts in research funding, academic priorities, and the impact of global crises, such as the COVID-19 pandemic, on knowledge production (Fink & Freedman, 2022). This is particularly critical for urban planning, as the pandemic has exacerbated housing insecurity and challenged traditional planning paradigms. The need for resilient, inclusive, and equitable urban policies has become more pressing than ever, making continued research on homelessness and urban security a necessity rather than an academic afterthought (Bhan et al., 2020).

The keyword analysis further strengthens the practical relevance of this study by revealing thematic interconnections that are essential for evidence-based policymaking and urban planning. By identifying

dominant themes such as housing insecurity, mental health, food security, and urban crime, the analysis underscores the complexity of homelessness as a multidimensional phenomenon (Desmond & Shyr, 2014; Padgett et al., 2016). This co-occurrence mapping is particularly valuable for urban planners, who must navigate the interdependence of social, economic, and environmental factors when designing cities. Incorporating themes such as "housing insecurity" and "urban crime" into planning strategies enables the development of holistic, place-based interventions that extend beyond traditional approaches like emergency shelters or policing. For example, the rise of "Housing First" policies, which prioritize stable housing as a prerequisite for addressing other social issues, aligns with the recognition that secure, affordable, and well-integrated housing solutions are more effective than punitive or temporary measures (Tsemberis, 2010). The keyword analysis also points to the importance of mixed-use developments, public space activation, and pedestrian-friendly urban design in fostering inclusive urban environments that reduce homelessness-related vulnerabilities (Gehl, 2011).

Another critical contribution of this bibliometric review lies in its analysis of national and institutional research trends. The dominance of publications from the United States, Canada, and Australia highlights the role of national policy frameworks, research funding, and institutional capacities in shaping knowledge production (Gaetz et al., 2019; Padgett et al., 2016). This geographic mapping is crucial for urban planning because it exposes disparities in research attention and policy innovation. While cities in the Global North have implemented advanced urban design interventions – such as inclusive zoning laws, transit-oriented development, and social housing programs – many urban centers in the Global South continue to grapple with informal settlements, inadequate infrastructure, and limited research capacity (Parnell & Pieterse, 2014). Understanding these global trends is vital for urban planners, particularly in cities with high levels of informality, where conventional planning approaches may not be applicable. For example, African cities like Johannesburg and Nairobi require urban strategies that integrate informal settlements into formal planning frameworks rather than perpetuating exclusionary policies that displace vulnerable populations (Huchzermeyer, 2011). Insights from this bibliometric analysis can therefore guide comparative urban policy studies, fostering cross-regional learning and adaptive planning strategies that prioritize housing justice and inclusive urban design.

The bibliometric analysis also provides a foundation for conceptual advancements by informing the development of an integrated framework for homelessness and urban security. The proposed conceptual model, which includes dimensions such as housing instability, social determinants of health, policy interventions, and urban crime prevention, offers a structured approach for future research and policy formulation. This theoretical contribution goes beyond mere documentation of existing research trends by synthesizing fragmented knowledge into a cohesive analytical framework (Hwang, 2001; Gundersen et al., 2018). For urban planners, such a framework can serve as a tool for designing inclusive urban policies that account for the socio-spatial dynamics of homelessness. The framework emphasizes the importance of participatory planning, where affected communities are actively involved in decision-making processes related to housing and public space management (Healey, 1997). Additionally, it reinforces the role of spatial justice – ensuring that marginalized populations have equitable access to urban resources, mobility networks, and social infrastructure (Soja, 2010).

Finally, the analysis enhances knowledge translation by making complex academic trends accessible to non-academic stakeholders, including urban planners, policymakers, and community organizations. Given that planners often operate within politically charged environments, where economic interests and social justice goals may conflict, having empirically grounded insights is crucial for advocating progressive urban policies. In conclusion, while bibliometric analyses are sometimes critiqued for being purely formal exercises, this study demonstrates substantial added value in terms of content and practical relevance to urban planning. It provides a historical perspective on research evolution, identifies critical thematic linkages, maps global research contributions, proposes a conceptual framework, and enhances knowledge accessibility for urban planners and policymakers. As homelessness and urban security remain pressing global issues, such analyses are essential in guiding future research agendas, fostering interdisciplinary collaboration, and informing evidence-based urban planning interventions.

DOI: 10.48494/REALCORP2025.0085

1 ABSTRACT

Affordable housing remains a crucial factor in addressing spatial inequality and fostering inclusive urban development in Johannesburg, a city that continues to grapple with issues rooted in its apartheid legacy, including persistent socio-economic divides, inadequate infrastructure, and entrenched spatial segregation. This paper provides a comprehensive literature analysis on the challenges and approaches to affordable housing, highlighting critical insights from existing research and the implications for social integration and spatial equity.

Utilising a mixed-methods approach, the study focuses on a thorough literature review and a bibliometric analysis to contextualise the historical and contemporary challenges of housing equity. It examines policy shortcomings and socio-economic barriers that limit access to adequate housing, particularly for marginalised communities in informal settlements and low-income areas. Programs like the Reconstruction and Development Programme (RDP) and Breaking New Ground (BNG) have sought to tackle these issues but often fall short of overcoming economic disparities and the spatial disconnect between affordable housing developments and economic opportunities. The bibliometric analysis further highlights trends and gaps in current research, underscoring the urgent need for innovative, community-driven housing solutions to effectively combat segregation and promote social cohesion in urban environments.

Keywords: Affordable Housing, Urban Segregation, Spatial Inequality, Inclusive Urban Development, Community-driven Solutions

2 INTRODUCTION

Johannesburg, South Africa's economic hub, continues to grapple with entrenched spatial inequality and urban segregation. These challenges are deeply rooted in the city's apartheid history, which established racially divided neighborhoods with stark disparities in access to resources, infrastructure, and economic opportunities (Turok, 2016). Despite post-apartheid efforts to integrate urban spaces, socio-economic divides persist, with low-income communities often relegated to the urban periphery (Charlton & Kihato, 2006). The lack of affordable housing in well-located areas exacerbates these issues, forcing many low-income residents to seek accommodation in informal settlements or overcrowded dwellings with inadequate infrastructure. This continued marginalisation limits their access to essential services, employment opportunities, and quality education, perpetuating cycles of poverty and exclusion.

Addressing these issues requires a targeted approach that provides affordable housing and ensures that these developments are integrated within the broader urban fabric, allowing for sustainable and inclusive city growth. This study serves as an analysis of the existing literature regarding affordable housing in Johannesburg, contextualising historical and contemporary challenges while exploring the systemic barriers and socio-economic factors that shape access to equitable housing. Affordable housing is a crucial mechanism for redressing historical injustices and fostering inclusive urban development. By providing low- and middle-income households with stable and well-located housing, the city can break cycles of poverty and segregation, enabling better access to employment, education, and social services (Harrison & Todes, 2015). However, achieving this requires policy innovation and sustainable urban planning efforts.

3 LITERATURE REVIEW

3.1 Historical Context: Apartheid-Era Spatial Planning and Its Legacy

Apartheid (1948–1994) fundamentally shaped Johannesburg's urban landscape through deliberate spatial segregation along racial lines. Black South Africans were systematically confined to underdeveloped townships, often far removed from economic centers and opportunities (Mabin & Smit, 1997). The

cornerstone of this segregation was the Group Areas Act (1950), which legally formalised racial zoning and led to the forced removal of millions of people. This act created a deeply entrenched spatial inequality that continues to impact Johannesburg today (Bremner, 2000). Beyond simply restricting land access, the apartheid regime implemented policies that systematically marginalised Black communities, denying them access to adequate housing, basic infrastructure like sanitation and electricity, and essential services such as healthcare and education (Parnell & Pieterse, 2010). The legacy of this exclusion is starkly visible in many former townships, which still struggle with poor connectivity to Johannesburg's economic nodes, limited access to quality education and healthcare, and persistent poverty. These historical injustices continue to shape contemporary urban planning challenges, with affordable housing recognised as a crucial tool for bridging these spatial and socio-economic divides.

The apartheid government's planning agenda was explicitly designed to prioritise the economic interests of the white minority. This resulted in the systematic neglect of the housing needs of Black South Africans, leading to severe infrastructural deficits and poor service delivery in townships like Soweto, Alexandra, and Tembisa (Christopher, 2001). The fragmentation of urban space was further compounded by policies that severely restricted homeownership and property rights for non-white citizens, further exacerbating existing socio-economic disparities. Even after the dismantling of apartheid-era legislation, the spatial and economic consequences of these policies have proven remarkably resilient. Post-apartheid urban restructuring initiatives have sought to redress these imbalances, but progress has been hampered by deeply entrenched structural inequalities, limited financial resources, and the sheer scale of the historical damage (Harrison & Todes, 2015).

3.2 Current Housing Policies and Programs: RDP, BNG, and Their Limitations

Following the transition to democracy in 1994, the South African government launched the Reconstruction and Development Programme (RDP) as a comprehensive strategy to address the massive housing backlog and provide low-cost housing for historically disadvantaged citizens (Tomlinson, 1999). While the RDP achieved significant success in delivering millions of housing units, it has also faced criticism for inadvertently reinforcing apartheid-era spatial patterns. Many RDP developments were located on the periphery of cities, far from employment opportunities and social amenities, replicating the spatial isolation of the past (Huchzermeyer, 2003). Furthermore, the standardised, low-density design of RDP housing often proved inadequate for accommodating the rapid growth of the urban population, contributing to overcrowding and the emergence of informal settlements adjacent to these developments.

In response to these shortcomings, the government introduced the Breaking New Ground (BNG) policy in 2004. BNG aimed to promote the development of integrated, sustainable human settlements by prioritising mixed-income housing developments and urban densification (Department of Human Settlements, 2004). The policy sought to move away from the mass production of standardised RDP houses and towards the creation of more integrated and sustainable communities. However, the implementation of BNG has encountered numerous challenges. Inadequate funding, persistent socio-economic inequalities, and complex bureaucratic processes have limited its overall impact (Charlton, 2009). Many BNG projects have struggled to attract middle-income residents, resulting in the continued spatial disconnection and socio-economic isolation of low-income communities. The availability of suitable urban land and the high cost of land in well-located areas have also posed significant obstacles, hindering the program's ability to develop affordable housing in prime urban locations and perpetuating urban segregation rather than reversing it. While BNG emphasises housing quality over quantity, financial and logistical barriers have hampered its large-scale implementation (Tissington, 2013).

3.3 Socio-Economic Barriers to Affordable Housing Access

Access to affordable housing in Johannesburg is constrained by a complex interplay of socio-economic factors:

- Income Disparities: A significant portion of the population, particularly low-income households, does not qualify for housing finance from banks or government subsidies, leaving them trapped in informal settlements or overcrowded and often exploitative rental housing (Napier, 2007). The wide gap between government-subsidised housing and market-rate housing creates a "missing middle" where many working-class families are excluded from accessing adequate accommodation.

- Land and Infrastructure Costs: The high cost of land in well-located urban areas, coupled with existing infrastructure deficits, makes it extremely challenging to develop affordable housing in central locations (Biermann & Van Ryneveld, 2007). This economic reality often pushes developers to construct affordable housing in peripheral areas with limited access to economic opportunities, further reinforcing spatial segregation and limiting social mobility.
- Administrative and Bureaucratic Hurdles: Lengthy and often opaque approval processes, coupled with instances of corruption and inefficiencies within housing allocation systems, significantly delay the delivery of affordable housing (Lemanski, 2011). Many low-income applicants face years of waiting lists and bureaucratic hurdles, leading to frustration and contributing to the continued growth of informal settlements.
- Lack of Effective Public-Private Collaboration: Successful affordable housing initiatives often depend on strong partnerships between government entities and private developers. However, in Johannesburg, limited collaboration, misaligned incentives, and a lack of trust between the public and private sectors have slowed the pace of development and hindered innovation in affordable housing solutions (Harrison, 2006).

3.4 The Role of Affordable Housing in Social and Economic Integration

Affordable housing plays a crucial role in reversing the spatial legacy of apartheid and fostering social and economic integration. Well-located affordable housing developments can enhance economic mobility by providing low-income residents with better access to employment opportunities, education, and other essential services. By locating affordable housing near economic hubs and transport networks, residents can reduce their commuting costs and time, freeing up resources and enabling greater participation in the city's economy. Furthermore, innovative housing solutions such as inclusionary zoning, cooperative housing models, and well-structured public-private partnerships can facilitate the integration of diverse income groups and create more socially cohesive neighborhoods (Parnell & Pieterse, 2010). Strategies such as densification, strategic urban land reform, and progressive housing policies can further support this integration, moving Johannesburg towards a more equitable and inclusive urban environment. The provision of affordable housing is not simply about providing shelter; it is about building a more just and integrated society.

4 CASE STUDIES FROM GLOBAL AND LOCAL CONTEXT

Examining successful affordable housing initiatives globally and locally provides valuable insights into how Johannesburg can improve its housing policies and programs.

4.1 Global Case Studies

4.1.1 Inclusionary Zoning Policies (United States, Canada, and the UK)

Cities such as New York, London, and Toronto have implemented inclusionary zoning policies that require private developers to allocate a percentage of new housing units for low- and moderate-income residents (Been et al., 2018; Moore & Bunce, 2009). This approach fosters social integration and ensures that affordable housing is distributed throughout the city rather than being concentrated in low-income areas (Mukhija et al., 2010).

4.1.2 Transit-Oriented Development (Singapore and Curitiba, Brazil)

In Singapore, public housing is integrated with mass transit systems, ensuring that residents have easy access to employment and social services (Yuen, 2007). Similarly, Curitiba's Bus Rapid Transit (BRT) system has helped create affordable, well-connected housing developments, demonstrating the importance of linking housing with transportation infrastructure (Cervero, 1998; Rabinovitch, 1996).

4.1.3 Cooperative Housing Models (Switzerland and Uruguay)

Switzerland's cooperative housing system provides an alternative to government-subsidised housing by encouraging community-driven development projects (Lang & Stober, 2021). Similarly, Uruguay’s self-managed housing cooperatives empower residents to participate in the design, financing, and management of their homes, leading to more sustainable and inclusive communities (Arruabarrena & Lanzaro, 2016).

4.2 Local Case Studies

4.2.1 Cosmo City, Johannesburg

One of South Africa's few successful integrated housing developments, Cosmo City combines subsidised, bonded, and rental housing within the same neighborhood (Bénit-Gbaffou, 2018). This mixed-income model has helped foster social cohesion and economic opportunities, though challenges such as infrastructure maintenance and service delivery persist (Charlton, 2018).

4.2.2 Savannah City, Gauteng

This large-scale mixed-income housing development aims to address spatial inequality by providing affordable housing options close to employment hubs and transportation networks (Turok & Borel-Saladin, 2018). The project emphasises urban densification and sustainable planning but faces financial and administrative constraints (Cirolia et al., 2021).

4.2.3 The Johannesburg Social Housing Company (JOSHCO)

JOSHCO has been instrumental in providing affordable rental housing in well-located urban areas (Tomlinson, 2017). By repurposing underutilised buildings and promoting social housing initiatives, JOSHCO demonstrates the potential of adaptive reuse strategies in addressing the city's housing crisis (Mosselson, 2019).

5 METHODOLOGY

5.1 Mixed-Methods Approach

This research utilised a mixed-methods approach, integrating a comprehensive review of existing literature with a bibliometric analysis. This combined methodology allows for a robust exploration of post-disaster housing solutions, merging qualitative insights gleaned from scholarly works with quantitative data-driven analysis (Johnson & Onwuegbuzie, 2004).

5.1.1 Literature Review

The literature review serves to contextualise the historical and contemporary challenges of housing equity in Johannesburg, South Africa. It explores systemic barriers, policy limitations, and socio-economic constraints that impact equitable access to adequate housing, particularly for marginalised communities in informal settlements and low-income areas (Turok, 2016). By analysing key policy documents, academic articles, and government reports, this review critically examines the successes and shortcomings of major housing programs such as the Reconstruction and Development Programme (RDP) and Breaking New Ground (BNG) (Department of Human Settlements, 2004). It is important to emphasise that the findings presented in this section are based on existing literature rather than new fieldwork or direct policy recommendations related to housing development.

5.1.2 Bibliometric Analysis

A bibliometric analysis, a rigorous quantitative approach for analysing large datasets, was employed to explore the knowledge structure and visually map the field of "social equity in housing" within the specific context of Johannesburg. This analysis focuses on existing scholarly publications to elucidate trends and gaps in research concerning affordable housing and social equity. The data collection process involved searching and extracting relevant publications from Scopus, a widely recognised bibliographic database. The search terms included "social equity in housing," "Johannesburg," "affordable housing Johannesburg," "housing policy," and "housing inequality Johannesburg." Publications spanning the years 2017 to 2025 were considered for inclusion in the analysis. The bibliometric analysis was conducted using a specialised tool called VOSviewer to map co-authorship networks, citation relationships, and thematic clusters, thereby illustrating the intellectual and social structures of research on affordable housing and social equity in Johannesburg. As with the literature review, it is crucial to note that the findings derived from this analysis reflect existing literature, focusing on the evolution of research rather than proposing new fieldwork or direct policy changes.

5.2 Research Questions

Guided by the overarching goal of understanding systemic barriers and potential solutions to affordable housing in Johannesburg, the study addresses the following key research questions:

(1) What are the dominant conceptual frameworks used to understand social equity in housing in this context?

(2) What constitutes the intellectual structure of this field, as evidenced by key publications and influential authors?

(3) How is the social structure of research on this topic configured, including collaborations and networks?

(4) How does the body of knowledge specifically addressing Johannesburg contribute to broader understandings of social equity in housing?

By integrating qualitative and quantitative approaches, this study aims to offer a holistic perspective on the role of affordable housing in fostering social and economic integration in Johannesburg. The mixed-methods approach ensures a nuanced understanding of both theoretical frameworks and empirical trends, enabling the formulation of evidence-based policy recommendations for more inclusive and equitable urban development.

6 RESULTS, ANALYSIS, AND DISCUSSION

6.1 Key Insights from the Literature Review

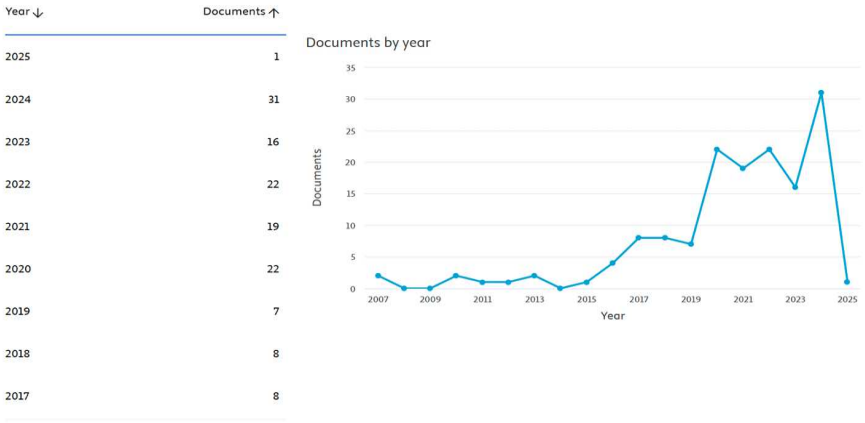
The literature review highlights several critical insights into the state of affordable housing in Johannesburg, drawing from existing scholarly work. A key theme is the persistent spatial segregation, a legacy of apartheid-era planning policies that continue to marginalise low-income communities. Despite post-apartheid housing policies such as the Reconstruction and Development Programme (RDP) and Breaking New Ground (BNG), affordable housing developments remain concentrated on the urban periphery, limiting access to economic hubs and essential services. While these policies have increased housing stock, they have not fully integrated low-income earners into mixed-income developments, reinforcing socio-economic divides. Additionally, the literature identifies structural inefficiencies such as bureaucratic delays, limited funding, and land scarcity in prime locations as major obstacles to achieving housing equity.

Another key insight is the critical role of community-driven approaches in fostering sustainable and inclusive urban development. Research suggests that active community involvement in housing initiatives leads to more sustainable outcomes better aligned with residents' needs. Collaborative urban planning, incorporating public-private partnerships and community engagement, is essential to overcoming the challenges posed by current housing models. Furthermore, the literature underscores the need for policy reforms that promote urban densification, transit-oriented development, and the integration of social services within affordable housing projects. These strategies can enhance economic mobility and social cohesion, addressing the limitations of existing housing frameworks. It is important to note that these findings stem from a comprehensive evaluation of existing research rather than new fieldwork.

6.2 Analysis of Annual Publications

The first data set focuses on the number of publications in the research field annually, illustrating how research trends have evolved significantly between 2007 and 2025. Figure 1 reveals distinct phases in the development of scholarly interest in affordable housing. The Foundational Phase (2007–2011) shows minimal activity, likely reflecting the early stages of research on affordable housing, with a focus on traditional approaches and limited exploration of complex housing challenges or sustainable housing solutions. This transitions into the Emerging Interest Phase (2012–2016), marked by a slight but steady increase, possibly driven by Johannesburg's growing urbanisation and early mixed-income housing initiatives like Cosmo City, which began shaping debates on housing integration and sustainability. The Growth Phase (2017–2019) highlights a shift toward applied studies addressing urban challenges, including housing, infrastructure, and environmental management. A Significant Surge (2020–2024) follows, with research output increasing dramatically, particularly during the COVID-19 pandemic, which exposed urban vulnerabilities and heightened interest in smart infrastructure, social inclusion, and sustainability. The peak in 2024 underscores an intensified focus on urban renewal and housing integration. This analysis, derived from existing studies, reflects prevailing scholarly trends rather than novel research outcomes, illustrating

how socio-economic shifts and a growing emphasis on sustainability have influenced the research landscape over time.



Year	Documents
2025	1
2024	31
2023	16
2022	22
2021	19
2020	22
2019	7
2018	8
2017	8

Figure 1: Graph depicting the publication trend of the topic area between 2007 and 2025.

6.3 Knowledge Evolution in the Field

The intellectual knowledge structure of the urban planning and housing integration field is reflected through

The intellectual knowledge structure of urban planning and housing integration is reflected through an analysis of research output trends, revealing the evolution of key concepts and thematic focus areas over time. By examining published documents, we can identify foundational periods of limited exploration, followed by thematic diversification and significant shifts driven by urban challenges and societal needs. Early research focused on traditional urban planning approaches, while later phases emphasised mixed-income housing integration, sustainability, smart infrastructure, and urban renewal. Key themes such as affordability, spatial inequality, and policy effectiveness have gained prominence, shaped by factors like rapid urbanisation and the COVID-19 pandemic. These shifts underscore how external influences drive scholarly focus and critical debates, shaping the field's future direction.

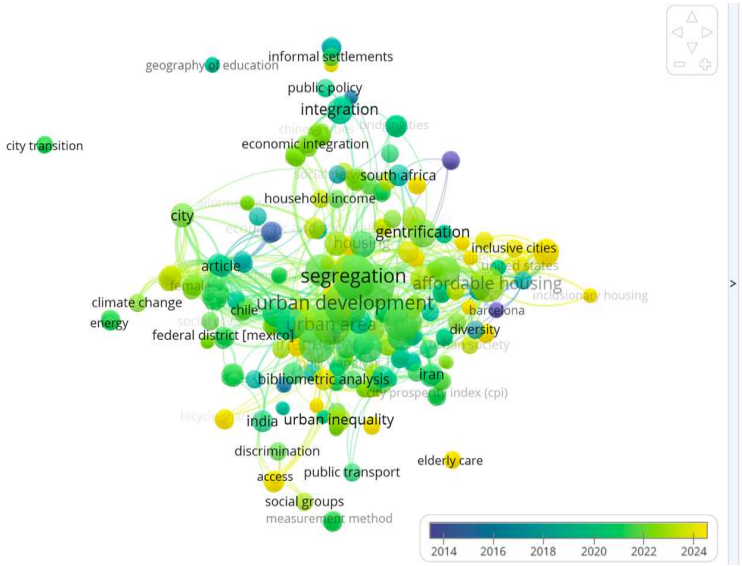


Figure 2: Visualised network map of research themes, overlay between 2014 and 2024 (10-year period) to understand the

Conceptual Structure

The dataset, which was second to be analysed for the study, focused on keyword co-occurrences. Referenced from the upward trend from the dataset, which was previously analysed and comprises research publications that were released between 2007 to 2025. It is evident that there is demand in this particular research field, and that explains the increase and upward trend over the years. There is also clear evidence that there is demand where the keyword variables are concerned. In the process of sorting the data, 540 keywords were exported from the Scopus database. For a minimum number of occurrences of a keyword being 5, of the 540

keywords, 19 met the threshold. For a minimum number of occurrences of a keyword being 4, of the 540 keywords, 26 met the threshold. For a minimum number of occurrences of a keyword being 3, of the 540 keywords, 44 met the threshold. For a minimum number of occurrences of a keyword being 2, of the 540 keywords, 115 met the threshold. All the above were insufficient as the main keywords used in this study did not all appear on the list. For a minimum number of occurrences of a keyword being 1, of the 540 keywords, all 540 keywords met the threshold. This turned out to be the best dataset to work with, as all of the required keywords appeared on the list consisting of 540 keywords.

Trajectory of research themes

540 keywords were gathered through the all keywords unit of analysis for the co-occurrence analysis type as having appeared in 66 readings which were extracted from SCOPUS. The keywords selected in this data set are they key words that are from or are closely linked to the main keywords used in this study.

KEYWORDS	OCCURRENCES	TOTAL LINK STRENGTH
Afdordable Housing	10	94
Community	1	18
Urban Segregation	1	39
Spatial Inequality	3	36
Urban Development	18	211
Inclusion	1	13

Table 1: The top 5 keywords in the research network

Intellectual Structure

To delve into the intellectual structure of affordable housing research in Johannesburg, a co-citation analysis was employed. This method, as described by Small (1973), examines the frequency with which two documents are cited together, revealing intellectual connections and mapping the knowledge structure of the field. By analysing author and document coupling, the co-citation analysis aimed to identify influential works that have shaped the discourse, discern emerging research clusters representing key thematic trends, and understand the evolution of ideas within this interdisciplinary area of study. This approach allows for a deeper understanding of how foundational research informs current investigations and highlights potential areas for future scholarly inquiry.

Document Co-Citation Analysis

A document co-citation analysis was conducted to map the intellectual landscape of affordable housing research in Johannesburg and identify influential works that have shaped the discourse. Utilising the Scopus database, 6,162 cited references were examined. A 50% threshold was applied, focusing on the 3,081 most frequently cited references to balance comprehensiveness and analytical manageability. This decision was made to include a substantial portion of highly cited works while maintaining a manageable dataset for analysis. Alternative thresholds 2, 3, and 4 were considered but were restrictive as they excluded potentially influential works and were too limiting, making analysis unwieldy. The resulting co-citation network was visualised using VOSviewer, revealing key thematic clusters that represent distinct areas of inquiry within the field.

These clusters encompassed topics such as:

- Spatial Segregation and Apartheid Legacy: Examining the historical roots of spatial inequality and the enduring impact of apartheid-era planning policies on access to affordable housing (Mabin & Smit, 1997; Turok, 2016).
- Policy Analysis and Critique: Analysing the effectiveness and limitations of post-apartheid housing policies and programs, such as the RDP and BNG, and their impact on spatial integration (Huchzermeyer, 2003; Tomlinson, 1999).
- Socio-Economic Barriers: Investigating the complex interplay of factors, including income disparities, land costs, and bureaucratic hurdles, that constrain access to affordable housing (Charlton & Kihato, 2006; Napier, 2007).
- Community-Driven Solutions: Exploring the role of community participation and collaborative planning in developing sustainable and inclusive housing initiatives (Parnell & Pieterse, 2010).

Several influential works emerged from the analysis, indicating foundational contributions that have significantly shaped the field. For instance, Turok's (2016) work on urban development in Africa suggests its

pivotal role in understanding the broader context of urban challenges and the role of affordable housing within it. Similarly, Napier (2007) underscores its enduring impact on income disparities and inequality. Harrison (2015) highlights its significance in shaping discussions around community participation and sustainable housing solutions that will indeed reduce segregation.

These frequently co-cited publications represent seminal texts and landmark studies that have significantly influenced subsequent research and practice in affordable housing in Johannesburg. By identifying these core works, thematic clusters, and the intellectual connections between them, the document co-citation analysis contributes to a deeper understanding of the evolution and current state of affordable housing research in Johannesburg, ultimately informing future research directions and policy interventions aimed at improving housing equity and integration.

Author Co-Citation Analysis

For this dataset, for a minimum number of citations of cited references being 4 and 5, out of the 6162 cited references, only 3 meet the threshold for both. This was not considered as the threshold was very limiting and would give results that are limited and not dependable. For a minimum number of citations of a cited reference being 3, out of 6162 cited references, 14 met the threshold, which was also not sufficient as that forms a mere 0.23% of the total number of cited references. For a minimum number of citations of cited references at a value of 2, 6162 cited references, 126 met the threshold. This was also not considered as this data excluded a number of documents with a high citation rate. Therefore, a minimum number of citations being 1, out of 6162 cited references, 6162 met the threshold and were considered. The chosen number of cited references was made to be 50%, which is 3081 cited references. A data set of 3081 references is large but better to work with compared to the total, which is 6162. Increasing it from 3081 to 6162 would make the analysis process very time-consuming and tedious. Out of the 3081 cited references, the top 10 of the highest citations were chosen as this is an indicator that these authors are really good or quite influential in the research area that this paper is focusing on.

Figure 3: Visualised document co-citation network map of affordable housing and segregation

Co-authorship Analysis

Co-authorship analysis is crucial for exploring the collaborative dynamics within a research field. It reveals networks and partnerships among scholars, institutions, and countries, providing valuable insights into how knowledge is co-produced and disseminated (Newman, 2001). By examining co-authorship patterns, researchers can identify key contributors, influential collaborations, and emerging research communities (Glänzel & Schubert, 2004). In this dataset, for a minimum number of documents of an author being 1 and a minimum number of citations of an author being 1, of the 172 authors, all 172 met the threshold. This was the perfect threshold as it was not limiting.

The table below shows co-authorship amongst authors. The selection of authors in this database was based on the number of citations being the determining factor of authors that were chosen.

Author	Documents	Citations	Total Link Strength
mcgranahan, gordon	1	95	2
schensul, daniel	1	95	2
singh, gayatri	1	95	2
audirac, ivonne	1	79	1
bonakdar, ahmad	1	79	1

Table 2: Co-authors with the highest citations

Analysis of Country Collaboration

Within the body of knowledge, there has to be an understanding of the impact that global collaboration has on the research area. It is also of importance to know and understand the influence of different authors on a global scale as this carries weight in terms of contribution. In this segment of the study, the top five clusters consisting of collaborations will be discussed. The highest rate of collaboration comes from 2 clusters being clusters 1 and 2. Cluster 1 has a total of 19 joint publications between Belgium, China, Erasmus University Rotterdam, Hong Kong, and the Netherlands. Clusters 1 and 2 have a tie as cluster 2 also consists of 19 joint publications between Chile, Colombia, France, Mexico, and the United States. In second place is Cluster 5, with 15 joint publications between Nigeria, South Africa, and the United Kingdom. In third place is Cluster 3, with a total of 6 joint publications between Germany and Switzerland, and in last place is Cluster 7, with a total of 4 joint publications between Estonia and Poland.

Global Network Knowledge

The analysis conducted throughout this study reveals a significant amount of global research activity in the field of affordable housing. This is evidenced by the participation of countries representing diverse continents, some of which may not have experienced severe housing crises directly. However, their engagement suggests a proactive approach to preparedness and resilience, recognising the unpredictable nature of housing challenges and the importance of a robust knowledge base. This aligns with the broader understanding of housing as a fundamental human right and a crucial component of sustainable development, as articulated by the United Nations in its Sustainable Development Goals (UN-Habitat, 2016).

This global research engagement reflects a commitment to proactive planning, with nations investing in understanding and addressing housing disparities even in the absence of immediate crises. The interconnectedness of academic networks facilitates cross-border knowledge sharing, enabling countries to learn from the experiences of others, particularly those facing persistent housing challenges (Castells, 2010). This exchange of knowledge is crucial for developing context-specific solutions and adapting best practices to local conditions. Furthermore, the growing recognition of the crucial role of adequate housing in social and economic development has driven global collaboration, as nations understand that housing issues have far-reaching societal impacts (Massey & Denton, 1993).

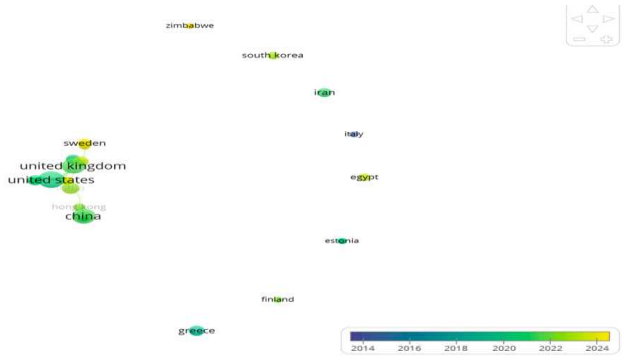

Figure 4: Visualisation of Global collaboration (country collaboration network)

This visualisation depicts international research collaborations on segregation and affordable housing, revealing a network dominated by the United States and the United Kingdom, as evidenced by their large node sizes and numerous connections. China also emerges as a significant player, indicating its growing research capacity and engagement in this field. The presence of other nations, including Sweden, Italy, Iran, South Korea, Egypt, Estonia, Finland, Greece, Hong Kong, and Zimbabwe, suggests a broadening global interest in this topic, extending beyond traditional research centers. The color gradient, spanning from 2014 to 2024, hints at the temporal evolution of these collaborations, with further analysis needed to pinpoint specific periods of increased activity or the emergence of new partnerships. This network structure facilitates

potential knowledge transfer between regions, allowing countries with varying experiences in addressing segregation and affordable housing to learn from one another. Connecting this visualisation to the previously analysed publication trends and examining the specific content of these collaborations would provide a more comprehensive understanding of the global research landscape and its relevance to the challenges faced by Johannesburg.

7 CONCLUSION

This study has explored the complex intersection of affordable housing, spatial inequality, and urban segregation in Johannesburg, utilising a mixed-methods approach encompassing a comprehensive literature review and a bibliometric analysis. The literature review contextualised the historical and contemporary challenges, tracing the roots of segregation to apartheid-era planning and examining the limitations of post-apartheid housing policies like the RDP and BNG. It highlighted the persistent socio-economic barriers hindering access to affordable housing and underscored the crucial role of community-driven approaches in fostering social and economic integration. The bibliometric analysis, including publication trend analysis, keyword co-occurrence mapping, and co-citation analysis, provided a quantitative lens through which to examine the evolution of research in this field. The analysis revealed a growing body of scholarship, with key themes emerging around spatial segregation, policy critique, socio-economic barriers, and community-driven solutions. Influential works and collaborative networks were identified, showcasing the intellectual and social structure of the research landscape. Furthermore, the analysis of country collaboration highlighted the global nature of this challenge and the importance of international knowledge exchange. Ultimately, this study reinforces the urgent need for innovative, community-driven affordable housing solutions in Johannesburg to combat segregation, promote social cohesion, and create a more equitable and inclusive urban environment. The findings presented here offer valuable insights for policymakers, urban planners, and community stakeholders working toward a future where affordable housing serves as a cornerstone for dismantling segregation and fostering sustainable urban development.

1 ABSTRACT

This bibliometric review examines global and international research trends on designing inclusive public spaces, with a focus on participatory approaches to improving accessibility and inclusivity in marginalized areas. Utilizing bibliometric analysis through VOSviewer, the study identifies key themes, methodologies, and conceptual frameworks shaping the discourse on inclusive urban design. It explores the influence of international guidelines, such as the United Nations' Sustainable Development Goals and Universal Design Principles, in driving innovative approaches to urban accessibility and participatory planning. The review maps collaboration networks, keyword co-occurrences, and citation trends to provide a comprehensive understanding of the global research landscape. Case studies from diverse geographical contexts illustrate how participatory practices have been adapted to address unique social, cultural, and economic challenges. By situating South African townships within this global research framework, the paper highlights opportunities and challenges in applying international best practices to local contexts. This study contributes to the broader dialogue on inclusive urban development by synthesizing global research insights and offering recommendations for future applications in marginalized areas.

Keywords: Sustainable Development Goals, Participatory Urban Design, Inclusive Public Spaces, Bibliometric review, Planning

2 INTRODUCTION AND BACKGROUND

The design of inclusive public spaces has become a critical focus in contemporary urban development, reflecting global efforts to create environments that are accessible, equitable, and responsive to diverse user needs. International frameworks such as the United Nations' Sustainable Development Goals (SDGs), particularly Goal 11, emphasize the importance of inclusive, safe, and sustainable cities. Additionally, the principles of Universal Design advocate for spaces that accommodate all individuals, ensuring social integration and spatial justice. However, despite growing international discourse on urban inclusivity, there remains a significant gap in understanding how participatory design approaches are shaping this field and how they can be effectively adapted to marginalized and historically underserved communities. A key challenge in advancing inclusive urban development lies in the fragmented understanding of global research trends on participatory urban design. While existing studies highlight the benefits of participatory planning in fostering inclusivity (Keeton, 2020), there has been no comprehensive bibliometric analysis of how research in this field has evolved over time. Furthermore, much of the scholarship on inclusive public spaces has been concentrated in high-income countries, with limited attention to low-income and informal urban settings, particularly in the Global South.

In South Africa, case studies such as Asiye eTafuleni in Durban (Lees & Dobson, 2021) and community-led placemaking initiatives in townships (Mafame & Horn, 2025) have demonstrated the transformative potential of participatory design. However, a systematic review of global research trends and how they inform local implementation remains underexplored. This study fills a critical gap by conducting a bibliometric review of global research trends on designing inclusive public spaces, focusing on participatory approaches. Unlike previous research that examines individual case studies or conceptual frameworks in isolation, this study will provide a data-driven synthesis of the dominant themes, methodologies, and collaborative networks shaping the discourse. By utilizing bibliometric tools such as VOSviewer, the study will map global research clusters, analyze key citation patterns, and explore the influence of international frameworks such as the SDGs and Universal Design Principles on scholarly output. The primary objective of this study is to conduct a bibliometric review to systematically map global research trends on participatory approaches to designing inclusive public spaces. In addition to mapping global research trends, this study intends to develop a conceptual framework based on the insights derived from the bibliometric analysis. By systematically

reviewing the dominant themes, methodologies, and theoretical underpinnings identified in the literature, the study will synthesize key principles that define participatory approaches to designing inclusive public spaces. This conceptual framework will serve as a structured lens for understanding how participatory urban design can be effectively implemented, particularly in marginalized areas such as South African townships. It will integrate global best practices with localized contextual factors, offering a model that can guide future research and policy interventions. Ultimately, the framework will provide a foundation for scholars, urban planners, and policymakers to critically engage with participatory design principles in ways that are adaptable, inclusive, and responsive to diverse urban challenges.

3 GLOBAL PERSPECTIVES ON INCLUSIVE PUBLIC SPACE DESIGN

The discourse on inclusive public spaces has gained momentum in global urban development, driven by frameworks such as the United Nations' Sustainable Development Goals (SDGs), particularly Goal 11, which calls for inclusive, safe, resilient, and sustainable cities (United Nations, 2015). The concept of universal design has also played a crucial role in shaping urban accessibility, emphasizing the need for environments that accommodate all individuals, regardless of their physical, cognitive, or social abilities (Imrie and Luck, 2021). Scholarly work highlights that participatory approaches to urban design are essential for fostering inclusivity, ensuring that public spaces reflect the needs and experiences of diverse users (Aelbrecht and Stevens, 2020). Participatory design methods, such as co-design workshops and citizen assemblies, have been increasingly integrated into urban planning processes to promote democratic engagement and social equity (Gehl, 2021). Research by Buser et al. (2021) emphasizes that participatory urbanism enhances spatial justice by allowing underrepresented groups to influence decision-making processes in public space development. Barcelona's Superblocks project is a leading global example of inclusive public space transformation. Initially implemented in response to urban congestion and pollution, this initiative reclaims street space for pedestrians, cyclists, and public activities (Rueda, 2020). The participatory planning approach involved consultations with local residents to ensure the redesigned spaces met the needs of different user groups, including people with disabilities, elderly residents, and children. The project demonstrates how inclusive urban design, combined with participatory governance, can enhance public space accessibility and social cohesion.

Despite the progress made, global studies acknowledge the challenges of sustaining participatory approaches in urban development, particularly in rapidly urbanizing regions where socio-economic disparities persist (Watson, 2020). These challenges necessitate context-specific strategies that align global best practices with local urban realities. n the African context, inclusive public space design is increasingly recognized as a key strategy for addressing spatial inequalities and historical legacies of segregation (Pieterse, 2021). Many cities across the continent face challenges related to informality, inadequate infrastructure, and exclusionary urban policies that limit access to well-designed public spaces for marginalized populations (Harrison, 2020). Participatory urban design in Africa is often linked to grassroots initiatives that empower local communities to take an active role in shaping their environments (Turok & Scheba, 2021). The concept of "placemaking" has been particularly influential in African cities, fostering collective ownership of public spaces through bottom-up interventions. The Nairobi Greenline Project, a collaborative initiative between civil society organizations and the Nairobi City Council, is an example of inclusive public space creation in Africa. The project aimed to restore and preserve green spaces in the city while providing recreational areas for diverse socio-economic groups (Mwau & Smit, 2020). By engaging local communities in tree-planting activities, design workshops, and decision-making processes, the initiative successfully integrated participatory methods into urban green space development. This case underscores the importance of community involvement in fostering inclusive and sustainable public spaces in African cities. Despite such efforts, urban development policies in many African cities remain top-down, limiting the extent to which participatory approaches can be institutionalized in formal planning processes (Parnell & Robinson, 2021). This calls for a rethinking of governance models to better incorporate local knowledge and grassroots activism in urban planning.

In the context of South Africa, urban landscape remains deeply shaped by apartheid-era spatial planning, which resulted in highly segregated and unequal cities (Todes et al., 2020). While post-apartheid policies have sought to promote spatial integration and inclusive urban development, many public spaces, particularly in townships and informal settlements, continue to suffer from neglect, poor infrastructure, and inadequate

safety measures (Landman, 2021). Participatory approaches to urban design have gained traction in South Africa as a means of addressing historical spatial injustices and fostering more inclusive city-making (Charlton & Meth, 2021). However, these efforts have often been challenged by bureaucratic inefficiencies, limited funding, and a lack of institutional support for grassroots initiatives (Bremner, 2020). A good case study of participatory urbanism that is community-centric is the example that was made reference to in earlier parts of this paper, namely Asiye eTafuleni which is a non-profit ogranisation in the City of Ethekweni, also known as Durban in the Kwa-Zulu Natal province of South Africa. The name Asiye eTafuleni is an isiZulu phrase that translates to "bringing to the table" in english. The name reflects the organization's mission of inclusivity and participation, particularly in advocating for the rights and needs of marganalized communities. The organization has successfully implemented participatory planning initiatives to improve informal trading spaces and public areas for marginalized communities. Working closely with street traders, the initiative has developed co-designed infrastructure, such as shaded trading stalls, public seating, and improved pedestrian pathways (Dobson & Skinner, 2020). By centering the voices of informal workers in the design process, Asiye eTafuleni has demonstrated the potential of participatory urbanism in fostering inclusive and economically vibrant public spaces. Despite these successes, the integration of participatory approaches into mainstream urban planning in South Africa remains inconsistent. Many township and urban areas still lack well-maintained public spaces, exacerbating social exclusion and limiting opportunities for community engagement (Mabin, 2021). This highlights the need for a more systematic approach to inclusive urban design, informed by both global best practices and locally grounded participatory frameworks.

While significant research has been conducted on participatory urban design and inclusive public spaces, there remains a gap in systematically analyzing how these approaches have evolved globally and how they can be effectively adapted to marginalized contexts such as South African townships. This study aims to address this gap by conducting a bibliometric analysis of existing literature to identify dominant themes, knowledge networks, and methodological approaches. Based on the insights gained from the bibliometric review, the study will develop a conceptual framework that integrates global best practices with localized contextual factors. This framework will serve as a guide for policymakers, urban planners, and researchers, providing structured principles for implementing participatory design in public spaces across different socio-economic and cultural settings. By bridging the gap between theory and practice, the framework will contribute to a more inclusive, evidence-based approach to urban design in marginalized communities.

4 METHODOLOGY

This study employs a bibliometric analysis to examine global research trends on inclusive public spaces and participatory urban design. Bibliometric analysis is a quantitative research method used to evaluate the intellectual structure, research impact, and knowledge networks in a particular field (Donthu et al., 2021). This approach enables the identification of key themes, influential authors, prominent publications, and collaboration patterns shaping discourse on inclusive public space design. The Scopus database was selected as the primary source of bibliographic data due to its extensive coverage of peer-reviewed journal articles, conference proceedings, and book chapters in urban studies, architecture, and social sciences (Elsevier, 2022). On 18 February 2025 a Scopus database search was conducted using the primary key search term: “Participatory AND public AND space AND design”.

The inclusion criteria focused on english-language publications from any country and any year up to 2025. The exclusion criteria eliminated editorials, errata, letters, notes, short surveys, publications with unidentified authors and books, book chapters, reviews, and conference papers not published in english. The PRISMA guidelines were followed to screen titles and abstracts and ensure eligible studies were selected. The initial search yielded 950 publications on. After applying the inclusion and exclusion criteria 98 publications were excluded, leaving a total of 852 eligible documents. VOSviewer was utilized to conduct the bibliometric analysis, as outlined in the figure below (Van Eck and Waltman, 2014). VOSviewer is a software tool that visually analyzes literature reviews, identifying trends, research foci, and key areas (Soegoto et al., 2022).

5 RESULTS AND DISCUSSIONS OF THE BIBLIOMETRIC ANALYSIS

The publication trend in participatory urban design, as depicted in the graph, highlights a significant rise in scholarly interest over the past two decades. From 1976 to the early 2000s, research output was minimal,

with fewer than 10 publications per year. However, from 2005 onwards, there is a noticeable upward trend, with research output accelerating around 2010 and experiencing exponential growth from 2015 to 2024. The highest number of publications occurs in 2024, with nearly 350 documents published. Interestingly, there is a sharp decline in 2025, which may be attributed to incomplete indexing, funding cycle shifts, or emerging research priorities.

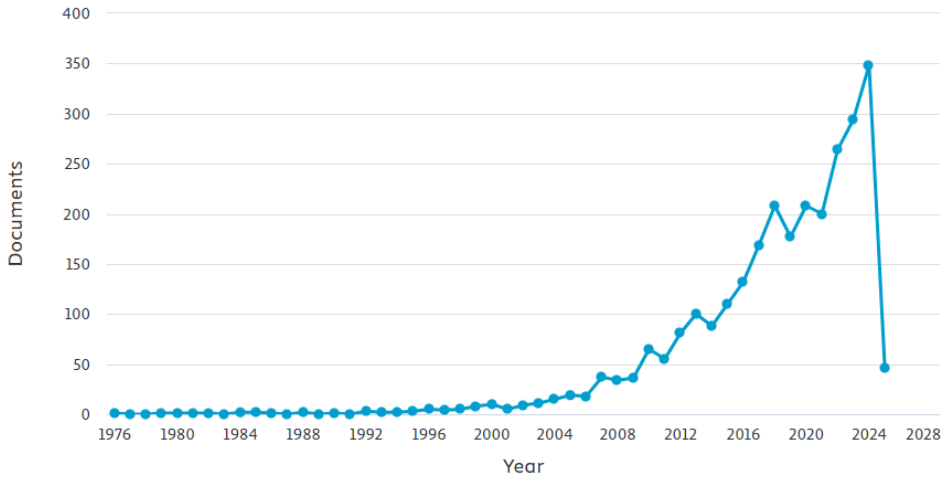

Fig. 1: Publication trend for research on participatory public space design.

This trend reflects a growing recognition of the importance of citizen engagement in urban planning and the increasing role of participatory approaches in urban governance (Frediani, 2016; Faga, 2006). The post-2010 surge aligns with global urban policies advocating for inclusive and participatory urban spaces, particularly influenced by the United Nations' Sustainable Development Goals (SDG 11) and the New Urban Agenda (2016) (UN-Habitat, 2016). Several key factors have contributed to the growth of participatory urban design research over the years. One significant driver has been the role of global urban policies. The United Nations' Sustainable Development Goals (SDGs), particularly SDG 11, emphasize making cities inclusive, safe, resilient, and sustainable (United Nations, 2015). Similarly, the New Urban Agenda (2016) promotes participatory governance and citizen-led urban design, encouraging greater scholarly interest in the field (UN-Habitat, 2016). These global frameworks have influenced both policy changes and academic research, positioning participatory urban design as a crucial component of urban planning and governance (Pieterse, 2019).

Another important factor is the rise of digital and smart city approaches, which have expanded the tools available for public participation in urban design. The increasing use of Geographic Information Systems (GIS), digital participatory mapping, and crowdsourcing has allowed for more effective citizen engagement in urban planning (McCall & Dunn, 2012). Additionally, the concept of smart cities and digital democracy has significantly shaped recent research trends, particularly in the last decade, as urban planning increasingly incorporates data-driven and technology-enabled participatory methods (Batty, 2018). The influence of social movements and the "Right to the City" discourse has also played a crucial role in shaping participatory urban design research. Inspired by Henri Lefebvre's (1996) theories, the "Right to the City" movement has gained momentum in urban discourse, advocating for citizen-centered urbanism (Harvey, 2012). Participatory urban design is increasingly viewed as a tool for spatial justice and urban equity, particularly in rapidly urbanizing cities of the Global South, where historically marginalized communities seek greater involvement in shaping their urban environments (Watson, 2014). Finally, the COVID-19 pandemic (2020–2022) had a profound impact on how cities approach public spaces, further driving research interest in participatory urban design. The pandemic underscored the need for inclusive urban design and walkability, prompting urban planners to explore innovative ways to involve citizens in shaping more resilient and adaptable urban environments (Honey-Rosés et al., 2020). The post-pandemic period (2020–2024) witnessed a surge in research on participatory urban design, as cities sought to reimagine public spaces, integrate health-conscious urban planning, and ensure equitable access to safe and inclusive spaces. This explains the sharp rise in publications in the last few years.

5.1 Keyword Analysis

The bibliometric visualization presented in the image provides an insightful mapping of key themes and conceptual linkages within the field of participatory design in urban spaces. The largest and most central node, labeled "participatory design," indicates that it is the dominant research focus, with strong connections to related concepts such as sustainability, public space, and urbanization. This suggests that participatory urban design research is deeply intertwined with broader urban sustainability and environmental planning discussions (Gehl, 2013). The color-coded clusters represent different thematic domains within participatory design research. The red cluster is strongly associated with gender and qualitative research, with prominent keywords such as "female" and "qualitative research." This signifies an increasing focus on gender-sensitive urban design and the role of women in participatory urban planning, aligning with feminist urbanism and feminist design theories (Kern, 2020). Additionally, keywords like "urban renewal" and "social aspects" suggest that researchers are exploring participatory approaches in urban regeneration projects, ensuring inclusivity and representation in urban transformation (Sandercock, 1998).

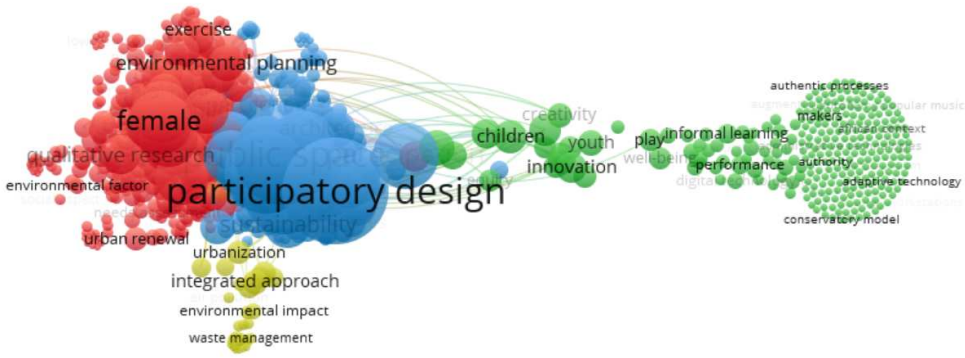

Fig. 2: Network map for keywords on research on participatory public space design.

The blue cluster is centered on sustainability, environmental planning, and integrated approaches. The strong association between "participatory design" and "sustainability" indicates that researchers are considering how inclusive design practices contribute to more resilient and adaptive urban spaces (Agyeman, 2013). Terms such as "waste management" and "environmental impact" highlight an emerging interest in ecological sustainability within participatory design frameworks, emphasizing circular economies and green urbanism (Newman et al., 2017). The green cluster focuses on youth, creativity, and innovation, highlighting participatory urban design's role in fostering child-friendly and youth-oriented urban environments. Keywords such as "children," "youth," "play," and "informal learning" suggest a growing recognition of the importance of designing public spaces that cater to younger populations, incorporating playfulness and creativity into urban design (Lester & Russell, 2010). This aligns with the shift towards child-friendly cities and participatory design methodologies that involve young people in co-creating urban spaces (Malone, 2013).

A particularly interesting aspect of the visualization is the smaller but highly connected cluster on the far right, which includes terms like "authentic processes," "makers," "digital technology," and "adaptive technology." This suggests an emerging research area where participatory design intersects with digital fabrication, maker movements, and adaptive urban technologies (Balestrini et al., 2017). The rise of digital participatory tools such as crowdsourced mapping, augmented reality, and computational design techniques is revolutionizing how urban spaces are co-created with communities (Batty, 2018).

The bibliometric network analysis reflects key contemporary debates in participatory urban design and demonstrates how the field has evolved to incorporate gender equity, sustainability, youth engagement, and digital innovation. The prominence of feminist and gender-sensitive approaches underscores the growing awareness of inclusive urbanism and the need to address historical gender biases in planning (Kern, 2020). Additionally, the strong connections between sustainability and participatory design indicate that researchers are prioritizing climate resilience, ecological planning, and community-led environmental governance (Agyeman, 2013). Moreover, the intersection of youth, play, and innovation within participatory design reveals an increasing emphasis on public spaces as sites of informal learning and creativity, which aligns with global trends in child-friendly and youth-inclusive urban planning (Malone, 2013). Lastly, the growing

presence of digital participatory tools and adaptive technologies points to the future of participatory urban design, where data-driven and technology-enhanced engagement methods will likely shape how cities involve residents in decision-making processes (Batty, 2018). Overall, the bibliometric trends indicate that participatory urban design is becoming increasingly interdisciplinary, integrating social, environmental, technological, and governance dimensions. Future research should continue exploring how these diverse elements interact, ensuring that participatory urban design remains a dynamic and inclusive framework for shaping equitable and sustainable cities.

5.2 Top countries publishing on participatory public space design

Participatory public space design is a growing area of research that intersects urban planning, architecture, environmental psychology, and social sustainability. The global distribution of research output in this field varies, with certain countries emerging as leaders in publication volume, citation impact, and collaboration networks. The table provides insight into the top ten countries contributing to this discourse, highlighting their research intensity, influence, and interconnectivity in the scholarly landscape.

Country	Documents	Citations	Total Link Strength
United Kingdom	140	1720	105
United States	164	2860	70
Spain	70	606	49
Sweden	36	1098	41
Netherlands	45	903	38
Australia	66	1050	35
Canada	54	630	35
Germany	39	766	33
Italy	83	641	33
Switzerland	12	395	33

Table 1: Top countries publishing on participatory public space design

The United States emerges as the most cited country, with 164 documents and 2860 citations, indicating its strong academic influence. The U.S. has a long history of community-based urban design initiatives, driven by movements such as New Urbanism and Tactical Urbanism (Lydon & Garcia, 2015). Scholars and institutions in the country have contributed extensively to placemaking strategies, community-led urban regeneration, and digital participation tools in urban planning (Mehta, 2019). Despite leading in citations, its total link strength of 70 suggests moderate international collaboration compared to the United Kingdom and Spain, reflecting a more nationally focused research agenda. The United Kingdom, with 140 publications and 1720 citations, stands out as a dominant contributor to participatory public space design research. Its total link strength of 105, the highest in the dataset, highlights extensive international collaboration. British research institutions focus on inclusive urban design, participatory governance, and sustainable urban spaces (Carmona, 2019). The UK's policy-driven approach, particularly through initiatives like the Town and Country Planning Association (TCPA), has contributed to a high degree of engagement with European and Global South scholars (Healey, 2010). Similarly, Spain, with 70 publications and 606 citations, has gained prominence in sustainable urbanism and citizen engagement in smart cities. Barcelona's pioneering Superblocks initiative is a globally recognized model of participatory urbanism that integrates community engagement into urban mobility and green space planning (Muñoz, 2018).

Sweden, despite having only 36 documents, has received 1098 citations, reflecting a high research impact. Swedish research is characterized by human-centered urbanism, child-friendly city planning, and social sustainability (Marcus & Colding, 2014). Scholars in Sweden contribute significantly to discussions on inclusive urban governance, green space co-creation, and participatory environmental planning (Stenberg, 2020). The Netherlands, with 45 documents and 903 citations, has also been at the forefront of living labs and experimental participatory urbanism. Cities like Amsterdam and Rotterdam are recognized for co-designing urban spaces with communities, integrating smart technologies, and testing participatory governance models (de Waal & Dignum, 2017). Australia, with 66 documents and 1050 citations, actively engages in participatory placemaking, indigenous-led urbanism, and resilient city planning (Steele & Legacy, 2017). Australian scholars emphasize bottom-up urbanism, participatory public art, and climate-adaptive design, often incorporating Indigenous knowledge systems into urban development frameworks (Porter,

2016). Similarly, Canada, with 54 documents and 630 citations, has made notable contributions to community-based public space design and participatory governance (Lehrer & Keil, 2019). Canadian research focuses on urban commons, participatory digital tools, and co-creation methods for equitable urban spaces, particularly in cities like Toronto and Vancouver.

Germany's 39 documents and 766 citations highlight a focus on participatory sustainability planning and citizen involvement in smart cities (Schäfer & Keppler, 2021). German research often explores green urban planning, digital participatory governance, and ecological urbanism, with Berlin leading in experimental participatory urban projects. Italy, with 83 publications and 641 citations, has a strong tradition of historical urbanism and participatory public space design in heritage sites (Rizzo & Thiel, 2017). Italian scholars emphasize adaptive reuse of historical urban spaces and community engagement in architectural conservation projects. Switzerland, though having only 12 publications, has 395 citations and a total link strength of 33, suggesting that its research is highly collaborative and impactful. Swiss research institutions focus on resilient urban planning, participatory environmental design, and climate-responsive public spaces (Blöchliger, 2020). Overall, the data highlights key trends in participatory public space design research. The Anglo-American dominance is evident, with the United States and the United Kingdom leading in citations and research collaboration, while European nations excel in experimental sustainability models. Australia and Canada bring strong Indigenous and community-led perspectives, and Switzerland, though smaller in volume, contributes significantly to resilient and climate-adaptive urban design. Future research should emphasize cross-regional collaboration to ensure that participatory urban design remains an inclusive and globally relevant field.

5.3 Top authors publishing on participatory public space design

The research landscape in participatory public space design is shaped by a group of scholars who contribute to critical themes such as digital participation, sustainability, and urban co-design.

Author	Documents	Citations	Total Link Strength
Olivier, Patrick	5	87	13
Boulanger, Pierre	3	56	12
Schofield, Guy	3	56	12
Shearer, John	3	56	12
Taylor, Robyn	3	56	12
Amato, Federico	3	27	9
Graziadei, Antonio	3	27	9
Murgante, Beniamino	3	27	9
Sassano, Gerardo	3	27	9
Soares, Isabelle	4	52	8

Table 2: Top countries publishing on participatory public space design

Patrick Olivier is one of the leading scholars in participatory public space design, with five publications, 87 citations, and a total link strength of 13. His work primarily focuses on human-computer interaction (HCI) and digital participation in urban design. Olivier's research investigates how digital technologies, such as smart city infrastructures, participatory mapping, and crowdsourced urban planning, can enhance community engagement in shaping public spaces (Olivier & Wright, 2015). His contributions align with smart urbanism and civic technology, emphasizing co-creation methodologies that empower local communities to influence urban planning decisions (Batty, 2018). Pierre Boulanger, Guy Schofield, John Shearer, and Robyn Taylor each have three publications, 56 citations, and a total link strength of 12. Their research collectively explores technological innovations in participatory public space design, integrating digital tools, virtual reality (VR), and augmented reality (AR) in community-driven urban planning. Their work contributes to discussions on immersive design techniques, where digital modeling and simulation are used to visualize community proposals for public space improvements (Boulanger et al., 2017). These authors are part of an emerging scholarly discourse on playable cities, a concept that integrates digital interaction and urban gamification to encourage public participation (Schofield et al., 2018).

Amato, Graziadei, Murgante, and Sassano each have three publications, 27 citations, and a total link strength of 9. Their contributions focus on sustainable urban planning, adaptive reuse of public spaces, and participatory resilience strategies. Their research examines how community engagement can shape climate-

adaptive urban spaces, particularly in European cities where historical preservation and modern sustainability principles intersect (Amato et al., 2019). Their work aligns with theories of ecological urbanism (Mostafavi & Doherty, 2016) and resilient urban governance (Ahern, 2011), emphasizing how participatory methods enhance environmental sustainability in urban design. Isabelle Soares, with four publications, 52 citations, and a total link strength of 8, focuses on gender-sensitive participatory planning, particularly in the Global South. Her research critically examines how urban spaces can be co-created to address the needs of women, children, and marginalized communities, drawing from feminist urbanism and intersectionality theory (Fainstein, 2010). Soares' work highlights how participatory approaches can challenge traditional, male-dominated urban planning paradigms, advocating for safe, inclusive, and accessible public spaces (Soares et al., 2020). Her contributions are particularly relevant to debates on feminist mobility and spatial justice, aligning with Lefebvre's (1996) concept of the Right to the City.

6 REFLECTION ON FINDINGS

While the bibliometric analysis provides a comprehensive overview of publication trends, keyword networks, and global research contributions in participatory urban design, it is essential to deepen the interpretative value by linking these findings to key theoretical and methodological developments in the field. This section critically reflects on the observed trends and their implications for participatory urban design research and practice. The observed rise in scholarly output post-2010 aligns with major global urban policy shifts, such as the adoption of the Sustainable Development Goals (SDG 11) and the New Urban Agenda (UN-Habitat, 2016). However, beyond policy alignment, the exponential increase in publications between 2015 and 2024 suggests an epistemological shift in how participation is conceptualized in urban design. The early phases of participatory design research predominantly focused on community engagement as a normative good (Arnstein, 1969; Faga, 2006). However, post-2015, there is a discernible pivot towards digital participation, data-driven co-design, and resilience-focused urbanism (Batty, 2018; Balestrini et al., 2017). This transformation reflects a broader movement from abstract participatory ideals to technology-enhanced, evidence-based urban design methodologies.

Additionally, the sudden decline in 2025 publications suggests potential research fatigue or a shift in funding and policy priorities. Analyzing the nature of recent publications can provide insights into whether participatory urban design is plateauing as a field or evolving into new sub-domains, such as AI-driven participatory planning or post-pandemic spatial justice frameworks. he keyword co-occurrence analysis reveals a strong clustering around sustainability, gender, youth engagement, and digital urbanism. This suggests that participatory urban design is no longer a singular field but an intersectional domain engaging with social equity, environmental planning, and digital governance. However, gaps remain evident such as:

- The relatively smaller presence of keywords related to informal urbanism and the Global South indicates an underrepresentation of participatory methodologies tailored to non-Western urban contexts (Watson, 2014; Parnell and Pieterse, 2014).
- Despite the prominence of gender-sensitive urban design, feminist urbanism remains a niche sub-domain, often overshadowed by broader discussions on inclusivity and social sustainability (Kern, 2020).
- Emerging research on participatory smart cities and digital co-creation points to an increasing reliance on technology in urban planning, yet critical debates on digital divide and participatory exclusion remain limited (Balestrini et al., 2017).

The bibliometric findings highlight a growing emphasis on interdisciplinary and transdisciplinary approaches in participatory urban design research. The prominence of scholars integrating geographic information systems (GIS), digital ethnography, and computational modeling suggests that methodological advancements are shaping research impact and scholarly influence (McCall and Dunn, 2012; Batty, 2018). However, the variation in citation impact across different regions indicates that methodological sophistication alone does not drive research influence – policy relevance, institutional backing, and socio-political context play critical roles in determining the uptake of participatory research outputs. For instance, the high citation count of Swedish and Dutch research correlates with strong government-university partnerships in experimental urbanism (Marcus and Colding, 2014; de Waal and Dignum, 2017). Meanwhile, research outputs from the Global South, despite their practical relevance, often remain under-cited due to limited integration into

global knowledge networks (Pieterse, 2019). This underscores the need for stronger collaborative frameworks that enhance the visibility and impact of participatory urban design research from diverse geopolitical contexts

7 CONCLUSION AND RECCOMMENDATIONS: CONCEPTUAL FRAMEWORK FOR PARTICIPATORY PUBLIC SPACE DESIGN

In conclusion, this study has demonstrated the growing significance of participatory approaches in designing inclusive public spaces, particularly in the context of urban environments that have historically been marginalized, such as townships in South Africa. The bibliometric analysis provides valuable insights into the evolution of research on participatory urban design, revealing trends that reflect a broader global shift toward inclusive, sustainable, and citizen-driven urban planning. The surge in publications, particularly after 2010, reflects increasing recognition of the role of participatory design in fostering more equitable and resilient urban environments. Despite this progress, challenges remain in adapting global research to local contexts, particularly in the Global South, where socio-economic disparities and historical legacies of exclusion continue to shape urban landscapes. This study contributes to bridging this gap by offering a conceptual framework that integrates global best practices with localized participatory approaches. The framework developed herein provides a structured lens through which urban planners, policymakers, and researchers can approach the design of inclusive public spaces, ensuring that they are accessible, equitable, and responsive to the needs of marginalized communities. Ultimately, the future of participatory urban design lies in its ability to adapt to the evolving needs of cities, particularly in addressing the intersections of social equity, environmental sustainability, and technological innovation. By fostering deeper collaboration across disciplines and geographies, and by prioritizing inclusivity in urban planning processes, cities worldwide can build public spaces that not only serve their current populations but also contribute to more just and sustainable urban futures.

Furthermore, considering the key themes that emerged from the network maps as well as the focus of the top authors in this research field and the gaps, a conceptual framework for participatory public space design is proposed. The proposed conceptual framework for participatory public space design emphasizes the integration of digital technologies, sustainability, inclusivity, and community-driven processes to create urban spaces that are adaptable, resilient, and equitable.

Fig 3: Conceptual framework for participatory public space design

The first key principle focuses on participatory digital technologies as tools for co-creation. The objective is to facilitate meaningful, real-time engagement through digital platforms that actively integrate local knowledge and community preferences into the design process. Techniques such as immersive design tools like virtual reality (VR), augmented reality (AR), and participatory mapping can allow communities to visualize potential changes and contribute to co-designing public spaces, ensuring that their voices are heard and incorporated (Zhao et al., 2021; Kitchin, 2014). The second principle, sustainability and resilience

through community-driven design, advocates for incorporating environmental sustainability and resilience strategies, particularly to adapt public spaces to the challenges posed by climate change. The objective is to foster adaptive urban spaces that are both environmentally sustainable and resilient, with the community playing a crucial role in proposing solutions. This approach draws from ecological urbanism and resilience governance, which emphasize the importance of community-led adaptations to ensure climate-resilient spaces (Pelling, 2011; Anguelovski et al., 2016). A third important aspect is the creation of gendered and inclusive urban spaces. This principle prioritizes gender-sensitive planning and intersectional approaches to urban design to ensure the inclusion of marginalized groups, particularly women and children. The objective is to create public spaces that cater to diverse needs, ensuring safety, accessibility, and inclusivity for all. By engaging marginalized communities in the design process, this approach challenges traditional urban planning structures and advocates for spatial justice, ensuring that public spaces reflect the lived experiences of those often excluded (Healey, 2004; McFarlane, 2012).

The fourth principle revolves around collaborative and playable cities, where urban spaces are designed to encourage play, interaction, and engagement through participatory methods blending both physical and digital elements. The objective here is to foster a sense of ownership and belonging among community members by enabling them to actively participate in co-creating their urban environments. The concept of "playable cities" integrates gamification and interactive digital models to promote ongoing community involvement, making the urban environment a dynamic, participatory space that evolves with its users (Bishop & Stocker, 2019). In conclusion, this framework advocates for a holistic, inclusive approach to participatory public space design that leverages digital technologies, sustainability, gender equity, and community empowerment. By ensuring that urban spaces are not only designed with community input but also remain adaptive, resilient, and equitable, the framework creates environments where all citizens – particularly marginalized groups – can thrive. This approach to urban planning supports the creation of spaces that are socially just, sustainable, and responsive to the needs of diverse communities.

1 ABSTRACT

It is a long-term strategic goal of the European Union to promote multimodal mobility and thereby create a more sustainable, efficient and liveable environment. Offering travellers a wider range of choices and promoting the integration of different transport modes can help to transform the way we get around. Despite existing infrastructure, a lack of accessible and integrated information creates significant barriers for travellers. Multimodal travel is even more difficult for people with disabilities because they have more specific needs in terms of infrastructure and their itinerary. More than 8% of the population in Austria have a registered disability.

This research proposes a solution from a data perspective. We aim for a non-discriminatory low-threshold access to mobility information, especially for the group of people with disabilities or impairments and for individuals with restricted mobility. The requirements have been worked out in a participatory process with co-creation workshops and expert interviews. A use case of a person with mobility impairments has been described together with a data requirements schema. This schema of data categories covers all passenger needs from travel itinerary, change between modes of transport, and getting support. It helps to identify data specifically for similar use cases.The requirements were the starting point to design and set up the prototypical data space for mobility data. Various data sources for mobility data in Austria have been identified and analysed for their content and quality. This subsequently allowed the definition of data products with their attributes and quality measures. Data products need to satisfy consumer's needs. In the context of this work, data products are for example: disabled parking spaces in Austria, or accessible routes in and around railway stations. The actual data also includes metadata that makes it easier to find the right data product and obtain information about its origin and license terms. A specific schema was defined to fulfil the requirements for mobility data.

To successfully operate a mobility data space, suitable operator models were analysed, and the legal requirements were defined. Digital services for mobility have significant market potential. We therefore suggest establishing a dedicated task force that brings together key public and private stakeholders to create a comprehensive implementation strategy. The primary goal should be to generate practical value through improved mobility services while maintaining a sustainable operational model that promotes broad participation from current market players and fosters ongoing innovation in the accessibility sector. Well-integrated and high-quality data are a prerequisite for more usable multimodal transport. People with disabilities or individuals with restricted mobility have additional requirements in data that must be taken into account. The general public also benefits from this development as more accessible options with better information strategies is valuable for everyone.

Keywords: Mobility Data, Data Space, Multimodal Transport, Inclusion, Co-creation

2 INTRODUCTION

Most of us who work are commuters, and many of us use various forms of public transport every day. We regularly use the same and well-known route, move from one bus to another in a familiar environment. But

remember the first time you were on your own in an unfamiliar, huge, sprawling railway station, just trying to find your way out. Now imagine a blind person or someone who relies on a wheelchair to find their way to the connecting train. Things turn out to be more complicated and take much longer. The further you get away from the big cities, the less information and travel options you have – another hurdle. 8.3% (around 760,000 people) of the population in Austria have a registered disability (BMSGPK 2024). Many more struggle with mobility restrictions or other challenges such as handling a pushchair, a dog and luggage at the same time.

Mobility is of great importance for social inclusion. Research shows that people with mobility impairments face numerous additional challenges and obstacles to mobility in everyday life (Prescott et al., 2020). This can be a bad condition of pavements or the difficulty to cross a road. It is known that there are still gaps in the integration of accessibility in the field of mobility (Disabled Coalition et al., 2023). Integrated mobility services must also take extensive account of accessibility and inclusion.It is a long-term strategic goal of the European Union to promote multimodal mobility and thereby create a more sustainable, efficient and liveable environment (EC, 2021). Offering travellers a wider range of choices and promoting the integration of different transport modes can help to transform the way we get around. Despite existing infrastructure, a lack of accessible and integrated information creates significant barriers for travellers. Multimodal travel is even more difficult for people with disabilities because they have more specific needs in terms of infrastructure and their itinerary.

To enable such services, integrated and linked data is required. Data spaces are being increasingly used for decentralised, secure, and trusted data sharing within a structured governance framework. Participants in a data space establish mutual trust, agree on common standards, and maintain sovereignty over their data by defining individual policies. Unlike centralised data platforms, data sharing within data spaces occurs peer-to-peer via connectors, ensuring that data remains under the control of its original owner while enabling efficient and secure exchanges. The main advantages of data spaces include interoperability, scalability, traceability, and findability of data, making them a viable alternative to centralised data platforms. The European strategy for data aims to create a single market for data, strengthening Europe's global competitiveness and data sovereignty. A key element of this strategy is the establishment of common European data spaces, ensuring that more data is made available for economic and societal use while allowing companies and individuals to retain control over their data (EC, 2020).

In this paper, we seek for data driven solutions to solve the problems mentioned above. The question is what is needed to establish a national mobility data space and examine this issue from different perspectives by involving the community. A participatory process was applied with the help of co-creation workshops and expert interviews. The contributions in this paper range from data requirements to a prototypical implementation, to the experiences we have made with the application in practice. In detail this comprises the following: a use case of a person with mobility impairments, and a data requirements schema which helps to identify data specifically for similar use cases. From a business perspective, we propose the formation of a dedicated task force combining key public and private stakeholders to develop a detailed implementation strategy. The focus should be on creating practical value through enhanced mobility services while maintaining a sustainable operational model that encourages broad participation from existing market players and enables continuous innovation in the accessibility sector. The legal perspective addresses the use of open data and lists more complex legal issues in the implementation of data spaces. From a technical viewpoint we further propose a concrete meta data schema for the use in a mobility data space. An important benefit for data space customers is the use of data products. We implemented a set of data products for the data space to fulfil the use case and will discuss two of them in more detail in this paper.

3 RELATED WORK

To advance theinitiative of data spaces, the Data Spaces Support Centre (DSSC)[1] facilitates these data-sharing environments, enabling data reuse across sectors while respecting EU values.Furthermore, the InternationalData Spaces Association (IDSA)[2] plays a leading role in developing the technical foundation for data spaces, ensuring secure and standardised data exchange. IDSA members have been working on key technologies, leading to major achievements such as the IDS Reference Architecture Model (latest version:

[1] https://dssc.eu/
[2] https://internationaldataspaces.org/

IDS-RAM 4.0), the IDSA Rulebook, and the Dataspace Protocol, all of which define clear rules for trusted data sharing. These efforts contribute to establishing the Dataspace Protocol as an international standard, reinforcing the foundation of a fair data economy.

Several initiatives have been undertaken to advance the development of mobility data spaces, including efforts addressing the needs of persons with limited mobility, which laid the groundwork and provided impetus for the CARINA project. In Austria, the DIANA 4 CCAM project (Aichholzer et al., 2022)has contributed to this advancement. DIANA 4 CCAM has pioneered a data cycle concept that supports the integration of AI functions in the mobility sector. Internationally, the most relevant precursors for CARINA include the European Mobility Data Space (MDS)[3], a virtual marketplace for the exchange of mobility data with over 150 participants, PrepDSpace4Mobility (Bakri et al., 2024), which provided the groundwork for the MDS, the French EONA-X Data Space[4], which integrates mobility and tourism data to enhance intermodal travel experiences, and the Data Space for Multimodal Passenger Mobility (DSMPM)[5], a secure and standardized platform that enables the seamless integration and sharing of diverse mobility data for inclusive multimodal travel experiences.

Building on these foundations and among other Austrian data space initiatives, the CARINA project will contribute to the foundations for a national mobility data space in Austria. Some other current initiatives are the project Övvvi[6], which has the aim to contribute to this cause through the collection, integration, analysis and structured provision of mobility data, and the project MultiMoFusion[7] where the goal is to enable demand-driven and sustainable transportation planning through data fusion of smartphone assisted self-interviewdata, floating phone data and other data sources. The most notable current Austrian data space initiative is the KoDRM-AT[8] project. KoDRM-AT shall develop legal, organisational and technical concepts and concrete implementation steps for a national mobility data space in line with the European Data Strategy (EC, 2020) to deliver a contribution to the Austrian mobility masterplan 2030 (BMK, 2021).

There are already several platforms in Austria that collect and provide extensive mobility data (BMK, 2024). The Graph Integration Platform (GIP)[9] for example, provides a basic structure of mobility data in Austria. It is implemented as a multimodal transport graph, enables a nationwide supply of high-quality transport services in a standardized way, based on a common data standard and it is the basis for various route planners and other applications. basemap.at[10] and EVIS.AT[11] also play an important role in the mobility data landscape in Austria. They utilise data from the GIP and the Verkehrsauskunft Österreich(VAO) . basemap.at is a cartographic product that includes a simplified representation of terrain, buildings, rivers and transport routes throughout Austria. EVIS.AT provides the current traffic situation, journey times and incident reports for the Austrian road network and is available for numerous traffic information services.

Static mobility data is available, but fragmented and difficult to access (Gatzert et al., 2023). The situation is different with dynamic mobility data. There is currently no regulation on how this data must be made available. Unforeseeable temporary changes, such as defective barrier-free facilities, construction sites or short-term organisational changes pose a particular challenge for people with mobility impairments. As a result, they are unable to participate in many activities (Prescott et al., 2020) (Disabled Coalition et al., 2023).

There are many applications and services that help end users in their everyday lives when it comes to mobility. For example, VAO[12] offers a mobility information platform including an intermodal dynamic real-time route planner. This route planner is used in various mobility apps in Austria with a usage of around 590 million routing requests in 2024 (BMK, 2024). It allows users to partially customise their query, such as selecting their preferred means of transport, the maximum distance they can cover on foot or the option of

using escalators, stairs and lifts. There are also some customisation options for cycling and driving. Nevertheless, there is no specific consideration of accessibility. There is further potential for improvement in better linking the various modes of transport within a route. Driving, cycling and public transport are currently considered separately. In addition, information such as public transport disruptions is not fully integrated.

The mobyome mobility app[13] aims to collect mobility data and raise awareness of users' own mobility behaviour. Users can record their everyday journeys. They then get feedback on the costs and emissions of their travel behaviour and possible alternatives. Although the app does not explicitly focus on accessibility, users have the option of choosing which alternatives are suitable for them afterwards.

Wheelmap[14] is a map on whichone can find wheelchair-accessible places and rate them according to their accessibility for wheelchair users. It is based on a crowd-sourcing principle, i.e., anyone can add places to Wheelmap and rate their accessibility based on various criteria. This approach helps to easily generate data about accessibility information on a broad basis, but it is not possible to guarantee certain data quality requirements. Continuous maintenance of the database cannot be guaranteed, as the provision of data is not regulated. Nevertheless, this is an important source for many people with disabilities.

4 METHODOLOGY

It all started with the idea of using data for more sustainable multimodal mobility and responding to individual mobility needs. A key driver was also to promote the inclusion of people with mobility impairments. As an initial activity the main stakeholders of the mobility scene in Austria were identified and invited to co-creation workshops. The workshops provided a good insight into the challenges and expectations of the stakeholders. Through the participation of different representatives, important aspects from the perspective of data providers and data operators as well as inputs from representatives of people with reduced mobility could be collected. The involvement of different stakeholders is important to ensure that the largest possible group of people benefit from the results.

The co-creation activities continued with expert interviews in the area of people with disabilities. The collected information was the basis to create personas and detailed use cases. In total three use cases were developed (Russegger, 2024) one of which we will focus on in this paper. With the help of the use cases, a data schema was developed which allows to determine the data requirements for travels especially for people with disabilities. This guided the concrete implementation. First the data sources were identified, and the required data sets were collected. Automatic data transformation processes were setup which clean and prepare the datasets. The results are data products which can be re-used in various use cases. The data products are shared in a data space as new data offerings. Implementing a prototype mobility data space with real data helped us in evaluating further business- and legal foundations. A contract was setup for exchange of raw data for a data intermediary who processes data and re-sells it on the mobility data space. Finally, the business foundations for operating a mobility data space were determined.

5 REQUIREMENTS ANALYSIS

This chapter describes the co-creation activities that were carried out. It first started with co-creation workshops and then continued with expert interviews. The collected information was the basis for the use case which then led to the development of the data requirements schema.

5.1 Co-Creation Workshops

Two co-creation workshops were held as video conference sessions lasting 90 minutes. In the first co-creation workshop 9 different stakeholder organisations participated and in the second 18 different organisations. The stakeholder organisations came from following areas: organisation for people with disabilities, operator of transport data infrastructure, tourism organisation association, legal or technical counsellor, public administration, public transport provider, research institution, interest group for public transport, business development consulting, and automobile association. To make the idea of a mobility data space clearer, an exemplary use case was prepared.The workshops were transcribed and then summarised

[13] https://app.mobyome.at/gemeinde
[14] https://wheelmap.org/

and structured. This was the basis for collecting the needs and availability of data, as well as collecting the challenges and expectations of people with disabilities.

The biggest challenges include a lack of easy access and intuitive user interfaces, but also the lack of links between different transport modes, as well as barriers for people with mobility impairments despite being labelled as barrier-free. Much information is still missing, e.g., information on the options for transferring between different modes of transport, or information on alternative routes in the event of breakdowns of barrier-free infrastructure. In some cases, the data does not even exist or has to be entered manually (e.g., failure of an escalator). In addition, the lack of regulated responsibilities and competences is a major problem, as it is not always clear who has to ensure that the data is up to date. Expectations of a data space were also mentioned: barrier-free access to information, a technically intuitive solution and a coherent data space to find as much of the required information as possible in one place, and up-to-date data on the accessibility of means of transport, stops, railway stations and underground stations.

5.2 Expert Interviews

Expert interviews were conducted to further refine the use cases and the specific scenarios. Therefore, a semi-structured interview format was chosen. The invited interview partners are themselves affected by mobility impairments as well as representatives of the interests of people with reduced mobility. The expert interviews included four participants. Two of them are dependent on a wheelchair, one is from an association for the blind, and one is an employee of an organisation for people with disabilities. The aim was to ensure that the developed use cases describe realistic scenarios and provide comprehensive insight of the challenges in mobility. The lack of information and therefore the results of it were discussed, as well as possible technical assistance, the requirements of people with different impairments (e.g., physical disability, cognitive impairment), and the everyday life of a person with disabilities.

5.3 Use Case

The following exemplary use case was developed to illustrate the data needs and to show how a typical itinerary of a person with disabilities looks like. (Russegger, 2024) describes in total three personas and mobility use cases for people with mobility impairments. In this paper we address as a representative the following one:

Markus is 36 years old and is dependent on a wheelchair. He lives in the outskirts of Graz and plans to visit his aunt Erna in Klagenfurt. He then travels on to an event in Tyrol. Markus is not reliant on public transport as he has his own car. Nevertheless, he would like to use public transport for the majority of his journey and plans to use his car only as far as a suitable public transport hub, such as a specific stop or train station.

A possible itinerary would look like this: By car via Keplerstraße – car park at the main station – express bus to St. Michael – ÖBB Railjet to Westbahnhof Klagenfurt – SURAAA shuttle to intermediate destination – <PAUSE> – SURAAA shuttle Westbahnhof Klagenfurt – to Innsbruck with ÖBB – Regiobus 160x to Reutte – Regioflink to final destination.

5.4 Data Requirements Schema

A data schema was developed to identifythe requirements on data in a structured way for this use case and also for similar other use cases for people with restricted mobility. This schema is a generalisation developed from the stakeholder interviews and co-creation workshops. Its aim is to identify the required data, to categorise it, and to check for completeness.

5.4.1 Travel Planning

Description: A service for creating an itinerary that is easy to use by considering the accessibility guidelines and is configurable or automatically adaptable for specific travel needs for people with restricted mobility.

Use case: For the described use case above this would be a smartphone app with a route planner to find the optimal route from his home to Klagenfurt.

Data needs: Public transport route network and timetables, road network including current traffic situation, information on accessibility of infrastructure, etc.

5.4.2 General Information about Travel Routes

Description: Giving the opportunity to choose between different options for a travel to get the personal best option. All necessary additional information about the equipment of the stations and means of transport.

Use case: Markus should only receive suggestions for travel routes that meet his needs. This means that both the modes of transport and the routes between the modes must be suitable for wheelchair users. This can be supplemented by photos, for example. If a reservation is required for one of the means of transport, Markus needs information about whom to contact and when. He must also be told exactly where he can park his car for routes that suggest using his car.

Data needs:Travel routes at different times; equipment of the modes of transport (ramps, braille lettering, suitable seats...) including current condition and capacity utilization; current condition and availability of ramps or stairs of the routes; location and condition of sanitary facilities.

5.4.3 Transfer Navigation

Description:Information on finding connecting transportation.

Use case: Markus needs additional information for transfer navigation information, for example how to get to lifts or wheelchair lifts or wheelchair ramps.

Data needs: Location and current condition on elevators, escalators; status and location on navigation aids at stations (boards, displays); precise indoor navigation including routes to elevators or escalators.

5.4.4 Transfer Times

Description: Information on transfer times depending on the user's mobility.

Use case: Depending on the circumstances, Markus may need longer to change than a person without a mobility impairment if, for example, access via the lift takes longer than via the escalator.

Data needs: Average time a person needs to change trains; reference values for transfer times for people travelling at different speeds and different mobility; transfer times if lifts have to be used.

5.4.5 Park/Bike and Ride

Description: Information about places where it is possible to change modes of transport and where cars or bicycles can be parked and at what cost.

Use case: If parts of the proposed route are to be travelled in Markus' own car, he needs to know where he can park it. It must also be known whether there are suitable car parks with more space for Markus to get out of the car.

Data needs:Locations of park/bike and ride facilities; current utilisation; locations of disabled parking spaces, including current capacity utilisation.

5.4.6 Last Mile

Description: Information on on-demand transportation providers, taxis or similar when travelling the last leg of a journey including where to find them, how to book it and how to use these services.

Use case: In addition to the information on what options are available for the last leg of the journey to his aunt and how he can use them, Markus also needs to know whether they are wheelchair accessible.

Data needs: Options for last mile transportations; on-demand transportation providers; location, opening hours, equipment of the means of transport offered.

5.4.7 Ticket Information

Description: Information should be provided on where to buy tickets for the modes of transport. If park and ride offers are included in the itinerary, information should also be provided on how to purchase tickets.

Use case: Markus has no special requirements regarding the way in which he buys his ticket. However, if extra tickets or seats need to be booked to use public transport with a wheelchair, this should also be clearly indicated.

Data needs: Location and opening hours of ticket counters; ticket purchase at ticket machines: notes on ease of use; different modalities of ticket purchase; need for extra tickets for wheelchair spaces, including capacity utilisation.

5.4.8 Deviations and Disruptions

Description: Travelers should be informed about deviations from the planned journey and offered suitable alternatives.

Use case:In the event of short-term deviations, Markus needs alternatives that continue to meet his needs. In the event of a different platform, Markus needs information on how to get to the new platform via a wheelchair-accessible route. In the event of train cancellations or delays, new routes must be calculated that also take the aforementioned aspects into account.

Data needs: Real-time information on cancellations, platform changes, delays or non-functioning infrastructure.

5.4.9 Personal Assistance

Description: Information on where and how to get further support should also be provided.

Use case: If Markus needs additional help, such as when changing trains or with his luggage, he should be able to call up information on where and how he can get help.

Data needs: Places or telephone numbers where one can get support; location and opening hours of information centres; connecting volunteers and people seeking help.

6 IMPLEMENTATION

This chapter describes the prototypical implementation of the data space and its results. It starts with the business relevance of such a project and the various legal considerations from free and open data to complex contractual relationships. The tasks of data governance are listed to build trust and interoperability. A concrete meta data schema for the use in a mobility data space was also implemented. The end of this chapter is dedicated to the data products – the digital asset in a data space for its customers.

6.1 Business and Legal Foundations for a Sustainable Mobility Data Space

The business perspective:A sustainable mobility data space must build upon and enhance existing infrastructure and applications rather than creating parallel structures. Current mobility applications and platforms already serve millions of users daily, including essential accessibility information needs. The business value lies in augmenting these established services with standardized accessibility data and enabling new integrated solutions. With around 760,000 people (8.3% of the population) having registered disabilities in Austria in 2022 (BMSGPK, 2024) there is significant potential for both improving existing services and developing specialized mobility solutions.

Given this market potential, we propose the formation of a dedicated task force combining key public and private stakeholders to develop a detailed implementation strategy. This task force should address critical questions of governance, data monetization models, and infrastructure funding, while ensuring both economic sustainability and public benefit. The focus should be on creating practical value through enhanced mobility services while maintaining a sustainable operational model that encourages broad participation from existing market players and enables continuous innovation in the accessibility sector.

The legal perspective:Numerous valuable mobility-related datasets are provided by public sector entities. These datasets are often available as open data (e.g., GIP data in Austria or the Mobilithek in Germany) or accessible via open standard interfaces (e.g., ÖBB or Wheelmap data upon registration). These data sources, whether directly or indirectly accessible, offer a rich repository of information on mobility activities and infrastructures. Leveraging these datasets enables the development of various applications that cover a substantial portion of mobility-related processes.

From a legal perspective, the use of public datasets is generally straightforward, as broad open licensing agreements govern their reuse. Open-data licenses, such as Creative Commons or the German Data License, typically allow extensive utilization. However, restrictions exist regarding liability and warranty. When utilizing such license-free datasets, data providers generally do not assume liability for their accuracy. This

issue becomes particularly relevant when dealing with real-time or near-real-time data, which are critical for accurately reflecting current mobility dynamics. In such cases, the open-data approach reaches its limitations.

Highly relevant real-time data are often not freely licensed or are technically challenging to obtain (e.g., sensor data along roadways or IoT-generated data from municipalities). In these cases, more complex legal issues must be resolved before the data can be utilized. Another challenge arises when data are collected by a municipality but subsequently transmitted, stored, and potentially shared by third-party intermediaries acting as data service providers. This results in a legal triangular relationship or data trusteeship. Such a structure is legally more intricate because the original data provider must first transfer the data both technically and legally to the intermediary, who then becomes a secondary data provider for further distribution. While legally feasible, this setup often presents challenges for stakeholders, as it necessitates establishing multiple contractual relationships.

This sometimes complex contractual landscape among mobility stakeholders can be streamlined if a data space assumes the role of a facilitator and curator, negotiating contractual agreements in advance and, in some cases, serving as a data trustee. Clearly defining the legal framework for data access rights, monetization models, and liability provisions is essential to ensure seamless data exchange. Furthermore, mechanisms for dispute resolution and arbitration play a critical role in efficiently managing conflicts and fostering long-term trust among stakeholders.

Compliance with data protection regulations must be ensured, particularly when mobility data could indirectly enable the identification of individuals. Adherence to the General Data Protection Regulation (GDPR) is therefore imperative.

6.2 Data Space Governance and Metadata Management

Data governance refers to the comprehensive set of rules, processes, and responsibilities for managing and utilizing data within an organization. The primary objectives are to ensure data quality, data protection, interoperability, and compliance, thereby enabling efficient, secure, and legally sound data usage.

Data spaces are decentralized data ecosystems, and this project contributes to the Austrian mobility data space. While data governance in data spaces follows the same fundamental principles as in organizations, aspects such as trust, data sovereignty, and legal certainty among participants are even more critical. Within a single organization, a higher level of inherent trust exists between data providers and consumers. However, in a heterogeneous and decentralized data ecosystem like a data space, trust and interoperability must be established first. Therefore, contract-based governance mechanisms – including access policies, interoperability standards, quality assurance frameworks, and compliance regulations – are essential for enabling controlled, transparent, and efficient data sharing (Guggenberger et al., 2025).

A core principle of data governance in data spaces is data sovereignty. Each participant must retain control over their data and be able to define the conditions under which data may be shared or utilized by others. This is implemented through contractual agreements and technical mechanisms, such as access control, identity management, and policy enforcement (ref. Margoni et al., 2023). Frameworks such as the IDS-RAM (International Data Spaces Reference Architecture Model) and Mobility DCAT-AP provide well-defined structures and guidelines for these requirements.

For the planned future implementation of a national mobility data space, it is recommended to establish a strong governance structure. To make this work, a steering committee of interested organisations should bring together key stakeholders of public administration, mobility providers, research institutions, and technology experts. Everyone needs clearly defined roles: Who will be the coordinator or operator, who provides data, under which conditions and contracts, who creates and operates data services, who administrates, curates and operates the data apps and data services, who will be the final beneficiary (end-user), who ensures everything runs smoothly (business continuity)? This setup should align with existing regulations, such as the EU Data Strategy, the Data Governance Act, and Austria's Mobility Masterplan 2030. Without solid governance structures, there is no trust. And without trust, data-sharing won't work. Contracts are just as important as technology. A secure and controlled data-sharing environment requires clear rules on who can access what, under which conditions, and for what purpose. In our project we developed standardized agreements which define data usage rights, licensing terms, and compliance

measures. These templates could be used as a blueprint for future initiatives to make sure data is shared efficiently, legally, and fairly.

For the operating of data space and/or data services it is necessary to have all components for the data journey and application journey are up and running smoothly. That includes high-quality data, accurate data science components and necessary connectors and other systems. A Mobility Data Space is only useful if the information it provides is accurate and up to date. Therefore, we propose to include a Data Quality Assurance Framework from the beginning to automatically check for missing or incorrect data.

Metadata management is another crucial component of data governance in data spaces. Standardized and uniform metadata are essential for ensuring that data is discoverable, interpretable, and reusable. In this context, vocabularies such as DCAT (Data Catalog Vocabulary) play a key role, particularly in domain-specific applications like mobility. Extensions such as MobilityDCAT-AP address the unique requirements of mobility data, including infrastructure information and transportation modalities (cf. DSSC, 2024).

An established standard in this field is DCAT – the Data Catalog Vocabulary. It is an RDF-based vocabulary designed to support interoperability between data catalogs and is currently in its third version (Albertoni et al., 2024). Various application profiles have been derived from the W3C recommendation to adapt the vocabulary to domain-specific use cases. For instance, dedicated profiles exist for mobility data (Molinas Comet et al., 2025) and statistical data (Sofou and Dragan, 2016). Depending on the specific application scenario and the type of data being exchanged, it is advisable to use DCAT for a mobility data space while extending it with mobility-specific metadata. As illustrated inFigure 1, classes and properties were adopted from MobilityDCAT-AP (Molinas Comet et al., 2025) for this purpose.

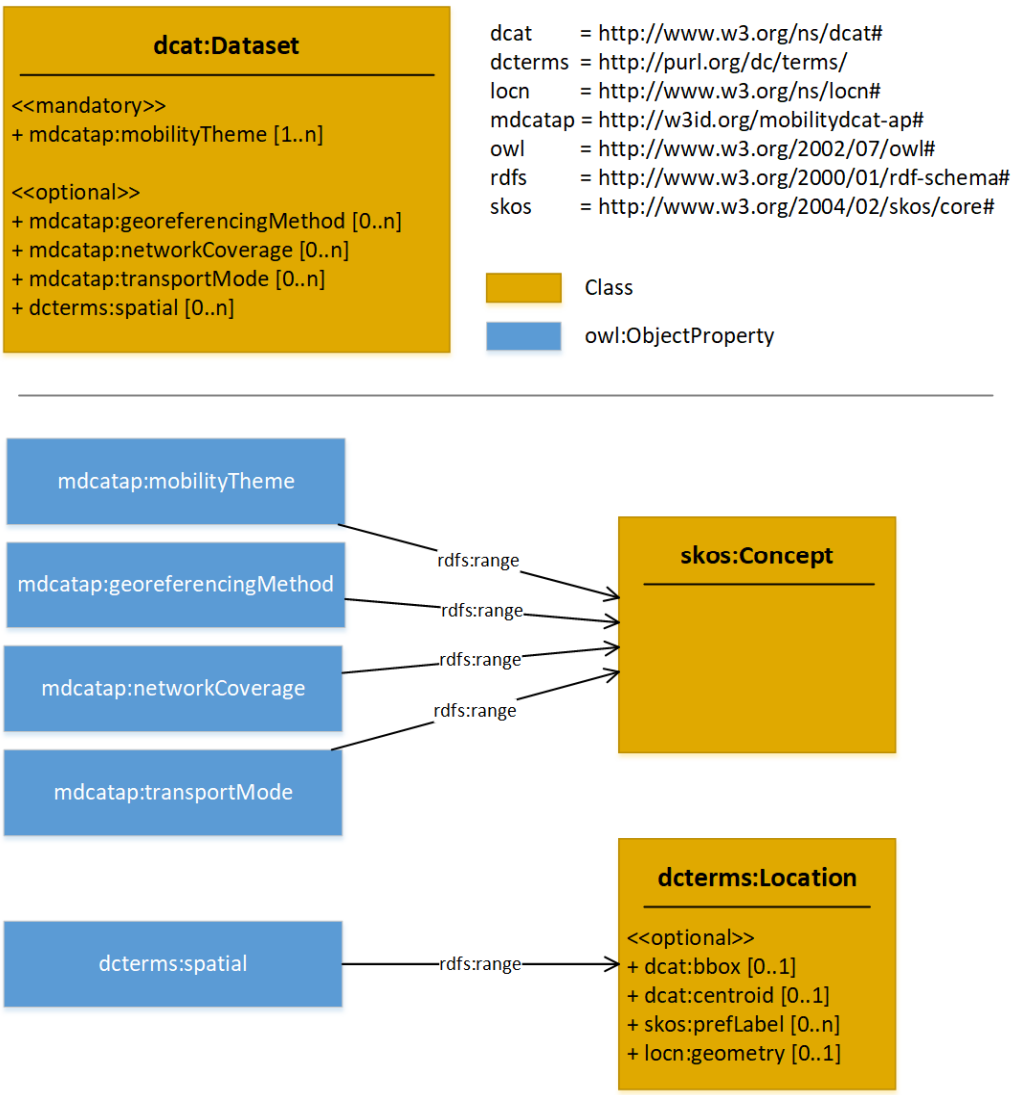

Figure 1: The proposed metadata schema builds upon the Data Catalog Vocabulary and the mobility extension for DCAT.

6.3 Data Products

Data spaces enable controlled and trusted data exchange between participants. The value creation typically begins with raw data provided by data providers. This data is processed, harmonized, and refined through specialized data processing services. The combination of relevant data and associated processing services ultimately forms a data product, which is made available to other participants in a standardized and quality-assured manner (DSSC, 2023).

Particularly valuable is that not only the final data product but also all intermediate results of the processing chain can be offered as new data assets within the data space. For example, normalized datasets, analysis results, or aggregated statistics can be made available as independent resources. This modular structure allows other participants to build upon different levels of the processing chain and develop new services or data products. This creates a dynamic ecosystem where data and services can be continuously evolved and used in new contexts.

This approach significantly reduces barriers to entry for new participants in the data space. Instead of building complete processing chains from scratch, organizations can leverage existing data products or intermediate results as building blocks for their services. This not only accelerates development but also promotes data quality through reuse of well-maintained datasets. Furthermore, the standardized description of properties and usage conditions in data productofferings creates transparency and facilitates the discovery of relevant data resources.

In the context of accessible multimodal transport, data products play a crucial role in combining various data sources into meaningful services. For instance, raw data about infrastructure accessibility, real-time vehicle locations, and service disruptions can be processed and combined into comprehensive mobility information services. Each step in this process potentially creates valuable intermediate data products that can be used for different purposes, from route planning to accessibility analysis. This flexibility is particularly important in addressing the diverse needs of people with limited mobility, as different applications may require different views or combinations of the same base data. Below we describe two exemplary data products that were implemented for the prototype.

6.3.1 Disabled Parking Spaces in Austria

This data set contains the geolocation, a corresponding address, and a description of disabled parking spaces in Austria. It combines data from Graz, Tyrol, Salzburg and Vienna, and it is updated once a day.

License: Creative Commons Attribution 4.0 International (CC BY 4.0)

Data Attributes

- provenance: origin of this record
- name: name of the parking place
- address: address name of the parking place
- municipality: municipality where this parking place belongs to
- comment: additional information for this record or parking place
- lat: latitude coordinate of this parking place
- lng: longitude coordinate of this parking place

6.3.2 Traffic Monitoring

Infrastructure based traffic monitoring data can be used in different ways to support multi-modal transport of passengers and goods. Real-time as well as long term data – or some kind of processed or post-processed set of datacreated from the original data –from specific parts of road infrastructure which are hot spots that cause delays or uncertainties for a timely arrival at the end destination of a transport mode, can be used to feed into any kind of end user application for travel planning. One kind of processed data that can be utilizedinend user travel planning applications, is long term traffic occurrence dataat said hot spots in different granularity, i.e., every minute, hour, day or month, depending on the applicationstraffic statusforecastaccuracy requirements. The main attributes forsuch data is the current time stamp (i.e., time, day or month), which

kind of road infrastructure the object is detected is on (e.g., road or sidewalk) andhow many objects are detected at a specific time stamp.

7 CONCLUSION

In more and more areas of mobility, data is being digitally recorded or even generated automatically. This ranges from train timetables and traffic monitoring systems to your own car that collects sensor data. Due to the different sources and responsibilities, this results in many heterogeneous and decentralised databases that are little or not at all linked with each other. We are in the middle of a digital transformation process that involves making these data sets available and usable. This was also taken up at the political level. Here are some examples: The European Union has released the data governance act and the data act to promote the exchange and use of data. In Austria the activities around intelligent transport systems (ITS) and the "Action Plan Digital Transformation in Mobility" (BMK, 2022) aiming to bring digital mobility services closer to users of the mobility system.

Developments in the field of data spaces in recent years are aiming at enabling homogeneous as well as trustworthy data exchange and governance within these frameworks. This is also the basis for a healthy and well-functioning data economy. Data exchange and data economy are still an unknown area for many people. As part of this implementation, we learned in interviews that people are often hesitant to take advantage of this opportunity. On the other hand, people have exaggerated expectations. They assume to generate high revenues within a short period of time. Both must be balanced, and the situation must be assessed realistically. There is some effort necessary to create substantial amount of high-quality data. Data must have integrity and a trustful framework for data exchange must be given. This includes technical and legal aspects at the same time.

Digital services for mobility have significant market potential. We therefore suggest establishing a dedicated task force that brings together key public and private stakeholders to create a comprehensive implementation strategy. The primary goal should be to generate practical value through improved mobility services while maintaining a sustainable operational model that promotes broad participation from current market players and fosters ongoing innovation in the accessibility sector.

Mobility is of great importance for all people and therefore also for social participation. Travelling multimodal faces various challenges but it is a strategic goal and has the potential to create a more sustainable, efficient and liveable environment. People with mobility impairments face numerous additional challenges and obstacles to mobility in everyday life. It is our goal to give this group the opportunity to participate in public transport on an equal basis. As a positive side effect, also other groups will benefit from a better adaptability to user needs. As a result, there is an urge for mobility services that are better tailored to individual needs. Interlinked and high-quality data provides the basis for such services.

8 ACKNOWLEDGEMENT

The collaborative research project "CARINA – publiC dAta foR mobIlity aNd trAnsport" in the context of which this paper was written, is funded by the Federal Ministry of Climate Action and Energy as part of the FTI-Programme Future Mobility. It will contribute to the foundations for a national mobility dataspace in Austria. The project consortium would like to thank all participants who took part in the discussions and thus made an important contribution to the project.

1 ABSTRACT

The urban socio-ecological transformation requires pathways for an urban energy transition, including the establishment of Positive Energy Districts (PEDs). Technical solutions and simulation tools for urban energy systems are needed for the planning, management and implementation of PEDs. In addition, the involvement of all societal stakeholders is needed to achieve the EU's ambitious target of 100 PEDs by 2025.[1] To this end, innovative research, information and communication strategies must be developed.The transnational funded research project DigiTwins4PEDs[2] focuses on developing an Urban Digital Twin as a dynamic digital representation of urban energy systems using advanced modelling tools. The framework facilitates the integrated energy demand-supply analysis at district scale. It enables the construction and analysis of future development scenarios to simulate the performance of PEDs.It supportsinformed decision-making by citizens and urban administration for a sustainable urban energy transition. The transnational project applies innovative methods and develops implementation strategies supported by a participatory process involving key stakeholders and citizens in co-design, co-creation and co-learning stages of research. Through the framework of living labs in four different case studies, citizens are continuously engaged throughout the project so that citizen-driven actions towards Positive Energy Districts can be considered and implemented more efficiently. New tools and methods are developed and adapted using Urban Digital Twins based on the CityGML data format to enhance public participation in advancing clean energy transition. These toolsenable citizens to actively engage in shaping the future energy transition of their communities and thus supporting informed decision-making.The developed and implemented urban digital twin framework is tested in different urban case study areas (Vienna, Stuttgart, Rotterdam, Wroclaw)within an innovative public participatory process to address the multifaceted aspects crucial for establishing PEDs together with the citizens.

This paper discusses the concept and first prototype of the developedparticipatory planning framework, a shared urban data and modelling scheme,utilizing a digital twin, as well as itsimplementation.It will show how the developed frameworkenables the simulation of urban energy systems with integrated local socio-economic and demographic parameters to identify and visualise current and future energy demand, renewable potential and different energy flexibility strategies in a district. It will discuss how the developed framework can be integrated/combined with other citizens' engagement tools, focussing on the ones used in

[1] https://setis.ec.europa.eu/working-groups/positive-energy-districts_en
[2] https://digitwins4peds.eu/

the case study sites. Furthermore, we draw conclusions on how this framework can be used to support co-design, co-creation and co-learning of community-driven solutions for energy transformation.

Keywords: Citizens Participation, Modelling and Simulation, Urban planning, Positive Energy Districts, Digital Twin

2 INTRODUCTION

Several initiatives have been started to support the clean energy transition and drive the sustainable urban transformation, like the EU SET-Plan, Action 3.2 that aims to have 100 PEDs in Europe expected to be by 2025 in concrete planning, construction, or operation1. An analysis [BOSSI et al. 2020] shows the role of stakeholder processes (citizens, urban stakeholders) as a primary factor for the success or failure of such energy transition, followed by the availability of shared information delivered by integrated technological solutions. The involvement of civil society in planning the built environment is well-established and common practice. However, little is known about their inclination towards community-based energy transition. While technological innovation is necessary to realise PEDs, the challenge is also one of societal transformation as energy transition must be accepted and pushed by citizens and not only by authorities. The participation of local communities in urban design is well-established; however, their involvement in the energy transition remains largely unexplored. While various technological solutions exist for green energy planning, achieving PEDs with strong community support continues to be a significant challenge. This ultimately presents a major obstacle to achieving ambitious targets, such as the EU's objective of deploying 100 Positive Energy Districts (PEDs) by 2025. To address this gap, DigiTwins4PEDs aims to implement an innovative public participation process using Urban Digital Twins (UDTs) embedded in a living lab concept on its four case study regions of Stuttgart, Vienna, Rotterdam, and Wroclaw.

3 CASE STUDIES

The case study in Stuttgart will focus on the neighbourhood of Nordbahnhofviertel, which is facing urban, infrastructure and societal challenges due to adjoining constructions of Stuttgart 21 and Rosensteinviertel. In addition to infrastructure and societal development, it becomes important for Nordbahnhofviertel to get itself developed in terms of energy infrastructure, together with Stuttgart 21 and Rosensteinviertel. Thus, its energetic transformation to PEDs can help Nordbahnhofviertel to ensure that it is no longer insular and ensure a sustainable basis of life for its current and future residents.

The case study in Vienna focuses on the project area "Grätzl 20 + 2" as a part of WieNeu+ urban renewal programme of the city of Vienna. Grätzl 20 + 2 is located in the neighbouring 2nd and 20th district of Vienna and was launched in early 2023 as a cross-district programme in the districts of Brigittenau and Leopoldstadt. It combines the area in the 20th district up to the Danube Canal and Stromstraße with the “Volkertviertel” and “Alliiertenviertel” neighbourhoods in the 2nd district, with Nordwestbahnstraße connecting the two areas. A special focus in these areas is to transform the currently gas-based energy supply system to alternative renewable energy sources and evaluate the implications of such conversion on the power and heat load management and related peak loads. Therefore, the intended approach within DigiTwins4PEDs is to co-design different district energy transformation scenarios with a focus on energy flexibilisation options using urban digital twins as simulation tools and co-create solutions and evaluate with residents and decision makers potentials and opportunities to transform the Grätzel 20+2 towards a PED.

The case study in Rotterdam will focus on the neighbourhoods of Prinsenland and Feijenoord. Rotterdam is committed to finding future-proof solutions to reduce its carbon footprint and become carbon-neutral by 2050. However, the city will not be able to achieve its climate action pledge alone: input from the government, province, and industries such as the port, as well as changes in city residents’ behaviour, will also be necessary. Within DigiTwins4PEDs the neighbourhoods of Prinsenland and Feijenoord will be used as a test case to experiment living labs and the development and evaluation of new IT-based tools for co-creation and community-based solutions to enable the civil society to drive energetic transformation by information exchange, visualising future energy demand for cooling, potential, flexibility scenarios and its socio-economic impact at a community level. City of Rotterdam has already established a “Digital City Rotterdam” to improve the efficiency of urban planning and management. Connecting the Digital City Rotterdam with the activities and outputs of DigiTwins4PEDs will be a very valuable opportunity to engage citizens in a co-creation process to start the transition towards PEDs.

The case study in Wroclaw focuses on the neighbourhood of Kleczków, which is facing infrastructural and societal challenges in connection with the implementation of "Nowe Kleczków" and the planned functional and spatial changes in the western and eastern parts of Kleczków. For the sustainable development of Kleczków it is important that it continues to future proof its energy infrastructure and thus its energetic transformation to PED can support in providing a sustainable living conditions for its current and future resident. Public buildings, including schools and municipal housing, often have high energy demands due to aging infrastructure. Investments in insulation, energy-efficient HVAC[3] systems, and solar panels could significantly reduce their environmental impact. Former industrial sites, repurposed into offices or cultural spaces, also present opportunities for modernization, such as renewable energy installations and smart systems to improve efficiency. Kleczków's diverse building stock, ranging from modern housing and historic churches to industrial-era tram depots, provides a solid foundation for transforming the district into a "positive energy district," where buildings not only minimize energy consumption but also generate surplus energy through renewable sources, contributing to a sustainable and self-sufficient urban environment.

4 METHODS: CONCEPTS AND FIRST PROTOTYPES

The project usesa bottom up end-use approach to model urban energy systems with focus on the district scale. The modelling methodology relays on sectoral spacio-temporal modells to conduct integrated energy demand and supply analysis,coveringselected flexibility options to balance energy demand with the volatile renewable energy supply in a timely manner. This ensures the required positive annual energy balance for the pilot PEDs.

Starting from the calibration of a base year reflecting the current district energy system, the approach allows for constructing future energydemand-supply scenarios following assumptions on the expected local demographic, socio-economic and technologicaldevelopment, the available local RES potential and the viable interaction with the neighbourhood energy system. The future development scenariosare constructed based on co-creation process involving key stakeholders and engaging citizens.

4.1 Energy flexibility analysis

PEDs represent urban energy systems relying upon variable renewable energy sources (RES) to cover district energy demand.Ensuring the timely demand-supply balance in view of such fluctuating conditions requires the provision of appropriate flexibility options to adjust demand and supply and maintain regional grid stability. Energy flexibility options involve strategies and technologies that dynamically balance energy demand and supply, ensuring optimized management for a positive annual energy balance of the PED.These options includedemand and supply sides, local energy storages, sector coupling (e.g., V2G) and smart energy management. Implementing flexibility options requires data collection and analysis to inform decision-making and develop a comprehensive implementation plan. Additionally, engaging local stakeholders is crucial to gathering qualitative insights, enhancing a data-driven approach, and promoting the benefits of utilizing local flexibility options.

Demand Response (DR) and Demand Side Management (DSM) are key measures for enhancing the flexibility of modern energy systems. It leverages the potential for temporal shifts in energy demand to better match supply fluctuations, optimizing energy use and reducing stress on the grid.Technologies such as heat pumps, thermal energy storage, and electric vehicle charging schedules can be dynamically adjusted to align with the grid conditions, contributing to more efficient and reliable energy systems. DR focuses on shifting or reducing energy consumption during peak times to off-peak periods in response to price signals or grid needs, while DSM encompasses a broader range of activities that include managing energy demand through smart devices and real-time controls. Both strategies rely heavily on advancements in information and communication technologies, allowing for seamless integration of flexible demand behaviours across residential, commercial, mobility, and industrial sectors.

DSM plays a pivotal role in enhancing the flexibility of modern energy systems, especially as the transition toward renewable energy sources accelerates. By dynamically adjusting energy consumption patterns in response to supply conditions, DSM allows for better alignment between demand and variable renewable energy options.This flexibility not only optimises energy use but also reduces strain on the grid, improves

[3] HVAC: Heating, Ventilation and Air Conditioning

system reliability, and supports the integration of clean energy resources.Furthermore, DSM and DR and advanced technologies like smart meters, empower consumers to actively participate in balancing supply and demand, fostering a more resilient and sustainable energy future. An important flexibility option is the active storage technologies like batteries and puffer tanks, but also thermal buildings inertia (concrete core activation)to capture surplus energy produced during peak renewable energy generation periodsfor using during times of low production or high consumption.

The general modelling scheme combining different tools developed in DigiTwins4PEDs enables to analyse the Demand Response and Demand Side Management for the entire district[4] and individual buildings.

4.2 General modelling scheme

The Figure 1 shows the general modelling scheme. In DigiTwins4PEDs, the CityGML 3D City Database (in short: 3DCityDB)for PostgresSQL serves as the central storage and exchange platform for CityGML-based building models enriched with Energy ADE, ensuring structured storage, retrieval, and processing of energy-related attributes. It plays a crucial role in managing complex urban datasets, allowing for efficient data exchange between simulation tools such as SimStadt and MAPED, and ensuring scalability, data consistency, and interoperability within the project's workflow.

Note: At the time of writing this article, Energy ADE 2 is in the Beta 6 stage and expected to be released in Q4 2025. To document a complete and functional workflow in this article, the Energy ADE 1 KIT profile has been used instead, as its full implementation is readily available on GitHub.[5] Once Energy ADE 2 reaches full development, it will seamlessly replace Energy ADE 1 without requiring any new modifications to the system architectures shown in Figure 1.

4.3 Data and Software Specifications

4.3.1 SimStadt

SimStadt is the name of an urban simulation environment developed at HFT Stuttgart and of a project of the same name, which in turn is the continuation of a project completed in 2015 (SimStadt). At its current stage, SimStadt has the capability to utilise data from real urban planning situations for energy analyses of buildings, city sectors, entire cities, and even regions. Its application scenarios encompass high-resolution simulations of building heating and cooling requirements, potential studies for photovoltaic installations on roofs, facades, and ground surfaces, as well as simulations of building refurbishment scenarios, renewable energy supply scenarios (including PV and biomass), electricity demand, load profiles, district heating networks, waterdemandand analyses of food demand and potential [1]. Thus, SimStadt can significantly assist architects, urban planners, urban energy experts and local authorities in integrated energy planning processes and the formulation of measures towards sustainable (re)design of buildings and neighbourhoods. As its primary input, SimStadt employs the open and standardised data model of CityGML to store urban objects (such as buildings, land use, trees, terrain, roads, etc.) and their associated attributes as a digital 3D city model. SimStadt processes 3D city models, enriches them with necessary attributes, and generates energy simulation results that can be seamlessly reintegrated back into the CityGML dataset. Beyond the physical shape of a building, which is derived from the input CityGML building dataset, SimStadt requires data on weather conditions and building properties, particularly to simulate the energy demand of buildings. Weather conditions are part of the weather preprocessor module of SimStadt. Based on the EPSGcode of the CityGML 3D city model, it retrieves weather data for the location of the model and creates synthetic hourly values from monthly means. Building properties are further divided into building physics properties and building usage properties. Both building physics and building usage properties are implemented as libraries and respective workflow steps in SimStadt. The buildingphysics library contains benchmarking data of building physics properties, constructions and materials, such as the U-values of the different building elements etc.With building usage, it is possible to define set-point temperatures, inner gains and occupation for different building functions (e.g. residential, office, hotel, retail ...).In the DigiTwins4PEDs project, SimStadt plays a key role in building-level energy simulations, supporting assessments of heating/cooling demand, PV potential, and different electric load profile scenarios.The simulation results are stored in 3DCityDB using Energy ADE, ensuring a structured and standardised data exchange with MAPED. The latest list of publications which use SimStadt for urban energy simulation can be found on https://simstadt.hft-stuttgart.de/about/publications/. The following figure showsan example of the Simstadt User Interfacefor a region in Stuttgart.

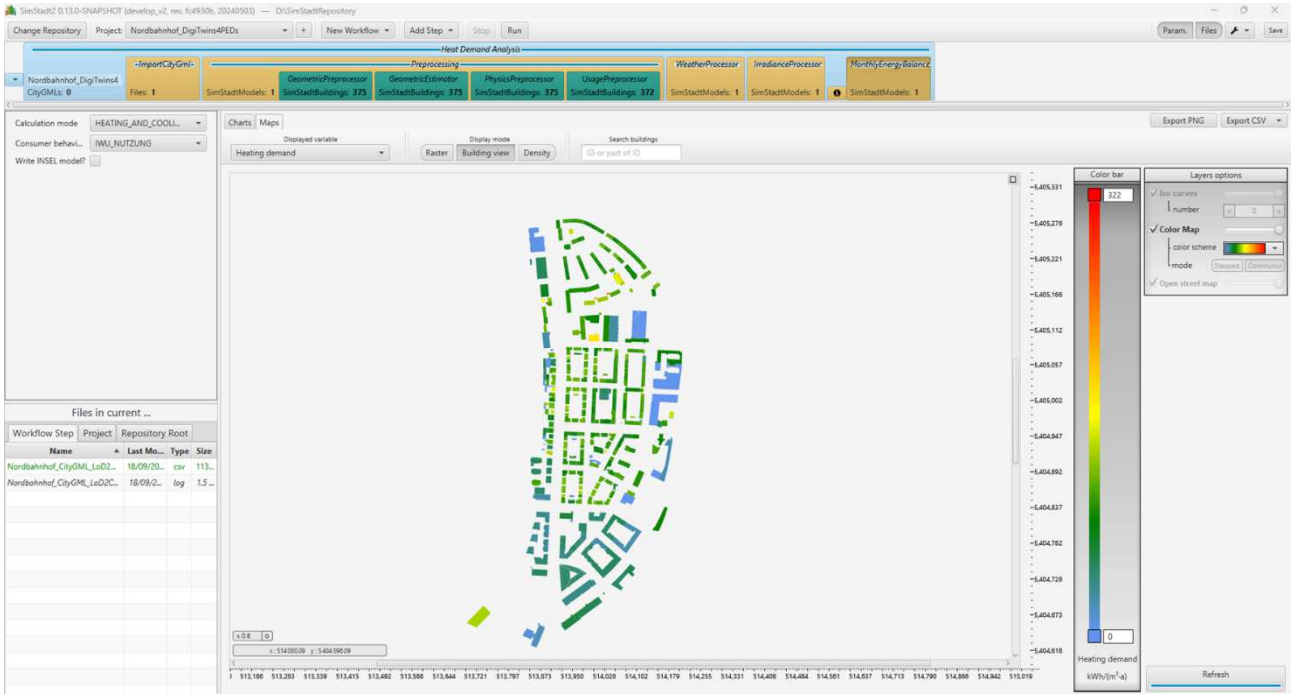

Fig. 2: Simstadt UI and heatng demand for Nordbahnhof buildings in Stuttgart ©HFT

4.3.2 MAPED

MAPED is a bottom-up rapid energy assessment tool for analysing the energy demand and supply of urban districts and assessing their qualification to reach an annual positive energy balance by exploiting local RES to cover district's electricity and heat demand. MAPED has been developed based on the proven end-use concept of the IAEA model MAED(NEUMANN et al., 2021). MAPED focuses on the evaluation of useful and final energy demand at the district scale, covering energy demand for household (residential) and service building (non-residential), urban farming, industry, and mobility. Moreover, it offers a simplified approach to evaluate and estimate the local renewable energy production to cover heat and electricity demand using photovoltaic, solar thermal energy and heat pumps. Other local supply options like biomass, waste heat and micro wind can also be considered given the prevailing boundaries, topology, social acceptance, and the applied regulations. MAPED approach evaluates final energy demand based on demographic, social, and technological data of the considered district. MAPED systematically relates the specific energy needs for providing goods and services to the social, economic and technological factors that affect the demand for a particular fuel. This implies population number and growth, number of inhabitants per dwelling, number of electrical appliances used in households and services, peoples' mobility and preferences for transport modes, evolution of the efficiency of certain types of equipment and market penetration of new technologies or energy forms. The expected future trends for these determining factors, which constitute 'scenarios' are exogenously introduced. This enables evaluating the needed measures to convert the considered district to a PED within the given demographic, social, technical and building types of specification.Since SimStadt and MAPED are integrated within the DigiTwins4PEDs workflow, building-level energy data generated by SimStadt is aggregated at the district scale using Energy ADE and then used in MAPED. This integration ensures that detailed building-level energy assessments, such as energy demand and photovoltaic potential, contribute to district-level energy flexibility strategies, includ-ing energy balancing, renewable energy integration, and demand-response measures.

4.3.3 CityGML Energy ADE

The international standard City Geography Markup Language (CityGML), issued by the Open Geospatial Consortium (OGC), offers the possibility to model urban environments, including buildings, in a 3D space. CityGML defines "basic entities, attributes, and relations" of relevant urban objects, functioning both as a conceptual data model for semantically enriched 3D city models and as a storage and exchange format. Currently, the most widely used version is CityGML 2.0, which was released in 2012.CityGML has been intentionally designed to be application independent. Nevertheless, in certain cases, additional classes or attributes may be needed for specific domains. For this reason, CityGML can be extended following two approaches. The first one allows for the definition of so-called generic attributes and GenericCityObjects without the need to extend the conceptual data model. The second one, on the other hand, offers more modelling capabilities but demands an extension of the data model. This second approach is referred to as the Application Domain Extension (ADE) mechanism.

The Energy ADE[6] is such an extension for CityGML [AGUGIARO, 2018]. It builds upon the CityGML 2.0 Core and Building modules and extends them by means of additional classes and properties. As such, it has been conceived and designed as a solution to model and store relevant data needed for UBEM. It offers the possibility to model both data serving as input for energy-related applications and as output, for example from the energy simulation results. The overall goal is to foster interoperability of energy-related data between different stakeholders and different software tools to perform city-wide energy assessments based on a bottom-up approach that starts from the granularity of the building. The Energy ADE was released in 2018 through a joint effort of various international parties and stakeholders (familiar/expert with/in either CityGML or UBEM). It is mentioned in the literature as a best-practice example when it comes to ADE development due to its technical maturity and available documentation. As a result, the Energy ADE has already been used in several national and international projects.One of the outcomes of the DigiTwins4PEDs project is to improve the current version of the Energy ADE and to release a new, improved version, tentatively named simply Energy ADE 2.0.

The Energy ADE 2.0 follows the same principles and goals of the previous versions, but it also incorporates the experiences and feedback from the projects carried out since its first release. At the same time, it takes into account new developments both in terms of ADEs and CityGML itself. In the former case, for example, a source of inspiration to improve and extend the data model comes from the Food-Water-Energy ADE (PADSALA et al., 2021) and the i-Urban Revitalisation ADE (AKAHOSHIet al., 2020). In the latter case, a new version of the CityGML data model has been published in 2021, reaching version 3.0 (OGC, 2021).As a result, the development of the new Energy ADE 2.0, although still based on CityGML 2.0, is already incorporating concepts that will ease its future conversion to CityGML 3.0.

Among the most significant changes introduced in the Energy ADE 2.0 is an improved “Building physics module”, which contains classes to model objects such as thermal zones, thermal boundaries and thermal openings, i.e. objects needed to compute the heat transfer through the thermal hull of the building. The new module overcomes some limitations of the previous version, in that, for example, now multiple representations of such objects are allowed (i.e. from LoD1 to LoD3), and, at the same time, the overall modelling approach has been brought closer to the overall “logic” of CityGML.

Additionally, the newly added “Resources module” completely overhauls the previous EnergyDemandclass by introducing the more general concept of resource, i.e. a quantifiable amount of “something” (i.e. energy, but also water, food, construction materials, waste, etc.) that can be associated to any city object and that can be expressed as yearly amount, or a time-dependent variable (via time series). The classes contained in the Resources module take inspiration and further elaborate concepts from the Food-Water-Energy ADE.

Besides other minor changes and simplifications, another addition of the Energy ADE 2.0 is the possibility to create a hierarechical partion of space (e.g. according to administrative boundaries: country, region, city, district, quarter, block, ...). Each of the objects at each level can associated to aggregated values (e.g. energy demand for heating at block, district, city level, etc.). This new addition, consisting in the so called UrbanFuntionArea, takes inspiration from a nearly equal class described in the i-UR ADE.

The Energy ADE 2.0 is currently in active development and is being implemented in terms of Java libraries (needed for the existing tools for CityGML 2.0) and a database schema that extends the CityGML 3D City Database (YAO et al., 2018). Eventually, the 3DCityDB-Tools plugin for QGIS is also planned to add support for it (AGUGIARO et al., 2024).

4.3.4 Urban Digital Twin Web Application

The front-end, the UDT Web Application (Figure 4 and 5), enables to interact with the simulation results and visualises the results at different spatial resolutions. Thus building-related information, as e.g. the specific energy demand over time of a building, as well as the entire demand and energy production potentials of the district.The UDT-Web Application will be developed as an information-sharing, gathering and/or a co-development platform for citizens and stakeholders to simulate and visualise different future PED scenarios for their communities before their real-world implementations. It will be an expert tool, which shall be used by public authorities and urban planners to inform and design together with citizens scenarios to realize PEDs. The system’s architecture has been depicted in the Figure 6below, showing main components and

[6] https://www.citygmlwiki.org/index.php/CityGML_Energy_ADE

technologies utilised. In the storage layer, we mainly use NoSQL – Firebase and google cloud where we have defined user roles and permissions in the system. Spatial data are stored in dedicated containers for their specific handling. The application layer uses mechanisms of services, business logic, communication API and user interface components to support specialized views and support the geoportal tool. The system components communicate with each other using the http protocol.In the design of the Web GIS application open-source libraries were used to render geospatial data. In particular, the Cesium.js technology for generating views of the globe, as 3D perspectives in a web browser environment.

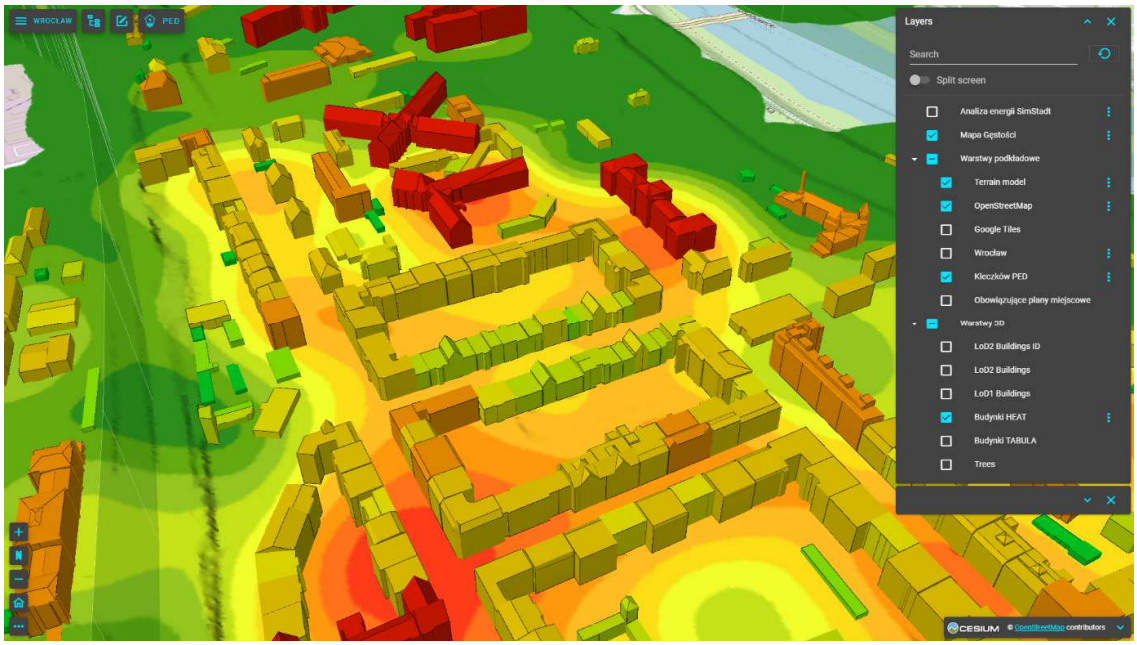

Fig. 4: UDT platform first prototype: Screenshot Wroclaw ULL: 3D Building Heat Demand ©INFOSOLUTIONS

Fig. 5: UDT platform first prototype: Screenshot WROCLAW ULL 3D Building information ©INFOSOLUTIONS

In addition, the service supports tools for generating analytical charts and static data sets. The views are presented in the form of a thematic geoportals for all the fouruse-cases (Stuttgart, Vienna, Roterdam, Wroclaw) equipped with a set of analytical and data management tools, including business intelligence dashlets to present thematic datasets. To build layouts Vue.js with the Vuetify library framework[7] was deployed as it allows building a responsive application.The data structure designed allows for flexible adaptation of the project while adhering to all rules regarding data access and project sharing with other

[7] https://vuetifyjs.com/en/

users. By "project," we refer to an isolated, thematically prepared dataset intended for presenting both general views and specific phenomena. Users can configure the project's layer settings, compositions, and dedicated documents for displaying static data. These configurations can then be incorporated into the application's layout and tools, providing a tailored user experience. Once the project is configured, the application allows presentations of 2D/3D data in formats supported by the Cesium.js API. As a standard, raster base layers such as TMS, WMS, GEJOSON, CZML, tiled 3D data are supported.

5 CO-CREATION: A PARTICIPATROY PLANNING FRAMEWORK

5.1 Urban Living Labs

Urban Living Labs (ULLs) represent a dynamic approachfostering participatory community engagement by testing and evaluating small-scale interventions in collaboration with local communities [AFACAN, 2023]. These labs serve as platforms for co-creation, where citizens actively contribute to experiments and innovations, facilitating engagement and transformative change [VAN DER JAGT, 2018]. By incorporating co-design processes, ULLs enable the development of long-term partnerships between science and the community, ensuring that local needs are addressed and tailored solutions are created [MAHAJAN, 2022;ZINGRAFF-HAMED, 2020]. Through collaborative, neighbourhood-based approaches, ULLs activate urban resources and significantly contribute to resilient urban development [PETRESCU, 2022]. They provide a normative framework for guiding real-world experimental processes, aligning them with broader social and environmental goals [ZIEHL, 2021]. These experiments test and refine innovative solutions, strengthen social interaction, promote practice-based knowledge, and inspire new thinking and action [ROBAZZA, 2024]. Moreover, ULLs facilitate cross-sector collaboration, supporting urban transformation and innovation across disciplines [ZINGRAFF-HAMED, 2019]. They offer a promising opportunity to address current and future challenges by developing responsive and innovative urban solutions that enhance participatory resilience [BELFIELD, 2024]. By creating spaces for experimentation and fostering community involvement, ULLs empower cities to align with transformative goals and ensure sustainable, inclusive urban development [FRANTZESKAKI, 2018].

In the DigiTwins4PEDs project, ULLs serve as adaptive spaces for informing, experiencing and learning about everyday energy needs and PEDs, enabling the development of viable transformation pathways. DigiTwins4PEDs uses ULLs to implement a co-design, co-creation and co-learning process, where local communities actively engage in the energy transition. The ULLs bridge the gap between technological innovation and societal needs by integrating new tools and methods using UDTs to support participatory planning at neighbourhood level and make more informed decisions. These digital tools are iteratively designed, tested, and refined within ULLs, allowing communities to explore energy solutions, make informed decisions, and drive urban transformation. To maximize participation and acceptance, hybrid formats – combining digital and analogue interventions – are implemented.The IT-based solutions developed within DigiTwins4PEDs will be integrated into ULLs to assess how UDT platforms can enhance citizen acceptance and encourage active participation in urban transformation. By engaging key target groups, the project aims to explore how UDTs can contribute to enhance urban resilience and quality of life. To raise public awareness, an UDT platform will be made accessible at the citizen level, allowing individuals to explore, test, and provide feedback through interactive participation formats. This hands-on approach will raise awareness among communities of the concept of a clean energy transition and empower them to take an active role in shaping sustainable neighbourhoods. By using UDTs as a catalyst for citizen-driven action, the project seeks to identify strategies for sustaining long-term engagement and strengthening social responsibility. We plan to address three key target groups – young people, tenants, and property owners – and have developed a participatory planning framework with three targeted interventions for integrating UDTs into energy transition.

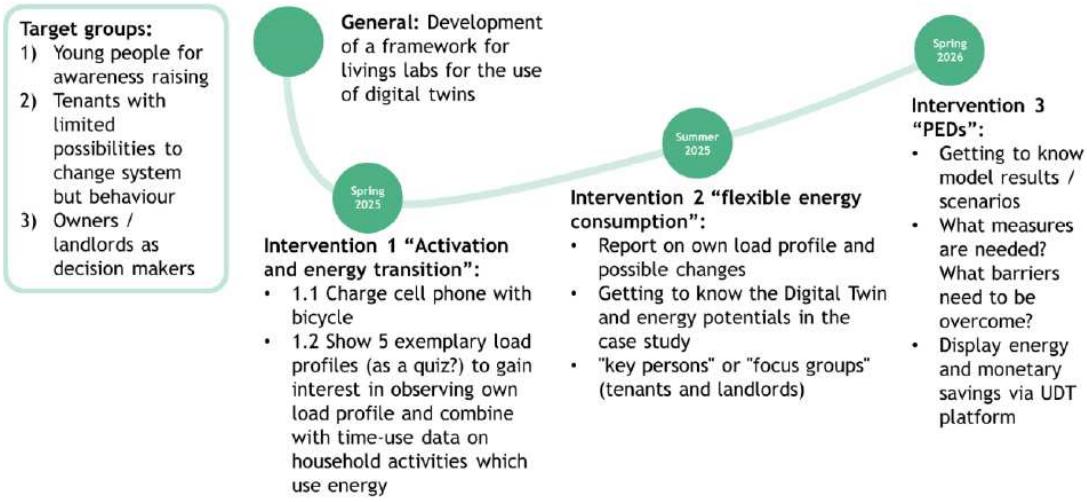

Fig. 7: Framework Idea for a cross-case study co-creation method

5.2 User "Behaviour" Stories for a Better Learning Process

The project'sresearch efforts are linked to the broader question of 1) how consumers can be empowered to become prosumers and 2) which measures are of interest and feasible for the citizens as end users.

The planned interventions will play a key role in enabling the flexibilisation necessary for the energy transition. Thus, behaviour-based scenarios will be created and implemented through the planned interventions covering activation and energy transition (intervention 1), flexible energy consumption (intervention 2) and PEDs (intervention 3). The three interventions developed in the framework focus on the following cross-sectional topics, providing end-users with insights into the impact, timing, and costs of various measures throught the UDT platform:

(1) Energy supplymeasures:such as installing photovoltaic systems, heat pumps, and district heating.

(2) Energy demand measures: actions focusing on energy-saving, including consumer behaviour, and energy efficiencymeasures, e.g., building refurbishment.

(3) Energyflexibilization measures: strategies like power and heat storage, sector coupling (like vehicle-to-grid) and demand-side management (e.g. shiftable use of appliances like washing machines).

The UDT platform will be tested using two prototypes of the UDT system: First, during the 2nd intervention, a prepared scenario will demonstrate the concept by the concept by testing 1-2 measures (e.g. PV installation and washing machine use). Second, if the system performs as expected, users of the UDT will independently formulate questions and select additional options for testing during the 3rd intervention.

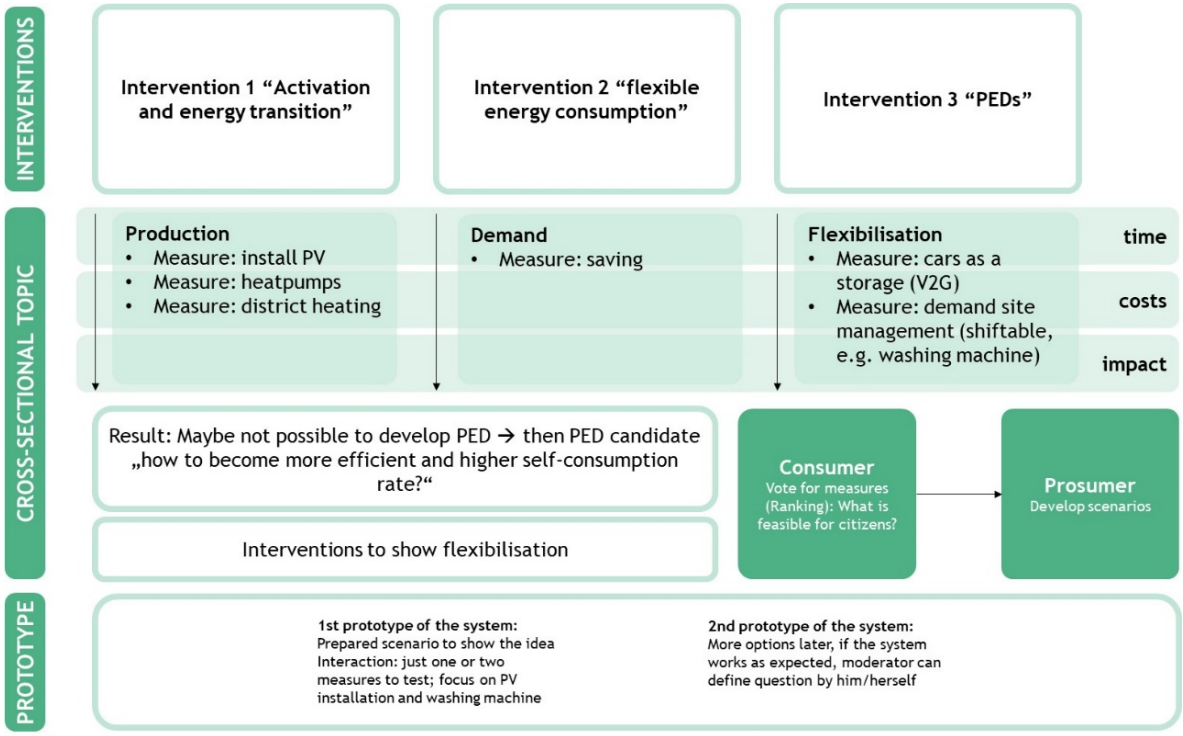

Fig. 8: Behaviour Stories to show energy flexibilisation

6 CONCLUSION AND OUTLOOK

The research project DigiTwins4PEDs develops an urban digital twin framework tested in different urban case study areas (Vienna, Stuttgart, Rotterdam, Wroclaw). Based on the 3D CityGML data format, the UDT integrates two urban energy simulation tools SimStadt and MAPED. To have a structured and standardised way of data sharing amongst the two simulation models, Energy ADE implemented in 3DCityDB PostgresSQL is used. The developed platform can be used in participatory processes to address the multifaceted aspects crucial for establishing PEDs together with the citizens.The concept and first prototypepresented above already show the potentials,e.g. how it can be used to explore behaviour stories for realizing the energy system transition, to change e.g. from pure energy consumer to become a prosumer. The first experiences also show that the UDT needs a facilitator (operator) to maximise its potential. Furthermore, that it is essential to integrate it in already existing citizens' engagement tools (platforms like Wien mitgestalten[8]) to be successful and accepted by the citizens and urban administration. Combining different Energy System Simulation tools, capable of simulating from the building level up to the district, enables us to show the broader picture for the district as well as give citizens (tenants and building owners) andpublic authorities the information to support their decisions and develop jointly sustainable scenarios for the future.The project sofar developed the Energy ADE 2.0, which is one of the major outputs of the projectneeded to enable this from a technical perspective.During the next phase of the projectwe will further improve the concept and test the prototype applied in the planned interventions in the four involved case study. The developed data-workflows in the different cities necessary to prepare the input data for the simulation tools are essential to learn how the framework can be used in other cities with their available data.For the stakeholders involved from the cities,this isan important aspect to keep the effort at minimum, whenever the UDT framework should be transferred after the project.

1 ABSTRACT

As climate change intensifies, cities must develop adaptive strategies to mitigate risks and enhance resilience. The FAIR2Adapt project applies FAIR (Findable, Accessible, Interoperable, and Reusable) principles to climate adaptation data, ensuring long-term usability and interoperability across urban planning tools. This paper presents our work on identifying requirements for the FAIRification of Hamburg's Risk Map, a critical resource for urban climate adaptation.

We outline the methodological framework used to enhance data findability, accessibility, and interoperability, integrating the Risk Map with broader urban data infrastructures. The approach involves a requirements elicitation process as a pre-phase of the FDO-driven FAIRification Framework we develop in the FAIR2Adapt project. Based on the description of the city of Hamburg case study, which is one of six in the FAIR2Adapt project, we identified user stories and extracted more specific requirements. To address these requirements customized FAIR Supporting Resources will be needed, such as a FAIR metadata schema for geospatial risk maps and simulation models, improving data sharing and reusability within ArcGIS-based risk assessment tools, and applying Scientific Knowledge Graphs (specifically, the Open Research Knowledge Graph) to ensure scientific transparency and reproducibility. Additionally, we will enhance urban climate modeling workflows making the developed procedures accessible via RO-Crates that allow to package the software together with structured documentation.

By embedding these principles, we strengthen decision-making for urban climate adaptation, providing city planners and stakeholders with actionable, interoperable data. We discuss challenges in the uptake of FAIR implementation, and present an outlook on scaling our approach to other cities. Our findings contribute to the broader discourse on how FAIR principles can accelerate climate resilience efforts in urban environments.

Keywords: climate change, resilience, climate adaptation, interoperability, urban planning

2 INTRODUCTION

2.1 FAIR2Adapt for advancing Climate Adaptation

Climate adaptation efforts require reliable, accessible, and interoperable data to inform evidence-based decision-making. The FAIR2Adapt project, financed by the Horizon-INFRA-2024-EOSC-01-01 program, addresses this challenge by applying FAIR (Findable, Accessible, Interoperable, and Reusable) principles (Wilkinson et al., 2016) to climate adaptation data, ensuring that critical environmental and socio-economic datasets can be effectively utilized for urban long-term planning. The project has recently started and is currently in the process of developing an FDO-driven FAIRification Framework. This paper focuses on requirement elicitation, an initial phase within the FAIRification process that aims to identify the specific needs of stakeholders involved.

2.1.1 Why the FAIR principles matter for data management in CCA

The FAIR principles are crucial for data management in Climate Change Adaptation (CCA) due to the complex and multidisciplinary nature of climate data. Effective climate adaptation strategies depend on integrating diverse datasets, such as meteorological data, socio-demographic information, and infrastructure resilience indicators. Applying the FAIR principles ensures that these datasets are:

- Findable: Easily discovered and located by both humans and machines, enabling efficient identification and visibility of relevant data through searchable resources.
- Accessible: Reliably retrieved through standardized, open, and secure protocols, ensuring long-term accessibility of metadata even if restrictions apply.
- Interoperable: Compatible with various systems and tools, allowing seamless data integration across platforms.
- Reusable: Properly documented and standardized, promoting long-term usability and reproducibility.

By improving data FAIRness, FAIR2Adapt enhances the usability of climate risk assessments, such as Hamburg's Flood Risk Map, by integrating diverse sources, including urban flood data, socio-demographic information, and infrastructure resilience indicators.

2.1.2 Added value for the CCA communities

The added value of applying the FAIR principles to CCA data management lies in several key areas:

- Enhanced Decision-Making: With FAIR-compliant data, city planners and stakeholders have access to high-quality, actionable information, enabling informed, data-driven decisions.
- Scientific Transparency: The FAIR principles promote the sharing of well-documented and reproducible data, which is essential for scientific credibility and progress.
- Long-Term Usability: By standardizing metadata and documentation, the FAIR principles ensure that data remains usable and relevant over time, supporting ongoing adaptation efforts.
- Interdisciplinary Collaboration: FAIR-compliant data facilitates collaboration across different sectors and disciplines, fostering holistic approaches to climate resilience.

2.1.3 Key barriers and challenges

Despite the benefits, several barriers and challenges must be addressed to effectively implement the FAIR principles in CCA data management:

- Data Integration: Combining diverse datasets from different sources can be technically challenging due to varying formats, standards, and quality.
- Metadata Standardization: Establishing and maintaining consistent metadata standards across datasets is crucial for interoperability, but can be resource-intensive.
- Infrastructure Limitations: Existing data platforms may lack the necessary support for the FAIR principles, requiring upgrades or new implementations.
- Stakeholder Engagement: Ensuring that all relevant stakeholders understand and adopt the FAIR principles requires significant outreach and education efforts.

In addition to advancing climate adaptation efforts, the FAIR2Adapt project aligns with broader policy goals such as those outlined in the EU Data Act. While FAIRification is not a strict legal requirement for all datasets, the Data Act promotes data sharing, access, and reusability, reinforcing the importance of FAIR practices, particularly for publicly funded research data. By embedding these principles, FAIR2Adapt contributes to enhancing data governance and interoperability in line with EU policy objectives.

Addressing these challenges is essential for maximizing the impact of the FAIR principles on urban climate resilience. Through a structured approach that integrates user-driven needs, metadata standardization, and technology integration, FAIR2Adapt fosters collaboration among researchers, policymakers, and urban planners, creating a scalable model for cities seeking to strengthen their climate adaptation strategies.

2.2 Hamburg's Climate Risk Mapping: challenges, goals and key assets

2.2.1 Challenges and opportunities

Hamburg, a city with various climate-related risks, needs to adapt to climate change in a systematic, sustainable and cross-sectoral approach. At the organisational level, the interaction between the administration and public enterprises is crucial for the implementation of adaptation strategies and the consideration of interactions between the different actors and sectors of the urban system, which is a

prerequisite for sustainable adaptation planning. In addition, adaptation and mitigation need to be weighed against each other to assess trade-offs and avoid incompatibilities (e.g. urban densification versus adaptation to climate-induced stressors), which requires tailored state-of-the-art climate and adaptation scenarios (e.g. Representative Concentration Pathways RCPs and Shared Socioeconomic Pathways SSPs).

2.2.2 Key assets for FAIR Climate Adaptation

Hamburg faces risks from pluvial flooding due to heavy rainfall events, exacerbated by urbanization and climate change. To support decision-making and adaptation strategies, the city has developed key assets that facilitate data integration, flood risk assessment, and predictive modeling. Unlike fluvial or coastal floods, pluvial floods are localized, unpredictable, and challenging for numerical weather models. Hamburg, with its flat topography and complex flood risks (pluvial, fluvial, coastal), serves as a case study for a high-resolution risk mapping approach.

The „Pluvial Flood Risk Assessment for Hamburg“ develops a risk assessment framework for pluvial flooding in Hamburg. The study follows the IPCC 2014 risk framework, considering hazard (flood levels), exposure (people in affected areas), and vulnerability (socio-economic factors) to develop Pluvial Flood Risk Indices related to well-being (PFRWB) and mobility/accessibility (PFRMA).

To quantify social vulnerability, the study incorporates socio-economic factors, namely children under 10, elderly singles, low education levels, and social welfare recipients. Exposure is defined by differentiating between people affected by mobility restrictions (all residents in a building) and direct flood impact on residential well-being (only ground-floor residents). The hazard component is derived from high-resolution flood simulations for Hamburg, based on a 100-year rainfall event (36 mm/h). The methodology applies TOPSIS and Shannon Entropy to quantify vulnerability and integrates spatial analyses using Delaunay-Triangulation for visualization.

The results identify risk hotspots in Hamburg, where high PFRWB and PFRMA values overlap. A key finding is that social vulnerability does not correlate directly with hazard occurrence, highlighting the complex spatial nature of urban flood risk. The study underscores the need for a holistic approach to risk assessment, integrating climate science, infrastructure planning, and social policies to enhance urban resilience. The methodology developed in this study is transferable to other urban areas, making it a valuable asset for climate adaptation planning and risk-informed decision-making.

The risk map was implemented in ArcGIS using a number of different tools after external data preparation. The whole procedure will be available as a customized ArcGIS tool, which will be prepared as a shareable resource to allow its application in other urban areas. This approach will be utilized for Hamburg's Risk Assessment Framework and will be used to produce a heat risk map for the city of Hamburg, adapting procedures with different input data.

In Hamburg, the Urban Data Platform Hamburg (UDP)[1] serves as a central hub for geospatial and hydrological data, enabling municipal agencies to access and analyze critical datasets such as those used to create the risk map. However, while it consolidates data from various sources, its FAIR compliance remains limited, posing challenges for data findability and integration with external data.

Complementing the UDP, the Urban Modelling Platform (UMP) provides advanced computational capabilities to run simulations using the OGC API Processes standard for easy access of executable models. Unlike the UDP, which primarily stores and visualizes data, the UMP enables the sharing of modeling methodologies like the flood risk assessment, enabling customization for local applications. Researchers and practitioners can contribute new methods and algorithms, which municipalities can then adopt and refine based on local needs. The platform supports Python-based frameworks such as SWMM (Storm Water Management Model) and TELEMAC for hydrological simulations, while leveraging ArcGIS-based spatial analysis tools for urban flood mapping. Through the integration of UDP and UMP, Hamburg fosters a collaborative ecosystem where researchers, municipalities, and policymakers can co-develop and share methodologies to address urban risks effectively.

3 METHODOLOGY

3.1 FAIR2Adapt's FDO-driven FAIRification Framework

Based on the FAIR Hourglass concept (Schultes 2023), the FAIR2Adapt project develops a FAIRification Framework to turn data into actionable knowledge to shape climate adaptation strategies.

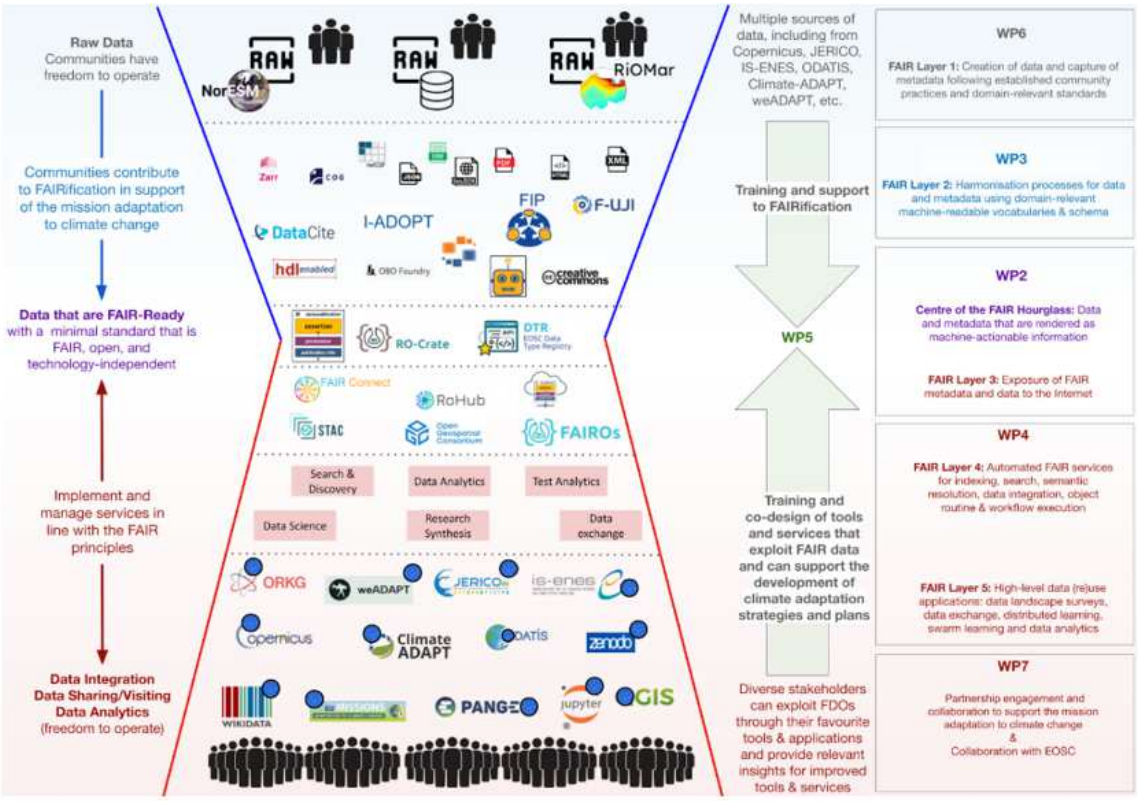

Fig. 1: The FAIR Hourglass applied to FAIR2Adapt.

The hourglass shape (Fig. 1) represents the flexibility at both the beginning and end of the process:

- The upper part focuses on FAIRifying community-provided data.
- The lower part ensures FAIR Orchestration, enabling services to act on FAIR-ready data.
- At the center, the FAIR Digital Object (FDO) ensures machine readability and interoperable reuse of digital objects.

To demonstrate the transformative impact of FAIR in advancing climate action and support the EU Mission on Adaptation, the FAIR2Adapt project engages in six case studies that address real-world challenges. The FAIR2Adapt case studies cover the six main steps defined by the Regional Adaptation Support Tool (RAST) to provide guidance to regional or local authorities during the adaptation planning process. By defining user requirements for each case study, the project develops tailored FAIR Supporting Resources to improve the FAIRness and semantic interoperability of critical CCA datasets and services. Where appropriate, these resources are transformed into FDOs using RO-Crate for packaging research data with their metadata and nanopublications for providing machine-readable metadata of FAIR Supporting Resources (FSRs). Additionally, the project provides training and support to the case study communities enhancing their awareness and capacity to effectively utilize the ecosystem of the developed and improved services.

3.2 Deriving requirements for the FAIRification process

This paper focuses on requirement elicitation, a pre-phase of the FAIRification process that aims to identify the specific needs of stakeholders. In agile software development, requirements are used to identify functions or features, constraints, rules, or other elements that must exist to satisfy user needs. A functional requirement defines what is needed, and not how it should be achieved (the solution). Non-functional requirements specify the criteria that will be used to test how well the solution meets the user's needs.

Gathering requirements to design the necessary services that the user expects is crucial, but is sometimes viewed as inefficient or overly restrictive when tried to be identified too early in the process because they can evolve over time. Thus, a more high-level requirement in the form of a user story is often used to express needs from the perspective of an end-user goal. A user story has three parts:

(1) The Who describes the user as a role (As a …)

(2) The What describes what is desired or needed, thus the goal as an activity (I want/need to …)

(3) The Why describes the reason or expected benefit (So that ..).

In FAIR2Adapt we apply user stories to identify the high-level FAIR requirements for each case study (see Fig. 2). We define a case study as a description of a real-life situation involving several users and digital objects. Hence, a case study refers to several user stories. While case studies are described by the case study provider by identifying the stakeholders involved, the addressed challenges, the goals and the aimed solutions, the user stories are extracted through interviews with stakeholders by FAIR data stewards as part of the Community Support and Engagement (WP5) activities.

From each user story, we derive specific functional requirements, identifying the necessary activities, as well as non-functional requirements, represented as constraints. Additionally, we determine the involved agents and digital objects (DOs) – some of which will be FAIRified, while others will serve as FSRs. It is crucial to keep the requirements free from concrete solutions, as these solutions should only be selected or developed after a thorough evaluation of the requirements. This ensures that the solutions align with the real needs, constraints, and goals of the stakeholders rather than being predetermined by available technologies or existing implementations.

By generalizing the requirements, we can distill reusable use cases that can be associated with potential FSRs, enabling their application in different CCA contexts. All components in the requirement elicitation process are planned to be collected via an online form. They will be represented in machine-readable format and made available within a queryable knowledge graph. A library of use cases can significantly help facilitate the uptake of FAIR implementation, allowing stakeholders to quickly adapt and apply proven solutions to their contexts ensuring consistency, scalability, and interoperability in CCA.

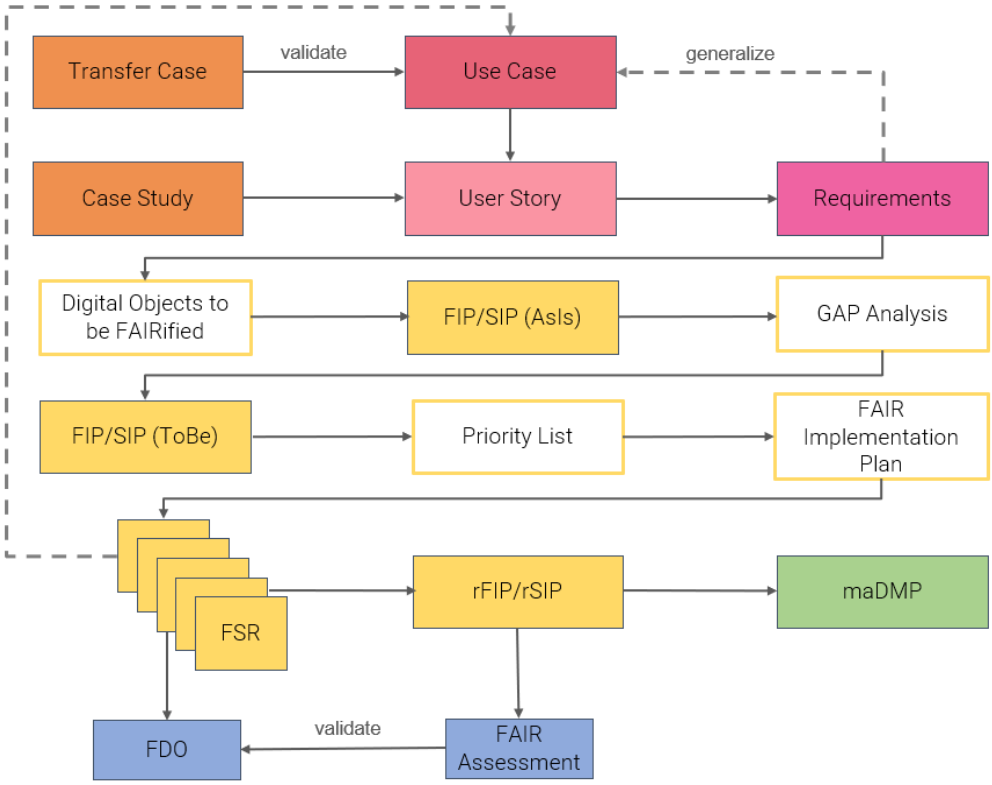

Fig. 2: Requirement elicitation process used in the FAIR2Adapt project.

To systematically address each of the FAIR Principles to enable the FAIRification of digital objects, the GO FAIR Foundation has developed the FAIR Implementation Profile (FIP) approach (Magagna et al., 2024). A

FIP is a structured questionnaire that documents relevant standards, technologies, and policies chosen by a community, made available as a collection of FDOs. In analogy, a Semantic Interoperability Profile (SIP) is a list of declared implementation choices focusing on the interoperability aspects of the FAIR principles including semantic artefacts and their supporting services. Rather than a one-size-fits-all approach, this methodology allows stakeholders from different case studies to specify the FAIR Supporting Resources best suited for their workflows. At the same time, FIPs and SIPs can serve as accelerators of FAIR convergence, as ready-made and well-tested collections of FSRs developed by trusted communities will be widely reused by other communities (Schultes et al., 2020).

In the context of FAIR2Adapt, FIPs and SIPs are used to:

- Assess the current state of the case study (AsIs)
- Identify the gaps in the profiles (Gap Analysis)
- Define the target state for a case study (ToBe)
- Prioritize and develop a FAIR implementation plan, agreeing on a reference list of FSRs (r)
- Integrate FSRs into researcher's daily workflows through machine actionable data management plans (maDMP)
- Validate FDOs via informed FAIR assessment tests

This systematic documentation helps evaluate the project's FAIR compliance decisions, ensuring the use of registries, vocabularies, and other resources that support FAIR data. We aim to assess FAIRness using specific tools, such as F-UJI or the RDA FAIR Maturity Indicators, to monitor progress. Establishing a baseline for FAIRness is essential, allowing reassessment after FAIRification of data, software, and workflows.

The FSRs listed in a rFIP may either already exist, or need to be created. In some cases, existing resources can be leveraged by FAIRifying them, while in other cases, new resources need to be developed from scratch. FAIRification begins with the provision of metadata. While there is a high degree of consensus on the use of domain-agnostic metadata standards to improve data discoverability, there is a lack of community-specific metadata schemas to enhance data reusability. Using the Metadata for Machines (M4M) approach, we will develop required metadata involving stakeholders from case studies. At the same time, we will ensure that these schemas are machine actionable by mapping them to existing standards and reusing FAIR vocabularies. The key role of M4M in the FAIRification process is to enable automated workflows for data discovery, retrieval, and integration, aligning with the FAIR principles.

3.3 Hamburg Risk Map user stories and their requirements

To demonstrate the user requirements elicitation process in FAIR2Adapt, we examine the case study of the city of Hamburg and describe three user stories that we were able to identify in a stakeholder meeting in Hamburg in early March 2025. Each user story is outlined with its corresponding requirements and thoroughly analyzed to identify the potential FAIR Supporting Resources that could be implemented to properly address the stakeholders' needs.

3.3.1 User Story 1: Sharing the ArcGIS Toolbox for Risk Mapping

User Story:

As a researcher I want to share the Hamburg Pluvial Flood Risk Map ArcGIS toolbox so that other implementers can use it to calculate risk and sensitivity maps in other urban areas.

Analysis:

FAIR2Adapt will evaluate together with the stakeholders of the case study how these requirements should be properly met. The aim of the toolbox is to create a reproducible framework, where stakeholder and flood risk managers can holistically assess flood risk providing information at building-resolving scale in order to support climate adaptation. From Table 1, it is clear that the ArcGIS toolbox needs to be FAIRified to some extent. For this a FIP will be developed to identify what is missing and what can be achieved within the timeframe of the FAIR2Adapt project. Nevertheless, here are a few preliminary thoughts on how we might FAIRify the tool:

- Requirement 1 calls for FAIR metadata about the high-resolution data needed to run the tool. A dedicated M4M workshop with the risk map developers will identify the required metadata elements to be included in the data description.
- Requirement 2 asks for the tool to be deposited in a public repository and GitHub is a good solution to make the software accessible and version controlled. ArcGIS is a proprietary and expensive tool and therefore it is recommended to transfer the code in open source systems like Python which makes geospatial workflows more efficient, scalable, and reproducible. Overall, it will be reasonable to follow the recommendations of the recommendations of the FAIR for Research Software RDA WG.
- Requirement 3 requires contextualizing the ArcGIS toolbox with a paper describing the technical procedures. The paper in preparation (Von Szombathely, 1) addressing the methodology of the Hamburg Pluvial Flood Risk Map describes the methods used and and toolbox developed, following the risk framework of the IPCC. It was tailored to high-resolution data and the assessment of two risk types (mobility/accessibility & well-being). Using RO-Crate allows to package and share the tool together with the paper in a FAIR-compliant manner, making it machine-actionable, well-documented, and interoperable.

Requirement 1	Information about the data required to run the tool.		
Activity	Provide metadata about data		
DO Name	Socio-economic data	Buildings and streets data	Modelled flood level data
DO Type	Dataset	Dataset	Dataset
Resource Type	DO to be FAIRified	DO to be FAIRified	DO to be FAIRified
Constraint	Metadata should be FAIR	Metadata should be FAIR	Metadata should be FAIR
Requirement 2	Make the ArcGIS tool accessible.		
Activity	1. Put ArcGIS toolbox in public repository	2. Transfer code in open source systems	
DO Name	ArcGIS tool	ArcGIS procedures	
DO Type	Software	Software	
Resource Type	DO to be FAIRified	DO to be FAIRified	
Constraint	Follow FAIR4RS Principles	Follow FAIR4RS Principles	
Requirement 3	Contextual information required for the ArcGIS toolbox		
Activity	Package tool together with a technical paper describing the ArcGIS toolbox.		
DO Name	Urban Pluvial Flood Risk: Methodological Framework		
DO Type	Puplication		
Resource Type	Supporting Resource		
Constraint	Increase Reusability		

Table 1: Requirements for user story 1.

3.3.2 User Story 2: Making my research paper machine-processable

User Story:

As a researcher I want to make the scientific knowledge and findings in my paper machine-processable, so that other researchers and systems can easily access, interpret, and reproduce my work.

Analysis:

Academic articles remain the primary expression of scientific knowledge. This form of knowledge recording and communication has persisted over centuries, which speaks for its usefulness for knowledge sharing among experts. However, knowledge expressed in narrative text documents is not machine readable, is hardly findable, interoperable, reusable. To integrate or synthesize scientific knowledge, for instance in

systematic reviews or meta-analysis, researchers routinely manually extract knowledge from documents and organize the extracted knowledge in databases that then support reuse. This extraction activity is time-consuming, error-prone, inaccurate, and potentially repeated, since (different) researchers may extract the same knowledge multiple times.

To address the requirement 1 (see Table 2), the Open Research Knowledge Graph (ORKG) (Stocker et al, 2023) has developed services for the production, curation, publication, and reuse of structured scientific knowledge. The ORKG's reborn article initiative (Stocker et al., 2024) has developed an approach that enables the production of high-quality and reproducible machine-readable scientific knowledge produced in (statistical) data analysis. Leveraging these systems, User Story 2 aims to FAIRify the scientific knowledge published in an upcoming article (Von Szombathely, 2) presenting the scientific findings on pluvial flood risk assessment for the city of Hamburg, Germany. By publishing a reborn article in addition to the original article we ensure that the scientific findings are published also in machine-readable format. Depending on whether the scientific findings are produced using open scripting languages (e.g. R or Python), it will also be possible to publish the findings so that they are reproducible. This is achieved by interlinking the scripts used to compute the findings. The requirement 2 can be addressed in the same way as requirement 3 of user story 1 by providing a RO-Crate.

Requirement 1	Make scientific knowledge in my paper machine-processable
Activity	Use services to extract knowledge
DO Name DO Type Resource Type Constraint	Research paper about Pluvial Flood Risk Assessment in Hamburg Puplication DO to be FAIRified
Requirement 2	Add data to the paper
Activity	Provide persistent identifier to refer to the input data.
DO Name DO Type Resource Type Constraint	Input data for deriving the risk map datasets DO to be FAIRified Increase Findability and Reusability

Table 2: Requirements for user story 2.

3.3.3 User Story 3: Improving Findability and Reusability of the Urban Data and Modelling Plattform

User Story:

As a data manager I want to make data and models more findable in Urban Data Platform (UDP) and Urban Modelling Platform (UMP) so that urban planners, climate modellers and citizens can make use of them according to defined usage licenses.

Requirement 1	Improve usability of UDP		
Activity	Provide metadata for datasets	Provide identifiers for datasets	Provide data usage license
DO Name DO Type Resource Type Constraint	UDP Datasets datasets DO to be FAIRified Increase Findability	UDP Datasets datasets DO to be FAIRified Increase Findability	UDP Datasets datasets DO to be FAIRified Increase Reusability
Requirement 2	Improve usability of UDM		
Activity	Provide metadata for models	Provide identifiers for datasets	Provide data usage license
DO Name DO Type Resource Type Constraint	UDM models models DO to be FAIRified Follow FAIR4RS Principles	UDM models models DO to be FAIRified Follow FAIR4RS Principles	UDM models models DO to be FAIRified Follow FAIR4RS Principles

Table 3: Requirements for user story 3.

Analysis:

User Story 3 focuses on FAIRifying the datasets in the Urban Data Platform (UDP) and models for Urban Modeling Platform (UMP). The goal of this FAIRification effort is to provide global unique persistent identifiers for all assets and to provide FAIR metadata, ensuring that the platform's outputs – such as climate risk predictions – are not only accessible but also findable and reusable under defined usage licenses. The key requirements include establishing a standardized metadata schema and ensuring interoperability with external models, which are essential for integrating UMP data into broader climate adaptation frameworks. A central activity involves enhancing discoverability and enabling efficient search and retrieval based on the reuse of common vocabularies. Potential measures for FAIRification include the development of a robust metadata framework based on ISO standards, as well as integration with Hamburg's Metadata Catalog. Identifying useful FAIR Supporting Resources can be best achieved by involving stakeholders in FIP workshops. Additionally, the FAIRification of models should also align with the FAIR for Research Software (FAIR4RS) approach, where not only the data but also the methods and algorithms used to generate it are made FAIR. This ensures full provenance, enabling researchers to track the inputs and parameters used in climate models. This holistic approach enhances the transparency and reusability of both the data and the underlying methods, contributing to the long-term sustainability and credibility of climate modeling efforts.

4 OUTLOOK AND UPSCALING

4.1 Overcoming Identified Barriers

One of the primary barriers to scaling the FAIRification process is the lack of convergence among existing standards, which can create challenges in ensuring interoperability across different systems, sectors, and regions. Furthermore, there is often a lack of interest from communities in adopting these standards, primarily because the added value of FAIRification may not be immediately evident. To overcome this, the FAIR2Adapt project uses real-world case studies to demonstrate the practical benefits of FAIR principles, helping to onboard key stakeholders and fostering a community-driven approach to climate adaptation. By showcasing tangible examples, we aim to highlight how FAIRification can enhance the discoverability, accessibility, and usability of data and tools, thereby driving greater engagement from the CCA (Climate Change Adaptation) community.

Another significant barrier is the lack of skills and knowledge in FAIR data management among CCA practitioners. To address this, FAIR2Adapt has developed a comprehensive capacity-building strategy, to raise FAIR awareness and embed the FAIR skills into the case study communities. Additionally, the use of AI technologies to support semi-automated FAIRification processes is a key aspect of this capacity-building effort. By integrating AI into the workflow, we aim to make the FAIRification process more efficient, reducing the burden on stakeholders and enabling them to focus on more strategic aspects of climate adaptation. Through these efforts, we not only address the barriers of interest and skills but also create a sustainable framework for scaling the adoption of FAIR principles across the CCA sector.

4.2 Vision for Future Developments (Upscaling)

To ensure a sustainable impact, comprehensive evaluation and dissemination of the project results in various formats is essential. A central component of this process is the implementation of transfer cases to validate the FAIRification framework, including the requirements elicitation process, in terms of its effectiveness and ease of adoption. These cases will showcase the process of applying FAIR principles to real-world datasets and workflows, highlighting both the challenges and opportunities in scaling across different contexts.

The concept of upscaling encompasses the scaling of the developed approaches beyond initial pilot projects with the aim of effectively addressing a larger number of users. This includes both geographical expansion and the structural development of political and administrative framework conditions in order to promote sustainable implementation. In addition, cross-sectoral dissemination of the results will be sought in order to maximise synergy effects between different areas and enable interdisciplinary application of the findings. (Guentchev et al., 2023)

The upscaling process in the FAIR2Adapt project will focus on two key aspects: the FAIRification framework and the reuse of FAIRified data, tools, and workflows.

As a pre-phase of the FAIRification framework the requirement elicitation process ensures that the real needs of stakeholders are captured in order to tailor the FAIRification of various components, including data, tools, and workflows. The goal is to enable CCA (Climate Change Adaptation) partners to independently apply this framework by the end of the project. The capacity-building effort in WP5 includes a "train the trainer" program that equips community members with the skills to teach and lead others in applying FAIR principles in their own contexts. The framework will be adaptable and scalable across diverse CCA sectors, empowering stakeholders to continuously apply FAIRification practices to new datasets and workflows.

For scaling the adoption of FAIR practices, we also aim to facilitate the reuse of identified use cases, along with their potential FAIRified datasets, tools, and workflows. The vision is to create a flexible ecosystem that allows various stakeholders to mix and match these components to support a wide range of use cases. By standardizing the FAIRification of data and tools, we create the conditions for easy reuse and adaptation to new scenarios. For example, a tool developed for Hamburg to assess pluvial flood risks could be easily adapted for other cities or regions facing similar challenges. This reuse model significantly reduces the cost of developing new solutions while enhancing the impact and scalability of the FAIR2Adapt project.

A comparison between FAIR2Adapt and other initiatives, such as VALORADO and FARCLIMATE reveals shared interests in applying FAIR principles to climate change adaptation data. Engaging with these projects can provide valuable insights and foster collaboration. Particularly, VALORADO partners involved in CLIMATE-ADAPT4EOSC, a project funded under the same EOSC topic, offer potential entry points for dialogue. Understanding these projects' approaches enriches our perspective on scaling FAIRification practices across different contexts.

The successful implementation and scaling of the FAIR principles requires coordinated efforts at various levels. The use of new technologies, targeted training measures and the promotion of international cooperation are essential building blocks for sustainably anchoring FAIR data management in climate adaptation.

5 CONCLUSION

In summary, the FAIR2Adapt project is not only focused on the technical FAIRification of data, tools, and workflows but also on ensuring that these components can be effectively scaled and reused across different case studies. Through WP3 and WP5, we aim to establish a robust FAIRification framework, preceded by a requirements elicitation process, that will enable CCA partners to integrate FAIR principles into their own work according to their needs, promoting long-term sustainability and impact. Furthermore, by fostering the reuse of FAIRified resources, we create an ecosystem that accelerates the development of new solutions, expands the reach of the project, and makes it easier to replicate successful approaches in diverse contexts.

The scaling process is thus twofold: building the capacity of stakeholders to apply FAIR practices independently and ensuring that the resources developed are flexible and adaptable enough to meet the needs of future case studies. This approach will enable the FAIR2Adapt project to have a lasting impact, offering scalable solutions that can be reused across various domains to support climate change adaptation efforts globally.

1 ABSTRACT

Amidst the global push for decarbonization, solar and wind energy are rapidly gaining acceptance due to their minimal environmental impact and low carbon footprint. This global shift towards green energy transition presents both opportunities and challenges, particularly in addressing regional disparities in infrastructure investment. Using South Africa as a case study, this study employs a mixed-methods research approach, drawing on both primary and secondary data sources. It examines the historical context, governance, and regulatory framework influencing the Just Energy Transition in South Africa. The findings highlight significant spatial disparities in green infrastructure development, with limited investment observed in regions like Mpumalanga and Limpopo, which remain heavily reliant on fossil fuels. The study concludes by recommending indicators to identify priority areas for green infrastructure planning, thereby supporting a more equitable energy transition.

Keywords: Green infrastructure, regional disparities, fossil fuels, Just Energy Transition, South Africa

2 INTRODUCTION

South Africa is the largest carbon emitter in Africa, accounting for 40% of the continent's total emissions. It is also one of the most carbon-intensive developing economies in the world (Salahuddin et al. 2019; Udeagha and Breitenbach, 2023). According to World Bank (2021) South Africa is the continent's largest contributor to climate change and the world's 15th-largest producer of CO2 (making up 1.09% of global emissions). One of the most unequal countries in the world is South Africa, where the wealthiest 10 percent of the population own 86% of the nation's total wealth, over 30% of workers are unemployed, with youth unemployment exceeding 65%, and 55% of people live in poverty (IRENA, 2023). South Africa is now confronted with the urgent need to transition to cleaner power sources as a nation historically reliant on coal for its energy needs.

Globally to fight the global climate crisis, the European Union has committed to reducing its greenhouse gas emissions to net zero by 2050 (Pacesila et al., 2016). A fundamental step on that road is phasing out coal-based industry as coal has been outlined as a highly polluting energy source. In 2019, the European Commission unveiled its new development strategy, the European Green Deal (EGD), that seeks to reduce GHG emissions to net-zero and a decoupling of economic growth from resource use by 2050. The aim of this strategy was to conserve and enhance the EU's natural capital while protecting the health and well-being of its citizens from environment-related risks and impacts (Potrč et al., 2021). The EGD also stressed the need for a just and inclusive transition and presented a set of policy measures in key areas such as energy, industry, construction, transportation, agriculture, ecosystems, and pollution control. Moreover, it highlighted the need to strengthen cooperation between key stakeholders, to jointly promote just transition policies that "leave no one behind" (Musiał, et al., 2021; Brodny et al., 2021).

Germany's transition away from coal has not result in the abandonment of traditional coal industries. Rather, a focus on strengthening or upgrading these industries to make them more sustainable (Maliszewska-Nienartowicz, 2024). This process involved upgrading equipment and technology, reducing production, and adjusting product portfolios to enhance competitiveness. To facilitate this transition, Germany has implemented a targeted industrial policy that created a favourable institutional framework and market environment for industrial development (Ozkan, et al., 2024). This included providing financial subsidies and reducing land costs where necessary. The aim is to incentivize SME development, thus promoting

vitality through the redevelopment. Additionally, policies aimed at improving the local investment environment attracted a significant number of emerging companies. Statistics show that during the transition period, the fast-growing services sector absorbed 40% of the workers leaving traditional coal industries (Pata et al., 2023).

Poland's coal sector has been in a gradual but steady decline since 1990. Annual production in Poland was reduced by 50% between 1988 and 2019. This was driven by policy-led strategies aimed at reductions in hard coal. The number of operating coal mines declined from 70 in 1990 to 24 in 2021, and more are scheduled for closure in 2024 (Sokołowski et al., 2022). The Poland energy transition has been slow due to financial stresses. The industry continues to suffer from weak market conditions and elevated production costs, partly due to surplus labour, and partly due to the low quality of coal produced. In the past years, employment in the coal sector has reduced. The construction, manufacturing, and energy sectors have the highest potential to replace the coal sector jobs. These industries provide relatively good wages, are similar in terms of the required skills and competencies and are also in line with regional specializations.

One potential solution to repurpose the site would be the installation of a solar power facility (solar farm). The transitioning from a power plant to a different kind of renewable power source upon decommissioning may be perceived by the public as less risky than transitioning to a non-energy use (Idoko et al., 2024). With respect to coal-based communities, community members have expressed a desire to preserve their way of life, which had been enabled by and formed around the coal power plant (Pata, 2021). Because of this, a transition between two kinds of energy generation may feel like a natural pathway for the host community. Additionally, many former plant sites have retained critical electric power infrastructure that could make the transition to solar easier (Nakhli et al., 2022). There is already a precedent for siting large-scale solar operations on formerly contaminated sites through a process called "RE-powering" (Lin et al., 2021; King et al., 2021). A solar farm may also appeal to a utility that needs to manage risk because, apart from installation, solar farms require significantly less maintenance, which means less need for worker access to the site (Borowski, 2022). While fewer onsite workers may be seen as an advantage by the utility, it does mean that a solar farm would likely do little to mitigate the loss of skilled jobs after nuclear power plant closure.

To address climate risks, the South African government has created and is still creating extensive institutional, regulatory, policy, and governance frameworks in collaboration with important social groups (see Figure 1). Together, they provide the frameworks that make climate-related investments in adaptation, mitigation, and the just transition possible (Mirzania et al., 2023; Streimikiene et al., 2021; Heffron, 2022). They also show that South Africa is committed to fundamentally reshaping the electricity industry to address energy poverty and competitiveness, guarantee fair and inexpensive access to clean energy, and develop the human capital necessary for a new energy economy. The shift to cleaner energy sectors offers job opportunities as well (Musonda et al., 2025). The 2019 Integrated Resource Plan (IRP), the government's electricity plan, describes a strategy to diversify electricity production with a major emphasis on renewable energy sources. Twenty percent of the new capacity will come from grid-connected solar photovoltaics (PV), and about fifty percent will come from wind energy (Huang & Liu, 2021).

Nevertheless, many parts used in renewable energy are currently made outside of the country. Investing in the knowledge and equipment needed to produce these parts locally – like wind turbines – can generate long-term employment opportunities here at home and lead to more opportunities via export. It's critical to understand that jobs generated in the renewable energy sector do not always result in employment for those previously employed in coal plants (Chirisa et al., 2021). A reskilling plan is necessary for a just energy transition to guarantee that people have access to sufficient training.

Given South Africa has several power plants that are planned for decommissioning. The study assesses regional disparities in infrastructure investment using South Africa as case study. The shutting down of the old plant station will not significantly impact the national electricity grid as the remaining unit only contributed 121MW. Eskom has transferred the majority of employees from power station that have shut down to support and augment skills in other power stations and areas of the business in line with operational requirements. As of October 5, 2023, Eskom is considering delaying the decommissioning of some coal plants until 2030. This is due to appeals that could force Eskom to shut down some stations to meet minimum emissions standards. Several power plants have plans to repurpose the sites for renewable energy

projects. The Komati power station had been operating at only 125 MW capacity since 2021. This will be replaced with a combination of 220 MW of renewable energy solutions (including 150 MW solar PV solar and 70 MW wind) and 150 MW batteries, improving power supply and grid stability. The World bank funds this project to assist energy transition plans in South Africa.

3 METHODOLOGY

Using South Africa as a case study, this study employs a mixed-methods research approach, drawing on both primary and secondary data sources. Historical and current literature on governance, and regulatory framework influencing the Just Energy Transition in South Africa was reviewed. Additionally, Open source geographic information datasets were obtained from the Department of Agriculture, Land Reform and Rural Development (see table 1). The approach sheds light on the trade-offs between renewable energy plans and energy sector employment impact, while examining the distributional implications of these policy choices.

4 FINDINGS AND DISCUSSION

The corridors are important for planning the distribution and transmission of electricity infrastructure. In 2018, the Government published a notice that identifies five strategic transmission corridors and the procedures for applying for environmental authorization. There are currently five renewable energy zones which have been earmarked for the development of large-scale wind and solar projects (commonly known as RED Zones) (Figure 2).

Five existing power corridors support the RED Zones to develop large-scale electricity transmission and distribution infrastructure. These areas were chosen based on the findings of strategic environmental assessments: development is prioritised in specific geographic locations which have an abundance of resources (such as wind and sun), low environmental sensitivity, and where there is an increased need for socio-economic development, among other things. For example, the placement of RED Zones in mining areas aims to provide opportunities for rehabilitation, the re-use of existing infrastructure, and continued employment for local communities when the mines are eventually decommissioned.

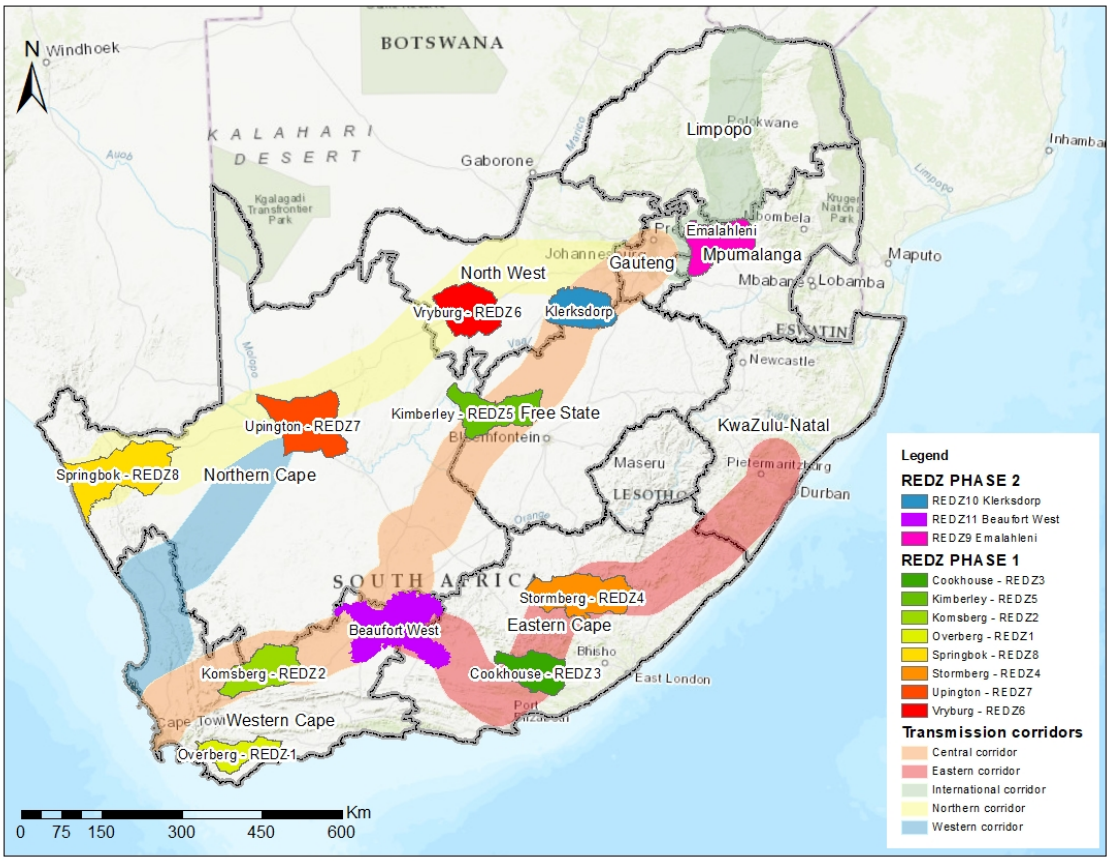

Figure 2: Renewable Energy Development zones.

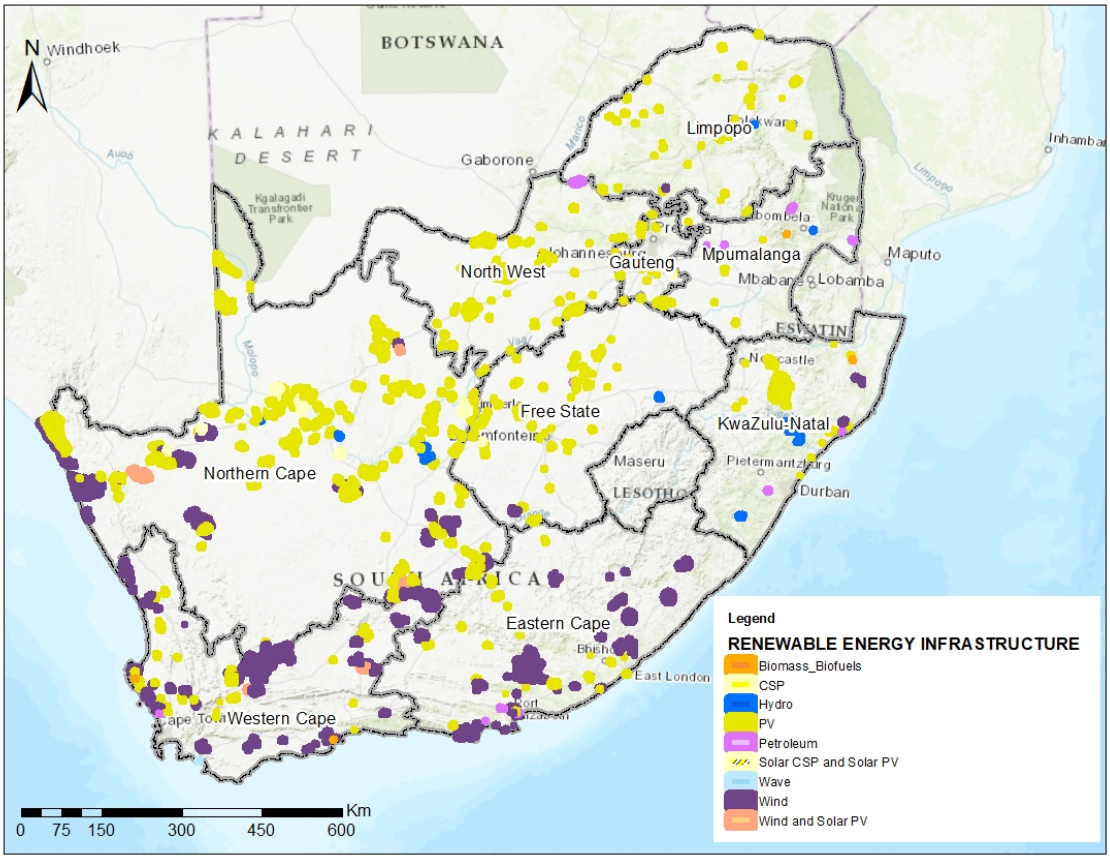

Figure 3: Spatial distribution of renewable energy projects.

The government has set goals to reduce emissions and increase the share of renewable energy in the national energy mix. To support this initiative several sites have been identified for clean energy projects, including solar, wind, and biomass (Figure 3). The South African Renewable Energy Masterplan informs these projects. Create and sustain decent employment across the value chain, from development and construction, to manufacturing and services, to operations and maintenance, to end-of-life management.

Expansion of the industrial capacity in the renewable energy and storage value chain should be supported with plans to develop the local industrial capabilities in the production of renewable energy and storage components, parts and systems to ensure the availability of supply for the domestic market as well as shield the local market from excessive price volatility.

1608 have been approved, 210 are under review, 29 projects were refused and 1 is currently under review (Figure 4). Renewable energy and battery value chains create a wide range of employment opportunities, particularly for skilled and semi-skilled workers. Over the first four bid windows, REIPPPP projects committed to the creation of 63 291 job-years (48 110 in construction and 15 182 in operations).[1] It is further estimated that about 20 000 people were directly employed in the solar energy value chain in South Africa in 2022.

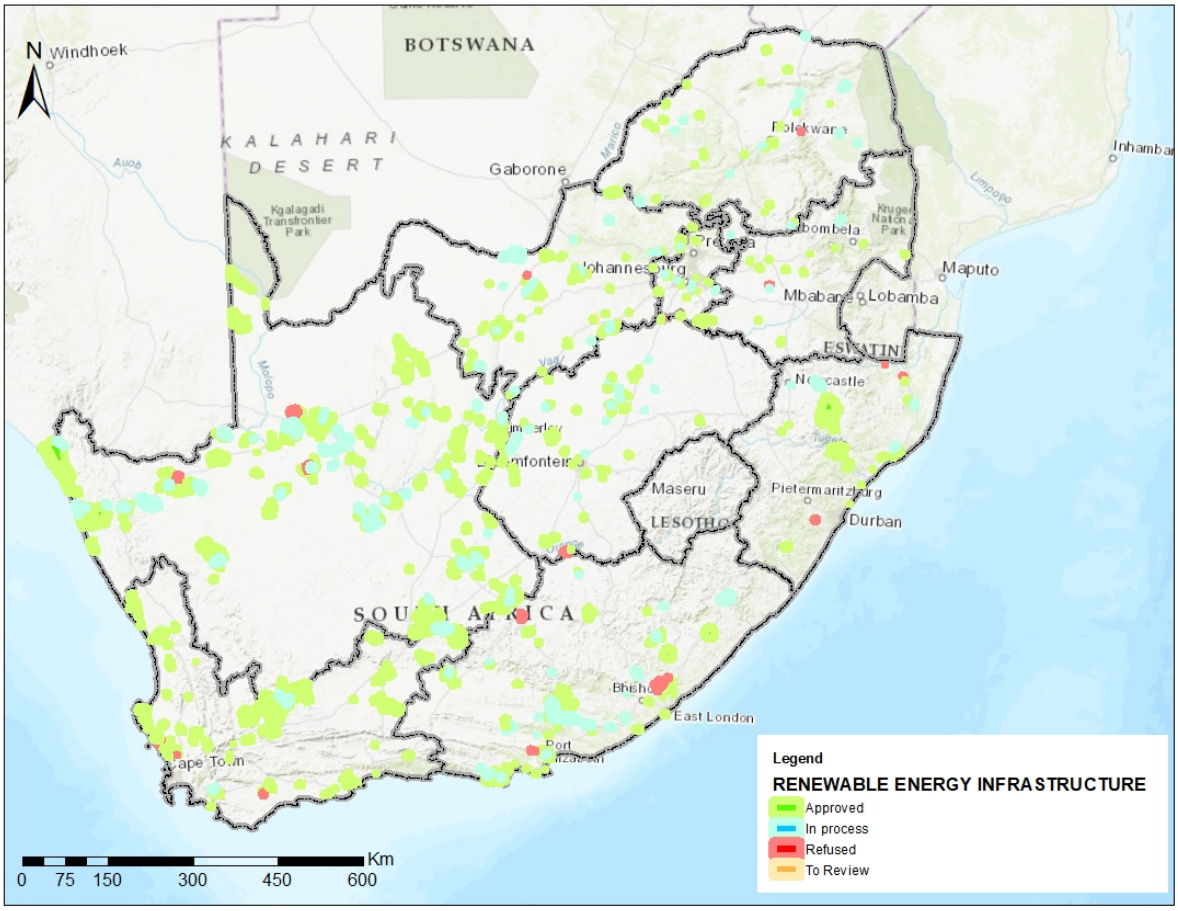

Figure 4: Status of projects.

5 LESSONS LEARNED AND IMPLICATIONS FOR POLICY

Overall, the case studies found that while many coals related jobs are at risk because of energy transition, there are available options retrain and upskill employees. Though the number of coal industry jobs is modest 4.7 million jobs globally and shrinking, the industry generates significant indirect jobs across economic sectors. Closing coal-based energy plants has implications for labour markets beyond the power plants

[1] IPPO, 2022. Independent Power Producers Procurement Programme (IPPPP): An Overview as at 31 December 2021. Independent Power Producer Office. Pretoria and Johannesburg: Department of Mineral Resources and Energy, Development Bank of Southern Africa and National Treasury.

workers. It negatively affects workers along the coal value chain, hurts local economies reliant on mine workers' earnings, fragments community well-being and social capital, and squeezes public finances.

In some communities, closing power plants can create a persistent, destabilizing demand shock as displaced workers struggle to transition to new jobs, because few alternatives are available, or workers are unwilling to accept lower-paying options or move to regions with greater labour demand. Given that coal production is concentrated in just a few countries, global coal phase-out targets could be achieved through ambitious action by a small number of key players. But, instead of phasing out, some countries are ramping up coal production for export.

Lessons from power plant closures illustrate the complexities and risks of inadequate planning, coordination and stakeholder consultation, insufficient investment, and poor policy design. A critical aspect to planning for coal transitions will be laying the foundations for attracting private investment and stimulating private-sector labour demand and business development. This calls for supportive infrastructure and institutions, education curricula aligned with the skill needs of emerging sectors, and a conducive regulatory environment. To address spatial misalignments related to employment, it was observered new jobs may be created in different communities, regions or countries than those where the principal job losses occur. This is particularly the case in locations that lack economic diversification. While sectoral misalignments rising from industries may draw more heavily on raw materials or intermediate inputs from sectors that are quite different from those that supply once prominent but now declining industries.

6 CONCLUSION

In conclusion the rise and decline of coal plant over the last century had the effect of building power-plant-dependent economies through coal-based employment, and then exposing these communities to severe negative shocks. Many of these relatively communities were already lagging in terms of socio-economic development; the sharp reduction in coal demand over the past several decades created further dislocation that undermined their economic sustainability. The magnitude of the impact across counties varies, as does the degree of economic resilience and capacity to transition to alternative industries. Some counties transitioned early, while others delayed the difficult and costly adjustment needed to diversify their local economies.

1 ABSTRACT

The increasing detrimental consequences of climate change and the decline in fossil fuel resources are leading to a rise in demand for food and energy. Agrivoltaics (Agri-PV) offers an opportunity to combine space-optimised photovoltaic (PV) use for sustainable agriculture. By feeding solar energy into the grid, PV is regarded a key component of renewable energy systems. Especially, the wine industry is facing increasing challenges due to climate change, particularly in regions where excessive solar radiation and rising temperatures negatively affect grape quality and yield.

In this article we have examined a cost-efficient technical solution that can also be used on a small scale. It is shown that by using mostly standardcomponents without special parts, a modular system with high photovoltaic output and the least possible disruption to agricultural use can be created. Due to bifacial solar modules, which have recently emerged on a massive scale, a cost-effective structure withoptimal use of the sun over the course of the day was realised. Initial resultsof PV utilization, especially in the winter months, with shading and rain influenceshow the technological and economic feasibility of the proposed technology.

Keywords: Sustainable Innovation, Photovoltaics, Climate Change, Food and Energy, Agriculture

2 INTRODUCTION

The synergy of agriculture and photovoltaics is reflected by the Sustainable Development Goals 2 and 7 (SDGs) of the United Nations: “Goal 2 is about creating a world free of hunger by 2030.The global issue of hunger and food insecurity has shown an alarming increase since 2015, a trend exacerbated by a combination of factors including the pandemic, conflict, climate change, and deepening inequalities” (https://www.un.org/sustainabledevelopment/hunger/); “Goal 7 is about ensuring access to clean and affordable energy, which is key to the development of agriculture, business, communications, education, healthcare and transportation(https://www.un.org/sustainabledevelopment/energy/).Sustainable innovations increasing the efficiency, resilience and profitability by cost saving and photovoltaic inspired quality improvement solutions might contribute to strike a balance to a currently prevalent existential crisis of vineyards in the Palatinate, the setting of the experiment in the South West of Germany, and the neighbouring wine region of Baden-Württemberg,which both suffer due to low wine prices and high cost burdens (Rheinpfalz, 2024; Suedkurier, 2024). A deterioration of wine quality, a ‘death’ of Winemakers and/or wine regions lying fallow will have very negative repercussions for tourism and wine and/or regional branding of the region in question (Correia Loureiro and Kaufmann, 2012; Kaufmann and Durst, 2008).

Prolonged heat stress can lead to reduced acidity and altered sugar content of grapes, as well as to an overall decline in wine quality, putting economic pressure on winemakers. Traditional shading methods offer only limited protection, and water-intensive irrigation strategies are becoming less sustainable due to increasing drought conditions.Agri-photovoltaics (agrivoltaics) presents a promising solution to mitigate these issues by integrating photovoltaic (PV) systems into vineyards. By providing partial shading, Agri-PV can help regulate microclimatic conditions, reducing heat stress while simultaneously generating renewable energy

(Zha et al. 2022; Ferrara et al., 2022). Recent advancements in bifacial PV technology further enhance this approach. Bifacial modules, which capture sunlight fromboth sides, are particularly well-suited for vineyard applications, as they can utilize light radiationthrough diffusion optimizing energy yield without significantly compromising agricultural productivity.The east-west orientation of the bifacial solar systems also offers advantages in terms of feeding electricity into the grid structure. The change in energy production during the day, with peaks in the morning and afternoon, is counteracted by conventional south-facing solar systems (Guo et al. 2013; Thomas Rosenzopf, 2022). This results in a more balanced feed-in of electricity generated by solar systems throughout the day. However, a major challenge in the widespread adoption of Agri-PV systems is the cost of implementation. Many existing Agri-PV installations rely on custom-built components, making them economically viable only in large-scale projects with high production volumes. This limits accessibility for smaller vineyards that could benefit from the technology but cannot justify the high initial investment. Therefore, this study focuses on the use of cost-effective, standardized components that enable small-scale Agri-PV installations to be financially viable even in low-volume production.

As a foundational step in this study, existing Agri-PV concepts will be examined based on the guidelines outlined in DIN SPEC 91434. The current state of technology will be analyzed through two key examples: commercially available Agri-PV solutions, such as those provided by Next2Sun, and research-based installations like the system developed by Krinner Carport GmbH as part of the HyPErFarm project. Additionally, concepts proposed by the energy provider RWE will be considered, even though they currently exist only as design renderings without real-world implementations.

Following this analysis, the advantages and disadvantages of these existing systems will be evaluated to determine which elements can be integrated into a novel prototype for a new Agri-PV concept. A key focus will be on cost-effective construction methods that enable small-scale feasibility. This includes the incorporation of standardized components, such as trusses from the event industry and steel cables as a low-cost mounting alternative. The latter offers significant structural benefits, particularly by reducing the impact of wind forces through the elimination of bending and torsional moments. These design optimizations aim to improve both economic and structural efficiency, making Agri-PV more accessible for smaller vineyards while maintaining high energy yield and agricultural productivity.

3 THEORY

The aim of agrivoltaic systems is targeted use on agricultural land that allows agricultural use to be largely unrestricted so that a wide variety of crops can continue to be grown. The photovoltaic system then offers an additional environmentally friendly way of generating electricity while protecting the plants from excessive solar radiation through shading. Intelligent irrigation systems can also be installed, allowing rainwater to be collected from unfavourable areas and used in a targeted manner on the planted areas. The dual utilisation of agriculture and electricity generation is illustrated in Figure 1. With an optimal and favourable set-up, the yield of agricultural crops can be significantly increased for the same usable area, while the electrical energy can either be sold or used for own consumption.

The system can be customised to the respective agricultural area of use. Agri-PV systems are categorised into different types of structure, which are suitable for specific areas of use and plant varieties.

The German DIN (German Institute for Standardisation) for specification 91434 distinguishes between two categories of Agri-PV: Agri-PV systems with an elevation with a clear height are designated as category one while category two systemshave an elevation close to the ground.

The design of an agricultural PV system must be such that the PV modules are evenly distributed across the height of the roof. In category 1, a minimum height of 2.10 m is required to comply with health and safety regulations and to allow agricultural use of the area. The area lost to the installation must not exceed 10% of the total usable area. In addition, it must be ensured that the area can continue to be cultivated and, depending on the crop, can be driven over if necessary. Light availability should meet the needs of the crops and be evenly distributed over the area. Potential shading should be checked. Water availability also plays a key role: either a targeted irrigation system must be integrated, or the system must be designed to allow rainwater to reach the crops unhindered. Measures must also be taken to prevent soil erosion and siltation, for example by using suitable drip edges on the PV modules, and the ability to completely disassemble and remove the modules without leaving any residue must not be the focus of the prototype. Economically, the

concept must be designed in such a way that the combination of energy production and agricultural use remains profitable for the farmer. Finally, a high level of land use efficiency should be aimed for, with the crop yield after installation of the agrivoltaic system being at least 66% of the original reference yield.

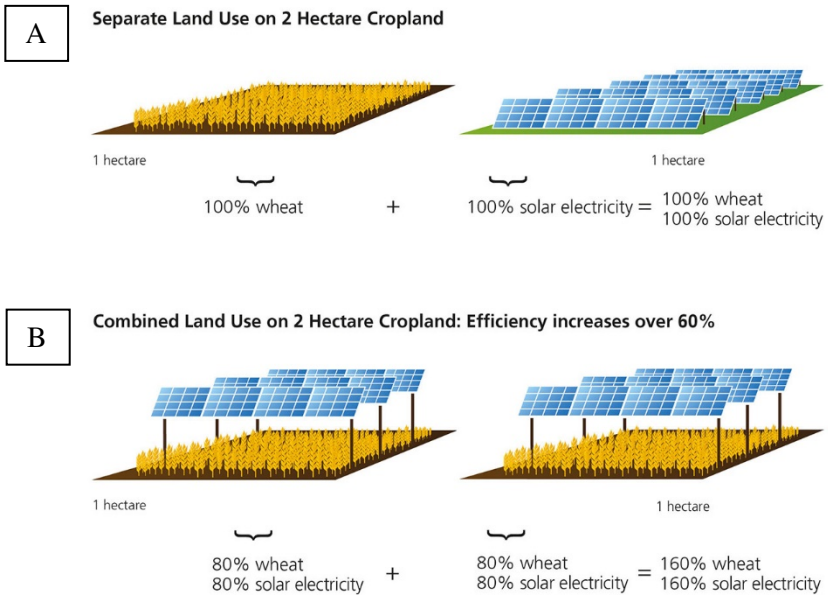

Figure 1: Theoretical benefits of agrivoltaics on an agricultural field: Separate use of agriculture and photovoltaics (A); combined use of agrivoltaics and agriculture (B)(Metsolar.eu, 2021)

The utilization area of Agri-PV systems is divided into four utilization categories based on agricultural requirements:

A: Permanent crops and perennial crops

B: Annual and perennial crops

C: Permanent grassland with cut use

D: Permanent grassland with pasture use

Permanent crops are plants that grow on agricultural land for at least five years and provide recurring yields during this time. These do not count in the crop rotation. Permanent grassland is not part of the crop rotation for at least five years and can either be used with cut grass for yield or as fodder for farm animals.

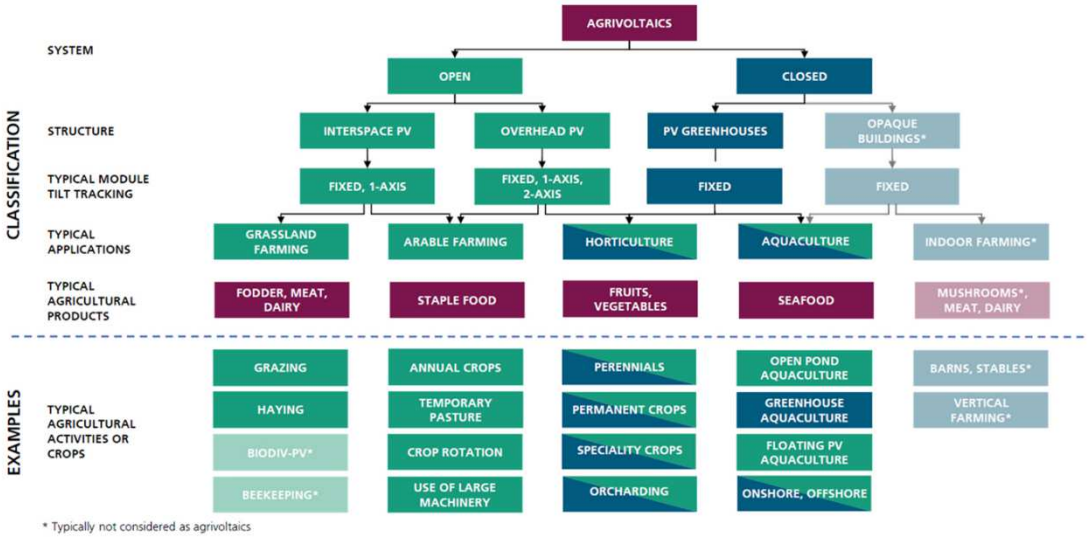

Figure 2: Classifcation of agrivoltaics system with different fields of application (Gorjian et al. 2022)

Furthermore, agrivoltaics can be categorised into two distinct systems: open and closed. Closed applications pertain to greenhouses and are classified as fixed solar systems mounted on the uppermost structure. These systems facilitate the cultivation of a diverse range of crops, including fruits, vegetables, and aquaculture. As

illustrated in Figure 2, open solar systems are further subdivided into the two previously delineated categories. Additionally, there exist various mounting variants, such as fixed and tracked configurations. The scope of application encompasses grassland and arable farming, as well as areas where closed agrivoltaics systems are employed in a complementary manner.

The current technical state of Agrivoltaics

The provider “Next2Sun” presents its ground-level agrivoltaic systems, which are placed on agricultural land like a kind of fence system. As can be seen in Figure 3, the PV modules are mounted in a frame system that provides for two transversely aligned modules one above the other, which are attached at both ends with two posts protruding vertically from the ground. According to the manufacturer, who specifies a patented mounting system, the posts are hydraulically driven into the ground. The advantage is the installation of bifacial modules, which can generate electricity on both sides of the modules through solar radiation. According to Next2Sun, the modules are optimally aligned to the east and west, which results in the highest energy yield in the morning and afternoon to early evening. According to the company, this results in significantly better power generation than with conventional south-facing PV installations. Luxor and Akcome silicon modules from China are used. The strips between two PV rows have a width of ten meters, which can be used for agricultural purposes. Next2Sun states the following about the shading: “The partial shade of the PV modules reduces the evaporation rate of the area. [...] In addition, higher crop yields can be expected in arable farming for shade-tolerant crops such as potatoes, spinach, carrots, etc.”

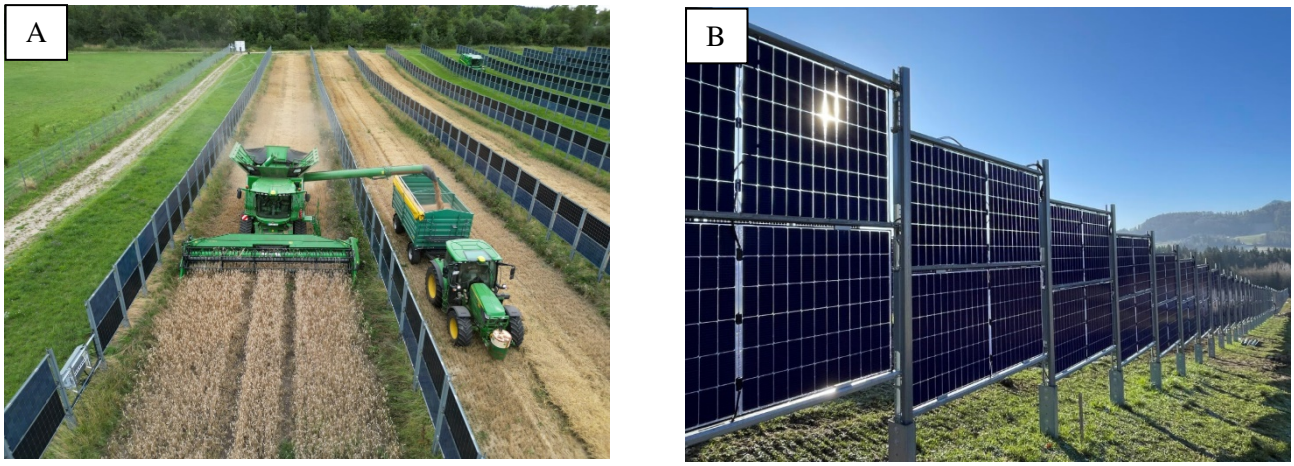

Figure 3. (A) Next2Sun agrivoltaics concept with arable farming (B) Next2Sun concept with grassland farming (Next2Sun, 2024)

The solar carport manufacturer Krinner Carport GmbH from Straßkirchen is presenting another agrivoltaic concept. Two demonstration systems have already been built here as part of the HyPErFarm research project, which involves the Fraunhofer Institute for Solar Energy Systems and a large number of other investors and companies. The publication by Asa’aet al.(2024) shows that this is a trackable PV system. As shown in Figure 4, this is a category one agrivoltaic system mounted at a clear height. The PV modules are mounted on a twelve-metre-long beam, which is mounted on two posts as a pivot axis. Galvanized steel is used as the material, and the steel beams are mounted on the posts using a custom-made suspension system. The length of the girder results in a construction on which 12 modules are installed per girder. The construction can be varied in its length by adding further cross beams and supports of the same dimensions (Figure 3B). The support pillars are inserted into a sleeve driven into the ground and braced with wire ropes at the edges of the Agri-PV system. The height of the structure is not specified, but according to Figure 4B it is large enough to ensure that the agricultural land can be driven on. The pivot axis results in a system that can be tracked. Figure 4A shows a grass strip in the line of the support pillars, which cannot be harvested by commercial vehicles. However, it is stated that these green strips, which make up 10% of the total area, can increase biodiversity as a flowering meadow by providing natural food sources for insects. Krinner Carport GmbH states that by tracking the module bridges, both the snow and wind load can be reduced and at the same time electricity generation is improved by tracking solar radiation.

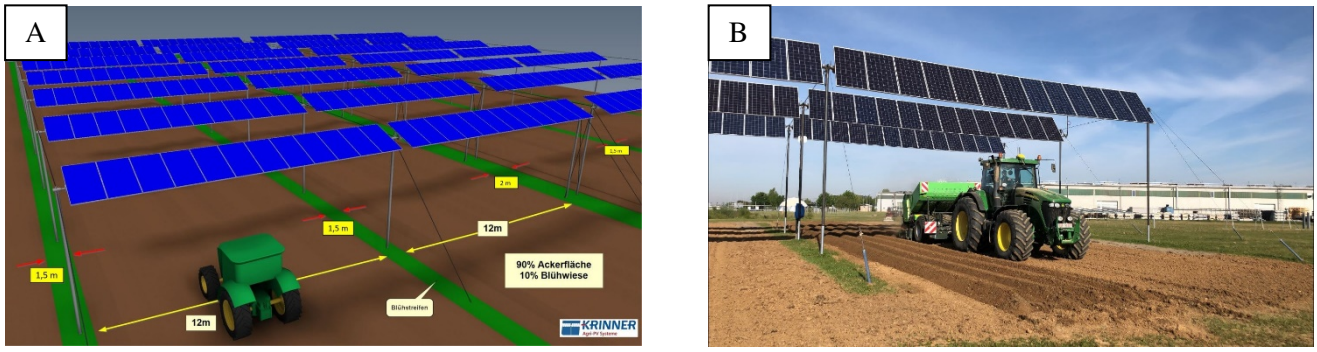

Figure 4. (A) Krinner Carport GmbH agrivoltaics concept (B)Krinner concept realization (Krinner Carport GmbH, 2024)

The RWE demonstration plant at the Garzweiler opencast mine near Bedburg is investigating the advantages of agrivoltaics in different concepts and systems. In co-operation with the Institute of Plant Sciences at the Jülich Research Center and the Fraunhofer Institute for Solar Energy Systems, a large-scale plant with 6100 modules and three different concepts was constructed. The plant has a capacity of 3.2 MWpeak and was built on an area of seven hectares. A ground-level system with a vertical module arrangement, a ground-level system with single-axis tracking and a highly elevated system constructed in a frame design with cross beams and support pillars as well as PV modules inclined at 45 degrees.

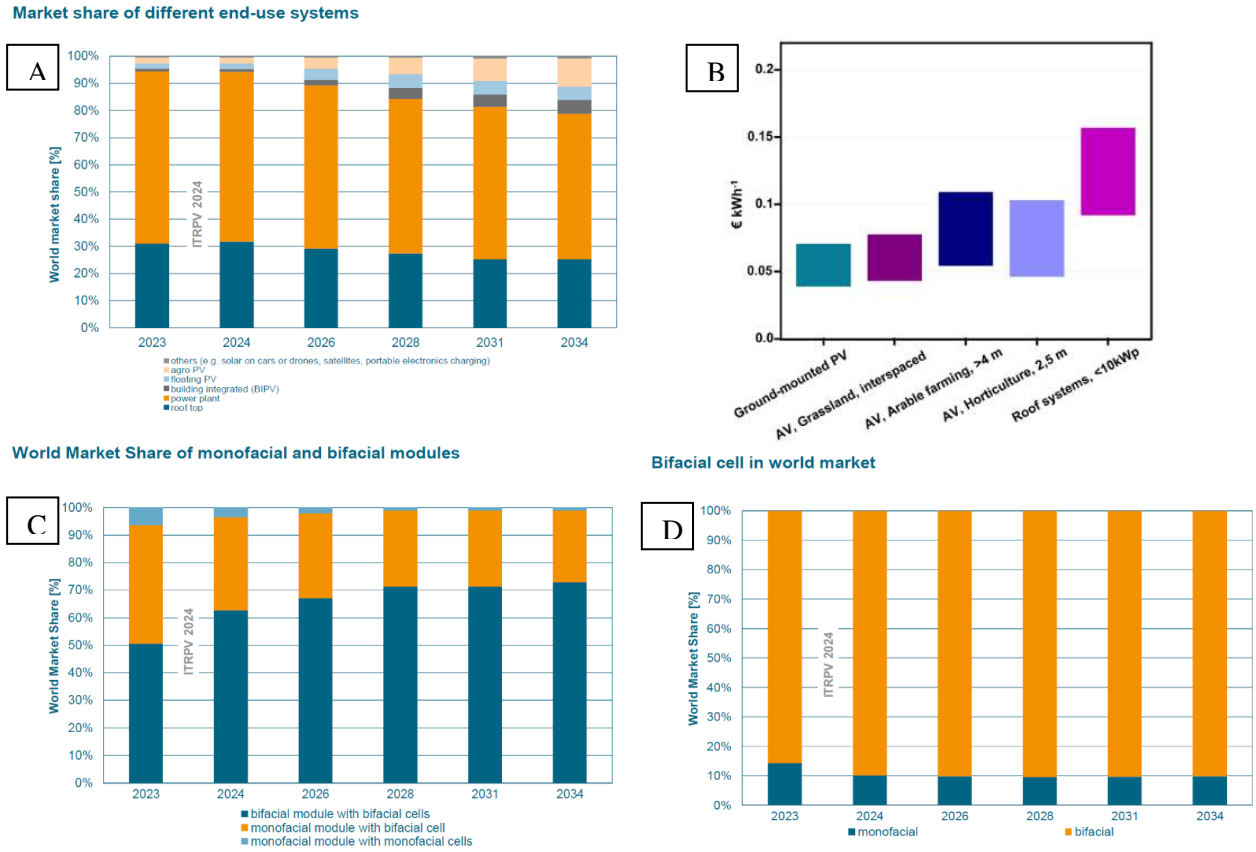

Figure 5. (A) world market share of differend end use systems (B) energy costs of different photovoltaic systems (C) world market share of monofacial and bifacial modueles (D) market share of bifacial cells(ITRPV, 2024; Trommsdorf et al., 2023)

The current market situation

Agri-photovoltaic systems that utilize bifacial PV modules offer significant advantages over traditional monofacial modules, especially when combined with an east-west orientation. Bifacial modules are capable of capturing light from both sides of the module – not only direct sunlight but also light reflected from the ground or surrounding environment. This results in higher energy production, as the reflected sunlight enhances the overall output of the modules, which is particularly beneficial in agricultural applications where reflected light from crops or the soil can be utilized. The east-west orientation maximizes energy production throughout the day and provides more consistent energy output compared to traditional south-facing

setups.In contrast, conventional monofacial silicon solar cells only capture direct sunlight, limiting their efficiency as they cannot harness reflected rays. Whilst a significant proportion of conventional monofacial c-Si cells are still being manufactured at present, Figure 5D demonstrates a favourable forecast for the escalating production of bifacial solar cells. Furthermore, an augmentation in the utilisation of bifacial modules is also predicted (Figure C).

Additionally, there are concentrating optical solar systems that rely on lenses or mirrors to focus sunlight onto small, high-performance solar cells. While these systems offer high efficiency, they are generally designed for specialized environments or large-scale installations and may be less practical for agri-PV applications, as they are not optimized for use in agricultural fields. Another emerging technology is tandem solar cells, which use multiple layers of different materials to absorb a broader spectrum of sunlight. However, tandem solar cells are still in the development phase and are currently less widespread and economically accessible compared to monofacial or bifacial systems.

By incorporating bifacial modules and an east-west orientation, the potential of agri-PV can be maximized, combining higher energy production with a more sustainable and efficient use of agricultural land.With increasing projections for renewable electricity production from agrivoltaic systems (Figure 5A), which are expected to account for over 10% of total solar electricity production by 2034, the focus must be on the price and viability of these systems. At the current stage of this work, category one open agrivoltaic systems represent the most expensive share of non-rooftop industrial electricity production (Figure 5B).Substructures for agrivoltaic systems in arable farming cost an average of 400 eurosper kWp (Landverpachten.de; 2024).

Materials and methods in the presented concept

In order to develop a cost-effective prototype, various aspects of the design were given due consideration. These included the design of the statics for weather influences, the optimal choice of solar modules for good efficiency, and the development of a construction system that is easy to assemble.

The wind pressure WD is calculated using the dimensionless pressure coefficient cp, the density ρ of the air and the wind speed v. The dimensionless pressure coefficient for vertical surfaces has a value of 1, which is assumed for simplification in the following calculations. Similarly, for wind speeds with a Mach number < 0.3, air is assumed to be an incompressible gas, which results in the density as a function of temperature and air pressure. The wind pressure is calculated as follows:

$$W_D = c_p \cdot \frac{\rho}{2} \cdot v^2$$

Free-standing solar installations must be able to withstand wind speeds of up to 151 km/h, i.e. 42 m/s, with their elevation. As the density varies with the temperature over the year and a safety margin is added for all mechanically and statically stressed components, a density at 20 °C and standard atmospheric pressure is assumed here.

$$W_D = 1 \cdot \frac{1{,}204\ kg \cdot m^{-3}}{2} \cdot \left(42\ \frac{m}{s}\right)^2 = 1058\ \frac{N}{m^2}$$

This considers a gale force wind of over 118 km/h with a safety margin for Germany, ensuring that the photovoltaic systems are stable in all weather conditions.

Agrivoltaics setup

The prototype, which was designed as part of this work, consists of two vertically aligned trusses (Global Truss F34400) with a height of 400 centimeters, which were set up eleven meters apart. These are set up on a base plate from the same manufacturer (Global Truss F34BASE). To ensure the stability of the trusses, two concrete foundations with dimensions of 50 x 50 cm and a depth of 80 cm were poured, reinforced with steel to enhance flexibility. Four ground anchors from Igel GmbH, model Spirafix, measuring 30 x 300 mm, were cast into the concrete to secure the base plates to the concrete foundations, thereby ensuring the necessary stability. To ensure the secure installation of the Agri-PV system, a system consisting of three guy ropes per truss, offset by 90° around the truss, was installed. The wire ropes for tensioning the trusses, manufactured by Drahtseile24, have a thickness of eight millimetres and a winding of 7x19 strands, with a tensile strength of 1960 N/mm2. These ropes were anchored to the ground using Spirafix ground anchors (50x1540 – AC type – M16 thread), with each anchor capable of supporting 1400 kg. Additionally, high-strength eye bolts (Igel GmbH eye bolt – M16 thread for AC type) were utilized, with each bolt possessing a tensile strength of

4000 kg. Two wire ropes, with a spacing of one meter, were attached horizontally between the trusses to suspend the solar modules. All wire ropes were mounted using wire rope clips from the manufacturer Drahtseile24, which correspond to the tensile strength of the wire ropes. Photovoltaic modules from the manufacturer Solarwatt were attached to the horizontally tensioned wire ropes with four quick-connect links each, which have a load capacity of 140 kg per bracket. The brackets are attached to the mounting holes of the module frames and then hooked into the wire ropes. Additional clips serve as spacers.To comply with safety standards for work and buildings, solar modules with appropriate overhead glazing certification were selected to prevent safety measures such as nets.

Due to pragmatic concerns, simplifications were implemented for the prototype, with the utilization of more cost-intensive materials enabling enhanced flexibility in operation and the modification of extensions. For instance, 400-centimeter trusses were procured in lieu of the originally specified 500-centimeter trusses, a decision that was made to facilitate the assembly process. However, these trusses can be extended with additional modules, thereby enhancing their functionality. Additionally, higher-priced clamps were utilized in lieu of inexpensive seals for tensioning the wire ropes, a choice that facilitates expeditious removal of the wire ropes.

4 EXPERIMENT AND UPSCALING

The prototype system developed and tested as part of this work demonstrates the suitability for upscaling to a large-scale agrivoltaics system.The chosen construction, consisting of two vertically erected trusses with three guy ropes per truss, forms a stable basis for a flexible expansion of the system (Figure 8).A key feature of this design is the ability to arrange the trusses one behind the other at a constant distance of 11 metres. This linear configuration facilitates the establishment of a route of any specified length, with the capacity to accommodate 8 to 10 solar modules between the crossbars.The total energy yield for a designated agricultural area is contingent on the parameters p (distance between the tracks) and h (height of the solar modules) (Figure 8) (Riaz et al. 2020).The ratio p/h exerts a dual influence on both the level of plant shading and the number of solar module tracks within a specific area (SOURCE). In order to optimise material efficiency and reduce the effort required to stabilise the structure, the bracing system was adapted (Figure 3): while the two end trusses of a route still need to be secured with three guy ropes, it is sufficient to fix the intermediate trusses in between with just two guy ropes. This significantly reduces the amount of material used and the installation costs per unit without compromising the structural integrity of the overall system.

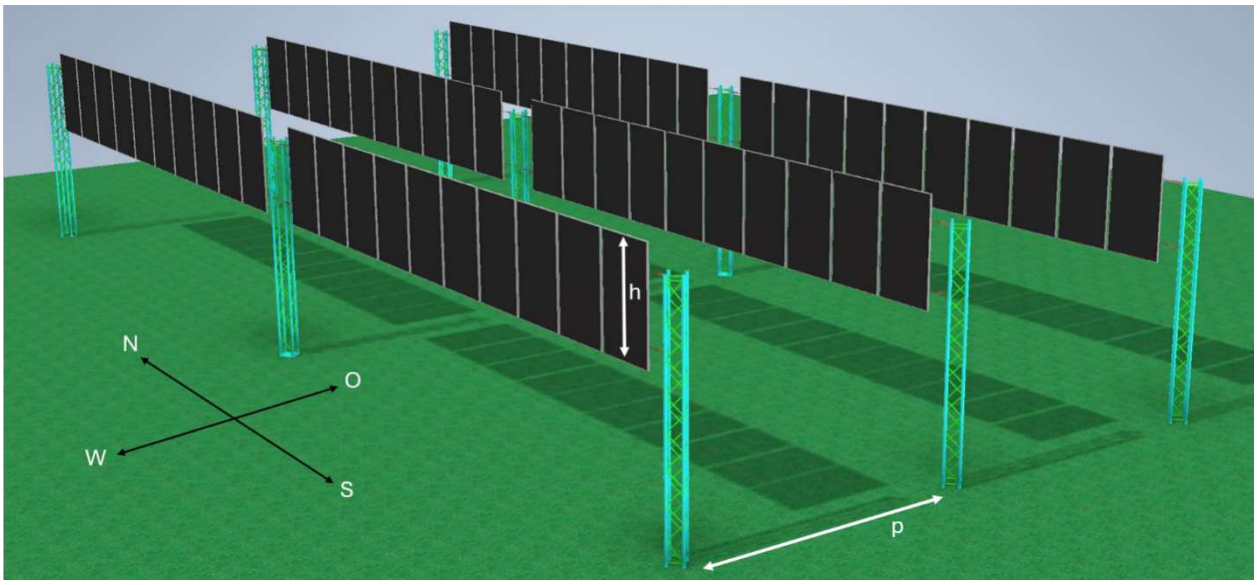

Figure 8. Visualization of the east-west oriented bifacial agrivoltaics concept in a scale up with a pitch (p) of five meters and a solar module height (h) of 1.7 meters

In the event of the agrivoltaic system being simulated within an agricultural area measuring one hectare, utilising a scale-up model, the following data is generated:Within an area of one hectare, with an edge length of 100 x 100 m, a total of 20 traverses can be configured with a pitch of five metres. Given a photovoltaic section length of 11 metres between traverses, this results in 9 sections, each with eight modules mounted on a single section. This calculation yields a total of 1455 solar modules per hectare.Utilising SOLARWATT Panel vision GM 3.0 construct solar modules with a nominal output of 370 Wp results in a total output of 538 kWp. For the test region of the prototype in the Southern Palatinate, approximately 1000 full-load hours of sunshine are estimated per year. According to current data, the sale of a kilowatt hour in Germany is

valued at 8 – 9.5 cents, with an average value of 8.75 ct, equating to a total of € 47090 for an annual yield of 538 MWh. Given the yield generated, the ROI (return on investment) of the pilot project is 10.3 years. The production costs for the prototype are €900 per kWp, and no labour hours are included in the cost breakdown, which results in pure material costs. For the real conditions of series production, the costs for labour must be taken into account, but the costs of the components are estimated to fall by two thirds in large-scale production.

The potential income for the farmer should be compared with a normal yield from wheat with up to 9 tons per hectare and a price of 300 € per ton. So the income from electricity is much higher, than the income from wheat.

The aforementioned synergistic effect of agriculture and photovoltaics is even more enhanced when the installation of photovoltaic systems on agricultural land improves ground conditions by the implicit shading effect. In these cases, the shading, while simultaneously generating energy, provides protection for crops and can lead to higher crop yields in selected regions. Such a positive combined effect is currently also occurring in wine-growing regions, where, for example, white wines are grown in areas affected by global warming. The warmer summers and autumns result in higher alcohol levels, which are not desired or expected by customers. Rain shading continues to be a key aspect in the development of Agri-PV. It can be desirable or undesirable. The different objectives lead to different proposed solutions. Last but not least, the price and the possibility of small-scale application play a role in the design decision. Often, however, current proposed agrivoltaics systems are almost exclusively associated with customised parts, which only makes large-scale production economically viable. For this reason, in the project presented, we focus on applications that can also be used on a small scale, where the sun shading effect is desired and rain shading is undesirable, and the total installation makes economic sense for the farmers or winemakers. This brings us to a solution approach that appears very simple in terms of design, but nevertheless exactly corresponds with an optimum of the required properties mentioned. An agrivoltaics prototype was designed and built, using bifacial photovoltaic modules with vertical orientation and low-cost standard components. These components are easily available everywhere and do not need an exclusive supply chain. After an analysis of current research in the agrivoltaics sector and the global market share of photovoltaic technologies (Metsolar, 2024; Asa'a et al., 2024; Ogobomo et al., 2017), the advantages of low agrivoltaics systems were combined with bifacial modules and high-mounted agrivoltaics systems. The developed system relies exclusively on standard components such as stage trusses and offers a raised height with fixed modern Passivated Emitter and Real Cell (PERC) modules, which makes the coverage of a wide range of agricultural space possible.

5 RESULTS AND DISCUSSION

The system set up on the area of the SIZ site in Neustadt/Weinstrasse currently undergoing testingallowsvarious aspects of the type of agri-PV proposed by the authors to be investigated. The yield tests to date have mainly covered the winter months, which are actually unfavorable in Germany. Nevertheless, useful energy harvests can be achieved here. The energy yields to dateextrapolated to the year as a whole is approximately 20-30% above theexpected value for monofacial PV modules. This can also be seen in the daily progression in figure 9A, which shows a long, uniform power delivery. Over the course of the month there are verystrong daily fluctuations according to varying cloud cover in the winter months.

Despite the extremely cost-saving design, the system withstood the winter storms without any problems.Several moisture sensors (figure 10) were positioned in order to be able to make statements about the rain distribution. It was found that an increased amount of water was registered directly below the vertically suspended modules. This is probably due to the oblique rainfall, which runs down the modules and drips off. Effects on the vegetation must therefore be taken into account.

From a business model perspective, the system's modular expandability ensures scalability, accommodating both small and large-scale agrivoltaics systems with efficiency. The tested prototype offers a robust foundation for upscaling, characterised by its simple expansion options, reduced guy ropes per intermediate traverse, and targeted spacing adjustments. These features position the system as a promising solution for large-scale agrivoltaics installations. The p/h ratio exerts a substantial influence on the implementation of the system as a scale-up, with a pitch of 5 metres and a solar module height h of 1.7 metres resulting in a ratio of 3 (Riaz et al. 2020). This indicates that the agrivoltaics system provides optimal shading conditions and efficient electricity production.With an estimated return on investment (ROI) of approximately 10 years, this

can be further optimised through cost reductions achieved by purchasing in larger quantities. The system's economic viability is further enhanced for small and medium-sized farmers, making it a viable option for a wide range of agricultural applications.The PERC modules in particular are notable for their rapid response to increased sunlight, achieving maximum energy yield even during the winter months, a trait that is a consequence of their inherent characteristics.

In addition, a business model design of the small scale wineries whose existence is threatened, must include wine marketing, wine tourism as well as networking perspectives embracing all the stakeholders of a wine region ecosystem (Koch, Martin and Nash, 2013). In more detail, whilst a higher level of resilience against the 'heat stress'and higher level of renewable energy use to be achieved by the introduced agrivoltaics system,will positively affect the product brand(acidity and sugar content; sustainability), other organisational-level branding (i.e. family, winery, friendliness), regional branding (i.e. place of origin, regional image)and, last but not least, emotional consumer aspects (i.e. brand love) should be considered in an integrated manner (Johnson and Bruwer, 2007; Panovic, Obermayer and Kovari, 2022;Kaufmann and Durst, 2008; Correia Loureiro and Kaufmann, 2012).

6 CONCLUSIONS

This paper aims to provide an innovative albeit economical contribution for the winemaking industry by developing a prototype of a system which exploits synergistic effects of agriculture and photovoltaics for winemakers currently facing a daunting economic future. In this respect, this paper presents the results of an experiment to develop a prototype of an invention to micro scaling a developed prototype for wine makers to possibly increase their resilience and "diversify their risk by entering into the business of bioenergy production and intelligent agrivoltaics (Fiorillo, Lo Zoppo and Saputo (2023, p.54). This experiment in progress will provide detailed figures on efficiency key performance indicators, area output as well as typical geometrical positions of the developed system. The synergy effect on agricultural and energy efficiency by agrivoltaics systems are regarded a promising basis for successful sustainablebusiness models for small scale wineries including multifaceted and multi-stakeholder branding strategies.

1 ABSTRACT

Ein Großteil der stetig wachsenden Weltbevölkerung lebt aktuell in Städten, die vor multiplen Herausforderungen stehen. Neben den unumgänglichen Anpassungen, die der menschengemachte Klimawandel erfordert, wird der urbane Raum maßgeblich von vielfältigen und divergierenden Stressfaktoren geprägt. Diese multiplen Stressfaktoren wirken sich auf die physische und psychologische Gesundheit der Menschen aus. Dazu zählt im urbanen Raum besonders Umgebungslärm, welcher beispielsweise auf Verkehrsemissionen basiert und laut WHO (2018) zu erheblichen gesundheitlichen Risiken bei betroffenen Personen führt. „Herz-Kreislauf-Erkrankungen, chronische Lärmbelästigung, Schlafstörungen, kognitive Beeinträchtigung sowie Tinnitus und Gehörschäden“ (UBA 19: 5) sind beispielsweise für die gesundheitlichen Auswirkungen von Umgebungslärm anzuführen. Eine nachhaltige urbane Entwicklung welche das Sustainable Development Goal (SDG) 11 adressiert,beinhaltet den zentralen Baustein für eine resiliente Quartiersentwicklung bis hin zur Gebäudeebene (Reicher at al. 2022: 71-76). Dabei spielt besonders auch eine gesundheitsorientierte Entwicklung eine zentrale Rolle.

Bisherige Forschung thematisiert vor allem den bauteilbezogenen „Lärmschutz“ beispielsweise bei Autobahnen, Gebäuden oder auch Innenräumen. Lärm tritt im urbanen Raum in Form von zahlreichen, unterschiedlichen Schallquellen auf. Herkömmliche und typische Bauweisen in Städten bedingen diese Lärmentwicklung mehr als diese zu reduzieren. Eine Adressierung gesamtheitlicher Schallreduzierung auf Stadtraum – beziehungsweise Quartiersebene ist dabei bisher wenig erforscht.

Innovative Maßnahmen, wie beispielsweise der Einsatz von schallabsorbierenden Textilfassaden, könnten allerdings einen Beitrag zur Lärmreduzierung im urbanen Raum liefern. In diesem Beitrag werden Erkenntnisse aus einem Projekt zur Untersuchung von schallabsorbierenden Textilfassaden im urbanen Raum vorgestellt. Das Projekt wird in Kooperation dreier Institute der RWTH Aachen durchgeführt, die sich mit Textiltechnik, Akustik und Städtebau beschäftigen.

Am Beispiel von Aachen wird die städtebauliche Integration der Textilfassaden im urbanen Raum untersucht. Zur Untersuchung werden verschiedene Methoden angewendet, die sich aus Material- und Eigenschaftsuntersuchungen, akustischen Simulationen und Auralisierungen sowie baulich-räumlicher Szenarienbildung der Textilfassaden zusammensetzen. In diesem Beitrag wird besonders die Perspektive des Städtebaus zur Lärmreduzierung in Stadträumen betrachtet, mit Textilfassaden als innovativen Beitrag für eine gesundheitsorientierte, nachhaltige Stadtentwicklung. Hierbei werden Erkenntnisse zur Verbesserung des „akustischen Wohlbefindens“ in Städten gewonnen.

Keywords: Innovation durch Textilfassaden, Akustisches Wohlbefinden, Gesunde Quartiersentwicklung, Akustik im Städtebau, Nachhaltige Stadtentwicklung

2 EINFÜHRUNG

Die aktuelle Debatte zur nachhaltigen Stadtentwicklung wird besonders durch die Einsparung von anthropogenen Emissionen geprägt. Dabei stehen insbesondere Luftemissionen im Betrachtungsfokus, wie beispielsweise CO_2-Emissionen und eine damit verbundene, angestrebte CO_2-Neutralität, welche beim Ziel desSustainable Development Goals (SDG) 11: „Nachhaltige Städte und Gemeinden“ (Vereinte Nationen 2022: 18) berücksichtigt wird. Parallel dazu soll auch das Sustainable Development Goal (SDG) 3: „Gesundheit und Wohlergehen“ (Vereinte Nationen 2022: 10) erreicht werden. Gerade für den urbanen Raum spielt eine nachhaltige aber auch eine gesundheitsorientierte Entwicklung eine entscheidende Rolle, da ausgestoßene Emissionen als Immissionen auf die Umwelt und die physische sowie psychologische Gesundheit der Menschen einwirken. Als Lebensraum einer immer weiter anwachsenden Weltbevölkerung,

ist besonders der urbane Raum von einer Vielzahl an Emissionen, die über die Luftemissionen hinaus gehen, betroffen und welche weitere Einsparungen für eine nachhaltige Entwicklung notwendig machen. Lärmemissionen im Stadtraum gelten als gesundheitsgefährdende Stressfaktoren, die zum Beispiel durch Verkehr emittiert werden. Zu den gesundheitlichen Gefahren gehören laut der WHO (2018) beispielsweise „Herz-Kreislauf-Erkrankungen, chronische Lärmbelästigung, Schlafstörungen, kognitive Beeinträchtigung sowie Tinnitus und Gehörschäden“ (UBA 19: 5).

Bereits 1957 hat Professor Erich Kühn mit seiner Publikation zu „medizin und städtebau“ (Vogler & Kühn: 1957) am Lehrstuhl für Städtebau an der RWTH Aachen zum Themenfeld der gesunden Stadtentwicklung in der gebauten Umwelt geforscht, zu der neben der Emissionssenkung, auch „Sicherheit“ oder „Walkability“ gehören. Es zeigt sich, dass die Aktualität dieser Forschungsbedarfe bis heute besteht und innovative Lösungen für den urbanen Raum notwendig sind.

3 VOM BAUTEILSBEZOGENEN LÄRMSCHUTZ ZUM GESAMTHEITLICHEN SCHALLSCHUTZ

Besonders der urbane Raum ist von einer Vielzahl sich immer wieder verändernder Schallemission betroffen. Diese stellen neue Bedarfe, Herausforderungen und Anforderungen an gesunde Lebensbedingungen in Städten. Neue Entwicklungen, wie beispielsweise die Einführung der neuen Gebietskategorie „Urbanes Quartier“ (BauGB: 2021), das einen höheren Grad der Nutzungsmischung sowie Dichte zwischen Arbeiten, Wohnen aber auch produzierenden Gewerbe beinhaltet, machen eine intensivere Beschäftigung mit der akustischen Qualität als gesunde Lebensräume, notwendig.

3.1 Herkömmliche Lärmschutzmaßnahmen im Städtebau

In der aktuellen Praxis finden Lärmschutzmaßnahmen im Städtebau, vor allem auf der Bauwerks- oder einer untergeordneterenBauteilsebene statt – und beziehen sich insbesondere auf den Innenraum von Gebäuden. Gängige städtebauliche Bauweisen fördern eher die Entwicklung von Lärm als diese zu reduzieren. Besonders in Gebäuden oder auch in Innenräumen eingesetzte spezielle Bauteile oder Materialien sollen Umgebungslärm reduzieren. Lärmschutzmaßnahmen, wie zum Beispiel Lärmschutzwände an Autobahnen, Flüsterasphalt auf Schnellstraßen oder auch Schallschutzfenster an Umgehungsstraßen sind diesbezüglich, als einige Beispiele zu benennen. Ziel ist es, die Einhaltung der Grenzwerte nach dem Bundes-Immissionsschutzgesetz (BImSchG), der Technischen Anleitung zum Schutz gegen Lärm (TA Lärm) oder auch der DIN 18005 zum Schallschutz im Städtebau zu gewährleisten. Diese Vorgaben orientieren sich vor allem an einzuhaltenden Grenzwerten und weniger an anzustrebenden gesamtheitlich betrachteten akustischen Umgebungen oder Qualitäten, die bei der Planung und Gestaltung unserer gebauten Umwelt zu Verbesserung der Aufenthaltsqualität führen könnten.

3.2 Gesamtheitlicher städtebaulicher Schallschutz

Die Reduzierung von Lärm in städtischen Räumen ist eine zentrale Herausforderung moderner Stadtplanung. Ein ganzheitlicher Ansatz zur Schallminderung berücksichtigt nicht nur die Reduktion von Lärmquellen, sondern auch die Gestaltung angenehmer akustischer Umgebungen, die das Wohlbefinden der Bewohnerinnen und Bewohner fördern können (Alves, 2015). Im Falle des Straßenverkehrs lässt sich neben einer Reduktion der direkten Schallpegel der Quellen, z. B. durch modernere Fahrzeugtypen, geringere Geschwindigkeiten oder der Verwendung spezieller Fahrbahnbeläge, ebenfalls eine Reduktion durch eine Veränderung des Reflexionsverhaltens der Umgebung erzielen.

Zu den allgemeinen Maßnahmen zur Verbesserung des akustischen Wohlbefindens in innerstädtischen Umgebungen gehören auch die Integration von Grünflächen, die als natürliche Schallabsorber und -Diffusoren wirken, sowie die Förderung von angenehmeren akustischen Klanglandschaft, sogenannten „Soundscapes“ (ISO 12913-1 2014), bei denen beispielsweise natürliche Klänge wie Vogelgesang oder Wasserplätschern die Schalldruckpegel nicht reduzieren, aber zu einer durch Menschen positiver bewerteten Klanglandschaft führen (Bilen & Can, 2021).

Die Betrachtung von Soundscapes ermöglicht es, akustische Umgebungen gezielt zu gestalten. Dabei wird nicht nur der Lärmpegel gemessen, sondern auch die Qualität der Klänge bewertet, um harmonische und angenehme akustische Umgebungen zu schaffen (Brown 2004). Eine ganzheitliche Lärmkontrolle in der Stadtplanung erfordert innovative Ansätze, die über die reine Lärmminderung hinausgehen. Die

Kombination von Soundscape-Design, grüner Infrastruktur und gezielten Maßnahmen zur Schaffung ruhiger Zonen kann die Lebensqualität in Städten erheblich verbessern.

Ein Teil davon sind auch alternative Fassadengestaltungen, die durch akustische Absorption und Streuung zur Lärmminderung in städtischen Umgebungen beitragen können – solche Maßnahmen sind Gegenstand der hier präsentierten Untersuchungen. Die Kombination von Absorption und Diffusion an Fassaden, insbesondere im unteren Bereich der Gebäude, kann zu einer relevanten Reduktion der Schalldruckpegel führen (Picaut 2009). Derartige Maßnahmen führen nicht nur zu einer ruhigeren Außenumgebung, sondern auch zu einer Reduktion des Innenlärms, ohne dass direkte Eingriffe in die Gebäudewände erforderlich sind (Magrini 2016).

3.3 Neue Forschungsbedarfe im städtebaulichen Kontext

Dabei bietet eine intensivere Beschäftigung mit einem umfassenden Schallschutz im Städtebau ein großes Potential Stadträume dauerhaft zu beruhigen. Der Ansatz basiert dabei nicht auf der Vermeidung von Schallemissionen, sondern auf der nachträglichen Reduzierung im gebauten Raum. Das akustische Wohlbefinden rückt dabei in den Betrachtungsfokus. Die Gestaltung und Untersuchung von Soundscapes, welche übergeordnete Verbindungen zwischen Umgebungslärm, Akustikqualität und gesundheitlicher Auswirkung im Stadtraum betrachten, stellen neue Forschungsbedarfe (Moebus et al. 2020). Erste Forschungsansätze untersuchen dazu „Klangraumgestaltung von Außenräumen“ (Sturm et al. 2019). Eine ganzheitliche Adressierung der Schallreduzierung von der Quartiers- bis zur Gebäudeebene ist wenig erforscht. Es gilt resiliente urbane Räume zu entwickeln (Reicher at al. 2022) und Emissionen durch beispielsweise innovative Maßnahmen zu senken.

4 TEXTILFASSADEN ALS INNOVATIVE MASSNAHMEN ZUR SCHALLREDUZIERUNG IM URBANEN RAUM

Als ein potentieller Ansatz zu Schallreduzierung im Städtebau wird im Folgenden das Potential für Textilfassaden interdisziplinär untersucht und vorgestellt. Textilfassaden stellen einen neuartigen Ansatz dar, die durch ihre Eigenschaften dazu beitragen können Stadtträume akustisch zu beruhigen.

4.1 Textilfassaden

Die Verkleidungselemente einer vorgehängten hinterlüfteten Fassade können aus technischen Textilien bestehen und werden in diesem Fall als Textilfassaden bezeichnet. In der Praxis bezieht sich der Begriff „Textilfassade“ jedoch überwiegend auf ein zusätzlich vorgelagertes Fassadensystem, das als Sekundärfassade fungiert. Sekundärfassaden werden als ergänzende Schicht vor die thermisch abgeschlossene Primärfassade montiert, da die durchlässige Struktur textiler Materialien die Schutzfunktionen der Verkleidungselemente nicht in vollem Umfang gewährleisten kann (FVHF 2017).

4.1.1 Materialität und Struktur

Die Konstruktion von auf dem Markt verfügbaren Textilfassaden basiert auf einer Unterkonstruktion, die in der Regel aus Aluminium oder Stahl besteht. Auf dieser Unterkonstruktion wird ein spezielles Gewebe gespannt, das aus synthetischen Fasern wie Polyester oder Glasfaser besteht und mit PVC oder PTFE beschichtet ist. Diese Beschichtungen verleihen dem Gewebe Eigenschaften wie Witterungsbeständigkeit, UV-Stabilität und eine hohe Reißfestigkeit. Die Wahl des Gewebes beeinflusst dabei maßgeblich die optische Wirkung der Fassade, von transluzenten bis hin zu opaken Erscheinungsbildern. Zudem ermöglicht die Flexibilität des Materials die Realisierung komplexer, dreidimensionaler Formen, die mit traditionellen Baustoffen schwer umzusetzen wären (König 2025.)

Aufgrund ihrer transluzenten Eigenschaften lassen sich textile Fassadenelemente auch vor Fensterflächen installieren, ohne die natürliche Belichtung vollständig zu blockieren. Dadurch wird ein effektiver Sonnen- und Blendschutz erzielt, während gleichzeitig der Sichtkontakt nach außen erhalten bleibt. Ein ausreichender Hinterlüftungsraum ermöglicht zudem die Öffnung von Fenstern und unterstützt so die natürliche Belüftung. Darüber hinaus schränken Textilfassaden den Einblick von außen in das Gebäude ein und tragen damit zur Wahrung der Privatsphäre bei. Durch die Absorption eines Großteils der solaren Einstrahlung reduziert die textile Sekundärfassade den Wärmeeintrag in das Gebäudeinnere, wodurch die thermische Gebäudehülle weniger stark aufgeheizt wird. Dies kann die Überhitzung im Sommer signifikant verringern und die

Kühllasten eines Gebäudes um bis zu 78 % senken. Angesichts der angestrebten Klimaneutralität im Gebäudesektor ist diese Einsparung von hoher Relevanz, um den Energiebedarf aktiver Kühlsysteme zu minimieren (Serode 2022).

Ein vielversprechender Ansatz zur Weiterentwicklung von Textilfassaden ist der Einsatz von 3D-Textilien. Diese mehrlagigen 3D-Gewebe bieten erweiterte funktionale und ästhetische Möglichkeiten im Fassadenbau. Durch die gezielte Variation von Materialdichte, Webtechniken und Strukturbildung lassen sich spezifische Eigenschaften wie verbesserte Schallabsorption, gesteuerte Lichtstreuung oder eine optimierte Luftzirkulation realisieren. Darüber hinaus können 3D-Textilien durch ihre dreidimensionale Formgebung die thermische Regulierung des Gebäudes unterstützen, indem sie beispielsweise als zusätzliche Verschattungselemente fungieren oder durch gezielte Luftführung den Wärmeaustausch zwischen Fassade und Umgebung steuern. Aufgrund ihrer strukturellen Vielfalt eröffnen sie zudem neue gestalterische Freiheiten, indem sie komplexe Oberflächenstrukturen ermöglichen, die mit konventionellen textilen Flächenmaterialien nicht realisierbar wären.

4.1.2 Einsatz und Verwendung

Neben funktionalen Vorteilen eröffnen Textilfassaden auch neue gestalterische Möglichkeiten. Durch eine gezielte Modulation der Unterkonstruktion können dreidimensionale Fassadenstrukturen realisiert werden. Zudem ermöglichen die transluzenten Eigenschaften des Materials in Kombination mit Lichtinszenierungen die Erzeugung ästhetischer Akzente, die das architektonische Erscheinungsbild eines Gebäudes maßgeblich prägen können.

4.2 Projekteinführung STumM

Das Projekt „STumM – Schallabsorbierende Textilfassaden im urbanen Raum – Machbarkeitsstudie“ beschäftigt sich mit der Fragestellung, welchen Beitrag Textilfassaden zu einer akustischen Schallreduzierung im Stadtraum leisten können. Ziel des Forschungsvorhabens ist es, eine Verbesserung der akustische Fassadenoberflächenwirksamkeit von Gebäuden zu erzielen, um urbane Lärmpegel, beispielsweise im öffentlichen Raum, der Stadt zu minimieren. Dazu gilt es, im urbanen Gefüge Szenarien zur Evaluierung ihrer städtebaulichen Integration von textilen Fassaden und ihrer Anwendbarkeit zu überprüfen. Aufgrund der Komplexität urbaner Räume gilt es, akustische Berechnungen und Messungen zu validieren und einen Vergleich mit simulierten Daten durchzuführen. Abschließend soll die technologische und differenzierte, funktionale Weiterentwicklung der textilen Fassaden, was beispielsweise Öffnungs- sowie Wandelemente betrifft, überprüft werden.

Innerhalb des Projekts wird eine perspektivische Betrachtung der Forschung auf drei Betrachtungsebenen vorgenommen. Auf einer übergeordneten, städtebaulichen Macro-Ebene wird eine städtebauliche Analyse der Integration von textilen Lärmschutzfassaden betrachtet. Auf der Mesoebene wird die akustische Simulation verschiedener Szenarienräume vorgesehen. Als abschließende Perspektive auf Microebene erfolgt eine Untersuchung der Ebene der Materialität. Diese zeigt, den interdisziplinären Ansatz des Projektes, vom Stadtraum bis zur bauteilsbezogenen Ebene, was die Notwenigkeit einer interdisziplinären Querschnittsbetrachtung verdeutlicht.

4.3 Urbane Szenarien

Um den methodischen Ansatz umzusetzen werden Szenarienräume aufgestellt. Diese Szenarienräume stellen drei divergierende baulich-räumliche Situationen auf dem „Campus Mitte“ der RWTH Aachen dar, welche unterschiedliche Lärmquellen aufweisen.

Gerade Universitätscampusareale werden in der aktuellen Forschung nicht mehr nur als reine „Lern – und Arbeitsorte“ angesehen sondern als „Living Lab“ (Verhoef, Bossert 2019), die sich durch eine 24h-Nutzung zu abwechslungsreichen Lebensorten (Potulski 2020; Fusi 2019) wandeln, für die eine nachhaltige aber auch gesundheitsorientierte Entwicklung von großer Bedeutung ist (Okanagan Charta 2015).

Der sogenannte „Campus Mitte“ rund um das historische Hauptgebäude der RWTH Aachen, bietet sich dabei besonders gut als Betrachtungsraum an, aufgrund der räumlichen Nähe und vorliegenden Expertise der beteiligten Institute. Gleichzeitig weist dieser eine Vielzahl an divergierenden Geräuschemissionen und Nutzungen auf, die in zentraler urbaner Innenstadtlage angrenzend an Wohnnutzungen liegen, die besonders

geräuschempfindliche Nutzungen darstellen. Die drei ausgewählten Szenarienräume setzen sich wie folgt zusammen:

Szenarienraum Mensa, dieser stellt einen zentralen Anlaufspunkt und Aufenthaltsbereich auf dem Campus Mitte dar. Besonders der Vorplatz und Außensitzbereich der Mensa ist von den hohen Geräuschemissionen der angrenzenden stark befahrenen Turmstraße betroffen.

SzenarienraumSemitemp, dieser Raum stellt eine Art Nachverdichtung im rückwertigen Campusbereich dar. Das „Semitemp“, als temporäres Seminargebäude wurde auf einen Teil der Parkplatzfläche aufgestellt, mit den angrenzenden Lärmemisssionen der verlaufenden Bahnstrecke.

Abb. 1: Foto des Szeanrienraums „Wüllnerstraße“ (Mathilda Murray, 2025)

SzenarienraumWüllnerstraße, dieser wird als Verbindungsstraße sowie als Zufahrt zu einem angrenzenden Parkplatz (Talbotparkplatz) ebenfalls maßgeblich durch verkehrliche Geräuschemissionen geprägt, ergänzt durch einzelne Schallemissionen dort ansässigen RWTH Institute.

Alle drei Szenarienräume eignen sich besonders gut, da die ausgewählten Bestandsgebäude unterschiedliche konstruktive Fassadentypen aufweisen und damit auch divergierende Umsetzbarkeiten der Fassadentypologien ermöglichen.

4.3.1 Baulich-räumliche Integration

Anhand der drei definierten und vorgestellten Szenarienräume, wird in einem Forschungsfeld mit Masterstudierenden der Architektur und Stadtplanung der RWTH Aachen untersucht, wie an den definierten Gebäuden der Szenarienräume, schallabsorbierende Textilfassaden nachträglich ergänzt werden können. In einem zweiten Schritt wird die baulich-räumliche Integration dieser neuen Fassaden in ihr Umfeld erforscht. Dazu werden nach einer ersten inhaltlichen Auseinandersetzung mit Textilfassaden, Testentwürfe durch die Studierenden erstellt. Pro Szenarienraum sollten dafür drei divergierende Varianten ausgearbeitet werden, die auf unterschiedlichen Konstruktionsweisen basieren und multiple Erscheinungen der Fassade hervorrufen. Dafür werden je nach Fassadentypus der Bestandsgebäude die bestehenden Fassaden durch Textilfassaden ersetzt oder eine neue textile Fassadenhülle additiv ergänzt. Trotz der unterschiedlichen Szenarienräume mit divergierenden Ausgangsgebäuden zeigen die Ergebnisse, dass drei Grundtypen bei der Erstellung der Fassaden immer wieder Anwendung finden. Dazu zählt die flächig, vorgespannte Fassade, eine Aufteilung in verschieb- oder verstellbare Teilelemente sowie eine panelartige Ausführung (siehe Abb. 2).

Gerade der flächig festvorgespannte Fassadentypus, lässt sich gut additiv ergänzen. Bestehende Fensterflächen werden allerdings ebenfalls mit dem Textil überspannt, was zu Einbußen oder zu

Beeinträchtigung der visuellen Sichtbezüge zwischen Innen- und Außenraum führen kann. Die verschiebbaren elementartigen Textilfassaden, weisen diesbezüglich Einschränkungen ebenfalls auf, lassen sich aber für freie Sichtbezug zur Seite verschieben, was gerade bei beispielswiese dauerhafter Büronutzung, eine große Bedeutung für die Innenraumqualität spielen könnte. Die dritte Variante der unbeweglichen elementierten Panelfassade, welche gerade Textilflächen im rechten Winkle zur Fassaden stellt, kombiniert die Gewährleistung der Freihaltung der Sichtbezüge und bietet eine größtmögliche aktivierbare textile Fläche an, die akustischen Auswirkungen dieser Fassaden gilt es im Weiteren zu erforschen.

Abb. 2: Baulich-räumliche Ausführungsvarianten von Textilfassaden im Städtebau am Beispiel des Szenarienraums „Wüllnerstraße“ – (v. l.) „fest verspannt, beweglich, panelartig“ (Judith Möhringer & Selina Pick 2024)

Im zweiten Schritt, sollten die Studierenden in selbst durchgeführten Umfragen die Akzeptanz für den Einsatz textiler Fassaden im urbanen Raum untersuchen. Als Grundlage der Integration werden dafür, die aus der Literatur abgeleiteten Integrationsparameter nach Reicher (2017: 218), die von „Einordnung“, „Unterordnung“ und „Überordnung“ sprechen, verwendet. Die Ergebnisse dieser Umfragen zu den verschiedenen Szenarienräumen zeigen querschnittsartig, dass Textilfassaden an sich als wichtige Innovation angesehen werden, allerdings visuell besonders einheitliche Fassadenerscheinungen, die weniger auffällig sind, im Stadtraum bevorzugt werden.

4.3.2 Akustische Auswirkung

Da eine Veränderung einer urbanen Umgebung, mit dem Ziel die Lärmpegel in dieser zu reduzieren, im Regelfall mit erheblichem Aufwand verbunden ist, werden bei der Planung der Veränderung üblicherweise akustische Berechnungs- und Simulationsmodelle verwendet. Durch eine Beschreibung der akustischen Charakteristik von Oberflächen (Fassaden), ist es mit verhältnismäßig einfachen Rechnungen möglich, die akustische Wirkung einer veränderten Fassade zu beschreiben, indem der Schalldruck der an der Fassade zurückgeworfenen Reflexion bestimmt wird. In der nicht-isolierten realen Situation einer urbanen Szene befinden sich jedoch eine Vielzahl von Schallquellen und Reflexionsflächen, was zu einer wesentlich komplexeren Berechnung der akustischen Auswirkung führt.

Für die Vorhersage von urbaner Schallausbreitung existieren eine Vielzahl verschiedener Normen und Richtlinien (ISO 9613-2 1996; CNOSSOS-EU 2012) sowie Berechnungsmodelle (Attenborough 1995; Pasareanu 2018). Soll jedoch nicht nur Parameter bzw. Schalldruckpegel bestimmt werden, ist die Anwendung der geometrischen Akustik ein übliches Verfahren, mit dem es möglich ist, eine definierte Situation an verschiedenen Hörpositionen auch zu auralisieren (hörbar zu machen). Die Betrachtung der geometrischen Schallausbreitung erlaubt eine effiziente Durchführung der Ausbreitungssimulation und in Kombination mit akustischer Signalverarbeitung ist so eine Auralisierung auch für interaktive Szenarien möglich (Stienen 2023).

Mit Hilfe der Simulationssoftware RAVEN (Schröder 2011) wird in diesem Projekt in einem ersten Schritt untersucht, welche Auswirkungen die Veränderung der akustischen Fassadeneigenschaften hat. Dazu wurden die Szenarien in 3D-Modelle (beispielsweise für Szenarienraum Wüllnerstraße dargestellt in Abb. 3) konvertiert, die den Anforderungen des verwendeten akustischen Simulationsmodells genügen. Durch eine Definition der akustischen Parameter der Oberflächen (Absorption und Streugrad) ist so eine kontrollierte Untersuchung des Einflusses der Fassaden möglich. Die resultierenden Impulsantworten für die in der Szene definierten Schallquellen hin zu festgelegten Hörpositionen können mit entsprechenden Signalen kombiniert werden, was zur einem plausiblen Höreindruck des definierten Szenarios führt.

Um erwartbare Effekte für verschiedene Szenarien zu bestimmen, wird für eine kontrollierten Modellsituation (Szenarienraum Wüllnerstraße) eine akustische Simulation von verschiedenen

Quellpositionen (Q1, Q2 und Q3) betrachtet. Die in Abb. 3 dargestellten Fassaden in den Farben grün und rot werden in drei Varianten in ihre akustischen Absorptionseigenschaft variiert (alle frequenzunabhängig) :

- Variante A: Absorptionsgrad von 10 % (Referenz)
- Variante B: Absorptionsgrad von 40 %
- Variante C: Absorptionsgrad von 80 %

Diese angenommenen akustischen Eigenschaften stellen stark vereinfachte eher extreme Werte dar und sind in der Realität, in Kombination mit der gewählten Großflächigkeit der angepassten Fassaden, nicht zu erwarten, sollten aber einen Eindruck von erwartbaren Auswirkungen vermitteln.

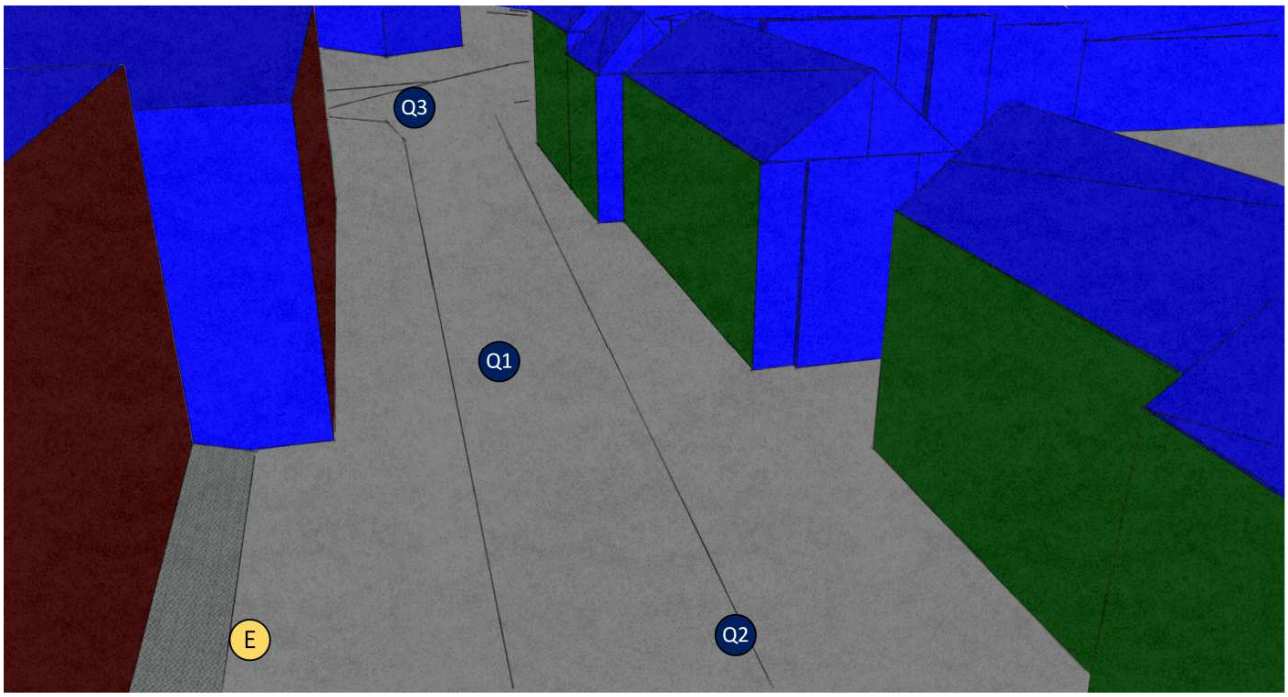

Abb. 3: Beispielhafte Untersuchung von Fassaden mit akustischen Simulationsmodell für den Szenarienraum Wüllnerstraße. (IHTA)

Variante A wird für die Ergebnisse als Referenz betrachtet. Für Quellpositionen Q1 und Q2 (ca. 26m und 18m Distanz zum Empfänger E) sind aufgrund der relativen Nähe zum Empfänger durch eine Veränderung der Fassaden in den Ergebnissen kaum Pegelreduktionen zu beobachten, sowohl für Q1 als wurden für Q2 sind -0. 2 dB und für Variante B -0. 4 dB bestimmt. Im Falle von Quellposition Q3 (Distanz ca. 95m), die keine direkte Sichtverbindung zum Empfänger besitzt und somit der Direktschall (zum Teil) durch die versetzte Fassade blockiert wird, liegen die Pegelveränderungen entsprechend höher: -1. 9 dB für Variante B und -6. 6 dB für Variante C, im Vergleich zur Referenzbedingung (Variante A).

Diese Ergebnisse zeigen, dass durch eine Veränderung der Fassaden in der betrachteten städtischen Umgebung keine extremen Änderungen des Schalldruckpegels zu erwarten sind – wenn sich die Lärmquellen in der Nähe der Hörposition befinden. Bei größeren Distanzen zu Lärmquellen und insbesondere wenn der Schall nicht direkt zum Empfänger gelangt, sind größere Pegelunterschiede möglich. Diese zeigen, dass akustische Maßnahmen bei den Fassaden eine mögliche Maßnahme zur Verbesserung der Lebensqualität im urbanen Raum darstellen kann – denn selbst geringfügige Pegelreduktionen im Bereich von 1-3 dB machen insbesondere bei ständiger bzw. dauerhafter Aussetzung einen Unterschied für Menschen und Tiere in der Umgebung aus.

Im weiteren Verlauf des Projektes sollen die angesprochenen Szenarien und die entsprechende akustische Simulation schrittweise in Richtung realitätsnahe Konzepte angepasst werden. Dazu werden sowohl die Eingabedaten (realistische Absorptions- und Streudaten für die Fassaden, detaillierte Modellierung der Lärmquellen, genaue Modellierung der möglichen Fassadenflächen) als auch das verwendete Simulationsmodell angepasst. Dabei wird auch untersucht, ob die verwendeten Simulationsmodelle auch die akustischen Eigenschaften von komplexen, dreidimensionale Fassadenstrukturen (vgl. Abb. 2 rechts) berücksichtigen können.

Neben der Bestimmung der Reduktion von Schalldruckpegeln bei verschiedenen betrachteten Fassadenvarianten, werden für die Szenarienräume typische Lärmsituationen auralisiert (hörbar gemacht). Diese Auralisierungen können zukünftig auch in Wahrnehmungs- und Soundscape-Studien eingesetzt werden.

4.3.3 Materialbezogene Bedingungen

Da Textilfassaden sich zum Teil auch vor Fenstern befinden, ist die Untersuchung der Lichtdurchlässigkeit relevant. Eine Lichtdurchlässigkeitsprüfung kann mithilfe eines Lichttisches durchgeführt werden, welcher aus einer lichtdurchlässigen Grundplatte besteht, unter der eine gleichmäßige Lichtquelle installiert ist. Diese Anordnung sorgt dafür, dass das Licht von unten auf das zu prüfende Textil strahlt. Bei jeder Messung wird ein Foto des Textils aufgenommen, bei gleichbleibender technischer Konfiguration in einem definierten und gleichbleibenden Abstand um eine Vergleichbarkeit zu gewährleisten. Nach erfolgter Aufnahme wird das Bild mit Hilfe von Software in ein reines Schwarz-Weiß-Bild konvertiert. Diese Umwandlung ermöglicht eine differenzierte Analyse der Helligkeitswerte, die durch die unterschiedlichen Textilien und deren Dichte beeinflusst werden. Anhand dessen kann die Geschlossenheit des Textils quantifiziert werden. Die Geschlossenheit ist ein entscheidender Faktor für die Bestimmung der Lichtdurchlässigkeit. Ein höherer Grad an Geschlossenheit führt typischerweise zu einer geringeren Lichtdurchlässigkeit und vice versa. Mit diesem Verfahren können sowohl 2D als auch 3D-Textilien untersucht werden. Die in Abb. 4 so erzielten Ergebnisse, beispielhaft für zwei Textilvarianten, zeigen eindeutige Unterschiede in der Lichtdurchlässigkeit (30 % vs. 51 %).

Weitere materialbezogenen relevante Faktoren sind unter anderem die Elastizität und Dauerhaftigkeit. Diese Parameter sind unter anderem von den verwendeten Fasermaterialien sowie von deren Nachbehandlung abhängig. Bei der Wahl und Herstellung von Material für Textilfassaden sollte die Dauerhaftigkeit, unter Berücksichtigung der am Einsatzort zu erwarteten üblichen Witterungsbedinungen, betrachtet werden. Die Drapierfähigkeit und Flexibilität von Textilen hat einen positiven Einfluss auf die Formgebung der Fassade. Nicht nur durch das Fasermaterial und der Textilart sondern auch durch die Einspannung kann die Optik der Fassade beeinflusst werden.

5 SCHLUSSFOLGERUNGEN

5.1 Erkenntnisse

Die Ergebnisse des vorgestellten Projektes verdeutlicht, dass durch innovative Maßnahmen, wie dem Einsatz von schallabsorbierender Textilfassaden, Umgebungslärm in urbanen Räumen reduziert werden kann. Die Höhe der Reduktion hängt dabei maßgeblich vom eingesetzten Materialumfang sowie der Materialdicke der eingesetzten Textilien ab. Durch größere Flächen und eine höhere Materialstärke kann im Regelfall eine höhere Schallabsorption erzielt werden. Vollflächig bespannte Fassaden besitzen damit den größten akustischen Effekt, mit dem Nachteil, dass die Textilien gerade in Festerbereichen zu Einschränkungen der Sichtbezüge zwischen Innen- und Außenraum sowie des Tageslichteinfalls führen können. Die Auseinandersetzung mit dieser Problematik hat zur Ausbildung verschiedenster Fassadenvarianten geführt, die neben einer Vollbespannung, kleinteiligere Formate in Form von verschiedenartigen Panelen oder Segeln

vorsehen. Gerade durch die Ausbildung vertikal aufgestellter Panele kann die Innenraumqualität bei Fensterflächen gewahrt werden. Allerdings werden diese panelartigen Fassadentypologien als deutlich dominanter im Stadtraum wahrgenommen und als weniger gut, in den urbanen Raum, integriert.

5.2 Weiterer Forschungsbedarf

Als weiteren Forschungsbedarf lässt sich die vermehrte Implementierung von schallabsorbierenden Fassaden im urbanen Raum anführen. Es gilt im Weiteren zu erforschen, wie eine Steigerung der Einsetzbarkeit und Verwendung von schallabsorbierenden Textilfassaden im Neubau, aber auch in der Bestandsentwicklung in der Stadt generiert werden kann und welche rechtlichen aber auch funktionalen Rahmenbedingungen es dafür benötigt. Dazu gilt es, die schallabsorbierende Wirkung verbunden mit einer kleinteiligeren, panelartigen Aufteilung auf ihre akustische Wirkung hin genauer zu untersuchen sowie weitere Untersuchungen auf der Konstruktions- sowie Materialebene anzustellen, die beispielsweise eine höhere Durchsichtigkeit generieren, um die Verwendbarkeit der Fassaden zu erhöhen.

5.3 Notwendigkeit interdisziplinärer Perspektiven

Abschließend zeigt sich deutlich, dass zur Adressierung und Verbesserung der akustischen Qualität im urbanen Raum ein interdisziplinärer Ansatz zur ganzheitlichen Emissionssenkung notwendig wird. Das vorgestellte Projekt „STumM“, als interdisziplinäre Schnittstelle zwischen Städtebau, Elektrotechnik und Maschinenbau, untersucht innovative Ansätze zum Umgang mit komplexen Herausforderungen um urbane Lärmemissionen und damit gesundheitsgefährdende Stressfaktoren ganzheitlich zu senken und wohltuendere Lebensumgebungen in Städten zu schaffen. Damit zeigt sich, dass die Auseinandersetzung mit Akustik im Städtebau ein hohes Potential für eine gesundheitsorientierte, nachhaltige Stadtentwicklung birgt, im Sinne des SDG 11 den urbanen Raum zu entwickeln.

6 ACKNOWLEDGEMENT

Die in dieser Arbeit präsentierten Forschungsinhalte wurden zum Teil gefördert vom Bundesministerium für Bildung und Forschung (BMBF) und dem Ministerium für Kultur und Wissenschaft des Landes Nordrhein-Westfalen (MKW) im Rahmen der Exzellenzstrategie von Bund und Ländern, als Teil des ERS-Projektes STumM: Schallabsorbierende Textilfassaden im urbanen Raum – Machbarkeitsstudie (ZUK2-SF-SFBLE014).

Al-Bireh Resilient City

Amneh Abu Sharar

(Amneh Abu Sharar, Head of city Beautician Al-Bireh City, Palestine; arch.amneh@gmail.com)

DOI: 10.48494/REALCORP2025.0079

1 ABSTRACT

Al-Bireh city, located in the central West Bank, faces growing challenges due to climate change, Israeli occupation, and settlers. The municipality has implemented five key strategies to enhance resilience and sustainability: Adaptive urban planning, Climate change mitigation policies, Building community resilience, Enhancing food security, and Sustainable mobility. These strategies are aligned with the Sustainable Development Goals (SDGs), aiming to create a resilient, adaptive, and sustainable urban environment. The implementation of these strategies positions Al-Bireh as a model for cities facing similar challenges worldwide.

Keywords: sustainability, community, resilience, Al-Bireh, climate change

2 INTRODUCTION

Al-Bireh, a key urban center in the West Bank, faces significant challenges related to urban planning, green space reduction, environmental degradation, and political constraints stemming from the Israeli occupation. The city's rapid expansion, compounded by territorial restrictions and urban sprawl, has created a complex situation for sustainable development. Furthermore, Al-Bireh is experiencing a decline in green spaces, compounded by pressure from residential and commercial development. Environmental challenges, including climate change, air and water pollution, and limited natural resources, exacerbate these issues. This paper explores the municipality's strategies to enhance urban resilience and sustainability in the face of these challenges, while aligning with the United Nations Sustainable Development Goals (SDGs).

3 METHODS

3.1 Research Design

This study follows a qualitative research methodology to assess the resilience strategies of Al-Bireh. The research combines primary data (interviews with municipal officials, field observations) and secondary data (academic literature, municipal reports, international reports) that are aligned with global sustainability standards and the Sustainable Development Goals (SDGs). This approach helps evaluate Al-Bireh's efforts in sustainable urban planning, climate resilience, and community-building in the context of international best practices and frameworks for sustainable development.2.2 Data Collection

Primary data was collected through interviews with key municipal departments, such as the Planning and Engineering Department, the Cultural Department, and the Media and Public Relations Department, as well as field observations of the urban landscape. Secondary data sources included plans, policies, reports, and documents provided by the Al-Bireh Municipality, academic publications on urban sustainability, and international reports on climate resilience and SDG localization.

3.2 Data Analysis

The data was analyzed thematically, with a focus on identifying the collected data was analyzed using a thematic approach, focusing on identifying key themes and patterns related to the alignment of Al-Bireh's urban strategies with the Sustainable Development Goals (SDGs). The analysis aimed to assess the effectiveness of municipal strategies in fostering urban sustainability and resilience, with particular emphasis on the integration of climate action, social inclusion, and environmental stewardship.The five primary strategies evaluated in this analysis include:

Al-Bireh Urban Planning:

Current Situation and Issues:

(1) The Master Plan and Limited Green Spaces: The approved master and organizational plan for the city of Al-Bireh, which was ratified in 2003 covering an area of 10,854 dunams, suffers from shortcomings in

maintaining an environmental balance between residential areas and green spaces. This plan did not allocate enough space for green areas, leading to a significant shortage, as green spaces make up less than 1% of the city's organizational area. This deficiency negatively impacts the quality of life in the city, contributing to environmental challenges such as air pollution and rising temperatures, as well as reducing spaces dedicated to recreation and leisure.

(2) Population Growth and Migration: Al-Bireh suffers from a significant population increase due to its centrality in the West Bank, with a large influx of people migrating from the north and south of the West Bank. This population growth places additional pressure on the city's infrastructure and public services, increasing the need to allocate more space for urban expansion and sustainable growth, the currently city population around 120,000 capita.

(3) Land Restrictions under Israeli Control: The city of Al-Bireh covers an area of approximately 22,198 dunams, but 51% of this area is classified as "Area C" according to the Oslo Accords, meaning it is under Israeli civil and military control. As a result, citizens and the municipality are not allowed to invest in or utilize these lands, which restricts urban growth and development in the city.

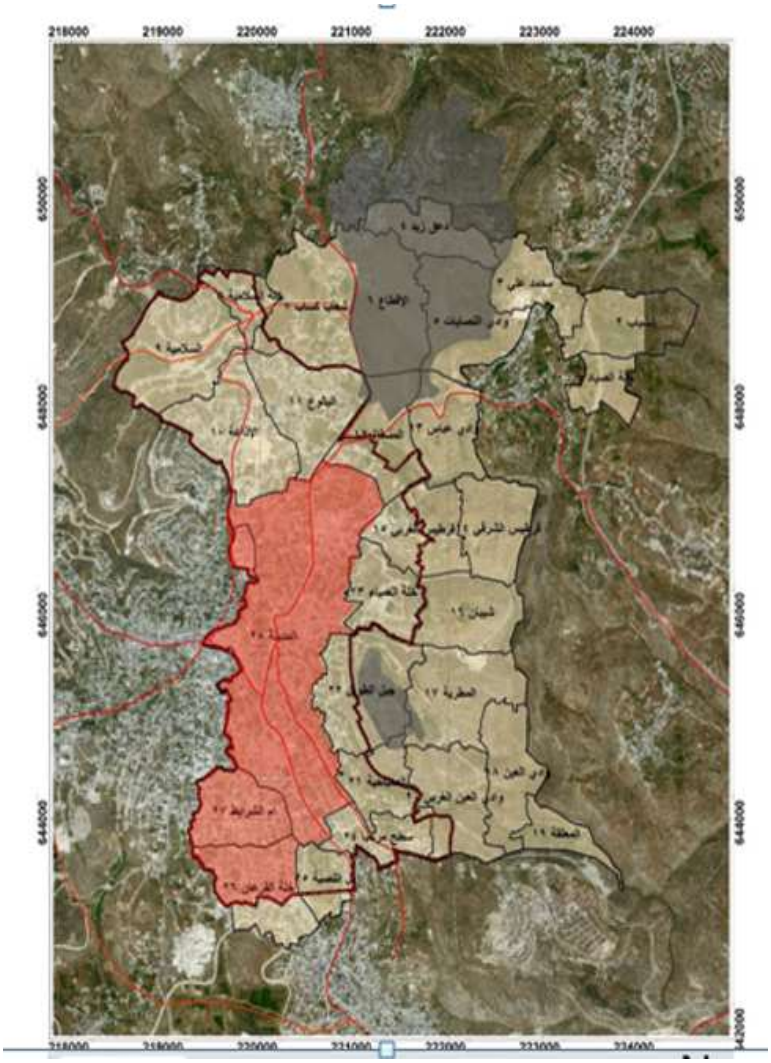

Figure 1.

(4) Israeli Settlements: Two Israeli settlements are located to the north and east of the city: the Beit El settlement (covering 1,800 dunams) and the Psagot settlement (covering 308 dunams). This distribution leads to the division of the city and limits equitable access to services across all areas of the city.

3.3 Impacts of Climate Change in Al-Bireh:

Current Situation and Issues:

Al-Bireh, like many cities around the world, is experiencing the increasing impacts of climate change. These impacts are clearly manifested through rising temperatures and decreasing rainfall, which exacerbate the

city's environmental challenges. One of the most prominent impacts is the urban heat island effect, where the city records a significant rise in temperatures due to the lack of green spaces and the increase in urban density. This leads to higher temperatures as buildings and infrastructures reflect heat.

Additionally, the lack of green spaces is a major factor contributing to the increased local temperatures. The scarcity of parks and recreational areas prevents the city from benefiting from the natural cooling effects provided by green spaces. Therefore, preserving and expanding green spaces is a crucial strategy to mitigate the effects of urban heat islands and improve the overall quality of life in the city.

Challenges Related to Water and Electricity:

In addition to the climate impacts, the residents of Al-Bireh face significant challenges concerning basic natural resources, such as water and electricity, due to the restrictions imposed by the Israeli occupation.

(2) Control over Water Resources: Water sources in the West Bank, including Al-Bireh, are under strict Israeli control. Israeli authorities prevent Palestinians from drilling new deep wells or deepening existing wells and impose restrictions on the amount of water that can be extracted, limiting the city's ability to meet the needs of its population. In contrast, Israeli settlements are permitted to use groundwater for agricultural irrigation, leading to the depletion of local water resources. For example, the drilling of deep wells in the Al-Auja settlements near Jericho has resulted in the drying up of local springs and increased water salinity, negatively affecting local agriculture.

(2) Challenges in the Electricity Sector: Al-Bireh also faces challenges in the electricity sector, as the city's electricity distribution companies do not have the license to generate or produce electricity. The city's electricity supply is limited to what is provided by the Israeli electricity company "Mekorot," which can reduce the amount of electricity allocated to Palestinians, leading to frequent power outages. Additionally, there are limited efforts to import electricity from some Arab countries, but these attempts face many obstacles due to Israeli policies and available infrastructure.

3.4 Al-Bireh City and Community

Current Situation and Issues:

Al-Bireh city is one of the central cities in the West Bank, playing a vital role in the political, economic, and social life of the region. It has around 25,000 families, with a population of approximately 120,000 people. The city also hosts numerous governmental and private institutions that contribute to promoting sustainable development, providing essential services, and supporting the local community in various fields. In this context, the institutions in Al-Bireh can be divided into the following categories: Charitable and Developmental Associations: There are around 30 associations working in various fields such as community development, health, environment, and education. These associations significantly contribute to improving the quality of life and supporting vulnerable groups in the community.

Government Ministries and Institutions: Al-Bireh hosts several government ministry offices, including the Ministry of Education, Ministry of Health, Ministry of Interior, and others. The city has about 10-15 government offices, reflecting its important role in providing services to the citizens.

Non-Governmental Organizations (NGOs): There are numerous NGOs in the city that work in the fields of human rights, sustainable development, and environmental support. The number of these organizations ranges from 30-40, reflecting active community engagement and cooperation with local and international institutions.

Consulates and Diplomatic Offices: Although Al-Bireh does not directly host consulates, it is located near Ramallah, where there are approximately 15-20 consular offices representing different countries. These offices enhance diplomatic and administrative communication with the Palestinian community.

3.5 Limited Agricultural Land and Resource Access in Al-Bireh

Current Situation and Challenges:

(1) Unused Lands in Area C:

A large portion of Al-Bireh's lands, especially in Area C (which is under full Israeli control according to the Oslo Accords) which is around 51% from Al-Bireh Area, remains unused or restricted. Area C is a vital region for both urban and agricultural expansion, but it is subject to restrictions imposed by Israeli

authorities. These restrictions prevent Palestinians from fully utilizing the land for agricultural or construction purposes, limiting the ability to expand food production or enhance food security through sustainable farming.

The lack of access to these lands makes it difficult for the municipality to implement large agricultural projects that could contribute to local food production and enhance food security.

(2) Land Classification and Uses:

As a central city, Al-Bireh experiences high demand for land for urban and commercial expansion. As a result, most of the land in the city is classified for commercial or residential use rather than agricultural purposes. This classification limits the use of available land for agriculture and makes it more challenging to increase local food production.

Additionally, land prices in the city are extremely high due to the demand for urban and commercial expansion, making it difficult for local agricultural initiatives to invest in these lands for sustainable agriculture or food security purposes.

(3) Limited Agricultural Land in the City:

The amount of land available for farming within Al-Bireh is limited due to urbanization in the area and the restrictions on land use. Therefore, agricultural activities within the city are restricted, and much of the food supply relies on external sources, which increases the challenges associated with price fluctuations and supply disruptions.

Furthermore, the city lacks sufficient space for food cultivation within urban areas, which has led to a reduction in land designated for agriculture due to the increasing demand for residential and infrastructural land.

(4) Water and Resource Scarcity:

Access to water, which is a crucial resource for agriculture, is a significant challenge in Al-Bireh due to the restrictions imposed by Israeli authorities on access to water. The city, like many other Palestinian areas, struggles to secure its water needs for both urban and agricultural use.

In addition to water scarcity, the availability of resources such as fertilizers and other agricultural inputs is often limited, hindering the ability to expand agricultural projects and sustain them.

3.6 Challenges in Sustainable Mobility and Connectivity in Al-Bireh

Current Situation and Challenges:

Al-Bireh city faces several challenges related to sustainable mobility and connectivity, highlighting the urgent need to improve the city's transportation infrastructure. Despite ongoing efforts to improve transportation means, several factors hinder the development of this sector in the city.

(1) Traffic Congestion and High Emissions

Al-Bireh suffers from severe traffic congestion, especially during peak hours, as the city is a residential and commercial hub in the West Bank. This congestion leads to increased carbon emissions from vehicles, significantly contributing to air pollution and rising temperatures in the city.

Additionally, the absence of sustainable transportation options, such as bike lanes or an effective public transportation system, exacerbates this issue, making most residents rely on private cars for daily commuting.

(2) Road and Sidewalk Infrastructure

Road Conditions: The road network in Al-Bireh is outdated and does not meet the needs of the growing population or increasing traffic. Many roads are narrow or poorly maintained and lack traffic signals or effective traffic monitoring systems, leading to accidents and decreased efficiency in road usage.

Sidewalks: Although there are some sidewalks in parts of the city, they are often incomplete or in poor condition, posing risks to pedestrians and discouraging walking. Some sidewalks are obstructed by parked cars, hindering pedestrian movement, which makes walking an uncomfortable option for residents.

(3) Lack of Effective Public Transportation

Although Al-Bireh has a network of small buses (microbuses), this network is still inefficient and disorganized. Public transportation covers some areas but lacks integration in transportation networks or proper connectivity with other parts of the city or surrounding areas. Furthermore, the bus routes are often irregular, leading to long wait times and overcrowding on public transport.

The city lacks a unified, effective public transportation system that connects urban areas with each other or coordinates with neighboring municipalities such as Ramallah and Betunia, creating significant gaps in inter-city mobility.

Limited Bicycle and Walking Infrastructure

Despite the global shift towards promoting cycling and walking as sustainable modes of transportation, Al-Bireh lacks the necessary infrastructure for these activities. There are no dedicated bike lanes, and the streets in the city are not pedestrian-friendly, making it difficult for residents to adopt these modes of transport. Furthermore, these factors hinder the move towards reducing reliance on private cars.

4 RESULTS AND MUNICIPALITY STRATEGIES

In response to the multifaceted challenges facing Al-Bireh which mentioned above, the municipality has developed a set of innovative and strategic initiatives aimed at fostering sustainable development. These efforts are designed not only to address the city's immediate challenges but also to lay the groundwork for a resilient, inclusive, and environmentally conscious future. By integrating adaptive urban planning, climate change mitigation measures, community empowerment, food security initiatives, and sustainable mobility, These strategies are aligned with global frameworks such as the Sustainable Development Goals (SDGs), ensuring that the city's progress is both locally relevant and globally impactful. The following sections present the key results and strategic actions the municipality is undertaking to navigate its challenges.

4.1 Adaptive and Sustainable Urban Planning (SDG 11: Sustainable Cities and Communities)

- Urban Growth, Environmental Sustainability, and Green Spaces Integration: The updated master plan of Al-Bireh focuses on balancing urban growth with environmental sustainability. Despite the challenges posed by political and territorial constraints, the municipality has ensured the inclusion of green spaces, environmental preservation, and resilience-building strategies in its planning. A key feature of this plan is the strategic incorporation of green spaces and open areas, which are designed to enhance the city's environmental quality, provide recreational spaces for the community, and mitigate the urban heat island effect. This integration not only promotes a healthier urban environment but also contributes to the city's overall resilience, making it more adaptable to climate challenges. The goal is to create an urban environment that respects nature while accommodating population growth and development needs.
- Service Area Redistribution: The updated plan also focuses on the equitable distribution of services across the city. By redistributing service areas, the municipality aims to promote social equity and ensure that all neighborhoods, especially underdeveloped ones, receive adequate access to essential services such as water, sanitation, and transportation.
- Incorporation of Area C Lands: The master plan also includes lands in Area C, which are subject to Israeli control. Despite the legal and territorial restrictions, the municipality has developed urban and environmental master plans for these lands to ensure comprehensive and sustainable development. The goal is to use these lands effectively for residential, commercial, and green space projects, despite the challenges posed by the occupation.

4.2 Policies for Climate Change Mitigation (SDG 13: Climate Action)

- Tree Protection Policy: Al-Bireh has implemented strict regulations to protect trees by prohibiting their removal, imposing significant fines, and requiring environmental compensation based on international standards (DBH – Diameter at Breast Height). These regulations are essential in preserving the city's green canopy and mitigating the effects of climate change.
- Rainwater Harvesting: New residential and commercial buildings are mandated to install rainwater harvesting systems. This policy aims to reduce the pressure on local water resources by collecting and utilizing rainwater, promoting water sustainability within the city.

- Renewable Energy Initiatives: The municipality has begun installing solar panels in most government schools and is exploring incentives for private homeowners and investors to adopt clean energy solutions. This initiative is being carried out in collaboration with relevant authorities. Additionally, the municipality plans to build a new school that will be a green building according to the EDGE classification, making it the first green school in Palestine. The design tender for this project will be issued soon.
- Green Spaces: Building regulations and municipality policies ensure that at least 10% of the front setback area in new developments must remain green and permeable. This initiative is designed to improve water infiltration, reduce the urban heat island effect, and promote environmental sustainability in urban areas.

This set of policies highlights Al-Bireh's commitment to adapting to climate change, enhancing resilience, and contributing to global climate action goals.

Figure 2.

4.3 Building Community Resilience

(SDG 16: Peace, Justice, and Strong Institutions)

To enhance the community's ability to adapt to challenges, the Al-Bireh Municipality has implemented several initiatives aimed at fostering resilience. These efforts focus on increasing awareness, building capacity, promoting social cohesion, and empowering vulnerable groups. The key actions taken to develop a more resilient and inclusive community include:

- Awareness Campaigns: Conducting public awareness campaigns to educate schools and the community about climate change adaptation and disaster response.
- Capacity Building: Organizing training programs for staff and community members on sustainable infrastructure, emergency management, and climate change adaptation.
- Social Cohesion: The Al-Bireh Municipality serves as the primary umbrella for charitable associations and civil society organizations in the city, working to strengthen community bonds by providing necessary logistical support and services to ensure the resilience and sustainability of these institutions. The municipality also coordinates efforts and unifies programs aimed at enhancing social cohesion and contributing to sustainable community development.
- Support for Farmers and Artisans: Allocating municipal squares and central halls weekly for farmers and artisans to display and sell their products, thereby enhancing their economic resilience and supporting local craftsmanship.
- Empowering Women: Operating a specialized center dedicated to supporting and empowering women, which currently includes approximately 200 women. The center organizes workshops and training sessions aimed at economically and socially empowering women, highlighting their pivotal role in society.
- Collaborative Approach: Establishing partnerships with local organizations and neighboring municipalities to ensure coordinated disaster response and the sharing of best practices, thereby strengthening community resilience.

Through these initiatives, the Al-Bireh Municipality aims to build a strong, cohesive community capable of effectively facing social, economic, and environmental challenges with resilience and sustainability.

4.4 Enhancing Food Security and Utilizing Unused Lands

(SDG 2: Zero Hunger, SDG 12: Responsible Consumption and Production)

Al-Bireh Municipality is committed to enhancing food security by effectively utilizing unused lands, particularly in Area C, through the establishment of community orchards. These initiatives aim to provide locally grown food and promote sustainable agricultural practices.

Community Orchards: The municipality collaborates with landowners in Area C and local institutions to develop community orchards. These efforts offer residents access to fresh, locally produced goods and strengthen community bonds.

Figure 3.

Challenges in Area C: Area C constitutes approximately 61% of the West Bank's territory and remains under full Israeli control, both administratively and militarily. Palestinians face significant obstacles in obtaining permits for construction or land development in this area, with the Israeli authorities often rejecting such applications on grounds of lacking approved master plans.

By implementing these initiatives, Al-Bireh Municipality strives to enhance food security and support sustainable agricultural practices, contributing to the well-being of the local community and reinforcing their resilience in the face of ongoing challenges.

4.5 Sustainable Mobility and Connectivity (SDG 9: Industry, Innovation, and Infrastructure)

Al-Bireh Municipality, in collaboration with the municipalities of Ramallah, Beitunia, Surda, and Abu Qash, aims to develop a sustainable transportation system that enhances mobility between these cities and reduces harmful emissions. To achieve this, a joint master plan has been prepared, encompassing short-term, medium-term, and long-term strategies developed by specialized consulting teams.

- Short-Term Transportation Plans: These include immediate solutions to improve traffic flow and reduce congestion, such as optimizing traffic signal timings and designating dedicated lanes for public transportation.
- Medium-Term Transportation Plans: These focus on developing transportation infrastructure, including expanding road networks and establishing modern public transit stations to enhance connectivity among the cities.
- Long-Term Transportation Plans: The goal here is to create a sustainable transportation system that incorporates public and smart transportation options, as well as developing pedestrian and bicycle networks to promote clean and healthy mobility.

5 DISCUSSION

Al-Bireh's resilience strategies effectively address urban growth and environmental sustainability, demonstrating alignment with several SDGs. The city's adaptive urban planning integrates green spaces, climate adaptation measures, and sustainable urban growth, which is vital given the political challenges the city faces. The municipality's climate change mitigation policies, including tree protection, renewable energy, and water conservation measures, showcase a proactive approach to reducing environmental impact.

Community resilience-building efforts, such as awareness campaigns and disaster response training, empower residents to address climate-related challenges. Local food security initiatives, such as community orchards, foster sustainable agriculture and reduce reliance on external food supplies. The city's sustainable mobility initiatives, focusing on reducing emissions and improving regional transportation connectivity, support long-term urban sustainability.

However, the political constraints imposed by the Israeli occupation, including the division of land into different zones and the expansion of Israeli settlements, present significant challenges to fully implementing these strategies. These factors limit the municipality's ability to expand green spaces, develop new infrastructure, and utilize land in Area C, highlighting the need for adaptive and flexible planning in the face of such external pressures.

6 CONCLUSION

Al-Bireh's strategies provide valuable lessons for other cities facing similar political and environmental challenges. By integrating sustainable urban planning, climate change mitigation, community resilience-building, food security initiatives, and sustainable mobility, Al-Bireh has demonstrated how cities can adapt to complex challenges while promoting long-term sustainability. Despite the constraints imposed by Israeli occupation, the city's efforts align with the SDGs, positioning Al-Bireh as a model for other cities in conflict zones seeking to enhance resilience and sustainability.

1 ABSTRACT

The focal point of this analysis would be an attempt to evaluate the role of beauty in architecture, for example, how and to what extent it could be related to a feeling of happiness during the urban regeneration process.

One of the hypotheses concerns the importance of beauty in architecture through its significance and influence in a spiritual way. Beauty, it seems, encompasses, as an indivisible part, the notions of happiness, fulfilment, and pleasure in the widest possible sense.

Some important historical sources approach the otherwise insufficiently researched question of beauty in a spiritual way.

It started with Thomas Aquinas, back in the 13th Century. His preliminary ideas of spiritual beauty are recomposed and transposed for our modern times by the unsurpassed author Umberto Eco. They both presented an emotional and intellectual journey towards a better understanding of a model of beauty. We could say, those references should represent a role model for all of us, thoughtful architects, advanced-thinking urbanists, and city planners. Those who need primarily to think and observe to analyze, synthesize, and find a final model through harmonizing different inputs.

We are mostly exhilarated and touched by the so-called model of moral beauty (or the opposite: shaken by moral ugliness). The public could be petrified of assertive designers and architects all the way to corrupted regime(s). They could spoil one's view, happiness, etc. through their bad models: facades without proportion or even complexes without any sense, spoil the environment, but also spoil entire streets, area and therefore destroy an image, a setting of the whole city.

Moral ugliness is somehow connected not only to general poverty but also to corrupted society. Meddling with planning rules and regulations could put decent architects out of the system and unscrupulous ones push forward.

One can speculate that Investors in societies without rules (or rules and regulations are there but not being followed) have enormous greediness for profit and will do anything to achieve their goals.

Therefore, to battle moral ugliness, or to reach happiness under the frame of beauty, or moral beauty, we have to follow important steps.

Keywords: urban regeneration, moral beauty, moral ugliness, corrupt society, responsibility

2 INTRODUCTION

Urban land is one of the most important sources for countries and it is planned and controlled by the government according to the laws (Cochrane, 2006: Harvey, 2012). Furthermore, the built environment presents the "frozen history of cultural transformation" and should be treated as a valuable resource. Global environmental and political change pose huge challenges for spatial planning and urban planners deal with a lot of obstacles and face numerous problems on different levels (Hartmann, Needham,2012).

During a process of urban regeneration in not sufficiently developed democracies like Serbia, mega new developments and/or reconstructions, with not enough respect for the already built environment, cultural and architectural heritage, (let's call it the "Urban chaos"), is caused by lack of law and order, and therefore, the lack of repercussions. Mostly not civilized or better to put it: the rude behaviour of some actors of the construction industry showed their bad impact. Sometimes buildings are even collapsing without needed or sufficient building permits, for example: on the 1st of November last year a failed eaves of the rail station in Novi Sad killed 15 citizens. Terrible event. Construction and design procedures were not followed. Also, it

could be speculated that political affiliation produced a bad selection of morally suspicious and less talented individuals, selected by political groups and/or different interest groups.

2.1 Only profit-oriented urban regeneration

Wrapped in that shiny phrase "economic and urban redevelopment", only pure profit presents the most important benefit for the parties involved (Vujošević, Zeković, 2012). Since construction is one of the most lucrative branches of industry, gaining maximum profit by, for example, multiplying the same residential buildings, seems to be the constructor's only goal.

With a lack of transparency, difficult-to-track projects, etc. we suddenly wake up with a project being built up with a lack of public spaces, not enough greenery or sports and cultural facilities. In short, a massive loss to the public (Zekovic, Vujošević, 2006). There is an absence of a so-called "pyramid of responsibility".

Basic workers are not overwatched by middle managers, neither the supervisors nor the highest supervisors. Without diaries or written reports, anything could go wrong. One could speculate that the biggest weight on the scale belongs to the concentration of corruption in public offices, especially institutions dealing with urbanization. The greater amount of money is circulating, those issues will be more difficult to resolve.

So, hypothetically, if we were dealing with money laundering of so-called "grey money" or even from criminal resources (drugs, trafficking, or else), there would be hardly possible effective investigation that could lead to real success. Often, one can suspect, we could spot that some politicians and controversial businessmen proceed forward together with no regard for anyone or anything to gain more money and benefits.

We can note that corruption moved decades ago from an economically neglected Africa, all the way to Europe. This could be one of the important reasons why there is so much inequality and disharmony in the present age.

Corruption goes global. It may not be openly visible as it is in the Balkans, but the statistical facts show: That northern countries like Denmark, Finland, and Norway, rank among the least corrupt globally. Established democracy included honesty and obeying principles of order and law. Those principles have a long tradition in those countries (https://www.transparency.org/en/cpi/2024)

Eastern Europe, on the contrary, for example, Ukraine and Moldova, or the Balkans tend to score much lower, indicating higher levels of perceived corruption. It is due to several reasons, but mostly because of the fast transformation of the political system from communism to capitalism & mercantilism, but also, consequently to a huge gap between ordinary working-class citizens, small and medium enterprises owned by families, and "new money" controversial businessmen.

In the context of corruption, Serbia has faced a significant rise in recent years. Democratic changes took place in Serbia in the 2000s. But the path onwards was very rough: political battles were influenced by the direct intervention of criminal gangs and post-war paramilitary groups. As a result, the first democratically elected Prime Minister was killed by criminal gangs of, some would say, political opponents in 2003. The autocratic regime, which has been in power now for more than 12 years, split people between Urban, urban rural, and rural inhabitants through aggressive populist media. During the expulsion and migrations of the 90's of Serbs from Croatia and Bosnia to Serbia, the inhabitants' structure changed, and a feeling of stronger nationalism took place. The most brutal civil war in Europe from the Second World War took place in ex-Yugoslavia and made an ugly impact that is still in the air.

European "Transparency International", a non-governmental organization, was founded in 1993 with the purpose of monitoring, advocating and if possible, battling general corruption.

According to them, in the Perceptions Index (CPI) 2024, Serbia scored 38 out of 100, where 0 indicates high levels of perceived corruption and 100 indicates very low levels of corruption and it is placed 105 among 180 countries (https://www.transparency.org/en/cpi/2024). So, Serbia seems to be in the low to medium range of the index, reflecting ongoing concerns about corruption in public & urbanistic institutions, judiciary, health institutions, etc.

Key issues in Serbia related to corruption include:

(1) Public Sector Corruption: There are persistent reports of corruption within government agencies, state-owned enterprises, and law enforcement.

(2) Judicial Corruption: The judicial system is often criticized for inefficiency and lack of independence, which can contribute to corruption.

(3) Political Influence: Concerns about the influence of politics in business and public procurement processes are prevalent. Building and architecture design are strongly influenced by political affinity. Only selected architects and design studios close to the regime could obtain bigger lucrative jobs.

According to Transparency International's Corruption Perceptions Index (CPI) for 2024, many Western European countries tend to score higher (Denmark, Finland), indicating lower levels of perceived corruption. On the other hand, some Eastern European nations struggle more with corruption issues (OECD, 2024).

Initiatives include expert assessments and opinion surveys. This helps in the creation of awareness and advocacy for accountability. Transparency International (TI) encourages the signing and ratification of international and regional anticorruption conventions such as UNCAC (United Nations Convention against Corruption) and the OECD Anti-Bribery Convention. TI advises on how to assess and strengthen national integrity systems, including governance, accountability, and participation in the process of reducing opportunities for corruption. The agency calls for integrity pacts that forbid corrupt practices in public contracts. TI, as well, pushes for the establishment of solid whistleblower protection to encourage people to come forward without fear of retaliation. TI imparts training and resources to top governments, businesses, and civil society organizations around the world so that they develop their knowledge and build effective policies against corruption. But unfortunately, TI stays under the theoretical frame. There is also a document for combatting high-level corruption in Eastern Europe. (OECD, 2024).

3 FROM DISORDER TO MORAL UGLINESS

Back in 13th century Italy, Thomas Aquinas[1] recognized all those signals that could quite possibly be in different doses rooted in our human nature. He observed in his environment of the Middle Ages all sorts of disrespect, greed, unruliness, individual caprices, and tyranny. But, Thomas Aquinas, under all these obstacles noted, proceeds to try to observe the plain inputs as „beauty of proportion and wholeness"- the prime condition for harmony. "Splendor" was trying to reach through colours and proportion. Despite all those difficult circumstances, he tried to abandon ugliness (both moral and physical) by choosing the path of beauty, in particular, moral beauty.

For those of us, architects, with a focus on cities, his pure idea of the "arrangement of things that leads to an exact goal", could be one of the key elements to reaching true compatibility and balance. According to the initial idea, everything added by force and with no particular need and purpose is considered as excess. ("Less is more", which Loos proclaimed five centuries later).

To identify spiritual beauty, or we can say beauty in the soul of an entity, Thomas Aquinas considered the general lack of order and balance as the first element towards chaos. He was a seeker of purity.

Under the wider picture, today, life under chaos and crumbling institutions, put us from civilization down, by breaking the ancient laws from the times of the Bible. We are witnessing more and more people taking a quicker path toward success while stomping over others and that being acknowledged as a goal worthy of respect in the 21st Century. Lots of negative attributes have been raised: disorder, lack of justice, disharmony, etc.

That is why nowadays, when, and if rules are not obeyed, we do have very important doubts about the style of progress of urban regeneration, in particular concerning cultural heritage.

4 LEVELS OF MORAL BEAUTY (OR UGLINESS) AND HOW WE COULD DEFINE THEM THROUGH GRADES UNDER THE SCOPE OF URBAN REGENERATION:

To show practical case studies, we selected three case studies with different capital investment sizes in Belgrade, Serbia, upon which we will try to implement the first level of the most basic analysis of quality.

[1] Thomas Aquinas, 13th century philosopher and a Dominican monk (Castle near Aquino, 1225 – Fossanova 1274.), the greatest systematician of his age who adapted Aristotle's thinking for the needs of the Catholic church dogma. His life coincides with the awakening of the philosophic consciousness in Paris, Padua, and Bologna, where he lived. Quodvisum placet – the beauty is what we like – leads us with no doubt towards more subjective elements in questions of aesthetics.

Not to involve real names we will call them A, B, and C cases. There could be a hypothesis or a subjective view which is not easy to prove, that the mutual characteristic of all of them is that smaller or bigger corruption in the process has affected all three types of new projects.

So, when Umberto Eco says moral ugliness, transposed words of Tomas Aquinas from the 13th Century, we can conclude that greediness remains a human weakness from our biological beginnings. That is why both historical personalities introduce the word "moral" ugliness.

(1) MEGA project/state mega project with foreign partners

(2) MIDDLE project "Golden cage" system,big block project by foreign and local investors

(3) LOCAL project, suburb streets with small villas and gardens became a concentration of 7 floors infill buildings: as small and medium projects, by local investors

4.1 Mega State project with a foreign investor

Parameters to define grades of quality,unfortunately, depend among other factors, on personal subjectivity. This raises awareness and inserts a sort of relativism in these tables, but, for a primary categorisation it could be a decent start for the analysis:

1	Value of location in between focal points of the city and transport facilities	9
2	Maximum sustainability, sources: inputs of sun, wind, freshwater, and clear air	7
3	High architectural value as a whole (subjective) and affordability	3
4	High-quality residential buildings (apartments and buildings)	4
5	Affordability	2
6	Comfort: Enough greenery, public places, sports, and cultural facilities	5
7	Urban safety	10
8	Education, Culture, and entertainment nearby	5
9	Retail & shopping areas nearby	10
10	Local characteristics, integrity with context	1
		56

Table 1: 100 Points are matter maximum = (moral) beauty.

This project could tempt several observations, possibly conclusions: the project is designed as a top state project, but without transparency. Foreign architects without the implementation of local experts or public design. Therefore, the whole project started with a negative prefix. The location is the best possible, near the river Sava. The previous railway station and industrial zone were abandoned for several decades. It would not be possible without big changes in urbanistic plans, and annexes of plans. Today it is known as a most extravagant and expensive area, where only very rich people can buy apartments for EUR 10,000.- per square meter. Therefore, only a selected few can get into purchasing those, while the public can not afford it even in their dreams. So, there is no mix of different layers of population. Ghetto, although the luxury one, is already established.

Schools and sports facilities exist only in the plans. Greenery is beginning to develop; public places are refined and luxurious.

The mega luxurious shopping mall is the soul of the area, so consumerism is an important part/goal of this project. There is no, however, any link with local architecture, past or present, so the identity of the whole city is getting diminished.

It could be stated that this project represents a kind of foreign model from the Middle East, erased without any link with the continuity of local architecture and characteristics.

4.2 "Golden cage" system, big block project by foreign and local investors.

1	Value of location in between focal points of the city and transport facilities	7
2	Maximum sustainability, sources: sun, wind, fresh water, and clear air	6
3	High architectural value as a whole (subjective) and affordability	7

4	High building quality of residential (apartments and buildings)	7
5	Affordability	4
6	Comfort: Enough greenery, public places, sports and cultural facilities	5
7	Urban safety	10
8	Education, Culture, and entertainment nearby	5
9	Retail & shopping areas nearby	6
10	Local characteristic, integrity with context	3
		60

Table 2.

"Golden cage" (Gated compound) is an already known system and comes originally from Latin America. Due to a huge wealth gap between citizens, the rich are hiding "intra mures", in a "closed cage" to protect themselves from the poor. Latin American system gradually moved to new Russia and Eastern European countries, with a lot of "new money "circulating, creating a new, wealthy class. Inhabitants are only allowed to enter their compound, where there usually is a nice kids' playground in the centre, and the most needed under-terrain garage is placed under the whole location.

Some side locations are used as well for construction, but it could be stated that they are too close to the traffic system. Therefore, issues of safety, security, noise pollution, etc. could be raised. (Djukic, Brajkovic, 2025). Using the perceived benefits of a broader location compensates for the absence of schools and kindergartens, culture, or sports facilities.

Architecture is vernacular and contemporary, like in every other city in the world, without any trace of integration with local architecture. Sustainable architecture is not planned, and greenery is also shared with the neighbourhood blocks. It could be argued that the quality of apartments is average, meaning too expensive, not providing value for money.

Of course, all these notions above can be put into debate, and different opinions and arguments could be put on the table, therefore creating more transparency about these projects, so the public can be better informed about them before they start.

For some reason, this is not the case. Why? Well, we can only speculate!

4.3 Suburb Streets, small and medium projects, by local investors

1	Value of location in between focal points of the city and transport facilities	8
2	Maximum sustainability, sources: sun, wind, fresh water, and clear air	6
3	High architectural value as a whole (subjective) &affordability	5
4	High quality of residential (apartments and buildings)	3
5	Value of comfort as a neighbourhood, public places	4
6	Enough greenery and sports facilities	4
7	Urban safety	3
8	Education, Culture, and entertainment nearby	4
9	Retail & shopping areas nearby	8
10	Local characteristics, integrity	4
		49

Table 3.

One of the hypothetical case studies of hundreds of new infills is in the longest street in Belgrade called "Vojvode Stepe" street (7 km) in the area named Vozdovac. From the beginning, the street was a vernacular suburbia street without cultural legacy and value. The system was formed by small, modest individual houses with tiny gardens. Without high-quality buildings, in the 1960s, several, one can say, brutal, high-rise complexes were erected. In the late 1990s, it could be speculated that, allegedly, corruption showed up in local municipalities and both urbanistic institutions enabling small and medium companies to build, without regard to building rules and regulations. Excessively high buildings were allowed to be raised by local planning authorities (at least six, or seven floored rises).Investors themselves, hard to believe, designed some

of the buildings, without professionals being involved, namely, architects. Surprisingly, firstly built dwellings being constructed like that, influenced what followed: balconies were constructed small, with fences full of concrete to stay cheap, and the colours used were not pleasant; green and kaki, etc.

Over time, the high street changed its profile entirely. Density became high, traffic became unsustainable. Amazingly, the population gradually got used to it. One can speculate that thanks to corruption around building works, this street became ugly and chaotic (without proportion, harmony, or beauty in general) reminding some people of the eastern way, for example in some parts of Turkey or North Greece, where poor architecture could be noted in small cities and suburbs of big cities.

5 CONCLUSION

The Transformative processes dealing with land use should be more sensible and responsible. Urban transformations as fundamental, multi-dimensional changes in urban land-use patterns, should be followed by establishing sustainable and democratic values, norms, procedures, and behaviours (Banzhaf et al., 2017).

One perhaps cannot be wrong by noting that not obeying rules leads to anarchy. If we look backward in history; Japanese people are real experts in rigidness and responsibility. Therefore, under that scope corruption seems unnecessary. On the contrary, in countries where corruption is high, people die working in or under unsafe constructions, like in Turkey while an earthquake took place or in Serbia, because of lousy business dealings, low level of general morality, etc. Not very different from Tomas Aquinas's "Moral ugliness" from the Middle Ages.

Each of these case studies hypothetically shares one common trend: corruption, for example, to obtain regular building permits, or fake permits, by paying different interest groups involved, being people working on building sites, or in planning commissions and public institutions, to change or amend planning rules. Ultimately, with so much cash, allegedly, certain lawyers are paid handsome fees to fight on the side of these unscrupulous investors, with the final goal always to obtain even bigger profits.

By analyzing those three (mega, medium, and small size) examples above, perhaps one can conclude that case number 3 (small case investments starting circa from the year 1990), has the biggest bad influence on the general beauty of architecture. Projects built with, in comparison, much bigger investments look generally better, at least we can say civilized, although without any value as first-grade author's architecture. Smaller investments use context and neighbourhood for sports, greenery, or education facilities nearby. That is their advantage. Nevertheless, in those cases, general urban safety is not at a high level. So, every case looks at the end of the day with approximately similar grades. Unfortunately, the level of unclean regulations to achieve more and more, (greediness) could be spotted everywhere.

The catastrophic loss of 15 lives at Novi Sad Railway station on the 1st of November 2024 was a trigger for citizens in Belgrade and Serbia to raise against deeply embedded corruption, to try to change the system, and to make a positive difference. To obtain wider democracy. The narrative about urban regeneration in Serbia without mentioning these, biggest student protests since the year 1968,wouldn't be possible. The whole picture would not make any sense. There is hope for a better future. Future with far less corruption. In arranged country.

Analysing Population Displacement and Financial Precarity Induced by Gentrification based on Social Mix Perspective

Tzu-Ling Chen

(Associate Professor, Tzu-Ling Chen, University of Taipei, No.101, Sec. 2, Zhongcheng Rd., Shilin Dist., Taipei Cit, skylight@mail2000.com)

DOI: 10.48494/REALCORP2025.5052

1 ABSTRACT

This study investigates the spatial dynamics of gentrification and upward filtering in Taipei City, a metropolis characterized by Taiwan's highest population density and acute housing affordability challenges. Examining the interplay between financial precarity and population displacement, this research analyzes distinct patterns of neighborhood change within this dense urban context. Comparative analysis reveals that areas experiencing upward filtering, marked by increased real estate transaction volumes, exhibit a stronger correlation between market activity and rent prices, highlighting the direct impact of real estate dynamics on affordability. Conversely, the observed decline in high-income and highly educated residents in other areas suggests potential displacement pressures. Despite these shifts, the absence of strong spatial autocorrelation between real estate transactions and rent prices indicates the significant influence of localized factors, such as zoning policies, on rent price dynamics. Bivariate spatial autocorrelation analysis further underscores the interconnectedness of demographic changes, particularly the clustering of high-income and highly educated populations in upward-filtering areas. These findings contribute to a nuanced understanding of gentrification and upward filtering within Taipei's unique urban landscape, providing insights for policies aimed at mitigating financial precarity and fostering equitable urban development.

Keywords: Gentrification, Financial Precarity, Population Displacement, Bivariate Spatial Autocorrelation, Planning

2 INTRODUCTION

Gentrification, originally conceptualized in 1964 by British sociologist Ruth Glass, describes the process of social mobility within urban centers. Glass observed that in London, the middle class progressively encroached upon working-class neighborhoods. As rental contracts expired, deteriorated housing units were reclaimed, renovated, or even reconstructed, facilitating the redevelopment of declining urban areas. This transformation, however, led to the displacement of the proletariat, triggering significant socio-economic consequences (Glass, 1964). Gentrification is no longer confined to inner-city areas but has expanded to peripheral urban zones (Williams, 1984) and even economically abandoned spaces that were previously developed but have since been left vacant (Schaffer & Smith, 19 86). Urban shrinkage has been identified as a driver that creates new potential for gentrification (Oswalt, 2006). As a dynamic urban process, gentrification reshapes the socio-economic composition of neighborhoods, leading to class replacement and the emergence of new industries (Hamnett, 2003; Kennedy & Leonard, 2001). In the early 2000s, policy-oriented research began framing gentrification as a positive urban development strategy – one that could foster the revitalization of disadvantaged areas and promote social integration. Through infrastructure improvements, better housing conditions, and job creation, gentrification has been seen as a means to drive the redevelopment of marginalized urban areas and enhance social cohesion (Arthurson, 2010; Lees, 2008).

However, numerous studies have found that gentrification often leads to the displacement of economically vulnerable households and contributes to psychosocial stress and educational resource disparities in gentrified areas (Martin & Beck, 2018; Davidson, 2010; Wyly et al., 2010). While gentrification, as an urban renewal strategy, can promote community integration and reduce social exclusion in certain contexts, it also presents significant negative consequences in practice. For instance, the East End Regeneration Program in London aimed to revitalize impoverished communities in East London by improving infrastructure and attracting new industries to stimulate local economic development. In the short term, the program successfully enhanced housing quality and public amenities, attracting young professionals to the area (Butler & Robson, 2003). However, it simultaneously exacerbated housing affordability issues for long-term residents, forcing some low-income families to relocate (Atkinson, 2004).

The factors driving displacement can be broadly categorized into material and conceptual aspects. Material factors include direct influences such as housing prices and living conditions, while conceptual factors are primarily based on residents' perceptions and lived experiences (Phillips et al., 2021). Displacement itself can be classified into three types: direct or physical, indirect or economic, and exclusionary factors. Forced displacement refers to situations where legal policies or external forces compel residents to relocate, while "responses and impacts" describe the broader consequences of environmental change. Among these factors, indirect or economic displacement is closely linked to gentrification. For example, transportation infrastructure projects and public investments often lead to rising property values and rental costs, making housing unaffordable for existing residents and triggering migration (Zuk et al., 2017).

Original residents and tenants may be forced to relocate due to economic pressures, environmental changes, or personal development factors. This migration pattern is often characterized by "downward filtering", where displaced populations move to areas with lower living costs and standards. Conversely, "upward filtering" refers to higher-income individuals moving into city centers or well-developed neighborhoods, driving up housing prices and gradually replacing lower-income residents with an upper-middle-class demographic (Covington & Taylor, 1989).

On the other hand, the relationship between gentrification and financial precarity has increasingly become a crucial topic in urban studies (Smith, 1987; Lees et al., 2008; Zuk et al., 2018). Financial precarity is generally understood as a multidimensional phenomenon, encompassing financial stress and vulnerabilities at the individual, household, and community levels (Standing, 2012; Kalleberg, 2018). During the gentrification process, the influx of high-income groups reshapes the local economic structure, leading to rising housing costs and increasing overall living expenses, which further intensifies financial pressures on original residents (Smith, 1996; Zuk et al., 2017). This economic pressure often manifests in rising housing prices and rents, increasing costs for basic services, and overall higher daily living expenses. Previous studies indicate that financial precarity typically reduces individuals' and households' financial resources, limiting their ability to cope with economic fluctuations or unexpected crises (Desmond, 2016; Morduch & Schneider, 2017). In gentrified neighborhoods, low-income families frequently experience financial stress, including declining savings capacity, rising debt burdens, and even forced displacement from their communities (Newman & Wyly, 2006; Holme, 2002). Economic precarity in gentrification also extends to changes in the local labor market. The influx of high-income residents often drives a transformation of the regional economic structure, fostering the growth of high-end service industries while simultaneously displacing traditional service sectors and local workers, leading to labor market polarization (Hamnett, 2003). In the short term, this transition may contribute to economic growth, but for original residents, it often results in a mismatch between skill demand and income structures, exacerbating their economic vulnerability (Braveman et al., 2011).

Moreover, financial precarity induced by gentrification is often intertwined with issues of spatial inequality. While urban development policies aim to promote urban renewal, they often lead to unequal resource distribution, further widening social and economic disparities within urban spaces (Adger, 2000; Smith, 1996). For instance, the upgrading of public infrastructure and the influx of high-value commercial investments attract additional capital to gentrified areas, pushing housing costs even higher. At the same time, public service resources may be reallocated to cater to high-income groups, potentially reducing access to essential services for lower-income residents (Morduch & Schneider, 2017). This phenomenon not only weakens marginalized groups' ability to access public resources but may also reinforce financial precarity within gentrified neighborhoods (Holme, 2002). In the gentrification process, balancing economic development and social equity while mitigating the impact of financial precarity on vulnerable populations remains a key challenge for urban development policies (Standing, 2012; Newman & Wyly, 2006).

This study aims to investigate the spatial distribution characteristics and correlation between financial precarity factors and population displacement factors in the context of gentrification by examining the spatial composition characteristics of gentrification.

3 RESEARCH DESIGN

3.1 Materials

3.1.1 Study area

This study focuses on the metropolitan area of Taipei City (Fig. 1) as the research site, excluding areas such as mountains, rivers, parks (e.g., Daan Forest Park, Youth Park), and Songshan Airport. Taipei City, characterized by Taiwan's highest population density and high housing prices, is a suitable location for investigating gentrification.

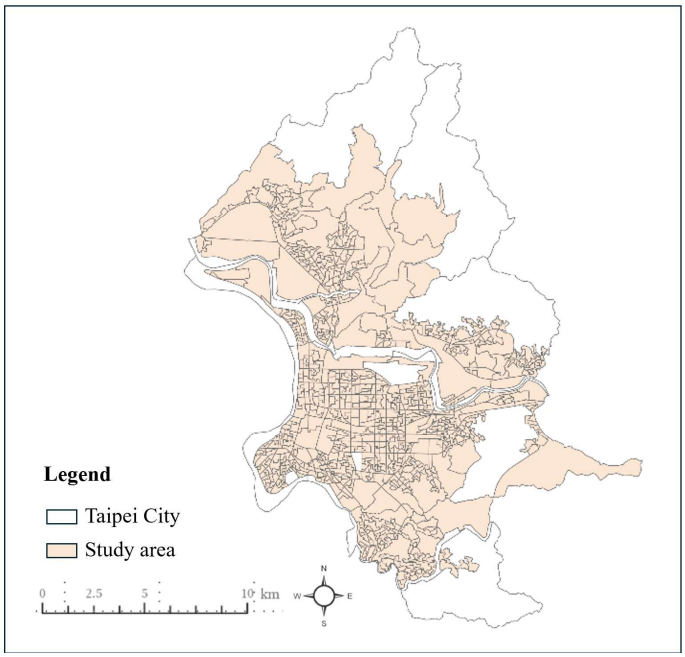

Fig. 1: Study area

3.1.2 Indicators of gentrification and financial precarity

To ensure temporal and spatial consistency in identifying gentrified displacement areas, it is important to have precise indicator years. Therefore, this study sets the data collection period from 2013 to 2019, and all data sources and years are shown in Table 1.

Subject	Indicator		Data Source (Year)
Demographic mobility	M1	Total number of immigrants	Social Economic Data Service Platform (2023)
	M2	Total number of emigrants	
	M3	Change rate of high-income population	Ministry of Finance, Executive Yuan (2022)
	M4	Change rate of low-income population	
	M5	Change rate of highly educated population	Social Economic Data Service Platform (2023)
Demographic Structure	P1	Percentage of high-income population	Ministry of Finance, Executive Yuan (2022)
	P2	Percentage of low-income population	
	P3	Percentage of highly educated population	Social Economic Data Service Platform (2023)
	P4	Percentage of young and middle-aged population	Social Economic Data Service Platform (2023)
	P5	Percentage of disabled population	Social Economic Data Service Platform (2023)
Real Estate characteristic	R1	Real estate transaction volume	Real Estate Transaction Cases – Actual Information Data Supply System, Ministry of the Interior, Executive Yuan (2023)
	R2	Housing rent price	
	R3	Change rate of housing purchases	
	R4	Change rate of housing rent	

Table 1: Indicators of gentrification

This study focuses on the phenomenon of gentrification and, specifically, examines variables related to "financial precarity" within this context. From the broader set of gentrification indicators, a selection of key variables has been identified and isolated for further analysis due to their direct relevance to financial

precarity. These selected indicators, along with their explanations and supporting academic literature, are detailed below (Table 2). This focused approach allows for a deeper investigation into the complex relationship between gentrification and the precarious economic conditions that can arise within changing neighborhoods.

Indicator	Explanation	References
M3 Change Rate of High-Income Population	Influx of high-income residents can inflate housing costs, displacing existing residents and creating financial strain. Outflow can signal declining opportunities.	Florida, R. (2002); Moretti, E. (2012)
M5 Change Rate of Highly Educated Population	Shifts in the educated population can intensify job competition, creating or worsening financial precarity for less-educated residents.	Lucas, R. E. (1988); Goldin, C. D., & Katz, L. F. (2018); Autor, D. H. (2014)
R1 Real Estate Transaction Volume	High transaction volume can signal speculation and rapid neighborhood change, leading to displacement and increased financial precarity.	Case, K. E., & Shiller, R. J. (1989); Glaeser, E. L., & Nathanson, N. (2017)
R2 Housing Rent Price	Rapid rent increases directly strain budgets and can lead to displacement, a key mechanism of gentrification-driven financial precarity.	Glaeser, E. L., & Gyourko, J. (2008); Mayer, C., & Somerville, C. T. (2000); Desmond, M. (2016)

3.2 Methods

3.2.1 Principal components analysis

Principal Component Analysis (PCA), a widely employed multivariate statistical technique, serves as a dimensionality reduction method. Initially proposed by Pearson (1901) and further developed by Hotelling (1933), PCA is primarily utilized to determine the weights of individual variables in order to construct composite indicators. The primary objective of PCA is to identify a set of linear combinations that retain the information inherent in the original variables (representativeness), ensure that the composite indicators (principal components) are uncorrelated (independence), and achieve a parsimonious representation of the original variables by a reduced number of composite indicators (parsimony).

$$\begin{cases} U_1 = l_{11}x_1 + l_{12}x_2 + \cdots + l_{1p}x_p \\ U_2 = l_{21}x_1 + l_{22}x_2 + \cdots + l_{2p}x_p \\ \cdots \\ U_m = l_{m1}x_1 + l_{m2}x_2 + \cdots + l_{mp}x_p \end{cases}$$

where m refers to the spatial units, p refers to the number of attributes, x_p refers to the original attributes, l_{mp} is the factor loading, and U_m refers to the principal components. U_1, U_2, …, U_m (with $m \leq p$) are linear combinations of x_p.

Gentrification is composed of a variety of indicators, and the appropriate indicator forms vary depending on the country, city, historical culture, and other factors. Therefore, it is crucial to determine how to calculate and combine these indicators to reflect the texture of gentrification in Taipei. In this study, the standardized indicator values of each indicator will be integrated and weighted using Principal Component Analysis (PCA) to construct "Principal Component Groups" (hereinafter referred to as composite indicators) under various measurement standards. This approach allows for the analysis of gentrification patterns under different composite indicators. Finally, the composite indicator scores will be calculated and mapped, followed by spatial analysis to identify the secondary release areas with migratory characteristics of gentrification in Taipei City.

3.2.2 Pearson's Correlation Coefficient

Pearson's Correlation Coefficient, developed by Karl Pearson, is a statistical measure that quantifies the degree of linear association between two continuous variables. It is widely used in various fields to explore the relationships between variables.

$$r(x,y) = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}}$$

The coefficient, denoted as r, ranges from -1 to +1. +1 indicates a perfect positive correlation, meaning that the two variables increase or decrease together in a perfectly linear fashion. 0 indicates no linear correlation, suggesting that the variables do not have a linear relationship.

In this study, Pearson's Correlation Coefficient will be employed to investigate the linear relationships between variables related to gentrification and financial precarity.

3.2.3 Local indicators of spatial association (LISA) and Bivariate Spatial Autocorrelation

The local index of spatial correlation can be used to identify the different spatial correlation and aggregation patterns that may exist in different spatial locations, and then find out the spatial heterogeneity between data (Anselin 2010). Also known as Local Moran's I Index. It mainly uses the spatial pattern comparison with neighboring areas to find out areas with similar or different patterns to define cluster areas and expresses them with local correlation distribution maps. Statistics calculation method:

$$I_i = \frac{n(x_i - \bar{x})\sum_j W_{ij}(x_j - \bar{x})}{\sum_i (x_i - \bar{x})^2} = \frac{nz_i \sum_j W_{ij} z_j}{z^T z} = z_i^T \sum_j W_{ij} z_j^T$$

Among them z_i^T and z_j^T Tare the average standardized observation values of the observation values. W_{ij} is the spatial adjacent weight matrix of space unit *i* and *j* area *(j=1,2,3,...,n)* within the research scope, Wij=1 means *i* and *j* are adjacent, and W_{ij}=0 means *i* and *j* are not adjacent.

In the local spatial autocorrelation analysis, when the observation value of itself and the neighboring area are both high (higher than the average), it can be represented by High-High (HH); when the observation value of itself and the neighboring area are both low, it can be Low -Low (LL) means; in addition when the own observation value is high, the surrounding low is expressed as High-Low, and when the own observation value is low, the surrounding high is expressed as Low-High.

Based on spatial correlation analysis, Anselin et al. (2010) developed a bivariate local indicator of spatial association (LISA) to measure local spatial correlation and identify the type of spatial correlation between the two variables. This method is a local bivariate Moran's I statistic and is defined as:

$$I_{kl}^i = Z_k^i \sum_{j=1}^n W_{ij} Z_j^i$$

where W_{ij} represents the spatially weighted matrix,

$Z_j^i = [x_k^i - \overline{x_k}]/\sigma_k$, $Z_l^i = [x_l^j - \overline{x_l}]/\sigma_l$,

where x_k^i is variable *k* at location *i*, x_k^i is observation *l* at location *j*, and σ_k and σ_l are the variance of x_k and x_l, respectively.

4 RESULTS

4.1 Principal Component Analysis of Gentrification Composite Indicators

This study used Principal Component Analysis (PCA) on 14 collected gentrification indicators. The results are shown in Table 15, which yielded five principal components, explaining 19.827%, 18.575%, 13.732%, 7.744%, and 7.505% of the variance, respectively (Table 3). This study used principal components with variance greater than 10% as the basis for classifying gentrification indicators. Table 16 summarizes the framework of the composite indicators. Based on the indicator properties of each group, the composite indicators are defined as "Undergoing Gentrification," "Gentrified," and "Upward-filtering Effect." The subsequent spatial analysis results will explain the common results of gentrified areas in the three composite indicators (Table 4).

Composite Indicator	Undergoing Gentrification (Component 1)	Gentrified (Component 2)	Upward-filtering Effect (Component 3)
Indicators	M1 – Total number of immigrants M2 – Total number of emigrants P1 – Percentage of high-income population P2 – Percentage of low-income population	P3 – Percentage of highly educated population R2 – Housing rent price	M3 – Change rate of high-income population M5 – Change rate of highly educated population P4 – Percentage of young and middle-aged population R1 – Real estate transaction volume
Weights	2.776	2.601	1.922

Table 4: Gentrification Composite Indicators

The indicator values of each spatial unit were multiplied by the component loadings of that indicator to perform weighting, and the 'composite indicator score' of that spatial unit in the composite indicator was obtained. Fig. 2 below shows the mapping results of the composite indicators after weighting:

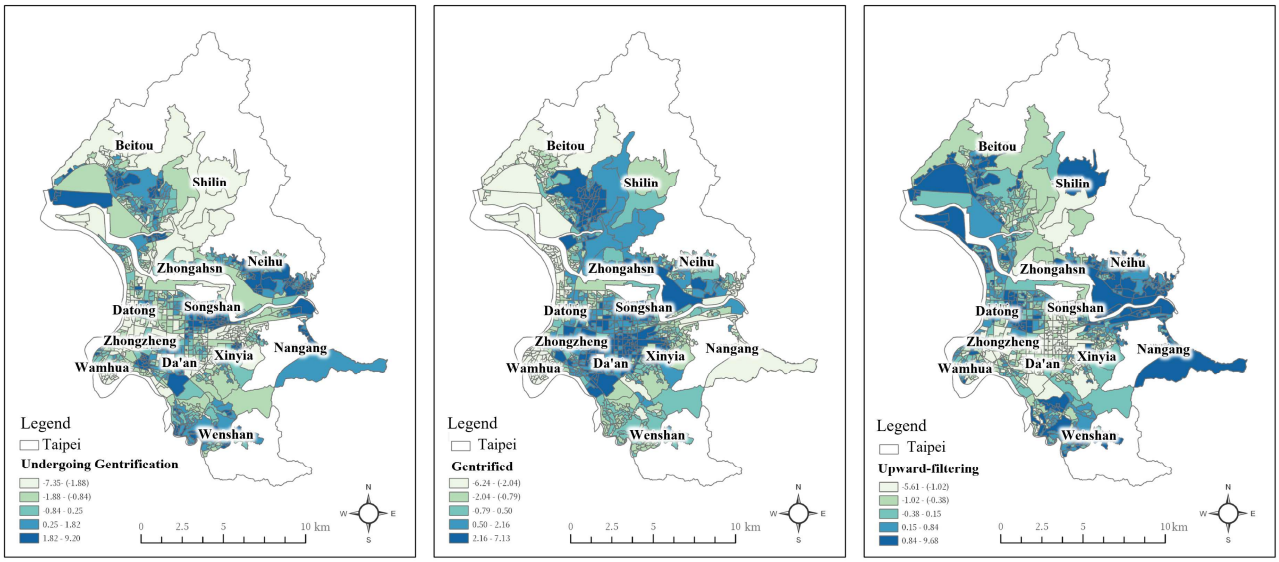

Fig. 2: Mapping of Composite Indicators – Gentrification Patterns

4.2 Spatial correlation of gentrification indicators

To verify whether the gentrification composite indicators have a global spatial autocorrelation aggregation phenomenon, Moran's I was used as the verification method, and the results are shown in Table 17 below. Among them, the P-value is 0 and the Z-scores are all greater than 1.96, which means that all three composite indicators are 'significantly clustered' in the verification results (Table 5):

	Undergoing Gentrification (Component 1)	Gentrified (Component 2)	Upward-filtering Effect (Component 3)
Moran's Index:	0.271455	0.630205	0.394249
Expected Index:	-0.001129	-0.001129	-0.001129
Variance:	0.000047	0.000047	0.000047
z-score:	39.663892*	91.791183*	57.697443*
p-value:	0.000000*	0.000000*	0.000000*

Table 5: Global Spatial Autocorrelation Results of Gentrification Composite Indicators

To use the regional spatial autocorrelation method to find the location of internal spatial clustering of each composite indicator. The results of the "Gentrification Pattern – Regional Spatial Correlation Index" calculated by LISA are as follows (Fig. 3). As can be seen from Figure 32, the High-High values of 'Undergoing Gentrification' are mainly located in the south of Beitou District, the intersection of Songshan District, Da'an District and Zhongzheng District, Neihu District, and Wenshan District; the High-High values of "Gentrified" are mainly located in large areas of Zhongzheng, Songshan, and Da'an Districts, and Shilin District; the High-High values of "Upward-filtering Effect" are located in Beitou District, along the Datong District to Shezidao line, and Neihu District.

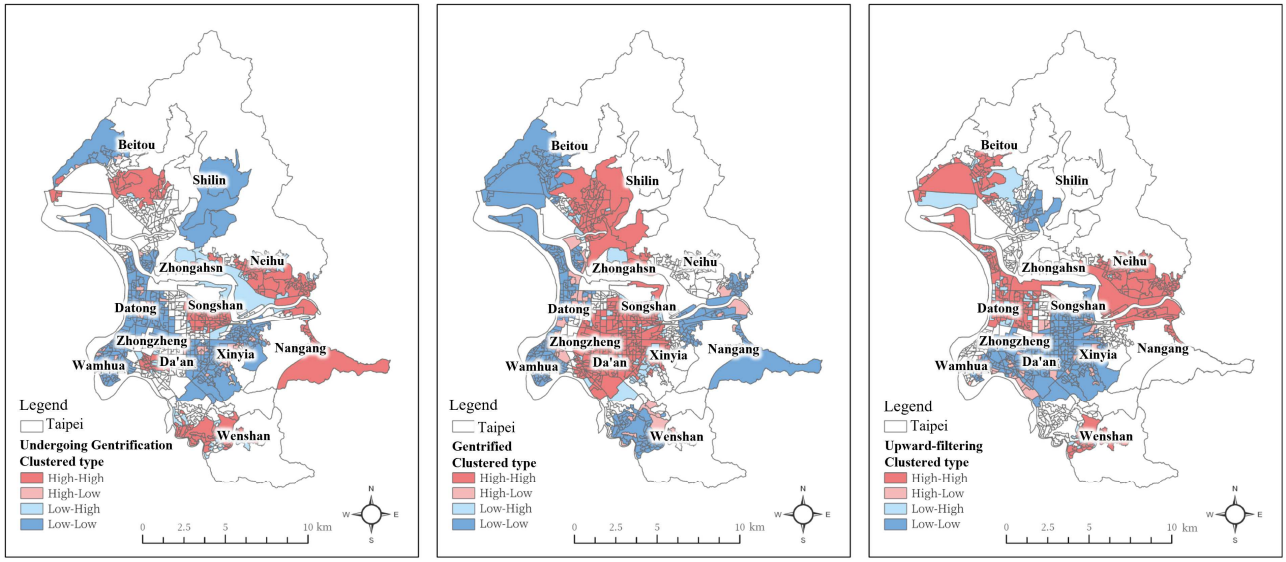

Fig. 3: Spatial Clustering Distribution of Each Gentrification Pattern

4.3 Comparative Analysis of Financial precarity in Gentrified and Upward-filtering Neighborhoods

Given that the principal components of the Upward-filtering areas did not include R2 housing rent prices, and as the figures illustrate a clear divergence in the spatial clustering distribution of the high-value areas between gentrified (Principal Component 2) and Upward-filtering effects (Principal Component 3), a subsequent analysis was conducted to examine the characteristics of financial precarity within these distinct high-value (HH) areas.

This study investigates the nuanced dynamics of financial precarity within urban areas undergoing socio-economic transformation. Specifically, we compare and contrast two distinct neighborhood types: those experiencing gentrification and those exhibiting a Upward-filtering effect. Gentrification, characterized by the influx of higher-income residents and subsequent displacement of existing populations, often leads to significant changes in the social and economic fabric of a neighborhood. The Upward-filtering effect, while also involving an influx of more affluent individuals, may not necessarily result in direct displacement but rather a gradual shift in the area's character and affordability.

The analysis focuses on key indicators of financial precarity, examining how these manifest differently in gentrified versus filtering-up neighborhoods.

4.3.1 Analysis of financial precarity variables in Gentrified HH Areas and Upward-filtering HH Areas

A comparative overview of these indicators in gentrified and Upward-filtering high-value (HH) areas reveals notable differences (Table 6).

(A) Change Rate of High-Income Population(M3):

The mean value of M3 is negative in both gentrified and Upward-filtering areas, suggesting a general trend of high-income population decrease. However, the magnitude of decrease is smaller in Upward-filtering areas (-1.29) compared to gentrified areas (-2.61). This may indicate that while both area types experience some level of high-income population loss, Upward-filtering areas are relatively more stable in attracting and retaining affluent residents. The higher standard deviation in Upward-filtering areas (1.18 vs. 1.06) suggests a greater variability in the change rate of high-income population, potentially reflecting a more dynamic economic environment.

Indicator	Gentrified HH Areas	Upward-filtering HH Areas	Remaining Areas
Mean M3	-2.61	-1.29	-2.5335
Standard Deviation M3	1.06	1.18	1.13820
Mean M5	0.79	1.7	1.1284
Standard Deviation M5	0.55	0.79	0.72114
Mean R1	124.28	184.62	113.2759
Standard Deviation R1	69.58	182.73	82.36377
Mean R2	47500.24	30218.63	28997.7741
Standard Deviation R2	12942.61	10259.75	10557.86973

Table 6: Observations of Financial Precarity Variables in Gentrified HH Areas and Upward-filtering HH Areas

(B) Change Rate of Highly Educated Population (M5):

The mean value of M5 is positive in both gentrified and Upward-filtering areas, indicating an overall increase in the highly educated population. Notably, the mean value is substantially higher in Upward-filtering areas (1.70) compared to gentrified areas (0.79). This suggests that Upward-filtering areas experience a more pronounced influx of highly educated individuals. The standard deviation is also higher in Upward-filtering areas (0.79 vs. 0.55), implying a greater range of variation in the change rate of the highly educated population.

(C) Real Estate Transaction Volume(R1):

The mean real estate transaction volume (R1) is significantly higher in Upward-filtering areas (184.62) than in gentrified areas (124.28), indicating a more active real estate market. The standard deviation is also considerably higher in Upward-filtering areas (182.73 vs. 69.58), suggesting greater volatility in real estate transactions. This may reflect increased speculative activity and rapid neighborhood change in Upward-filtering areas.

(D) Housing Rent Price(R2):

The mean housing rent price (R2) is substantially higher in gentrified areas (47500.24) than in Upward-filtering areas (30218.63). This is consistent with the conventional understanding of gentrification as a process that drives up housing costs. However, the standard deviation is also higher in gentrified areas (12942.61 vs. 10259.75), implying a wider range of rent price variation.

4.3.2 Correlation analysis of financial precarity variables between Gentrified HH Areas and Upward-filtering HH Areas

Furthermore, an examination of correlations between these variables provides insights into the interconnectedness of financial precarity factors in HH Areas(Table 7):

Indicator	Gentrified HH Areas	Upward-filtering HH Areas	Remaining Areas
Correlation between M3 and M5	0.226**	0.106	0.117*
Correlation between M3 and R1	0.123*	0.116	0.026
Correlation between M3 and R2	-0.028	0.049	0.165**
Correlation between M5 and R1	0.382**	0.393**	0.343**
Correlation between M5 and R2	0.069	0.021	-0.066
Correlation between R1 and R2	0.075	0.267**	0.035

Table 7: Correlation of Financial Precarity Variables in Gentrified HH Areas and Upward-filtering HH Areas

(A) Correlation between M3 and M5:

In both gentrified and Upward-filtering areas, there is a positive correlation between the change rate of high-income population (M3) and the change rate of highly educated population (M5). This suggests that areas experiencing an influx of high-income residents also tend to attract highly educated individuals. However, the correlation is stronger in gentrified areas (0.226**) compared to Upward-filtering areas (0.106).

(B) Correlation between M5 and R1:

A strong positive correlation between the change rate of highly educated population (M5) and real estate transaction volume (R1) is observed in both gentrified (0.382**) and Upward-filtering areas (0.393**). This indicates a close relationship between the influx of highly educated individuals and increased real estate market activity.

(C) Correlation between R1 and R2:

Notably, the correlation between real estate transaction volume (R1) and housing rent price (R2) is substantially stronger in Upward-filtering areas (0.267**) compared to gentrified areas (0.075). This suggests that in Upward-filtering areas, changes in real estate market activity have a more direct impact on rent prices.

4.3.3 Bivariate spatial autocorrelation analysis

This study further employs bivariate spatial autocorrelation analysis to investigate the spatial clustering patterns of correlated variables within Gentrified and Upward-filtering HH Areas. This approach allows for the observation of how the spatial distribution of one variable relates to the spatial distribution of another, providing insights into the geographic co-location of socio-economic changes.

The spatial autocorrelation analysis reveals distinct patterns in the relationships between key socio-economic variables across gentrified and Upward-filtering neighborhoods. The significant positive spatial autocorrelation between M3 (high-income population change) and M5 (highly educated population change) suggests a strong spatial linkage between these demographic shifts, with areas experiencing changes in one group tending to experience corresponding changes in the other. This pattern is particularly pronounced in gentrified areas (Table 8).

Furthermore, the positive spatial autocorrelation between M5 and R1 (real estate transaction volume) in both neighborhood types underscores the connection between human capital influx and real estate market activity. Areas attracting highly educated individuals also tend to experience increased real estate transactions, potentially reflecting speculative investment and development pressures.

However, while a statistically significant correlation was found between R1 and R2 (housing rent price) in earlier analysis, the lack of significant spatial autocorrelation suggests that this relationship is not uniform across space. Localized factors, such as zoning or housing policies, may play a more influential role in rent price variation, highlighting the importance of considering both correlation and spatial relationships in examining neighborhood change.

	M3 and M5	M5 and R1	R1 and R2
Moran's Index:	0.269	0.136	-0.0058
Expected Index:	-0.0011	-0.0011	-0.0011
z-score:	16.2337	8.3257	-0.3975
p-value:	0.001*	0.001*	0.37200

Table 8: Bivariate Spatial Autocorrelation Results of Financial Precarity Variables in Gentrified HH Areas and Upward-filtering HH Areas

The analysis reveals that HH areas characterized by high values of both M3 (change rate of high-income population) and M5 (change rate of highly educated population) are predominantly concentrated within Upward-filtering HH Areas (Fig. 4). This suggests that the influx of both high-income individuals and highly educated residents tends to occur in the same geographic locations, specifically within areas experiencing the filtering-up effect. Conversely, LL areas with low values for both M3 and M5 are more frequently clustered within Gentrified HH Areas. This may indicate that areas undergoing gentrification experience a relative decline in both high-income and highly educated residents, potentially due to displacement pressures and affordability challenges.

Furthermore, HH areas exhibiting high values for both M5 (change rate of highly educated population) and R1 (real estate transaction volume) are also largely concentrated within Upward-filtering HH Areas. This finding underscores the strong connection between the influx of highly educated individuals and heightened real estate market activity in these areas (Fig. 4).

5 CONCLUSION

This study examined gentrification and upward filtering dynamics in Taipei City, focusing on financial precarity and displacement. Principal component analysis identified three neighborhood change patterns: “Undergoing Gentrification”, “Gentrified”, and “Upward-filtering Effect”, each with significant spatial clustering. "Gentrified" areas saw declining high-income and highly educated residents, potentially due to displacement. “Upward-filtering Effect” areas attracted more of these groups, coupled with increased real estate transactions.

Comparative analysis revealed further distinctions. While both area types experienced demographic and real estate shifts, the strength and spatial relationships varied. The correlation between real estate transaction volume and rent prices was stronger in upward-filtering areas, indicating a more direct impact on affordability. However, the lack of significant spatial autocorrelation suggests localized factors like zoning influence rent price dynamics.

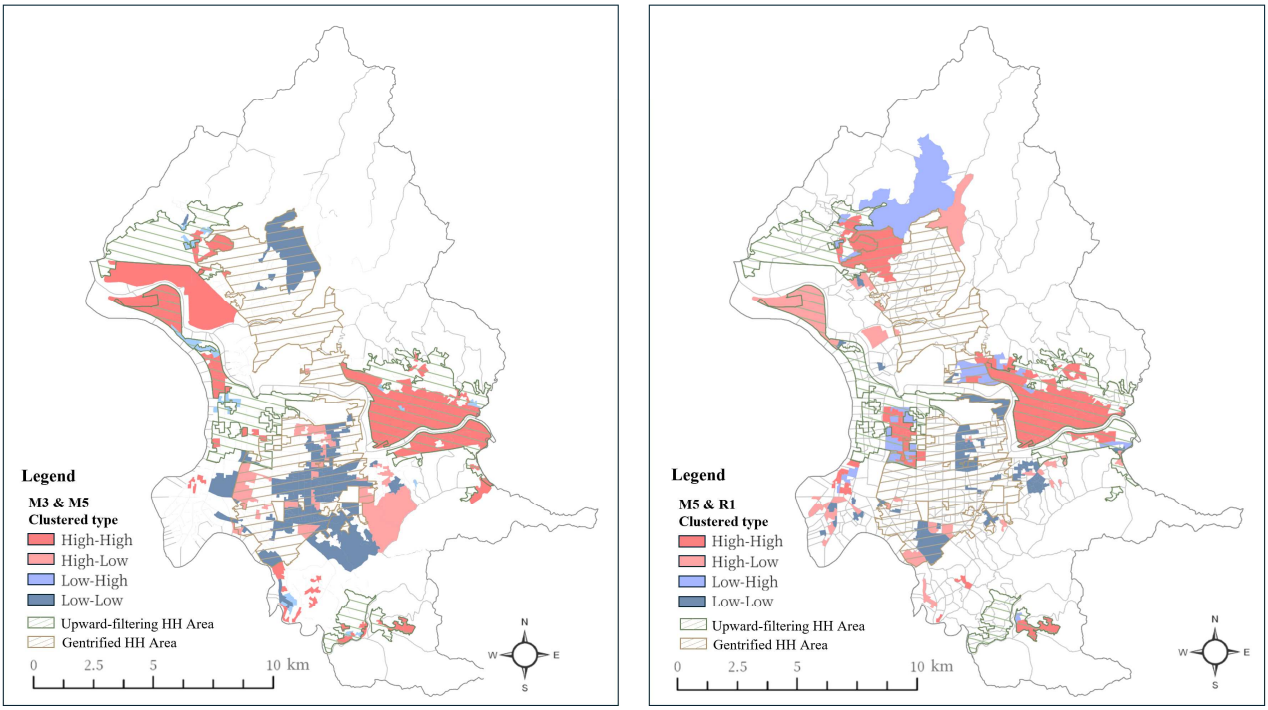

Fig. 4: Spatial Clustering Distribution of Financial Precarity Variables with Gentrified HH Areas and Upward-filtering HH Areas

Bivariate spatial autocorrelation revealed spatial linkages. The clustering of areas with high rates of change in high-income and highly educated populations in upward-filtering areas reinforces the interconnectedness of these shifts. Similarly, high rates of change in the highly educated population and real estate transaction volume highlight the connection between human capital and real estate activity. These findings contribute to a nuanced understanding of gentrification and upward filtering, emphasizing the need for policies mitigating financial precarity and displacement while promoting equiable urban development. Future research could explore targeted interventions to address these challenges.

1 ABSTRACT

This study evaluates the integration of reversible solid oxide cell (rSOC) systems within Positive Energy Districts (PEDs) to enhance energy self-sufficiency and optimize the use of renewable energy based on seasonal energy storaging. rSOC systems are dual-mode technologies capable of operating as both electrolyzers and fuel cells, enabling seasonal energy storage by converting surplus energy, in this case from photovoltaic (PV) systems, into hydrogen during the summer months and converting it back to electricity and heat during winter. The heat generated is of a high temperature, making it suitable for both heating and hot water preparation.

For the investigation, an own simulation model was developed using Python-based tools, incorporating detailed component characteristics and operating models. The emphasis was shifted towards seasonal operation, as it became evident that there were no benefits to be gained from short-term storage in comparison to battery storages. For the saisonal operation, two operation models have been investigated: continuous operation (Scenario I) and predictive operation based on short-term forecasts (Scenario II). Results show that predictive operation reduces electricity grid dependency by aligning rSOC activity with PED energy demands and PV generation patterns. Parameter studies identified optimal configurations of rSOC power, battery capacity, and battery inverter dimensions to balance self-sufficiency and economic performance. While the system exhibits considerable technical potential, its economic integration represents a significant challenge, caused by high investment costs of rSOC systems and the comparatively low electrical efficiency for hydrogen production and subsequent reconversion into electricity. Consequently, it was not possible to identify an economically viable business model within the prevailing framework conditions, whether for Scenario I or Scenario II. Sensitive analyses taking into account the further development of the technology and the relevant framework contions however, shows, that rSOC has the potential to be an interesting option for use in PEDs in the future.

The investigation was carried out as part of the Cell4Live[1] project, focusing on technical and economic aspects of rSOC systems integrated in PEDs.

Keywords: Fuel Cell, Simulation Model, Positiv Energy District, hydrogen, rSOC-system

2 INTRODUCTION

The efficient energy supply of PED is still a major challenge. Especially when, in addition to the positive energy balance – total annual generation exceeds total annual demand – the degree of self-sufficiency is also considered. If the temporal synchronization of energy demand and energy generation is also addressed, the PED can make a significant contribution to relieving the burden on public grids and benefit from increased security of supply in the event of a power outage.

In this respect, rSOC systems are an interesting technology. They can operate in both electrolysis and fuel cell mode. Therefore, surplus electricity can be converted into green hydrogen and converted back into electricity at a later point in time. In fuel cell mode, heat is released in addition to electricity, which can be used to cover (a part of) the heat demand as well as domestic hot water demand. Thanks to the high storage capacity of hydrogen, this system makes it possible to store energy seasonally, i.e. to shift it from summer to winter. This can significantly increase the self-sufficiency rate of the PED, as photovoltaic systems (PV) are usually the main energy sources of such districts.

[1] Das Projekt wird innerhalb des Förderprogrammes „Stadt der Zukunft“ durch das Bundesministerium für Klimaschutz, Umwelt, Energie, Mobilität, Innovation und Technologie gefördert, Project description: https://www.4wardenergy.at/en/references/cell4life-1

Within this study, both the technical and the economic aspects of integrating a rSOC system into PED for seasonal storage of renewable electricity from a PV system, with the goal of later supplying the PED with electrical and thermal energy are examined.

3 TECHNO-ECONOMIC MODELLING APPROACH

It has been assumed that the rSOC system is integrated into a higher-level energy supply system, meaning that the rSOC system is not solely responsible for the entire energy supply of the PED. In addition, the focus was on seasonal operation. Therefore, the rSOC system operates exclusively as an electrolyzer during the summer months and as a fuel cell during the winter months. Generally, in both seasons, electricity generated by the PV is first used to meet the PED electricity demand. In electrolyzer mode (see Fig 1), any additional surplus PV electricity is used to operate the electrolyzer, storing renewable energy as hydrogen for seasonal use.

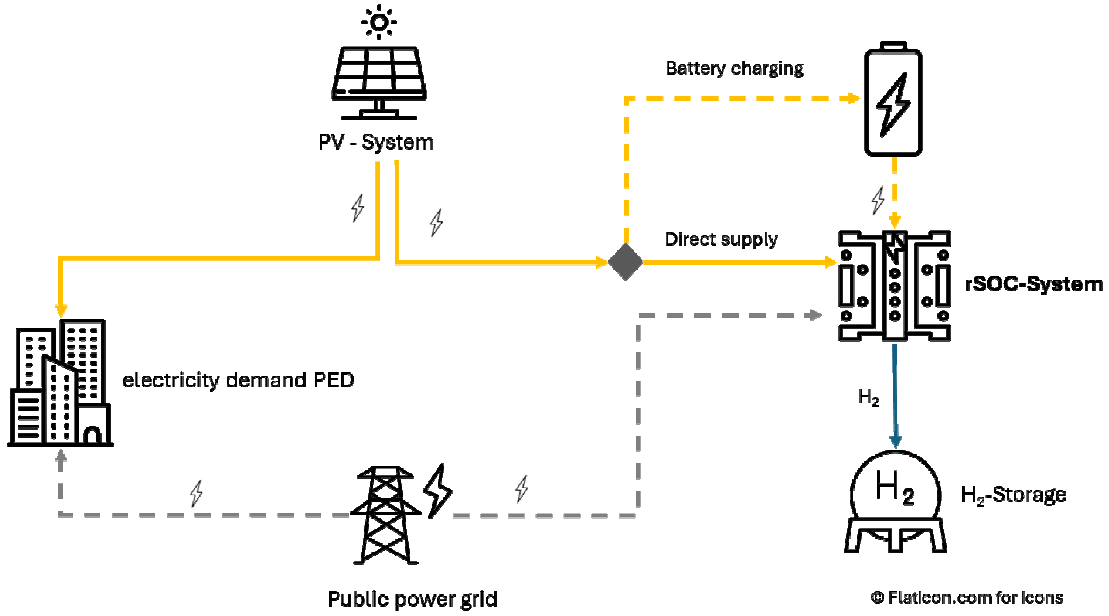

Fig. 1: Schematic diagram of the rSOC-system operating as electrolyzer (“summer operation”).

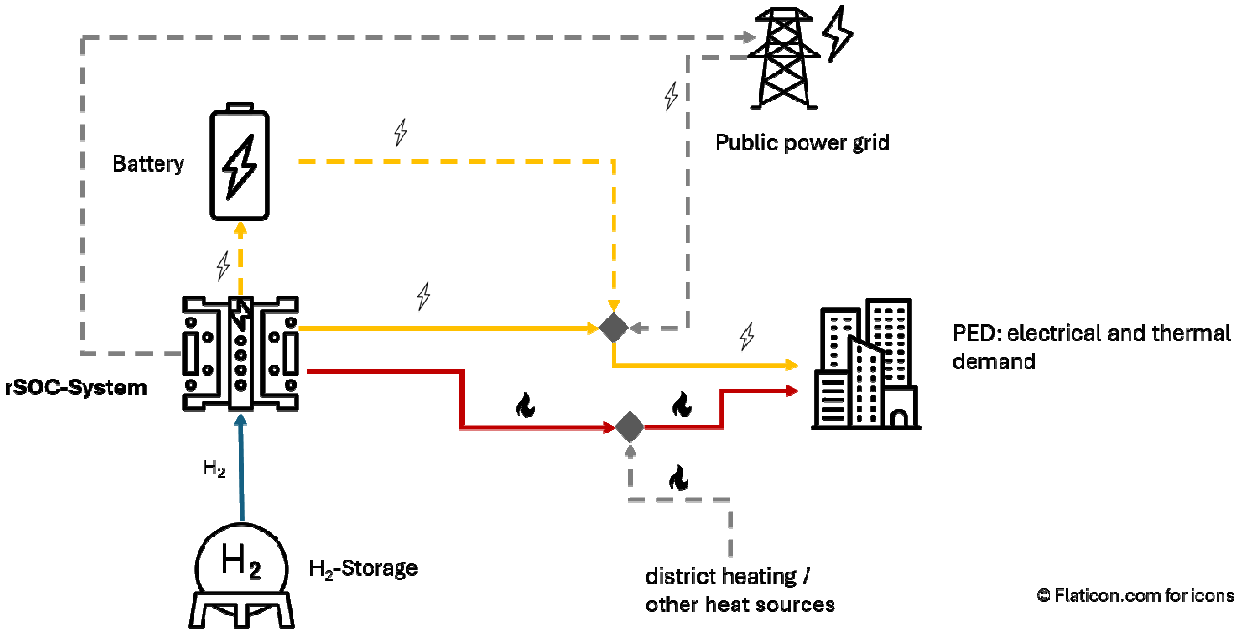

Fig. 2: Schematic diagram of the rSOC-system operating as fuell cell (“winter operation”).

During the winter months, the stored hydrogen is reconverted by the rSOC system into both electricity and heat. The generated electricity is used to cover household electricity needs, while the heat from the rSOC

system is used for heating and domestic hot water preperation (see Fig 2). Moreover, the rSOC is coupled with a battery to further optimize the operation of the system and minimize the share of grid electricity used for the operation of the rSOC system.

To calculate the energy flows between the components (rSOC system, battery, hydrogen storage, electricity grid) and to determine the optimum dimensions of the system for specific PED, a simulation model in Python was created. This model is based on the so called houshold infrastructure and building simulator "hisim" (Pflugradt, 2020). The respective models of the components were interconnected according to the PED requirements and extended regarding the technical and physical properties of real components (e.g. efficiency of the rSOC system, energy requirement for storing hydrogen in a pressurized storage tank). The operation of the rSOC system is investigated within two scenarios:

- In Scenario I, the rSOC system operates continuously, independent of PV surplus and electricity demand of the PED. The rSOC system is operated in electrolysis mode during the summer months and in fuel cell mode during winter. When the system was being dimensioned, care was taken to ensure that the hydrogen produced during the summer months is sufficient to guarantee winter operation. In order to minimise the amount of electricity purchased from the public grid for the operation of the rSOC system in electrolysis mode, the system was equipped with an additional battery storage for day/night balancing. The determination of the optimum size of the battery storage in comparison with the rSOC-system was also investigated within the project.
- In Scenario II, forecasting methods are used to optimize the operation of the rSOC system. The emphasis remains on seasonal operations. Consequently, the rSOC system is still operated in electrolysis mode during the summer months and in fuel cell mode during the winter months. However, the system is not operated constantly, but rather put into standby mode if, for instance, the forecasts indicate that no PV surplus is expected in the subsequent hours in electrolysis mode.

In standby mode, the rSOC unit consumes electrical energy, e.g., to maintain temperature, ensuring rapid reactivation. The model incorporates values from the literature (Mottaghizadeh, 2021; Tomberg, 2023), specifying that 7% of the nominal power is required for electrolysis mode and 10% for fuel cell mode.

In standby operation, the battery state of charge is evaluated against predefined minimum or maximum thresholds, depending on the rSOC mode, to minimize grid feed-in or consumption (see Table 1).

Minimum running & minimum standby time	3 h
rSOC electrolyzer mode: Minimum state of charge of the battery	50 %
rSOC fuel cell mode: Upper state of charge of the battery	90 %
rSOC electrolyzer mode: standby energy demand of nominal power	7 %
rSOC fuel cell mode: standby energy demand of nominal power	10 %

Table 1: Relevant parameters of the Standby mode.

In Scenario II the rSOC system is operated based on predictions for the electricity demand and the electricity production. For the prediction of the electricity demand, a model was developed, which was capable of generating time series forecasts based on historical load data. With this model based on a neural network, good results were achieved for the total energy demand of the PED. However, it should be noted that the aim of the project was not to develop the best possible forecast, but to find a model that is able to deliver sufficiently good results to answer the research question. To determine the energy production, weather forecasts (solar radiation, temperature) from the GeoSphere Austria (2022) were used to calculate the expected PV production for the next three hours (short-term forecasts of GeoSphere Austria).

In fuel cell mode, the activation process involves assessing whether there is an energy demand in the PED after accounting for the energy supplied by the PV system. If an energy demand which cannot be covered by the PV supply is identified, the forecasted PV power generation and PED energy demand during the minimum operational period of the rSOC system are analyzed. Subsequently, the proportion of energy from the rSOC system that can be directly utilized by the PED is determined. If more than 75% of the energy provided by the rSOC system can be consumed directly by the PED without intermediate battery storage, the system is activated. After the minimum rSOC runtime, the battery state of charge and the PED energy

demand are checked again. If the upper state of charge level is reached and no electricity power is required by the PED from the rSOC system, it is switched to standby mode.

A similar approach is applied in electrolysis mode. The forecasted PV surplus electricity and PED energy demand during the minimum operational period of the rSOC system are evaluated. If sufficient PV surplus electricity is available and the electrolysis process can operate for at least 75 % of the minimum runtime using only PV surplus electricity (without additional battery discharge), the rSOC electrolysis mode is activated. Once the minimum runtime is reached, it is checked whether the surpluce energy provided by PV or battery charge is sufficient to continue operating the rSOC system actively. If not, the rSOC system is switched back to standby mode.

The model was used to carry out a parameter study and subsequently determine the optimum dimensions of the rSOC system based on the degree of self-sufficiency achieved and the expected net present value. The results were compared with alternative technologies. In addition, a comprehensive economic sensitivity analysis was carried out using selected scenarios in order to determine which parameters have a strong influence on the economic viability of this system and which framework conditions are necessary to ensure the economic use of the rSOC system.

3.1 Input data

The simulations were carried out based on generic energy demand and supply data of a representative PED in Austria and were conducted for an entire year with an hourly resolution. The aggregated energy input data are shown in Table 2. A parameter study with more than 1000 simulations was carried out, each of them considering the operation of the rSOC system for an entire year. In the parameter study, the battery capacity, the inverter power and the electrical power of the rSOC system were varied with the goal to find an optimum between the increase of the autarky rate on the one hand and the net present value of the investment on the other hand.

		Summer	Winter	Seasonal Transition	Year
Electricity demand	in MWh	209	263	455	927
Thermal energy demand	in MWh	82	343	224	649
Photovoltaik supply	in MWh	388	78	461	927

Table 2: Energy data of the PED used for the calculations.

It was assumed that the maximum electricity power demand of the rSOC system in electrolysis mode corresponds to the PV peak power. The electricity power of the battery inverter was at least equal to the electricity power demand of the rSOC system in electrolysis mode, including the power requirement of the hydrogen compressor. The minimum capacity of the battery was sufficient to operate the electrolyser and the hydrogen storage tank for at least one hour.

In both scenarios, the battery serves as short-term energy storage for the rSOC system. The parameter space is limited upwards by the fact that the battery has a maximum capacity to operate the electrolyser and hydrogen storage for 24 hours. In general, it was assumed that the rSOS system in fuel cell mode supplies around half the power demand in electrolysis mode.

		Minimum	Maximum
Photovoltaic peak power	in kW	781	
rSOC system electricity power demand	in kW	55	781
Battery inverter power	in kW	1 x rSOC system electricity power demand	15 x rSOC system electricity power demand
Battery capacity - enables rSOC system operation	in hours	1	24

Table 3: Characteristics of the parameter space. The rSOC system's electricity demand is specified for electrolysis mode, including the hydrogen tank power demand.

4 RESULTS AND DISCUSSIONS

This chapter is divided into two main sections. On the one hand, the effects of forecast-based operation (Scenario II) were analysed in comparison with constant operation (Scenario I) and, on the other hand, the economic efficiency of the use of an rSOC system in PEDs was evaluated in general.

4.1 Comparison of the constant operation with the forecast-based operation

For the following evaluation, the configuration of Scenario I which reaches the best combination between the remaining grid consumption (to be minimized) and the net present value (to be maximized) has been selected. For Scenario II, the same configuration (size of rSOC system, battery capacity and inverter power) has been chosen to make both scenarios better comparable. The optimum configuration of Scenario II would be slightly different, this however does not influence the general findings. As main reference a scenario without rSOC-system was calculated. Meaning, the PED was modelled with the same PV-system and the same energy demand but without any kind of storage system.

It could be shown that the use of forecastes in Sceneario II reduces the the necessary consumption from the public grid by additional 5 % (see Fig. 3) in comparison to Scenario I. The predictive operating strategy ensures that the rSOC system switches from electrolysis mode to standby mode when the photovoltaic supply is expected to be low or absent, e.g. at night or when it is cloudy. Predictive operation also reduces the amount of electricity fed into the grid. If a low electricity power demand from the PED is expected, which does not justify the operation of the rSOC system in fuel cell mode, it is also switched to standby mode.

In general, the predictive operation of the rSOC system in Scenario II can be seen as to be more grid supportive. In addition to providing seasonal balancing through long-term storage of electricity energy supplied by the PV system, the predictive control of the rSOC system also compensates for daily fluctuations in PV power generation and the PED's electricity consumption.

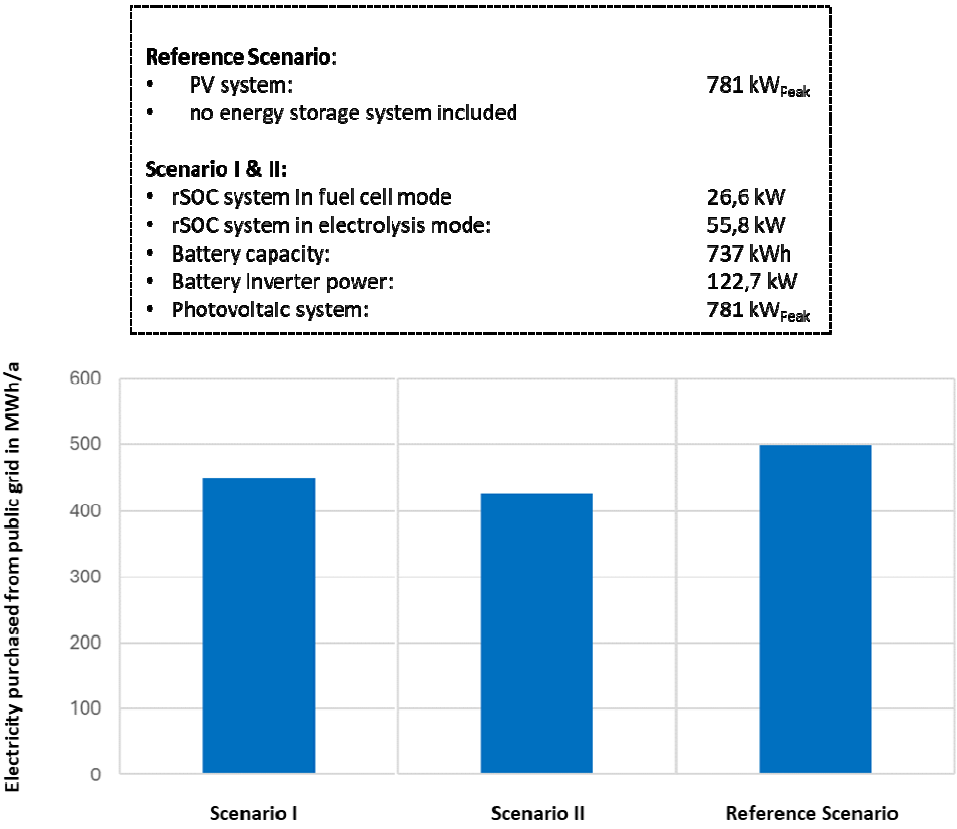

Fig. 3: Remaining share of electricity with needs to be purchages from the public grid, for Scenario I, II and the Reference Scenario.

From the technical perspective, the results of Scenario I show that with continuous operation of the rSOC system, the rSOC system power demand in electrolysis mode should be around 8 % to 12 % of peak power of the PV system to minimize electricity purchased from the public grid. The results of Scenario II show that in forecast-based operation, the rSOC system power demand can be around 10 % to 25 % of the photovoltaic

peak power to minimize electricity grid demand. These values are based on a PED where total annual electricity demand roughly meets annual electricity production.

In addition, according to the simulation results, the battery inverter power in both scenarios should be around two to three times the total electrical power of the rSOC system running in electrolysis mode feeding the hydrogen storage. The battery should have a capacity that makes it possible to operate the rSOC system in electrolysis mode for 18 to 24 hours. In continuous operation of the rSOC system (Scenario I), however, a higher battery capacity is beneficial.

4.2 Economic evaluation of the use of an rSOC system in PEDs

For the economic evaluation, the configurations which provide the best results have been chosen for Scenario I and Scenario II, resulting in different dimensions of the main components, as shown in Table 4:

		Scenario I	Scenario II	Reference Scenario	Scenario 100 % grid consumption
PV-System	kWp	781	781	781	-
rSOC System in fuel cell mode	kW	27	31	-	-
rSOC System in electrolysis mode	kW	56	65	-	-
Battery capacity	kWh	737	430	-	-
Batter inverter power	kW	122	215	-	-

Table 4: Dimensioning of main components of the overall rSOC system.

While the system exhibits considerable technical potential, its economic integration represents a significant challenge. From the economic perspective, unfortunately, no favourable configuration either for the Scenario I nor for the Scenario II could be found in comparison to the reference scenario under the current circumstances. This is mainly due to the high investment costs and the comparatively low electrical efficiency (approx. 55 % (Tokyo Gas Co, 2023)) for hydrogen production and subsequent reconversion into electricity. As shown in Fig 4 the expected net present value for both rSOC scenarios is significantly lower than in the reference scenario, which is supplied exclusively by a PV system and does have its own storage system. Both scenarios have been set in relation to a 100 % grid supply. Meaning that the investment in the PV-system would be amortised within four years, while it is evident that no amortisation occurs in the period under review for the scenario involving the rSOC system.

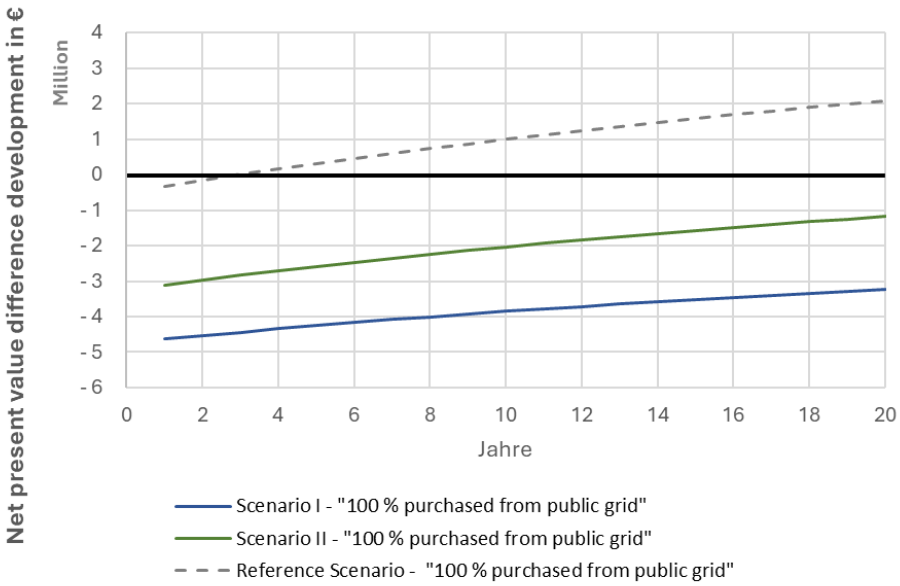

Fig. 4: Development of the net present value for the rSOC-system and the reference scenario (PV system without storage) – both in relation to 100 % grid supply – Basic Scenario.

In the absence of a positive operating model within the prevailing framework conditions, a sensitivity analysis was conducted to ascertain the impact of various parameters on economic outcomes. It has been shown that investment costs and subsidies have the most significant impact on economic efficiency. Given that rSOC systems are a young technology, it is reasonable to assume that investment costs will decrease as the market matures.

Based on these findings, further scenarios predicated on favourable development of the rSOC-technology and the related framework conditions have been defined. The assumptions underlying both the basic scenarios and the "Future Development Scenario" are outlined in Table 5:

		Basis Scenario	Future Development
Investment costs			
PV-System	in EUR/kWp	900	855
Battery Storage	in EUR/kWh	800	680
rSOC-System	in EUR/kW	5000	2000
Hydrogen Storage	in EUR/kWh	835	334
Funding options			
PV-System	%*	30	30
Battery Storage	%*	20	50
rSOC-System	%*	30	50
Hydrogen Storage	%*	30	50
Operation costs			
PV-System	%*	2	1
Inverter	%*	2	0.5
Battery	%*	2	0.5
rSOC-System	%*	3	1
Hydrogen Storage	%*	1.5	0.75
Compressor	%*	1.5	1.5
Electricity tariff	EUR/kWh	0.3	0.3
Feed-in tariff	EUR/kWh	0.08	0.08
Heat tariff	EUR/	0.13	0.13
CO_2 Price	EUR/t_{CO2}	55	55
* % of the related investment costs			

Table 5: Assumptions for the economic evaluation, for the basic scenarios and for the scenario of the future development of the rSOC technology.

The results of the scenario for the future development of the rSOC technology are shown in Fig. 5. Significant better results could be achieved with the assumptions made. Compared with an 100 % grid consumption, the Scenario II is economically viable after nine years. Scenario I is expected to reach its amortisation point after fifteen years. In comparison with the reference scenario, however, there is still no amortisation. Nevertheless, the rSOC system has a considerable future potential especially for such PEDs, where a high degree of autarky is essential.

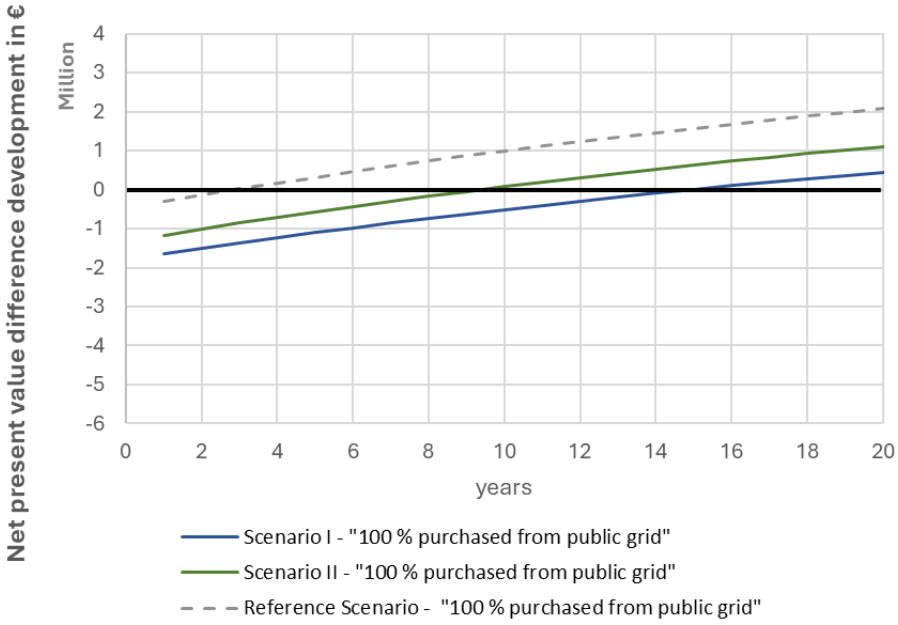

Fig. 5: Development of the net present value for the rSOC-system and the reference scenario (PV system without storage) – both in relation to 100 % grid supply –Scenario for the future development of the technology and the relevant framework conditions.

5 CONCLUSION

Although rSOC systems are an interesting technology for use in a PED from a technical point of view, it was not possible to find an economically viable use case under current conditions. However, as rSOC systems are an emerging technology, it can be assumed that there will be positive development in the coming years, both in terms of investment and achievable efficiency. Therefore, a sensitivity analysis was carried out, which shows that if investment costs and the relevant framework conditions develop favourably, rSOC technology can be an interesting option for use in PEDs in the future. The integration of rSOC systems is particularly favourable if a high degree of autarky should be achieved, as they are well suited for seasonal balancing.

1 ABSTRACT

Kreislauffähige Konstruktionen bieten erhebliche Vorteile im Hinblick auf den Klima- und Ressourcenschutz. Sie zeichnen sich durch eine hohe Ökoeffektivität[1] und Langlebigkeit aus und leisten einen wichtigen Beitrag zur Reduzierung des CO_2-Fußabdrucks, der Minimierung des Ressourcenverbrauchs und der Reduktion von Abfällen.[2] Der Schwerpunkt des kreislauffähigen Bauens liegt auf der Auswahl sortenreiner Materialien[3], die nach ihrem Gebrauch entweder erneut verwendet oder in geschlossene technische oder biologische Stoffkreisläufe überführt werden können.[4] Um eine sortenreine Trennung der eingesetzten Materialien zu ermöglichen, sind geeignete Fügetechnologien erforderlich, um die Demontage, Wiederverwendung und die materialgerechte Wiederverwertung von Bauteilen im Sinne der Kreislaufwirtschaft sicherzustellen.[5] Angesichts der globalen Notwendigkeit von Ressourcen- und Klimaschutz müssen die relevanten methodischen Konzepte des kreislauffähigen Bauens systematisch als auch informativ bis hin zur Detailzeichnung in den Planungsprozess integriert werden.

Das zeichnerische Detail ist ein zentraler Bestandteil des iterativen Entwurfsprozesses in der Architektur und dient vor allem als Medium für den Wissens- und Informationstransfer zwischen allen am Planungsprozess beteiligten Akteurinnen und Akteuren. Eine Möglichkeit, kreislauffähige Bauweisen zu fördern, ist das Hinterfragen der etablierten zeichnerischen Entwurfsgrundlagen und der Prüfung des Informationsgehalts der Detailzeichnungen auf ihre Eignung für das kreislauffähige Konstruieren. Für die folgende Ausarbeitung wurden siebzig ausgewählte zeichnerische Details von architektonischen Bauteilen mittels einer Analyse hinsichtlich ihres Darstellungs- und Informationsgehalts im Kontext der Kreislauffähigkeit evaluiert. Der Schwerpunkt lag dabei auf der Identifikation und Auswertung von Angaben zu verwendeten Materialien, Fügetechnologien sowie der potenziellen Wiederverwendbarkeit der Bauteile.

Ziel war es, zu ermitteln, inwieweit die Detailzeichnungen relevante Informationen für eine kreislaufgerechte Nachnutzung der Bauteile vermitteln und wie diese den Anforderungen der Kreislaufwirtschaft entsprechen. Durch die Untersuchung veröffentlichter Details aus Fachliteratur und Konstruktionskatalogen aus verschiedenen Zeiträumen zwischen 1965 und 2023 wurden die Darstellungen von Materialeigenschaften und Fügetechnologien sowie den Anforderungen für das kreislaufgerechte Bauen systematisch verglichen. Der Vergleich historischer und aktueller Zeichnungen liefert dabei Erkenntnisse über die Entwicklung und Potenziale zeichnerischer Details im Kontext der Kreislaufwirtschaft. Allerdings zeigt die Evaluierung auch, dass der Informationsgehalt aktueller Zeichnungen derzeit noch nicht ausreichend ist. Für die Festlegung des Informationsgehalts ist vorrangig ein methodisches Konzept erforderlich, das die relevanten Kriterien systematisch erfasst und definiert. Um eine umfassende Beurteilung zukünftiger Bauteile zu ermöglichen, ist es erforderlich, die Detailzeichnung um eine zusätzliche Schicht für die Fügetechniken zu erweitern. Zudem ist eine Betrachtung aus verschiedenen Perspektiven erforderlich, insbesondere im Hinblick auf die potenzielle Beschädigung der Materialschichten durch den Aufschluss der Fügetechnik. Durch eine

2 ANALYSE ZEICHNERISCHER DETAILS IM KONTEXT DER KREISLAUFFÄHIGKEIT

Das zeichnerische Detail hat sich über Jahrzehnte als bewährte Methodik in der Architekturplanung etabliert, um einfache als auch komplexe Konstruktionen und deren spezifische Merkmale zu dokumentieren.[6] Besonders bei der Planung von Bauteilkonstruktionen ist das zeichnerische Detail nicht nur ein Mittel der visuellen Darstellung, sondern auch ein zentraler Faktor, der die ökonomischen, ökologischen und gestalterischen Dimensionen eines Bauprojekts maßgeblich beeinflusst. Die Betrachtung von Detailzeichnungen unter Berücksichtigung normativer und projektspezifischer Anforderungen spielt eine entscheidende Rolle im Entwurfsprozess.

Im Kontext der Kreislaufwirtschaft gewinnt die Analyse solcher zeichnerischen Details an Bedeutung, da sie einen wichtigen Beitrag zur Integration von Kreislaufprinzipien in die Entwurfsphase leisten kann. Eine präzise Untersuchung in der Entwurfsphase zeichnerischer Darstellungen ermöglicht es, Planungs- und Optimierungspotenziale für das kreislauffähige Konstruieren zu identifizieren. Dabei können sowohl die effiziente Ressourcennutzung als auch die spätere Wiederverwendbarkeit der Bauteile gezielt verbessert werden. Die wesentlichen Aspekte sind dabei die Auswahl geeigneter Materialien und Fügetechnologien, die in der Entwurfsphase in einer Detailzeichnung festgehalten werden. Die vorliegende Untersuchung widmet sich der Analyse von Detailzeichnungen, die sowohl aus historischen, traditionellen als auch aus kreislauffähigen Bauprojekten stammen. Ziel ist es, neue Erkenntnisse zur Weiterentwicklung zeichnerischer Darstellungen im Hinblick auf die Anforderungen einer nachhaltigen Bauweise zu gewinnen.

2.1 Identifizierung der Schlüsselaspekte für die Analyse

Strategische Entscheidungen zur Entwicklung einer kreislauffähigen Konstruktion und ihrer Materialien sind eng miteinander verknüpft und beeinflussen maßgeblich den Gebäudelebenszyklus sowie die zirkuläre Nachnutzung der gesamten Bauweise. Um die Kreislauffähigkeit anhand einer Detailzeichnung bewerten und Verantwortlichkeiten für deren Umsetzung definieren zu können, müssen wesentliche Schlüsselaspekte berücksichtigt werden.

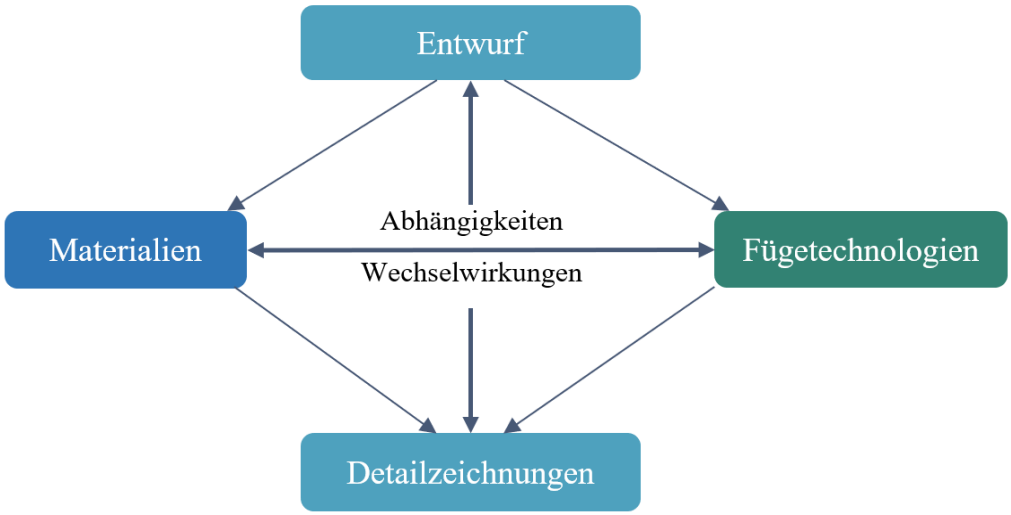

Abbildung 1: Aspekte der zeichnerischen Details im Entwurfsprozess

Abbildung 1 veranschaulicht die wesentlichen Aspekte zur Analyse der zeichnerischen Details im Entwurfsprozess. Die Ableitung und Integration dieser Faktoren sowie ihre Verankerung im zeichnerischen

[6] Schneider, D.: Die Relevanz der Bauteilanalyse. In: Nachhaltig Bauen, Ausgabe 04/2024. Berlin, 2024. S. 42-43

Detail spielen eine wesentliche Rolle bei der Auswahl geeigneter Materialien und reversibler Fügetechnologien. Im Folgenden werden diese Aspekte detaillierter erläutert.

Materialien

Die Wahl der Materialien legt die Grundlagen für das Konstruieren fest. In der Tabelle werden einzelne Faktoren aufgeschlüsselt, die für die sortenreine Materialwahl maßgeblich sind:

Aspekte	Gestaltung der Materialauswahl in der Entwurfsphase	Möglichkeiten der zeichnerischen Darstellung
Ziel	Auswahl sortenreiner Materialien, um eine Nachnutzung zu maximieren	Präzise Darstellung sortenreiner Materialien in den Zeichnungen
Kriterien	Die Auswahl erfolgt nach Kriterien: - Sortenreinheit, - Zusammensetzung, - Nachwachsende Rohstoffe, - Rezyklat - Umweltwirkungen, - Instandhaltung- und Reparatur-anfälligkeit[7] - Rücknahmemöglichkeit - Wieder- und Weiterverwendung - Recyclingverfahren	Die textlichen Beschreibungen ergänzen die dargestellten zeichnerischen Materialeigenschaften
Nachnutzung	Materialien sollen so ausgewählt werden, dass sie nach der Nutzung mit minimalem Aufwand und ohne aufwendige Aufschlussverfahren nachgenutzt werden können. Der Schwerpunkt liegt auf sortenreinen Materialien, die ohne Qualitätseinbußen wiederverwendet oder in den biologischen oder technischen Kreislauf zurückgeführt werden können	In den Detailzeichnungen werden sortenreine Materialien z.B. durch Symbole dargestellt, die den bestimmten Kreislaufansatz sicherstellen.

Tabelle 1: Auswahl und Darstellung von Materialien

Neben den oben genannten Aspekten, trägt die Reduzierung der Bauteilschichten eines Details zur Minimierung der Fügetechniken sowie zur Verringerung des Rückbau- und Demontageaufwandes bei und leistet bei der Reduzierung von Materialien gleichzeitig einen Betrag zur Reduzierung der Ressourcen und des ökologischen Fußabdrucks.

Fügetechnologien

Die Wahl der Fügetechnik sollte unter Berücksichtigung der in der Tabelle genannten Aspekte erfolgen:

Aspekte	Gestaltung und Wahl der Fügetechnik in der Entwurfsphase	Möglichkeiten der zeichnerischen Darstellung
Ziel	Die Auswahl der Fügetechnik erfolgt unter Berücksichtigung des bestimmen Kreislaufansatzes, die eine einfache Demontage und Wiederverwendbarkeit am Ende der Nutzungsphase ermöglichen	Fügetechniken werden in der zeichnerischen Darstellung durch eine eindeutige Kennzeichnung von reversiblen und demontierbaren Verbindungen dargestellt
Kriterien	Die Auswahl der Fügetechnologien wird durch Faktoren der Reversibilität, Flexibilität sowie durch die Fähigkeit zur materialgerechten Trennung und die Wiederverwendbarkeit der Bauteile bestimmt[8]	Die Verwendung von Symbolen stellt die Reversibilität der Fügetechnik sicher. Die Positionierung der Verbindungselemente wird in der Bemaßung angegeben, die Anzahl der Verbindungsmittel im textlichen Teil

[7] Schneider, D.: Die Relevanz der Bauteilanalyse. In: Nachhaltig Bauen, Ausgabe 04/2024. Berlin, 2024. S. 42-43.
[8] Schneider, D.: Reversible Füge- und Verbindungsmethoden. In: Hebel, D.; Wappner, L. et al.: Sortenrein bauen – Material, Konstruktion, Methodik. München, 2023. S.104-109

Tabelle 2: Auswahl und Darstellung von Fügetechnologien[9]

Die Darstellung von Abhängigkeiten und Wechselwirkungen von Material, Konstruktion und Flexibilität stellt sich als eine Herausforderung dar, da Materialien und Fügetechnologien in einer wechselseitigen Beziehung stehen. Ihre Kombination beeinflusst maßgeblich die Wiederverwendung und materielle Wiederverwertung baulicher Komponenten. Eine isolierte Betrachtung dieser Elemente würde potenzielle Synergien und Abhängigkeiten vernachlässigen. In der Entwurfsplanung stellt die Integration der kreislaufspezifischen Aspekte eine Herausforderung dar: das Detail entwickelt sich aus einem gesamtiterativen Prozess der übergeordneten und projektspezifischen Vorgaben an das Bauvorhaben heraus.

2.2 Definition und Eingrenzung der Untersuchungsgegenstände

Innerhalb der für das Paper durchgeführten Analyse wurde der Darstellungs- und Informationsgehalt ausgewählter Detailzeichnungen systematisch nach den in den Tabellen genannten Schlüsselkriterien evaluiert. Ziel war es, die enthaltenen Angaben in den Detailzeichnungen zu den vorgesehenen Materialien und Fügetechniken zu untersuchen und deren Relevanz für die Kreislauffähigkeit zu ermitteln.

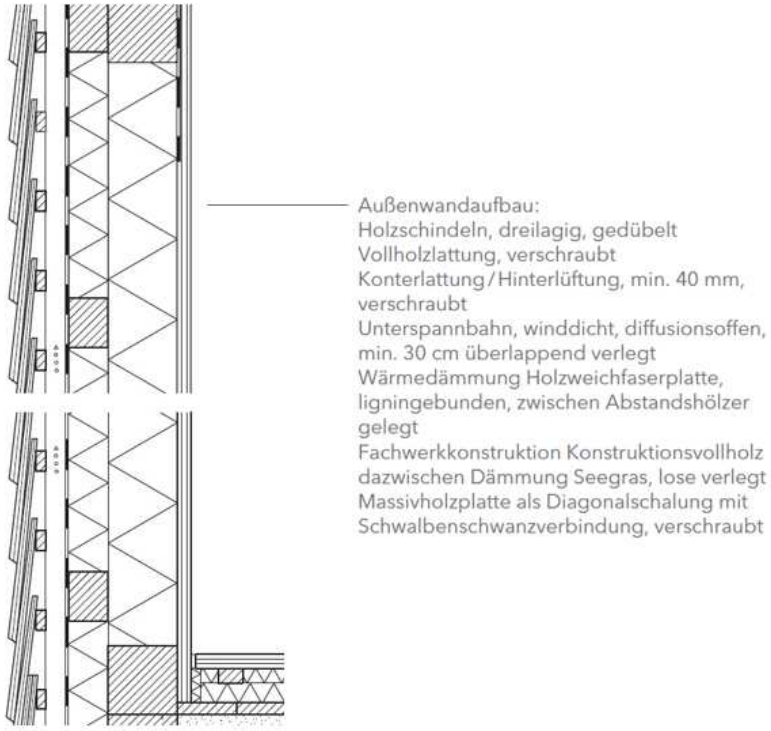

Abbildung 2: Beispiel eines analysierten Vertikalschnitts einer sortenreinen Holzständerbauweise

Die Analyse der Darstellungen zeichnerischer Details bezieht sich auch auf die Untersuchung und Interpretation grafischer Darstellungen, die in der Architekturplanung verwendet werden, um konstruktive und gestalterische Aspekte zu kommunizieren. Insgesamt wurden siebzig publizierte Detailzeichnungen untersucht, die aus historischen, traditionellen oder aktuellen nachhaltigen und kreislauffähigen Projekten entstammen. Der zeitliche Schwerpunkt umfasst Bauprojekte aus dem Jahr 1965 bis 1981 sowie im Zeitraum von 2000 bis 2023. Die untersuchten Details umfassten jeweils Konstruktionen aus der Holz-[10] [11] [12] [13] [14], Massiv- [15] [16] [17], Stahl- [18] [19] [20], Stahlbetonbauweise[21] [22] [23]. Die Datengrundlage setzte sich aus einschlägigen

Lehr- und Grundlagenwerken zur Baukonstruktion, Konstruktionskatalogen sowie Fachartikeln zusammen. Ein besonderer Schwerpunkt lag auf der Analyse des Schichtaufbaus von Außenwänden in Neu- und Bestandsbauten, wobei die Details auf ihre zeichnerische Tiefe und die Einhaltung der kreislaufspezifischen Schlüsselaspekte geprüft wurden. Der Fokus der Untersuchung lag ausschließlich auf dem Darstellungs- und Informationsgehalt hinsichtlich der verwendeten Materialien, der eingesetzten Materialschichten und Fügetechnologien sowie den dazugehörigen textlichen Angaben. Um eine methodisch fundierte Vergleichbarkeit der analysierten Details zu gewährleisten, wurden überwiegend Zeichnungen im Maßstab M 1:20 ausgewählt. Diese Maßstabsverhältnisse entsprechen den üblichen Abmessungen, die in der Entwurfs- und Werkplanung Anwendung finden und gewährleisten eine fundierte Datengrundlage für die Analyse. Der zeichnerische Detailierungsgrad und -tiefe im gewählten Maßstab M 1:20 basiert auch auf gängigen Normen und Vorgaben, die in der Architekturpraxis und Bauplanung verwendet werden.

3 METHODIK

3.1 Beschreibung der Methodik

Im ersten Schritt der Analyse wurden Konstruktionsatlanten unterschiedlicher Jahrgänge verschiedener Materialien ausgewählt, die sowohl im Studium als auch in der praktischen Anwendung der Entwurfsplanung Verwendung finden. Es wurden standardisierte Details aus den materialspezifischen Konstruktionskataloge für Holz[24] [25] [26], Stahlbeton[27] [28], Mauerwerk[29] [30] und Stahl[31] für die Analyse des Informations- und Darstellungsgehaltes in Bezug zur Kreislauffähigkeit selektiert. Auffallend ist die gestalterische Sprache der Details in den materialspezifischen Konstruktionskatalogen. Sie ist stark auf das Wesentliche reduziert, standardisiert und vereinfacht. In der ersten Betrachtung der zeichnerischen Details wurde festgestellt, dass es stark abweichende Detailierungsgrade der zeichnerischen Darstellung und der textlichen Beschreibung im Vergleich zu einschlägigen Normen gibt. Die zeichnerische Sprache entspricht typischerweise der gestalterischen Sprache eines Verlags oder einer Autorin oder eines Autors. Die publizierten Details konzentrieren sich hauptsächlich auf die Materialschichten und deren grundlegenden Eigenschaften. Die textliche Beschreibung der Materialangaben sowie die zeichnerische Darstellung von Verbindungsmitteln der einzelnen Materialschichten und Komponenten zeigten Schwachstellen hinsichtlich der Angaben zu den dargestellten Materialien und Fügetechnologien auf. Im Allgemeinen werden in den Details keine Aussagen zu kreislaufspezifischen Eigenschaften der Materialien getroffen, da dies nicht das Ziel eines materialspezifischen Konstruktionskataloges ist. Bedingt aussagekräftige Details mit Angaben zu den verwendeten Fügetechnologien wurden insoweit publiziert, sofern es sich um ein elementares Gestaltungselement einer Sonderkonstruktion, um eine statische Anforderung oder um die Belange eines spezifischen statischen Elements handelt.

Im zweiten Schritt der Untersuchung wurden auch Details aus der weiterführenden Fachliteratur einzelner nachhaltiger und kreislauffähiger Projekte analysiert. Dazu wurde die Publikation des Aktivhauses „B10“ in Stuttgart von Architekt und Bauingenieur Werner Sobek aus dem Jahr 2015 herangezogen.[32] In seiner Publikation zum Aktivhaus „B10“ finden sich nur wenige konkrete Informationen zum kreislauffähigen Konstruieren; die vorhandenen Inhalte beschränken sich überwiegend auf Fotos und Texte, die eher implizit

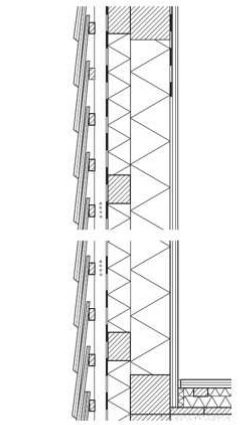
darauf hinweisen und entsprechend interpretiert werden können. Die zeichnerischen und textlichen Angaben bieten Potenzial zur Verbesserung, insbesondere durch die Ergänzung essenzieller Informationen zu den angewandten Fügetechnologien. Es lassen sich Angaben zu sortenrein verwendeten Materialien finden, die den Fokus auf eine kreislauffähige Bauweise betonen. Die textlichen Beschreibungen und Fotografien lassen dem Betrachtenden einen Spielraum offen, inwieweit eigens die für das Detail entwickelte Fügetechnologie nachzuplanen ist. Die Fügetechnologie spielt eine zentrale Rolle im kreislauffähigen Bauen, da sie maßgeblich die Demontierbarkeit und das Recyclingpotenzial von Bauteilen beeinflusst. Das Fehlen solcher Informationen schränkt die Anwendbarkeit der dargestellten Konzepte im Sinne einer vollständigen Kreislauffähigkeit ein. In einer weiteren Projektdokumentation der Experimentaleinheit Urban Mining und Recycling (UMAR) in Dübendorf aus dem Jahr 2019 wurden die zeichnerischen Details mit den Erläuterungen auf die von den Autoren zusammengestellten Schlüsselaspekte evaluiert. Die publizierten Details, ergänzt mit Fotografien und textlichen Angaben, konzentrieren sich auf eine vollständig kreislauffähige Konstruktion mit wiederverwertbaren und wiederverwendbaren Materialien.[33] Die Zeichnungen und Fotografien zeigen im Begleittext der Publikation, wie nachhaltige Materialien und eine kreislauffähige Planung zusammenwirken. Die von den Autoren genannten Schlüsselaspekte werden ausschließlich im erläuternden Begleittext dokumentiert und in den Detailzeichnungen nicht explizit dargestellt. Diese Zeichnungen beschränken sich auf die technische Ausführung und visualisieren keine spezifischen Hinweise zur Kreislauffähigkeit oder den zugrunde liegenden Materialstrategien.

Nachfolgend wurden in fachspezifischen Konstruktionskatalogen zum nachhaltigen oder kreislauffähigen Bauen aus den Jahren 2018 bis 2023[34] [35] weitere Details auf ihren Darstellungs- und Informationsgehalt auf die von den Autoren erstellten Schlüsselaspekte analysiert. Das nachfolgende Schaubild stellt einen Auszug aus der Analyse eines Vertikalschnitts einer sortenrein geplanten Außenwand in Holzständerbauweise dar:

Zeichnerisches Detail mit erläuterndem Text



Außenwandaufbau:
Holzschindeln, dreilagig, gedübelt
Vollholzlattung, verschraubt
Konterlattung/Hinterlüftung, min. 40 mm, verschraubt
Unterspannbahn, winddicht, diffusionsoffen, min. 30 cm überlappend verlegt
Wärmedämmung Holzweichfaserplatte, ligningebunden, zwischen Abstandshölzer gelegt
Fachwerkkonstruktion Konstruktionsvollholz dazwischen Dämmung Seegras, lose verlegt
Massivholzplatte als Diagonalschalung mit Schwalbenschwanzverbindung, verschraubt

Abbildung 3: Bewertung des Informationsgehalts eines Details hinsichtlich der Kreislauffähigkeit[36]

In den Details wurden Angaben zu den vorgesehenen Materialien und den verwendeten Fügetechniken gemacht. Im dazugehörigen Textteil wurde beschrieben, ob es sich um abbaubare, biologische oder sortenreine Materialien[37] [38] handelt. Ebenso liegt die Information vor, wie die Materialien gefügt werden z.B.

[33] Heinlein, F.: Recyclable by Werner Sobek. Stuttgart, 2019
[34] Seggewies, J.; Riegler-Floors, P. et al.: Atlas Recycling. München, 2018

[36] Eigene Darstellung auf Basis von: Hebel, D.; Wappner, L. et al.: Sortenrein bauen – Material, Konstruktion, Methodik. München, 2023. S.138-139
[37] Seggewies, J.; Riegler-Floors, P. et al.: Atlas Recycling. München, 2018

ob es sich um einen losen Verbund, das Auflegen oder Klemmen handelt[39] [40]. Diese Informationen bieten eine wichtige Grundlage, um die Umsetzung kreislaufgerechter Konstruktionsmethoden zu verstehen und die Eignung der Materialien sowie ihre Verbindungstechniken im Hinblick auf Wiederverwendbarkeit und Demontierbarkeit zu interpretieren.

In einem weiteren Vergleich wurden historische Konstruktionsatlanten aus den Jahren 1960 bis 1981[41] [42] [43] herangezogen, um die dort angegebenen Materialien und verwendeten Verbindungsmittel in den Details zu analysieren. Auffallend ist die Schlichtheit der Details und auch die bewusste Einfachheit in der Materialwahl, die heute vermehrt in Projekten des „Einfachen Bauens“[44] erneut Anwendung finden. Konstruktionsweisen in Massivbau- als auch Stahlbetonbauweise halten sich in der Anzahl der Bauteilschichten reduziert. Details in Holzbauweise entsprechen dem Grundsatz der heutigen Holzrahmenbauweise. Die Untersuchung der historischen Details ergab, dass in den ausgewählten zeichnerischen Darstellungen die Materialien als auch spezifische Verbindungselemente angegeben wurden. Ein Vergleich der Details zeigt, dass sowohl die Konstruktionsweise als auch die Materialwahl auf einem sehr einheitlichen Ansatz basieren. Es lässt sich davon ausgehen, dass in den 1970er Jahren eine bewusste Sparsamkeit im Umgang mit Verbindungsmitteln herrschte. Dies ist darauf zurückzuführen, dass die Verbindungselemente zu dieser Zeit als ebenso wertvoll und ressourcenintensiv, wie die verwendeten Baumaterialien selbst angesehen wurden. Die damalige praxisorientierte Haltung reflektiert ein Verständnis der Bautechnik, das Materialeinsatz und Ressourcenschonung in den Mittelpunkt stellte, was im Kontext der Kreislaufwirtschaft auch heute zunehmend mehr von Bedeutung wird. In den Detailzeichnungen wurden teilweise Verbindungen so gestaltet, dass sie die Wiederverwendbarkeit und Flexibilität der Bauwerke unterstützten, ohne unnötige Materialressourcen zu verschwenden. Diese Herangehensweise unterstreicht die damalige Sensibilität für den sparsameren Umgang mit materiellen Ressourcen und die nachhaltige Nutzung von Materialien. Daraus kann abgeleitet werden, dass ein einfaches und ressourcenschonendes Bauen aufgrund der Knappheit der Ressourcen und der Sparsamkeit in den 1970er Jahren und in den Jahren zuvor erfolgte.

3.2 Detailierungsgrad als Herausforderung

Unterschiedliche Detailierungsgrade publizierter Detailzeichnungen in den Konstruktionskatalogen und in der Fachliterur weisen unterschiedliche Detailierungsgrade von Materialien und Fügetechnologien im Maßstab M 1:20 auf. Je kleiner der Maßstab, desto schwerer ist es, eine Aussage über die Kreislauffähigkeit des Details treffen zu können. Für die kreislaufgerechte Planung ist in der Entwurfsphase der Detailierungsgrad als Standard für die Erstellung der Detailzeichnungen sowie dessen Maßgrößen anzupassen. Eine Darstellung der Details im Maßstab M 1:100 oder kleiner kann kaum dazu beitragen, die kreislaufspezifischen Prinzipien zu verorten. Für das kreislaufgerechte Planen sollten Detailzeichnungen im Maßstab M 1:20 oder größer bereits in der frühen Entwurfsphase angefertigt werden, sofern sie in die architektonische Gestaltung einfliesen und eine Rolle spielen sollen.

Die Analyse zeigt auch, dass die in den zeichnerischen Details enthaltenen Angaben für die breite Umsetzung in der Entwurfsphase (HOAI-Leistungsphase 3 in Deutschland) für das kreislauffähige Konstruieren von Relevanz sind, jedoch nicht als verbindlicher Planungsstandard gelten. Trotz ihrer Bedeutung für die praktische Umsetzung kreislauffähiger Prinzipien wird der Detailierungsgrad nicht systematisch in den Publikationen angewendet. Dies weist darauf hin, dass die Integration kreislaufspezifischer Anforderungen in den Planungsprozess noch nicht in den Bereichen der Architekturplanung etabliert ist. Insbesondere ist es häufig so, dass solche Details in der frühen Planungsphase nicht zwangsläufig in den Standardprozess aufgenommen werden, was die Umsetzung

nachhaltiger Bauprinzipien erschwert. Die fehlende Verbindlichkeit und der unzureichende Standardisierungsgrad dieser Informationen stellen eine Herausforderung für die flächendeckende Implementierung der Schlüsselaspekte dar.

4 ERGEBNISSE

Der Darstellungs- und Informationsgehalt eines zeichnerischen Details hat direkten Einfluss auf die Kreislauffähigkeit, da diese die Grundlage für deren Präzision und Aussagekraft bildet. Der Abgleich der ausgewählten Details mit den ermittelten Schlüsselaspekten zu Materialeigenschaften und den Fügetechniken zeigten teilweise Defizite in der Darstellung auf. Dies lässt sich auf den entsprechenden Jahrgang als auch den Fokus in der Ausrichtung der Architektur sowie auf die gesetzlichen Rahmenbedingungen zurückführen. Aus den gewonnenen Erkenntnissen der Analyse lassen sich folgende Ergebnisse ableiten, die zugleich als Grundlage für konkrete Handlungsempfehlungen dienen:

4.1 Erforderliche Darstellung von Materialeigenschaften und Fügetechniken

Ein zentraler Schritt in der Förderung der Kreislauffähigkeit der Architektur besteht in der präzisen Auswahl sortenreiner Materialien und der durchdachten Definition von Fügetechnologien. Die korrekte und vollständige Angabe von Materialien und Fügetechnologien in den zeichnerischen Details ist dabei von entscheidender Bedeutung. Verbindungsmittel und Fügetechniken müssen im Detail definiert werden und eine gleichwertige Berücksichtigung im Kontext der eingesetzten Materialien erfahren. Fehlen Angaben zu den Fügetechnologien, entstehen Unsicherheiten hinsichtlich der Fügbarkeit und Trennbarkeit der Materialien. Dies stellt die ausführenden Unternehmen als auch die Bauleitung vor Herausforderungen, da sie nicht eindeutig erkennen können, welche Technologien an der entsprechenden Stelle angewandt werden sollen, und behindert so eine konsequente Umsetzung der Kreislaufwirtschaft.

Zur Vervollständigung der zweidimensionalen Zeichnung sind die Fügetechnologien als eigenständige Schicht hinzuzufügen, analog zur Materialschicht, da ihr Informationsgehalt für die Kreislauffähigkeit von Bedeutung ist.

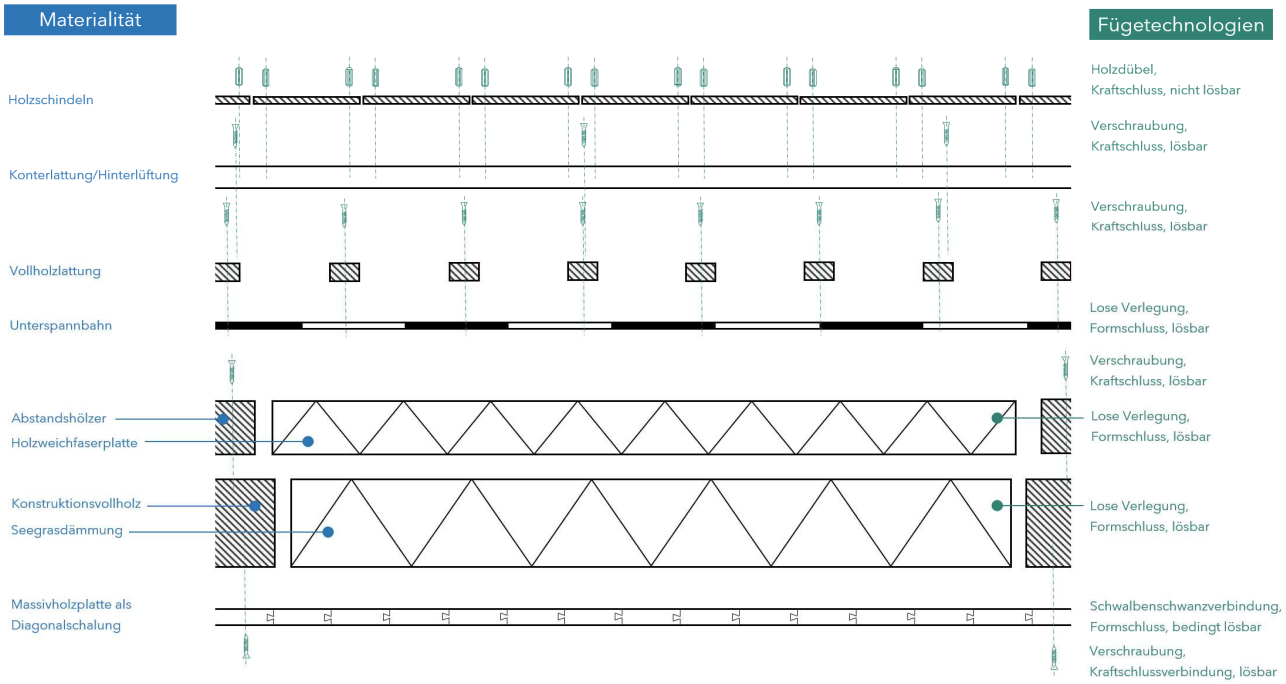

Abbildung 4: Fügetechnologien als eigenständige Informationsebene einer zweidimensionalen Horizontalzeichnung einer Außenwand[45]

Wie die Abbildung 4 zeigt, werden Fügetechnologien als eigenständige Informationsebene in der Detailzeichnung dargestellt, um ihren spezifischen Informationsgehalt in der Konstruktion deutlich

[45] Eigene Darstellung auf Basis von: Hebel, D.; Wappner, L. et al.: Sortenrein bauen – Material, Konstruktion, Methodik. München, 2023. S.138-139

hervorzuheben. Der erweiterte Informationsgehalt der Details kann eine spätere Trennung und Rückführung der Bauteile in den Materialkreislauf ermöglichen. Neben der klassischen zweidimensionalen Zeichnung bieten sich auch andere Darstellungsformen an, um die Fügetechnologien zu visualisieren. Beispielsweise kann eine dreidimensionale Zeichnung genutzt werden, um die Verbindungen und Fügetechniken in einer räumlichen Perspektive darzustellen, wodurch deren Funktion und Wechselwirkungen noch anschaulicher und greifbarer werden.

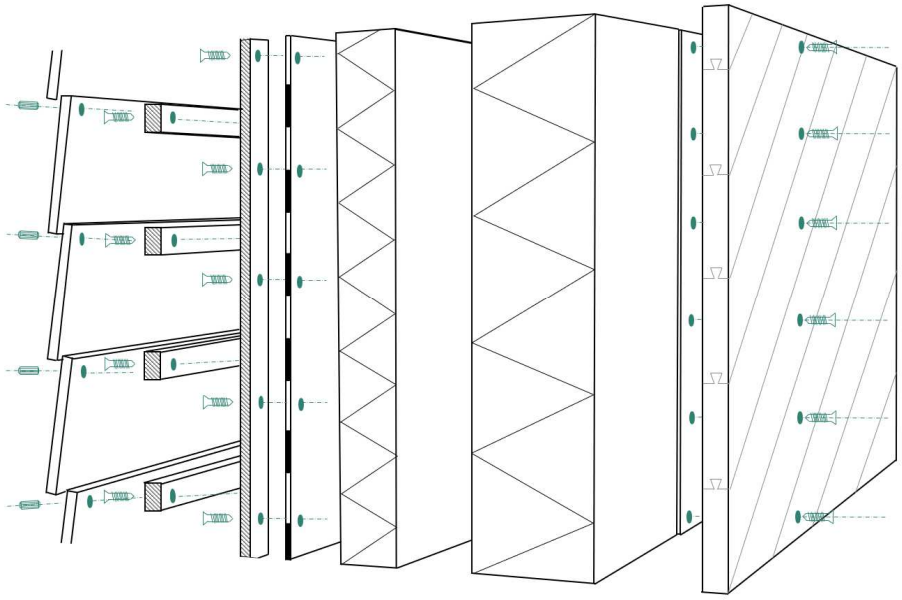

Abbildung 5: Fügetechnologien als eigenständige Informationsebene einer dreidimensionalen Detailzeichnung (maßstabslos)[46]

Eine Vorderansicht der vorgesehenen Materialschichten ermöglicht, die Schäden an den Materialien durch den potenziellen Aufschluss darzustellen und die Folgen der Demontageprozesse zu verdeutlichen. Des Weiteren verbessert diese Darstellungsweise auch den Informationsgehalt der vorgesehenen Fügetechniken.

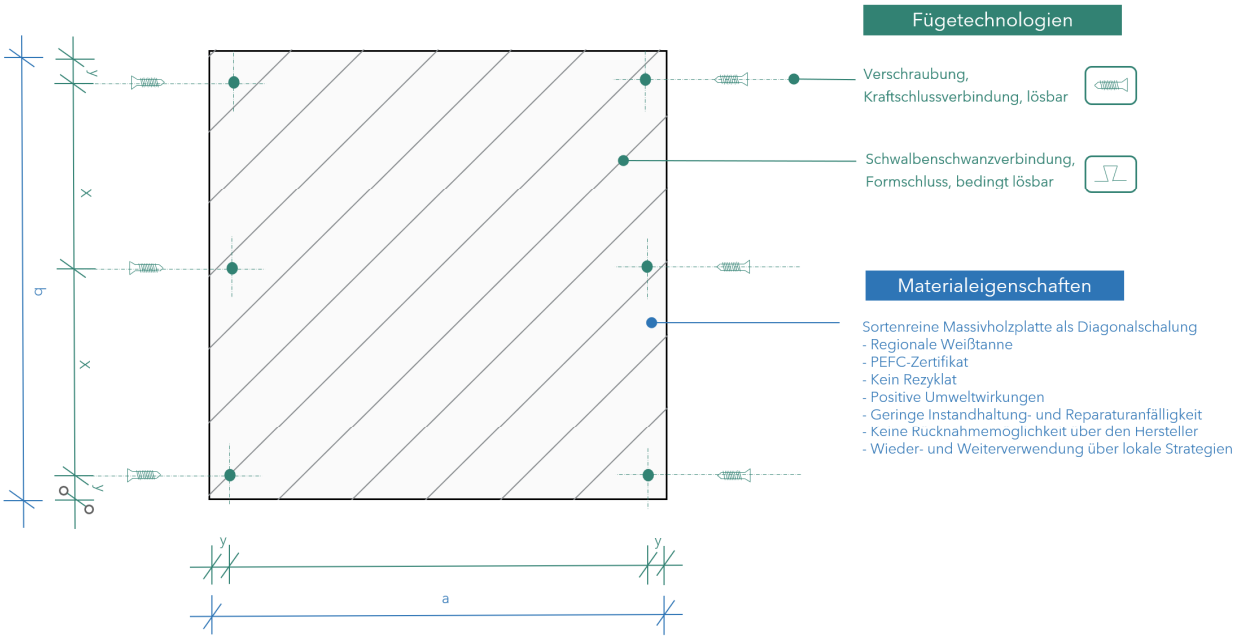

Abbildung 6: Vorderansicht einer sortenreinen Massivholzplatte als Diagonalschalung (maßstabslos)[47]

[46] Eigene Darstellung auf Basis von: Hebel, D.; Wappner, L. et al.: Sortenrein bauen – Material, Konstruktion, Methodik. München, 2023. S.138-139

Um die Auswirkungen der Demontage auf die Wiederverwendbarkeit oder Recyclingfähigkeit der Materialien besser bewerten zu können, sind zusätzliche Perspektiven auf das Detail bereits in der Entwurfsphase erforderlich. Weitere Anregungen zur zeichnerischen Detailierung sowie der Darstellung des Informationsgehaltes für Materialien und Fügetechnologien sind in den Tabellen 1 und 2 zu entnehmen.

4.2 Integration kreislaufspezifischer Aspekte in die Entwurfsplanung

Um die Kreislauffähigkeit von Materialien sicherzustellen, ist es unerlässlich, spezifische Eigenschaften der Materialien und Fügetechnologien bereits in der Entwurfsphase zu berücksichtigen. Diese Phase bietet die größte Flexibilität zur Verankerung kreislauffähiger Prinzipien in architektonischen Details, da in späteren Planungsphasen, insbesondere ab der Werkplanungsphase Änderungen an Konstruktionen oder Materialien nur bedingt umsetzbar sind. Der Grund hierfür liegt im fortgeschrittenen Planungsstand, der wenig Spielraum für grundlegende Anpassungen bietet. Die Verlagerung der konstruktiven Gestaltungselemente, die traditionell in der Werkplanung entwickelt werden, in die Entwurfsphase erfordert eine Umstrukturierung des Planungsprozesses (siehe Abbildung 3). Daher ist es erforderlich, den Anteil der konstruktiven Gestaltung, der üblicherweise in der Werkplanung (HOAI-Leistungsphase 5, Deutschland) erfolgt, in die Entwurfsphase (HOAI-Leistungsphase 3, Deutschland) vorzuverlagern.

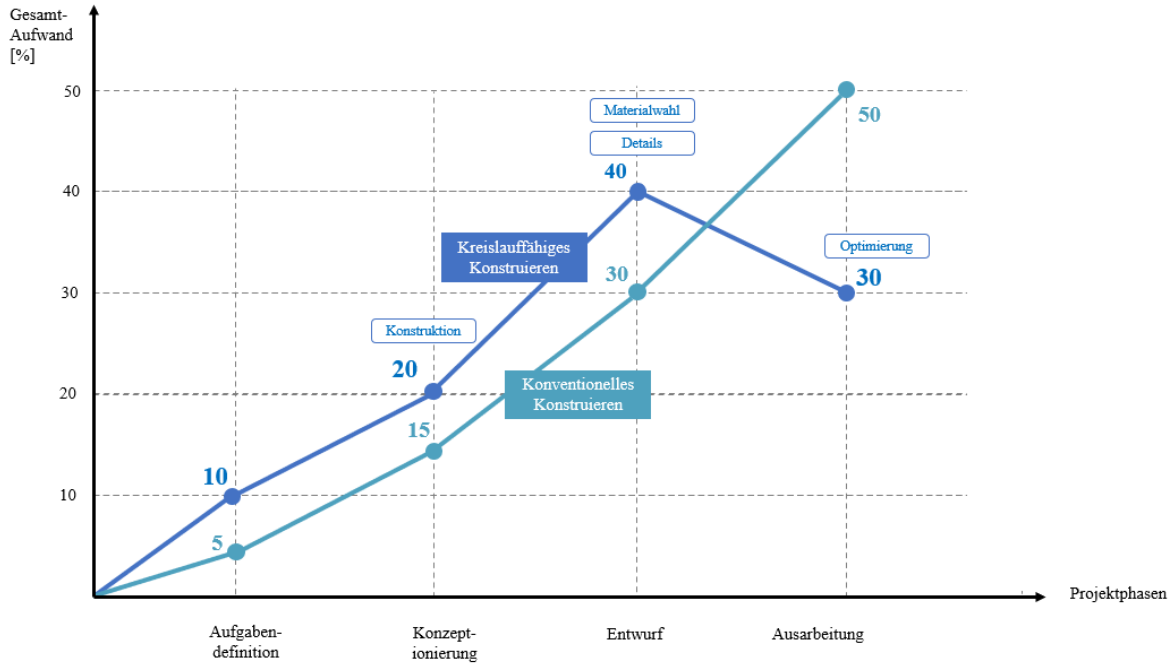

Abbildung 7: Vergleich konventionelles vs. kreislauffähiges iteratives Entwerfen

Dies ermöglicht eine frühzeitige Berücksichtigung und Optimierung von Material- und Konstruktionsentscheidungen im Hinblick auf ihre Kreislauffähigkeit. Die Verlagerung kann jedoch dazu führen, dass die Entwurfsphase verlängert wird, was im Planungsprozess entsprechend berücksichtigt werden sollte. Diese Maßnahme ermöglicht eine frühzeitige Optimierung hinsichtlich der Materialwahl, Fügetechnologien und Konstruktionstechniken, um die spätere Demontierbarkeit und Wiederverwendbarkeit der Bauteile sicherzustellen. Der verlängerte zeitliche Umfang der Entwurfsphase, der durch diese Verschiebung entstehen kann, sollte als strategische Investition in die Qualität und die Nachhaltigkeit des Bauvorhabens betrachtet werden.

4.3 Wissens- und Informationstransfer mittels kreislaufgerechter Detailzeichnung

Die Detailzeichnung stellt ein zentrales Kommunikations- und Planungsinstrument für das kreislauffähige Konstruieren dar, das über die rein dokumentarische Funktion hinausgeht. Sie ermöglicht die präzise Visualisierung der Anforderungen an die Kreislauffähigkeit eines Bauwerks und dient der übersichtlichen Darstellung technischer und gestalterischer Vorgaben. Auf diese Weise trägt sie wesentlich dazu bei, dass

[47] Eigene Darstellung auf Basis von: Hebel, D.; Wappner, L. et al.: Sortenrein bauen – Material, Konstruktion, Methodik. München, 2023. S.138-139

alle beteiligten Akteurinnen und Akteure ein gemeinsames Verständnis der Planungsziele entwickeln und Verantwortlichkeiten für die Ausführung klar definiert und nachvollziehbar festgelegt werden können. Die Schließung von Materialkreisläufen setzt voraus, dass die relevanten Informationskreisläufe vollständig und systematisch in den Planungsprozess integriert werden. Dazu gehört die Erstellung von Details im Maßstab M 1:20 während der Entwurfs- und Ausführungsplanung, die alle wesentlichen Angaben zu den verwendeten Materialien und Fügetechniken enthalten. Solche Details dienen nicht nur als Dokumentationsinstrument für eine Revisionsplanung, sondern auch als Grundlage für die spätere Nachverfolgbarkeit und Wiederverwendung von Bauteilen mittels eines Gebäuderessourcenpasses (vgl. DGNB-Ressourcenpass[48]).

Ein hoher Darstellungsgehalt in Zeichnungen mit den wesentlichen Informationen kann eine höhere Aussagekraft als ein schriftlicher Teil haben. Besonders Zeichnungen, die den Beschädigungsgrad der Materialschichten darstellen, sind von entscheidender Relevanz – sowohl für Architekten als auch für die Nutzer und spätere Rückbauunternehmen. Sie ermöglichen eine präzise Einschätzung der verfügbaren Ressourcen und helfen, die Wiederverwendbarkeit und Rezyklierbarkeit von Materialien zu beurteilen, wodurch eine fundierte Planung für zukünftige Umnutzungen oder den Rückbau ermöglicht wird.

5 SCHLUSSFOLGERUNG UND AUSBLICK

Die Analyse zeigt, dass in allgemein gültigen und materialspezifischen Konstruktionskatalogen die publizierten Bauteile weder kreislauffähig konstruiert noch nach den wesentlichen Schlüsselaspekten der Kreislauffähigkeit dargestellt worden sind. In weiterführender spezifischer Fachliteratur zum kreislauffähigen Bauen zeigt sich im Vergleich zu den Konstruktionskatalogen, eine Entwicklung im Darstellungsgrad von Informationen in der Zeichnung als auch in der textlichen Beschreibung der Details über die laufenden Jahre. Die wünschenswerten und erforderlichen Angaben in den Publikationen zur Kreislauffähigkeit haben Auswirkungen für Studium, Lehre und Praxis. Im digitalen Zeitalter gilt es, die zeichnerische Darstellungen von Materialschichten und Verbindungsmittel darzustellen und die Interaktion im zeichnerischen Entwurfsprozess aufzunehmen.

Es kann die Aussage getroffen werden, dass ein iterativer Entwurfsprozess, der die Sichtweise der Entwerfenden auf die Ansätze des kreislauforientierten Konstruierens einbezieht, ein wesentlicher Schlüssel zur Förderung der Wiederverwendung und zirkulären Nachnutzung von Konstruktionen darstellt. Idealerweise geht dem Entwurfsprozess die Gestaltung eines innovativen kreislauffähigen Konzeptes voraus, dass die Schlüsselaspekte für das kreislaufgerechte Entwerfen, die Darstellung und Dokumentation der Details beschreibt. Ein strategisches innovatives kreislauffähiges Konzept ist eine grundlegende und hilfreiche Unterstützung, dass die Entwicklung von Bauteilen definiert, die später in den jeweiligen Kreislauf für Produkte oder Materialien überführt werden können. Das Konzept umfasst übergeordnete Aspekte, um die Ziele der Kreislaufwirtschaft zu erreichen. Hierbei ist es entscheidend, dass die Materialwahl, die Konstruktionstechniken und die Fügung der Bauteile konzeptionell beschrieben werden, um eine Wiederverwendbarkeit zu fördern. Ein solches Konzept ist in der Vorentwurfsphase zu erstellen und erfordert die frühzeitige Integration in den interaktiven Design- und Entwurfsprozess. Eine erfolgreiche Implementierung eines kreislaufgerechten Konzeptes setzt eine systemische Denkweise voraus, die sowohl ökologische als auch ökonomische Potenziale der Kreislaufwirtschaft nutzt und in den gesamten Planungs- und Bauprozess integriert.

Als Ausblick kann festgehalten werden, dass die Entwicklung kreislauffähiger Bauteile einen Paradigmenwechsel in der Entwurfsplanung der Konstruktion erfordert. Durch die konsequente Berücksichtigung von Demontierbarkeit und Materialtrennung können bereits in der frühen Planungsphase sowohl ökologische als auch wirtschaftliche Vorteile erzielt werden. Eine verstärkte Fokussierung auf die Qualität der Detailplanung bietet die Möglichkeit, den Lebenszyklus von Baumaterialien zu verlängern und gleichzeitig den Ressourcenverbrauch zu minimieren. Die Umsetzung solcher Strategien erfordert eine enge Zusammenarbeit zwischen Architektinnen und Architekten, Ingenieurinnen und Ingenieuren sowie Herstellern sowie eine verstärkte Einbindung von Normen und Richtlinien, die die Prinzipien der Kreislaufwirtschaft unterstützen. Die konsequente Umsetzung solcher Strategien erfordert nicht nur eine

Anpassung bestehender Planungsprozesse, sondern auch eine stärkere Schulung und Sensibilisierung der beteiligten Akteurinnen und Akteure.

1 ABSTRACT

The transformation in mobility is driven by electrification and automation. This paper examines a shared mobility system that utilizes small, driverless pods for transporting passengers and goods, assessing its efficiency, economic feasibility, and environmental impact.

We model the assignment of vehicles totrips as a Single Load Pickup and Delivery Problem with Time Windows (SLPDPTW) and present an Integer Linear Programming (ILP) formulation. Additionally, a heuristic approach is proposed to optimize trip assignments and the benefit of slipstreaming. We conduct computational experiments based on case studies from Austria to simulate various levels of adoption.

The results indicate that there could be a reduction of up to 75% in the number of vehicles required. However, increased mileage can offset some of these benefits. While slipstreaming improves efficiency, the energy savings it provides remain uncertain. The economic viability of this system depends on reducing the per-kilometer costs of the pod, which may be achievable with advancements in technology.Automated shared mobility presents significant promise but also encounters challenges realted to sustainability and cost-effectiveness. Future research should explore larger vehicles, improved routing, and market developments.

Keywords: combinatorial optimisation, fleet size and mix, automated shared fleets, planning, mobility

2 INTRODUCTION

After multiple years or even decades of almost no paradigm change in mobility, we might face a disruptive evolution in mobility culture. Two main developments contribute to this effect: electrification and automation. The breakthrough in electrification is based on developments related to chemistry and physics, i.e., increasing energy density in batteries facilitating long-range electric vehicles. Automation is closely related to developments in new and advanced sensors and the ability to process and analyze the obtained data. Ironically, the automation of the automobile might finally come to completion. According to the Oxford English Dictionary automobile refers to self-moving [1]. Current technological developments raise hopes that self-driving cars will soon be the majority on our roads. Almost all modern cars are already equipped with some kind of driver-assisting technology, which ranges from parking assistants over lane keeping assist systems and cooperative adaptive cruise control to systems supporting overtaking [6]. However, such systems are designed to be assistants. That is, the driver of the car still has to be the driver. He has to be aware of the traffic situation all the time and needs to be able to intervene at any time. In many countries, regulations are even more strict. For example, in Austria, it is required that the driver has to have at least one hand on the steering wheel all the time [7]. However, exceptions exist according to the "Automatisiertes Fahren Verordnung" [8], enabling automated mobility in exceptional cases for testing and development.

In Phoenix, San Francisco, and Los Angeles (all USA), robotaxisare already serving customers regularly [2]. In Hamburg, it is planned to introduce a fleet of 10,000 "autonomous" electric shuttles. However, please note that one has to be careful when using the word autonomous in conjunction with vehicles. Usually, it is referred to as automated mobility. I.e., vehicles that can drive along a pre-defined path according to a set of learned rules. However, no autonomous decisions can be taken in case of (major) disruptions like unforeseen roadwork or even obstacles like broken-down vehicles. One strategy to overcome this is to allow for remote control of the vehicles in case of disruptions [4]. The benefits are evident as the number of personnel needed for vehicle operations can be significantly reduced. However, there are even ideas to at least introduce AI-based methods for supporting the human tele-operators [5].

Another trend that is already state-of-the-art in mobility is car-sharing. The basic principle of car-sharing is that cars are available (either at dedicated stations or free-floating), can be pickedup by customers, used for

one (or more trips), and then are returned (either at dedicated stations or free-floating) such that the next customer can use the car. In fact, car-sharing is an extended version of car rental with way fewer bureaucratic hurdles during pick-up and return. Nevertheless, authentication during pick-up and one-time registration is still necessary.

2.1 Concepts for Automated Shared Vehicles

When combining the concepts of car-sharing and automated mobility, two possible options can be followed: First, a more evolutionary approach would be that the basic car-sharing concept is applied, which comprises of users walking to the shared cars, picking them up, and returning them at specific locations. In combination with automated mobility, the driving process would be automated. I.e., the used is only passenger and not driver.

Second, and (technologically) more advanced, the pickup and return process is transferred to the car. I.e., a car-sharing user calls a car that picks up the user. When returning the car, the user gets off the car and does not further care where and how the car is parked. Instead, the car automatically searches a parking lot.Obviously, the second approach corresponds to a classical taxiservice without taxi drivers.

2.2 Contributions of this Paper

In this paper, we focus on the assessment of the second option for combination of automated mobility and car-sharing, i.e., the driver-less taxi service. However, the following assumptions are made. We assume that

- the used vehicles, called pods in the further context, provide space for at most two persons or one pallet of goods.
- the pods can be virtually connected while driving. I.e., they can build convoys. Pods can enter or leave convoys at any time without significantly interrupting the movement of the other pods in the convoy.
- pods can be used for both passenger and freight transport. It is not possible for goods and people to be transported in a pod at the same time. However, a person can be transported first and immediately afterwards a pallet can be transported (and vice versa).
- a significant number of passengers and good transports are shifted from conventional vehicles towards pods.

We assess the impacts of this change in mobility behavior concerning to the number of vehicles needed, the economic viablity, and the environmental impact. This is done via optimizing the assignment of pods to trip demand. The underlying ILP model and a basic heuristic for solving large-sized instances are presented. Based on computational experiments conducted for three potential application areas, conclusions are drawn.

2.3 Related Works

According to the ITF (International Transport Forum) [11], it is assumed that an autonomous (shared) fleet can reduce the number of needed vehicles by 90%. However, this study does not consider concurrent trips, as this work does.In [17], the authors assume that one car-sharing vehicle might replace 5 to 20 unshared vehicles.

In [9], Alessandrini et al. investigate the potential for shared automated fleets in the urban context. While the results are quite promising with respect to the expected number of saved lifes, reductions in fuel consumption, etc., they envisage a share of 50% of automated cars in approx. 2050 and 100% in 2070. However, their assessments are based on estimations, while this work focuses on applying an optimized vehicle-to-trip assignment.

In [12], the authors adress a real-world scheduling problem of automated shuttles. The underyling problem addressed is a dynamic pick-up and delivery problem which needs to be solved with a fleet of automated vehilces. The given problem is tackled with a large neighborhood search-based approach. Challenging is the fact that vehicles on the road might influence each other as maneuvers like overtaking are not possible for the chosen automated fleet.

Related but not directly significant for this work, the authors of [10] evaluate an average occupation rate of 1.3 persons per car in Austria. It has to be kept in mind, that autonomous vehicles will significantly reduce

this number, mainly if they are employed as envisioned in this work where (empty) cars are called to pick up customers.

3 PROBLEM FORMULATION

In this work, the given road network is a directed graph $G = (V, A)$, which consists of a set of nodes $N = \{0, \dots, n\}$ and a set of arcs A, representing the road segments between a pair of nodes $a_{\{i,j\}} \in A$ and $i, j \in N$.Each arc $a_{\{i,j\}} \in A$ has travel costs $c_{\{i,j\}}$ assigned. Furthermore, we consider a set of trip demands$D$, which represents the commuting distances from a given origin to a given destination. Thus, each trip demand$d \in D$ consists of an origin and destination node pair$\{r_d, s_d\}$, with $r_d, s_d \in N$, having a maximum load of two. The set of all origin and destination nodes is defined as$R \subseteq N$. Additionally, the earliest start time for the demand at the origin is available by e_{r_d}, and the latest end time at the destination is given by l_{s_d}.Since all trip demands must be completed without combining them with other trips, we model the problem as a *single load pickup and delivery problem with time windows (SLPDPTW)* [20]. There, all load from the origin must be transported directly to its destination, which causes empty moves between the destination and the origin of the next trip demand.For directly arriving at the destination, the shortest cost path between each pair of nodes $\{i, j\} \in R$ is computed as$\hat{c}_{ij}$. Furthermore, there is a set of pods P available to serve the given the number of trip demands.Each pod $p \in P$has a maximum capacity of two units. However, the capacity constraint can be neglected in this work, since demand combination is not allowed. Although this is not allowed, pods must not take the shortest path from the origin to the destination.This allows pods to take alternative paths. To prevent excessive deviation from the shortest path, a maximum allowed detour $\hat{T}$is defined, which must not be exceeded.

The SLPDPTW formulated in this work aims to serve all trips with the minimum number of pods while considering the time constraints, such as earliest start time, latest end time, and maximum allowed detour. The second objective is tomaximize the positive effects of slipstreaming while operating the pods. In a conventional traffic system with conventional vehicles, a minimum distance must be maintained between vehicles for safety reasons. However, for the pods considered in this work, it is feasible to form convoys in which two or more pods can benefit from slipstreaming, thus reducing energy consumption. This is possible because it is assumed that the pods can communicate with each other, cf. [14].Therefore, the overall goal is to minimize the number of pods (to reduce costs) while simultanously maximizing the formation of convoys(to enhance energy efficiency).Since defining a convoy in this dynamic environment cna be complex, we opted to maximize the slipstream kilometers of all vehicles. Note, that if only one vehicle is in a convoy, no slipstream kilometers are counted. However, every vehicle from the second onward in a convoy benefits from the slipstream effect, allowing for straightforward computation of slipstream kilometers.

$$x_{pd} = \begin{cases} 1 & \text{if pod } p \text{ fulfills demand } d \\ 0 & \text{otherwise} \end{cases} \qquad \forall p \in P, d \in D$$

Figure 2: The constraints of the ILP model.

We formulate the SLPDPTW model as an integer linear program. Therefore, we introduce the variables and the ILP formulation as shown in Figures 1 and 2.The objective is to minimize the total number of used pods and maximize the number of pods using the same arc at the same time (1). Constraint (2) ensures that each trip demand is fullfilled by exactly one pod. Constraint (3) enables pod p if it fullfills at least one demand and (4) allows pod p to be only enabled if podp-1 is active (symmetry break). Constraint (5) states that for a pod and a trip demand an arc can be used only once over time. Constraint (6) determines that a pod which

fullfills a demand enters an arc exactly once at exact one time.Constraint (7) expresses that each arc is used exactly once for a demand independent of the pod and time), and (8) expresses that each pod is used exactly once at a time, independent of the arc and the demand. Constraint (9) and (10) ensure that there is exactly one outgoing arc at the origin node of a demand and exactly one ingoing arc at the destination node. Constraint (11) ensures that a pod is not used for other demands while traversing an arc.Constraint (12) ensures the consistency of a path between origin and destination node. Constraint (13) and (14) ensure that there is no ingoing arc at the origin node and no outgoing arc at the destination node of a trip demand, because only paths from origin to destination are constructed instead of tours, and (15) ensures that there is enough time (at least the shortest path costs) to get the pod from the destination node to the origin node of the next trip demand. Two pods transporting different demands entering the same arc at the same time is stated in (16), while (17) and (18)force it to zero if this is not the case. Constraint (19) determines the begin time at the origin node and (21) ensures that this is after the given earliest allowed start time. And (20) and (22) determine the begin time at the destination and ensure that this is before the latest allowed end time. Finally, constraint (23) checks if the travel cost from the origin to the destination does not exceed the maximum allowed detour.

4 ALGORITHMIC APPROACH

The solving capability of the implemented ILP approach is quite limited when it comes to the size of the instances. It is not feasible to manage a road network with a large number of trip demands and with a planning horizon of one day while achieving a timely resolution within seconds. Therefore, we have also developed a heuristic algorithm for solving the SLPDPTW.

The heuristic begins by assigning pods to the trip demands. First, it preprocesses the data to calculate the shortest cost path from the origin to the destination for all trip demands. It then sorts the list of trip demands according to their earliest start time. Next, the greedy heuristic generates a starting solution by sequentially assigning the trip demands with the shortest path costs using a first-fit insertion method, while adhering to their earliest start and latest arrival times. If no feasible insertion can be found for a trip demand, it will be assigned to a new pod.

After establishing the starting solution, it is evaluated in terms of slipstreaming, which involves calculating the total slipstreaming travel costs for all pods and trip demands. We determine for each trip demand when the edges of their respective paths must be entered to maintain a feasible solution. This results in a map that records, for each visited edge, a list of trip demands that traverse that edge, along with a time window indicating possible entry times. The entries in this list serve as potential candidates for slipstreaming. In the subsequent step, the heuristic combines trip demands for slipstreaming if their entry time windows overlap. When overlap occurs, the time windows for all affected entries in the map must be updated. This involves reassessing all edges of the paths for the trip demands, as well as for any other trip demands that are already slipstreaming with them. Once all time windows for edge entry times are updated, the number of slipstreaming pods for all edges can be computed, and this number is then multiplied by the respective travel costs.

The objective is to improve slipstreaming, even if it results in additional travel time. To achieve this, we assess alternative routes for each trip demand, ensuring that these alternatives do not exceed the maximum allowed detour costs. The heuristic method involves ten iterations, during which we randomly select alternative travel paths for all trip demands and verify whether the solution is still feasible within the constraints of the earliest start and latest end times. If a proposed solution is not feasible, we retain the shortest cost path in the solution set. Following this, we evaluate the slipstreaming costs. Ultimately, the solution that maximizes slipstreaming, along with its corresponding paths (whether they are the shortest or alternatives), is returned as the final solution.

5 EXPERIMENTAL SETUP

The computational experiments conducted in this study are based on three showcases taken from Austria: IZ NÖ Süd (an industrial area in the south of Vienna), Vienna Airport region, and the triangle Korneuburg-Floridsdorf-Gerasdorf (a suburban region in the north of Vienna). We used the traffic network, statistics on commuting behaviour [15], and land use information [16] for each of these regions to generate instances mimicing real-world characteristics.Trip demand generation involves determining an origin, a destination,

and a desired departure time for each trip. Within the study area, origins and destinations are randomly selected based on land use patterns [16]. Specifically, commuter trips originate or terminate in residential or commercial zones. For trips that begin or end outside the study area, origins or destinations are designated as access points, which include highway entrances and public transit stations. The distribution of these access points between highway entrances and transit stations is strategically designed to reflect the observed modal split, informed by statistical data [15]. Departure times are also assigned based on statistical distributions [15]. For trips based on freight transports, a similar approach was chosen, although the numbers are based on educated estimations according to experience of the authors and the project partners. We refer to Table 1 to summarize the statisticsconsidered for the further used showcases. Please note that they are named A1, A2, and A3 as they are only based on the areas as mentioned above, but the results are not representative of these areas as some assumptions (e.g., freight transport) need to be made.

Based on these statistics, the following instances have been generated: For each area A1, A2, and A3, we assume that only 5%, 10%, 20%, 30%, and 40% of the people are willing to switch to the proposed pods. For each percentage, 20 instances have been randomly generated (based on the above mentioned statistics) resulting in an overall of 300 instances, which have been solved using the described heuristic approach.

In order to compare the impact of considered pod-based system, two comparisons are made. First, the overall number of pods is compared to the overall number of vehicles needed to satisfy all the trip demands. We consider that all freight trips are done via trucks. As the load unit for freight trips is considered to be pallets, the numbers given in Table 1 need to be divided by 33, i.e., the number of pallets to be loaded on a truck. For the commuters, we need to assume that each individual traveller uses his or her own car. That is, for example, that for A1 20,900 cars are needed to satisfy the trip demands done via car.

The second comparison is on the actual costs associated with the trips. For this purpose, we calculate the costs of the individual trips in the status quo based on the Austrian statutory mileage allowance, which is 0.52€/km.

	area [km^2]	commuters	freight (pallets)	avg.MIT [%]
A1	2.7	22,000	3,800	95
A2	73.0	37,750	9,700	87
A3	70.0	125,330	14,000	88

Table 1: Basic statistical data for the considered showcases. The area corresponds to the overall area in the showcase. Commuters, as well as freight, include inbound and outbound trips per day, and avg.MIT denotes the modal split for motorized individual traffic (MIT).

6 COMPUTATIONAL RESULTS

As described in the previous section, 300 randomly generated instances have been used for our computational experiments. Each of the instances has been solved using the proposed heuristic approach, as the exact model presented is not powerful enough to solve instances of these sizes.

In Figure 3-5 the obtained results are shown. For each showcase, the number of vehicles before the switch and the number of pods afterwards are shown in the left diagram (avg #cars vs. avg #pods). In addition, the relative reduction in the number of vehicles is shown. It can be seen that for the smallest instance (A1) only 56% reduction in cars could be achieved. For the larger instances up to 75% could be achieved. That is, the potential is enormous. At the same time, this number is in line with numbers found in the literature for car-sharing concepts, cf. [17].

In addition, we show on the right side of Figure 3-5 the comparison of the vehicle travel time. The red bar indicates the travel times (of vehicles) in the current situation. Vehicles are used for only one trip before being parked. The grey bar indicates the travel times of the pods. Please note that pods need to travel with the passenger (or goods), theytravel empty to the origin of the next trip demandand in addition, might take detours during occupied travel in order to profit from slipstreams. Therefore, the overall travel time of pods is longer. At the same time, slipstream travelling can be done (indicated by the purple bar). This is not possible for individual cars due to safety reasons). The line indicates how much energy consumption (compared to conventional trips) are "allowed" during slipstream travelling such that the pods system does not consume more energy than the conventional system. It can be clearly seen that this allowed energy

consumption significantly raises with the relative share of pod users. However, values are still quite low with a maximum of about 30%.

Please note that computational times for the heuristic are up to about two hours for the largest instances which is quite low compared to the observation that these computations are needed just once when planning the introduction of such a system.

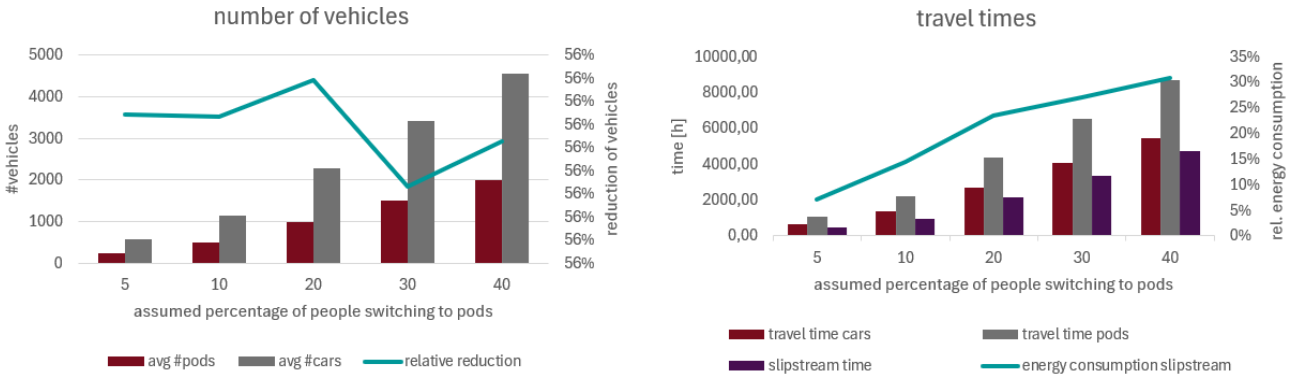

Figure 3: Showcase A1; comparison of the number of vehicles (left); comparison of the travel times (right)

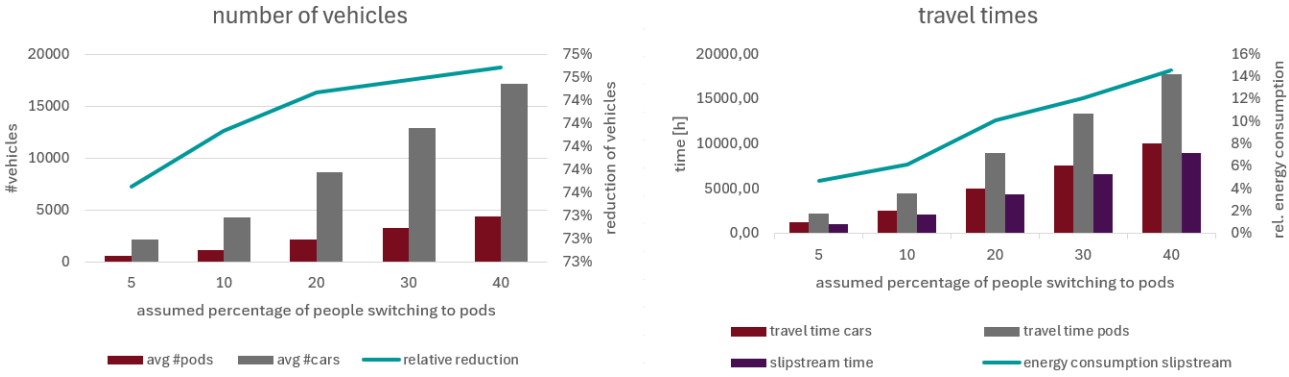

Figure 4: Showcase A2; comparison of the number of vehicles (left); comparison of the travel times (right)

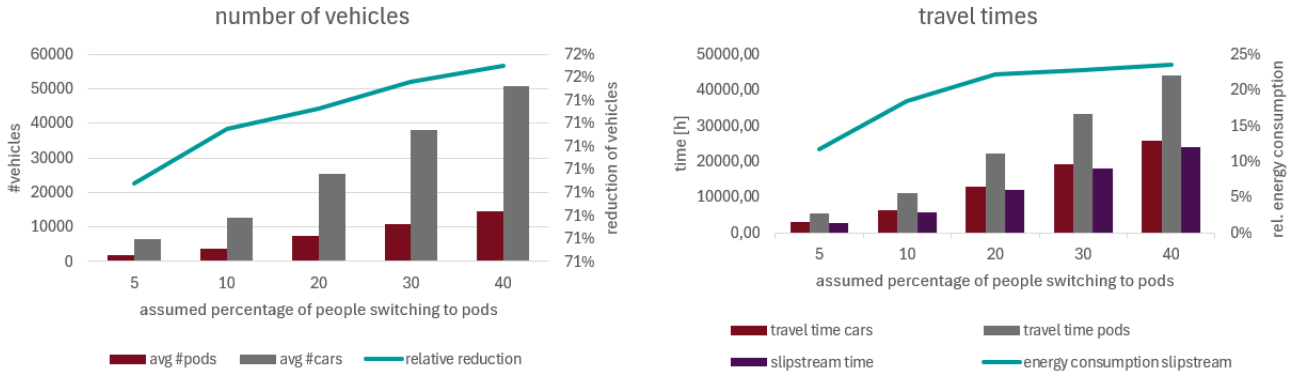

Figure 5: Showcase A3; comparison of the number of vehicles (left); comparison of the travel times (right)

7 ECONOMIC ASSESSMENT

While in Section 6 only traffic related evaluations are done, this section tries to focus on the economic part of the proposed system. A detailed assessment is quite hard, as many different options have to be considered. Therefore, a first estimate is tried within this section.

First, we compute the value for the overall travel costs according to the Austrian statutory mileage allowance, which is currently at 0.52€/km. As can be seen in Table 2, the costs range for the chosen test instances from around €9,000 to €335,000 per day on travel costs.

For the proposed pod-based mobility system, the maximum costs per kilometer such that the system is still economically viable (compared to the status quo) can be computed based on the costs of the current system divided by the distance to be traveled by the pods. As can be easily seen in Table 2, the economic viability of

the system is only given if the per-kilometer costs are far below the currently assumed costs for conventional vehicles.

Therefore, we made a short calculation trying to obtain a range of realistic cost values per kilometer for the operation of the pods. Based on a price list for renting pods [18], we obtained a range of 0.26€/km to 0.38€/km which indicates that operation at the economic break-even point might be realistic but strongly depends on the further development of the pod market.

	% of pod users	costs conventional (per day) [€]	resulting maximum costs per km for pods [€]
A1	5	8,800	0.32
	10	17,600	0.32
	20	35,300	0.32
	30	52,900	0.32
	40	70,500	0.32
A2	5	16,400	0.29
	10	32,800	0.29
	20	65,400	0.29
	30	93,100	0.29
	40	131,000	0.29
A3	5	42,000	0.30
	10	83,800	0.30
	20	167,700	0.30
	30	251,600	0.30
	40	335,300	0.30

Table 2: Estimated costs per day for trips using the conventional traffic system or the introduced pod-based mobility system.

8 SUMMARY AND CONCLUSIONS

Within this work, we proposed the introduction of a car-sharing system incorporating automated vehicles referred to as pods. These pods are considered to be rather small such that at most two persons or one pallet can be loaded. Based on three real-world motivated showcases, we assessed the traffic related as well as the economic impact. It can be easily shown that even when applying an optimized scheduling of vehicles to trip demands, additional mileage (compared to the status quo) needs to be covered by such a system. At the same time, the number of vehicles can be reduced by up to 75%. Further, it could be shown that such a system might benefit from the ability to use slipstream effects. However, due to the additional mileage, the energy consumption of the vehicles in the slipstream should be at most 30% compare to the energy consumption of vehicles not profiting from slipstreams. Although, it is necessary to evaluate whether such values can be achieved for pods, studies for trucks indicate that these values are far below realistic boundaries as for trucks energy savings in platooning are about 30% maximum [19].

The economic assessment revealed that the per-kilometer costs of conventional cars compared to the per-kilometer costs of automated pods can be much higher in order to obtain the same total system costs (related to travel). Based on prices promoted by one pod producer automated cars are much more expensive than conventional ones. Nevertheless, the first estimates show that the necessary cost reduction for per-kilometer prices could be achieved with automated pods. However, it is necessary to perform a further analysis considering costs for parking space and other effects as well. This is left for future work.

To summarize, from the current viewpoint it is very unlikely that a fully automated pod-based mobility system is ecological/traffic-related viable. From an economic point of view, the break-even point might be reached.However, it is necessary to further investigate whether different pods (e.g., larger with more bundling potential) could have a positive effect. In addition, future prices of pods might significantly drop, which could lead to more economic options.

9 ACKNOWLEDGEMENTS

This work received funding from the Austrian Federal Ministry for Climate Action, Environment, Energy, Mobility, Innovation and Technology (BMK) in the Mobilitätswende programme under grant FO999909875 (project IMAMTU). We acknowledge our project partners Fraunhofer Austria Research GmbH who strongly supported in data collection and data provision. We acknowledge the contribution of Clovis Seragiotto for helping at data processing and implementation of the optimization approaches.

1 ABSTRACT

A critical issue developing countries globally face is insufficient investment in road infrastructure, particularly in rural areas, where the lack of reliable road networks significantly makes development in these areas almost stagnant. Rural roads in these regions are often poorly constructed, predominantly consisting of gravel surfaces, unlike the paved roads commonly found in urban centres. This disparity creates substantial challenges in attracting private-sector funding or forming effective public-private partnerships for infrastructure development. Rural roads frequently lack proper signage and are inadequate for large-scale public transport, restricting mobility and accessibility. The absence of high-quality road networks not only limits public transport industry growth but also exacerbates transport challenges in these areas. Moreover, rural road infrastructure is often disconnected from national or regional networks, further isolating rural populations from urban centres and marginalizing them from opportunities for development. This paper explores the negative consequences of neglecting rural road infrastructure, focusing on its impact on rural development and economic growth. It also identifies key issues such as the lack of threshold densities for collective public transport and explores alternative solutions, including pilot projects implemented in developing countries. A bibliometric analysis will be conducted to uncover key research trends, identify gaps in existing literature, and highlight policy recommendations to address systemic inadequacies in rural road infrastructure. The study emphasizes the need for enhanced connectivity between rural and national/regional transport networks to support the rural economy, create development opportunities, and improve access to essential services like healthcare and education. Furthermore, the research underscores the importance of community empowerment in ensuring road development projects meet quality standards and are maintained properly.

Keywords: infrastructure neglect, transport challenges, rural road infrastructure, public transport, Community empowerment

2 INTRODUCTION

The development of any region relies heavily on well-developed road infrastructure particularly in rural areas which need frontier accessibility and connectivity as essential elements for economic expansion and social improvement (Bacior and Prus 2018). However, several obstacles exist within the scope of rural road infrastructure. Rural roads within developing countries fail to achieve basic development standards because they receive inadequate construction and maintenance services (Hemson et al., 2004). These situations worsen transportation difficulties, especially for people who reside in sparsely populated areas because they lack proper access to basic amenities such as healthcare services, educational opportunities, and economic prospects. Therefore, the paper reviews the literature of rural road infrastructure problems and the significant matter regarding inadequate threshold densities in collective public transport systems. We will examine proposed alternative solutions which have been implemented together with pilot projects developed in rural areas with local communities involved in transport planning activities.

3 DEFICIENCIES IN RURAL ROAD INFRASTRUCTURE

This section discusses the analysis of rural road infrastructure problems because road networks form the basis that determines rural transport system outcomes.

3.1 Poor Construction and Maintenance of Rural Roads

The major problems with rural road infrastructure include inadequate road construction quality and insufficient maintenance practices (Hauya, 2019). Developing countries maintain poor-quality road infrastructure, and some contain gravel surfaces which fail to support significant vehicle traffic. These paths remain exposed to all environmental hazards. Severe deterioration through erosion flooding and multiple other degradation processes that shorten their operational time and reduce their effectiveness is being experienced (Zhang and Alipour, 2020). Several regions experience premium road deterioration combined with landslides because their drainage systems are insufficient, their soil stabilization methods are weak, and their structural designs insufficient. The heavy rains of rainy seasons make unpaved roads impossible to travel, causing extensive mobility challenges. The problem runs severe in distant or mountainous areas because natural climate events, including heavy precipitation and snowy conditions, cause roads to disappear or develop deep tracking, which leads to unsafe travel conditions.

3.2 Lack of Connectivity to National and Regional Networks

The insufficient connection between rural road systems with national and regional road networks is another problem (Kanuganti et al., 2017). Rural roads face a significant problem because they do not link properly with the larger national and regional road networks. Personnel in rural areas face transportation hurdles because their roads lack connections to central transportation systems, which creates barriers to urban service access (Yu and Zhao, 2021). The absence of integration between rural road networks leads to deepening regional isolation because rural areas cannot execute economic processes or reach markets for their products (Aduda and Kalunda, 2012). The limited road connections to wider transportation networks create significant challenges to rural businesses. Farmers encounter transportation challenges when trying to move goods to urban markets because of poor road conditions, leading to price increases, wasted perishable products, and lost business prospects. This further hinders access to economic regional growth opportunities which restricts business expansion. Only limited access to extensive supply chains prevents rural industries from becoming large-scale operation.

3.3 Insufficient Infrastructure for Collective Public Transport

The transportation infrastructure shortfalls in rural regions negatively influence the implementation of public collective transportation networks (Pojani and Stead, 2015). The operation of public transport needs extensive roads that enable buses together with minibuses and alternative mass transit options. The road deficiencies, insufficient signage, and limited road capacity prevent collective transportation development, thus blocking mobility improvement and affordable public transit options for rural residents (Cervero et al., 2017). Economically sustainable public transportation becomes impossible to maintain because rural areas lack threshold densities (Hauya, 2019). Rural areas with low populations face such expensive bus and other public transit operation costs that small investments become unlikely to recover while maintaining dependable transport services remains challenging (Kanuganti et al., 2017).

3.4 Road Safety and Limited Infrastructure for Non-Motorized Transport

The absence of proper signage combined with insufficient road markings diminishes pedestrian infrastructure at rural areas thus causing severe road safety problems (Hauya, 2019). Deficiencies in road safety systems result in more accidents since pedestrians and cyclists, along with motorcycles, endure the highest risk on these roads. Lack of safety infrastructure discourages people from using present roads or public transport, which eventually restricts mobility in rural areas and deepens isolation for residents (Porter, 2014).

4 CAUSES OF THE DEFICIENCIES IN RURAL ROAD INFRASTRUCTURE

This section covers the causes of the deficits in rural road infrastructure. Once the root causes are understood, very targeted and effective solutions can be applied to overcome such problems; otherwise, most interventions will either be superficial or misdirected in nature.

4.1 Limited Investment and Budget Constraints

Budgetary constraints combined with low financial support create the main reason behind rural road infrastructure deficiencies in developing nations especially (Briceño-Garmendia et al., 2009). Governments

make budget decisions to fund urban infrastructure instead of funding rural areas because they deem urban centres to generate better direct contributions towards GDP growth. The funding dedicated to building and maintaining rural roads is usually insufficient or entirely absent which produces subpar infrastructure capability for rural growth (Magolie, 2024). However, the DRT systems in rural areas have failed to maintain financial stability as their main operational challenge. DRT systems were designed to cost less than public transportation, but the actual monetary gains are normally insufficient to cover operational expenses (Briceño-Garmendia et al., 2009). With low and unreliable rider numbers in rural areas, the fare-based revenue is inadequate to sustain the ongoing operations of the service.

4.2 Geographic and Economic Isolation of Rural Areas

Rural locations frequently exist in distant regions limiting their ability to obtain private investments. Lower population density, together with small markets in rural areas, reduces private firms' motivation to construct transport infrastructure (Hauya, F.K., 2019). Rural populations spread thinly across the land create challenges to building public transport networks because insufficient ridership numbers fail to match viability requirements.

4.3 Political and Institutional Challenges

Political mirrors, together with other factors, drive the limited growth of rural road networks. Rural regions throughout numerous nations typically receive little favours from political forces because these areas lack sufficient political power, so infrastructure development suffers as a result (Nelson, 2017). The combination of deficient institutional structures with weak governance practices and corrupt practices stops funds from reaching their intended purpose which blocks rural road development and upkeep.

5 ALTERNATIVE SOLUTIONS AND PILOT PROJECTS

Several pilot and alternative solutions across the globe were tested to overcome the perennial challenges that beset road infrastructure. These ranged from increasing road access to rural areas and other neglected niches to cutting down transportation costs and enhancing their overall quality. Many such pilot projects, therefore, focus on learning from possible ways to overcome the limitations that have traditionally dogged infrastructure development by venturing on innovative paths such as Demand- Responsive Transport, community-driven projects, Non-Motorized Transport Infrastructure, public-private partnerships and other sustainable construction methods. Therefore, this section investigates some of these initiatives.

5.1 Demand-Responsive Transport (DRT) Systems

The problem of low rural population density makes Demand-Responsive Transport systems (DRT) stand out as a flexible and budget-friendly answer. The transportation system operates using small vehicles including minibuses and shared taxis which adapt their operations based on immediate passenger requests instead of using predetermined schedules (Bacior and Prus, 2018). DRT systems provide suitable solutions for rural areas because they can operate efficiently based on inconsistent ridership patterns and the density of populations that do not support mass public transportation (Junaid and Ferretti, 2022). DRT pilot initiatives implemented in South Africa and Kenya have proven that these systems work effectively in rural areas, thus providing expanded mobility solutions to rural inhabitants.

5.2 Community-Based Transport Systems

Transport systems that rely on community management offer solutions for rural transport deficiencies. Local communities oversee systems that use minibuses, tuk-tuks, and local shuttle services for community management (Chondo, 2021). These transport systems use local insights and resources to provide rural populations with flexible but inexpensive modes of transport. Local community-based transport solutions in Tanzania and Uganda clarify that both community stakeholders and system administrators need active support from national administrators for centralized transport control to succeed (Rwigema, 2022)

5.3 Non-Motorized Transport Infrastructure

Basic walking and cycling infrastructure development constitutes an economical sustainability method for rural transportation systems. Public transport shortages lead people to choose non-motorized transport solutions to move over short distances. Rural pilot projects have installed bicycle-sharing schemes while

building pedestrian-friendly roads to increase mobility between essential services such as educational facilities and healthcare facilities.

5.4 Public-Private Partnerships

The development of rural road infrastructure receives major benefits through Public-Private Partnership (PPP) initiatives. Private investments in public programs create benefits that let governments strengthen rural roadway development programs and maintenance systems (Nallathiga, 2022). Public-private partnerships have become extensively successful in Latin America and numerous African regions through their improvements of road infrastructure and public transit systems (Kang et al., 2019). The framework elements established by rural stakeholder partnerships must include proper restrictions to ensure better services and access delivery to rural communities.

6 EFFECTIVENESS OF PILOT PROJECTS IN RURAL AREAS

Implementing pilot projects seeking rural transport improvements in developing countries has resulted in multiple outcomes, with some succeeding and others facing challenges. Two notable transport systems, Kenya's DRT system and Tanzania's shared minibus services, receive recognition because they solve problems of rural communities regarding mobility restrictions, market accessibility, and economic separation (Karema, 2021). The implemented projects activated wider access to vital public services, including healthcare facilities, medical care educational establishments and employment benefits. The transport system has produced money-making possibilities by employing drivers alongside conductors and other technical staff, which supports the local economy (Karema, 2019).

The initiatives encounter substantial barriers while trying to sustain their operations and make them scalable (Jackson, 2022). Most pilot projects survive through temporary grants and donor funding but face continued operation challenges after the external support ends. These services risk becoming unsustainable because they lack proper funding strategies and weak financial management systems. When a pilot project succeeds in a particular geographic area, expansion to new regions demands a successful resolution of logistical difficulties that include building necessary infrastructure and purchasing equipment (Siemens, 2010). Rural regions heavily depend on transportation systems that exist beyond official planning systems, including motorbike taxis and private vehicles. A new system should merge with informal networks yet maintain affordability to serve the rural population. The design of minibuses and DRT systems should focus on serving rural communities because their mobility patterns diverge substantially from urban areas (Bacior and Prus, 2018).

7 COMMUNITY INVOLVEMENT IN TRANSPORT PLANNING

Various experts claim that rural transport infrastructure failed due to the absence of rural community participation during planning decisions (Hauya, 2019). Rural populations receive inadequate participation in transport project planning steps, which leads to their development without proper consultation. When communities are not involved in the decision-making process, the infrastructure does not fulfil genuine rural needs; therefore, adoption levels decrease, and services become ineffective.

The complete involvement of local communities proves essential to creating transport solutions that fit population requirements, sustain them over time, and earn their acceptance (Roseland, 2012). Community participation in rural transport system planning and management demonstrated its effectiveness based on Ugandan and Ghanaian pilot experience. Transport system delivery becomes more successful through community involvement because people help shape services according to regional requirements while developing community ownership and commitment to lasting outcomes.

8 METHODOLOGY

This research investigates literature development through bibliometric review based on academic data from web of science databases. The research depends on organized methodologies for collecting data that involves both analysis of networks and data processing to reveal details about road infrastructure academic work (Donthu et al., 2021).

The authors starts by doing a database search for academic articles through Web of Science. The field identification uses multiple keywords that include "road infrastructure," "rural development," "transport

challenges," and "public transport." The data processing stage involves cleaning irrelevant items such as editorials and book reviews and non-academic articles after obtaining relevant article lists. The final collection includes 1496 publications. The noted bibliometric elements containing titles and authors and citations and keywords become eligible for subsequent research analysis.

The author uses VOSviewer for network visualization to show interactions between authors and publications and research themes. The software platform enables researchers to detect network patterns for co-authored, co-occurrences and co-citation networks and their spatial connections. Study findings revealed core aspects that appeared multiple times in these academic papers as well as key figures in the field of transportation.

9 PRESENTATION OF RESULTS

This section will present the findings of the study.

9.1 Publication and Citation Trend

The bibliometric review regarding road infrastructure and rural mobility grows more important due to its rising significance for developing areas. The scholarly interest during 1993 to 2013 rose significantly which led to higher publication rates and increased citations because research became theoretically grounded and interdisciplinary relevant. Overall expansion in the research field occurred despite temporarily fluctuating publication numbers between 2014 and 2019 because of changing priorities and novel transportation trends. 2020 marked the revival of rising trends that could have been triggered by extended research periods created by the COVID-19 pandemic. The steady increase in research citations demonstrates wider adoption of rural mobility findings by policymakers for developing transportation policies and resolving economic and sustainability problems. Road access plays an essential role in delivering linkages between rural settlements and enhances their economic bases while enhancing the standard of living for citizens in underdeveloped regions.

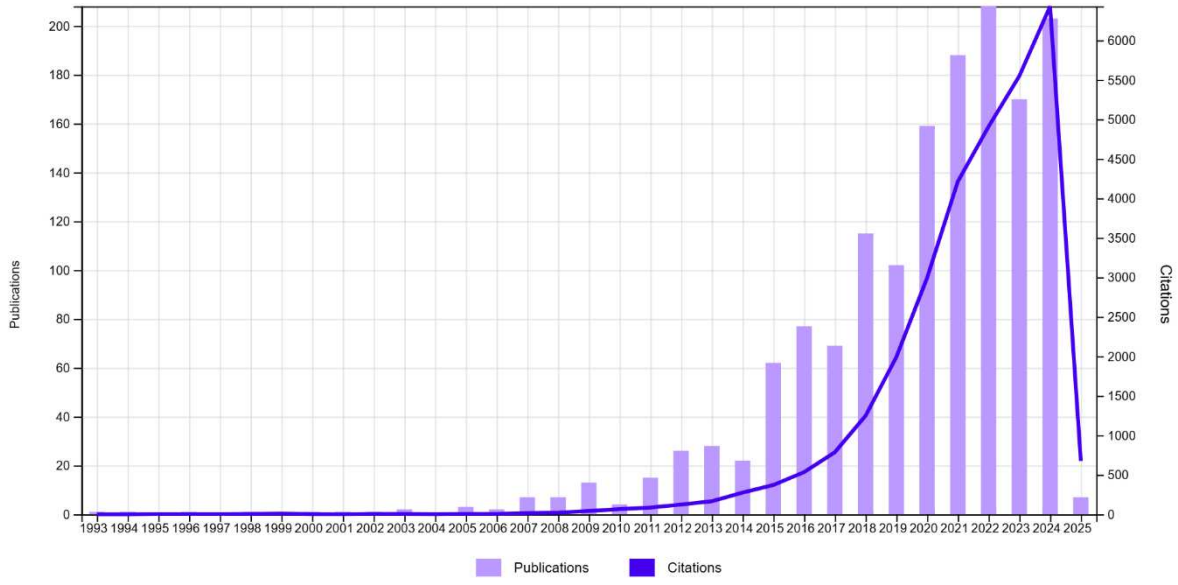

Figure 1: Publication and citation trend

9.2 Author Co-citation Analysis

The authors also focused on co-citation analysis to establish key research directions and contributions of the main authors in the field by the authors. Understanding the intellectual structure of knowledge demands the evaluation of influential authors and their network connections in this field (Song, Wu & Ma, 2021). The authors performed their analysis through co-citation methods while analysing cited authors as the basic units. The authors chose a minimum number of citations in this study of 5. The research included 1694 authors while meeting the criterion of 60 publications minimum. The obtained results present different levels of academic influence together with network connections between authors.

Research within the framework of co-citation network analysis is outlined into separate research clusters which correspond to rural road infrastructure and development topics studied in this paper. Studies on rural

transport accessibility challenges to marginalized communities are represented by the red cluster, which centres on De Vos and Ettema, along with additional authors. Research pertaining to transport planning and behavioural studies by Bamberg alongside Axhausen appears in the green cluster. Researchers Currie and Hickman operate within the blue cluster that investigates public transportation viability in low-density rural areas to address threshold density issues directly. Research on rural region economic development following infrastructure investment is represented by the studies conducted by Guzman and Borjesson who make up the purple cluster. Through this interpretation, the paper gains access to multiple intellectual structures, which enables it to conduct an all-encompassing analysis of rural road infrastructure betterment and development needs. These research fronts found in these clusters provide essential knowledge about community transportation solutions as well as community participation which help solve fundamental problems in the paper. This paper merges various theoretical approaches to advance a sophisticated comprehension of rural development challenges that can offer specific policy recommendations for sustainability.

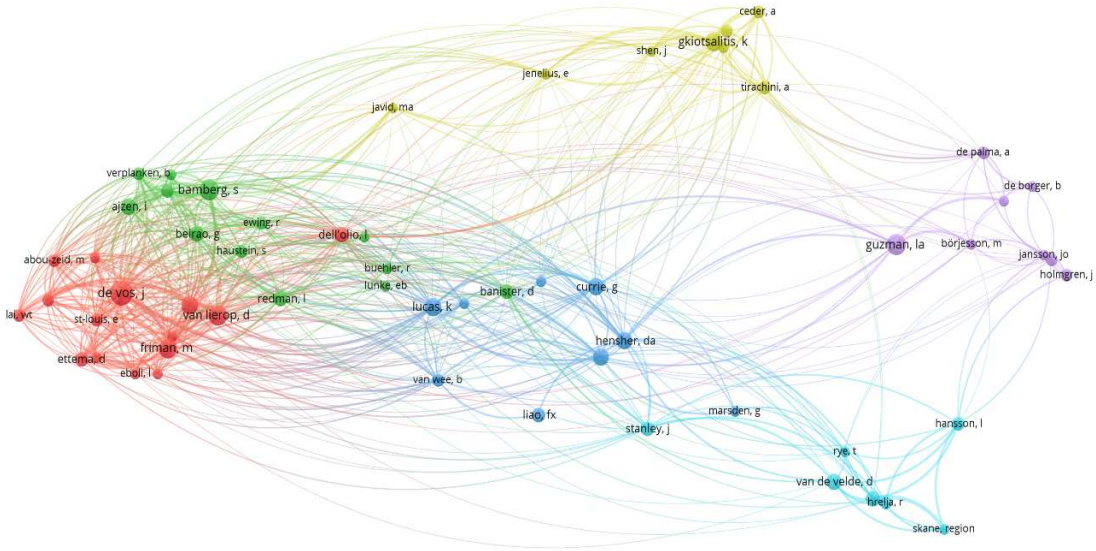

Figure 2: Author Co-citation Analysis

9.3 Co-citation of documents

Publication nodes possess a colour marking which identifies their assigned cluster affiliation, as indicated in Figure 3, which indicates the co-citation of document references. VOS viewer analysis shows that publications sharing identical colours in the network are co-cited frequently because they research related topics. VOS viewer implements computational methods to separate network items by analyzing how often they co-cite each other. The seven publications in Cluster 1 include AJZEN I, de Oña J, Dell'Olio I, Lai, W T, St-Louis E, Van Lierop D, and Ye, R. Cluster 2 features five publications with Beirão G, Ewing R, Lucas K, Redman I and Steg I. Cluster 3 comprises of three publications with Bamberg S, Shen J and Tirachini A.

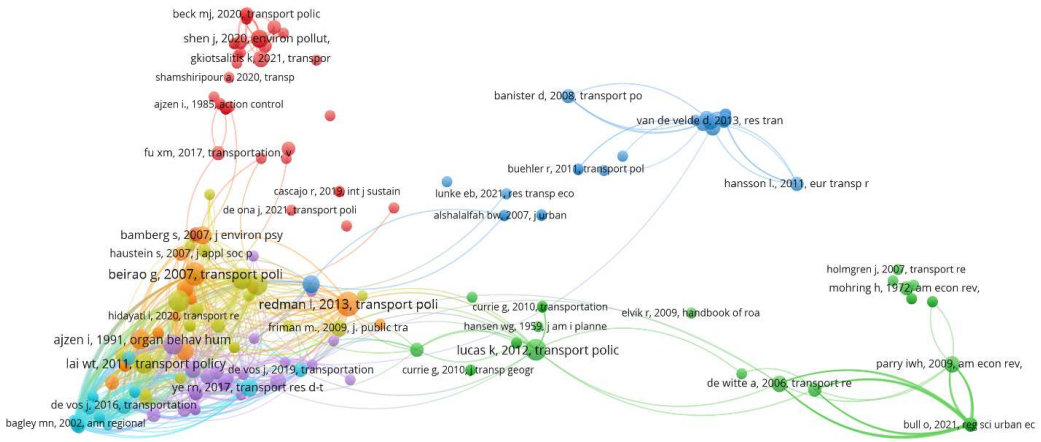

Figure 3: Co-citation of documents references

The co- document network analysis shows intellectual structures in the provided table that focus on public transport and travel behaviour within the rural road infrastructure development context of the paper. The total link strength between Beirão and Cabral (2007) and De Oña et al. (2013) indicates strong focus on investigating public transport attitudes and service quality perceptions because these elements are essential for addressing rural public transport challenges. Research from Van Lierop et al. (2018) and Dell'Olio et al. (2011) demonstrates how public transport service quality, together with the customer satisfaction factors, strongly influences public transport usage behaviour as well as addresses low threshold density problems. Research on behavioural intentions (Lai & Chen, 2011) and travel behaviour (Ye & Titheridge, 2017; Steg, 2005) offers valuable insights into how people make decisions because this knowledge is essential for developing suitable transport answers in rural areas. The paper reinforces its argument about rural population marginalization through an examination of social exclusion (Lucas, 2012) as well as the COVID-19 effects on public transportation systems (Shen et al., 2020). Therefore, the paper demonstrates its ability to utilize these theoretical frameworks to study the complex rural road infrastructure problems and develop solutions that evaluate user conduct together with wider economic effects. Such a combination of research areas within the paper will enable a wide-ranging examination of the issue followed by specific sustainability-oriented policies for rural development.

9.4 Country collaboration analysis

Extended research on road infrastructure along with rural mobility development makes Sweden and England the leading powers in transportation studies as developed countries. The scholarly research reveals that Sweden has 10 documents and 192 citations and a total link strength of 14, following Canadian research composed of 4 documents with 460 citations and a total link strength of 12. The Netherlands became third with 7 documents, 376 citations and a total link strength of 11. There are 9 documents in England with a total of 155 citations and a link strength measurement of 8. Norway ranks fifth with 4 documents that accumulate 156 citations, while the total ink strength reaches 7.

The country collaboration network traces its primary connections to European countries which include Sweden together with Germany and Belgium along with the Netherlands. This intellectual framework demonstrates proven research connections among European nations that focus on transportation development regarding infrastructure development. The strong partnership among these countries demonstrates their mutual dedication to solving transportation problems which may include the rural road infrastructure issues evaluated in the paper. This international interest in the field extends beyond Europe since researchers from

Canada and Australia and China maintain relationships with their European counterparts. The paper would enhance its findings by studying European rural road infrastructure through case studies and policy analysis because these nations potentially achieved more sophisticated or delicate approaches in this field. The research demonstrates gaps in partnership alongside knowledge exchange with developing nations through its emphasis on European entities. The paper could enhance its value by studying and reporting regional linkages and knowledge transfer activities with developing world entities dealing with rural road infrastructure problems. Such an expanded knowledge base would enable better solutions that fit the specific requirements of developing nations.

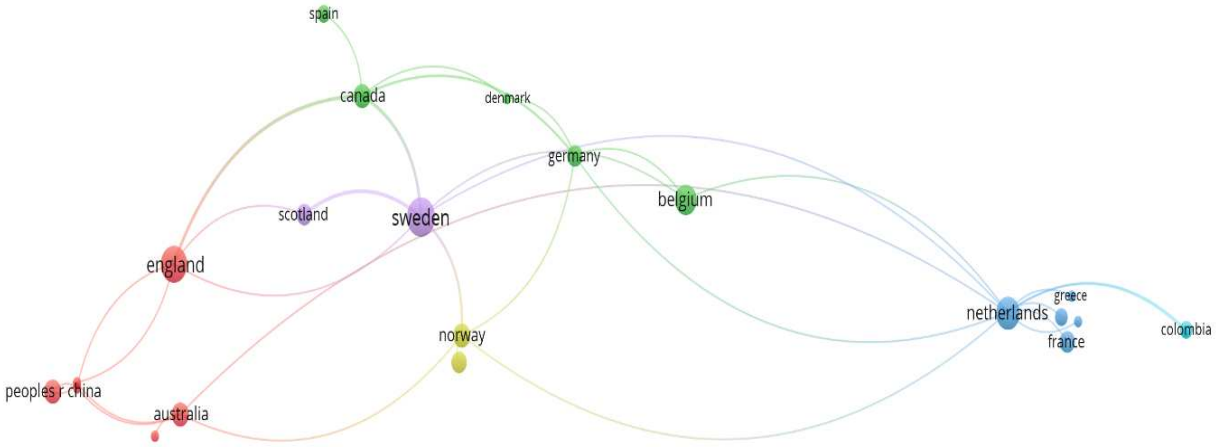

Figure 4: Country collaboration analysis

10 CONCLUSION

The poor condition of rural roads functions as an enormous obstacle for both mobility and regional economic expansion throughout rural developing regions. The lack of investment in construction and maintenance, poor connectivity to national and regional networks, and the absence of proper infrastructure for collective public transport all contribute to the isolation of rural populations. The effectiveness of alternative solutions like Demand-Responsive Transport and community-based systems and non-motorized transport infrastructure for rural areas depends on their local conditions as well as sustainability and proper implementation standards.

Rural testing projects achieve modest results but these initiatives do not deliver broad effects across many locations because services receive insufficient funding and designers fail to develop sound plans while rural inhabitants remain outside implementation stages. Community involvement at every stage of rural transport project planning and execution determines the success of new transport initiatives. Project design that includes rural populations from the start leads to better results in improving rural accessibility along with mobility options and communitywide development progress.

11 RECOMMENDATIONS

The recommendations for this study are discussed below.

11.1 Integrated Rural Transport Infrastructure Investment

National and regional budgets must establish highway development and restoration for rural areas as their top expenditure priority. The budget should contain designated funds for rural road maintenance which both maintains their condition and extends their longevity. The use of materials and technologies that demonstrate resistance to climate change should be applied during road building activities to minimize environmental threats. Local communities should take part in road condition monitoring alongside reporting activities to establish local ownership allowing timely response interventions.

11.2 Capacity Building and Technical Assistance for Local Transport Stakeholders

The government should invest resources toward establishing local expertise for proper rural transport system planning and management operations.A training program should be created to improve local government abilities alongside transport operator and community knowledge in transport planning with additional skills

in management and maintenance. Platform development aimed at distributing rural transport best practices to local situations while finding purposes of localized adaptations. Technical support should assist governmental entities by helping them deploy and expand observed prototype programs especially in data gathering and budget control operations.

DOI: 10.48494/REALCORP2025.1036

1 ABSTRACT

An important sector that contributes significantly towards climate change and global warming is the building sector. Buildings account for 30–40% of global final energy consumption [1] and nearly 40% of the global CO_2 emissions. In the last decade, policies such as the Directive on Energy Performance of Buildings (EPBD) have been introduced to address this issue, aiming to decarbonize the building stock by 2050 and to reach nearly zero energy buildings (NZEBs) [2].

The 2015 Paris Agreement has put more emphasis on international efforts to reduce CO_2 emissions, where urban areas with a 70% share of global emissions have a key role. Accordingly, the United Nations (UN) Sustainable Development Goals include as goal 11 "sustainable cities and communities" with the aim of supporting the transition towards low-carbon cities, in a general framework which also points towards, e.g., climate action, affordability, and clean energy. In 2015, when the Paris agreement was signed, the EU planned to move further ahead and reduce greenhouse gas emissions by 40% by 2030.

In order to tackle this challenge and to lead the global energy transition, the EU Commission proposed in 2016 a set of new and ambitious rules known as the Clean Energy Package for all Europeans [1]. Therefore, to reach the emission reduction goals it is important to focus both at the energy systems level and at the buildings or district level. At a global level, the need for energy efficiency and an increased share of renewable energy sources is evident, as is the crucial role of cities due to the rapid urbanization rate. As a consequence of this, the research work related to Positive Energy Districts (PED) has accelerated in recent years.

This paper is based on work in a 4 years research on positive energy districts (PED), the planning and implementation of them in various markets. It summarizes the findings on replication potential of the concept. First, the concept is explained and the key performance factors are discussed. Then, it analyses almost 100 PED projects that were collected during the research duration. The PED examples were classified into 3 categories and spread in different climatic, social, and political systems. Finally, the key success factors were derived from this analysis and the findings are highlighted in best practices. By addressing these aspects comprehensively, PEDs can create more sustainable, resilient, and equitable communities that are well-prepared for the challenges of the 21st century. They move beyond simply generating clean energy to fostering a holistic transformation of how we live and interact with our environment.

Keywords: Planning, districts, energy, positive, PED

2 INTRODUCTION

The systematic use of data, the collection of information about enabling factors, barriers and frameworks (regulatory and governmental) are fundamental to supporting the planning of urban interventions towards climate-neutral transition of our cities. Tackling the challenges of climate neutrality at an urban level, the European Commission set out the SET Plan 3.2. which contained several ambitions – i.e. 100 pioneer zero-emissions cities by 2030 [1] and 100 pilot PEDs by 2025 [2] by focusing on implementation and testing of solutions on district-scale and in an efficient, resilient and climate-neutral manner.

In this perspective, there are several international research activities ongoing that try to collect these ambitions, e.g. COST Action (CA) 'PED-EU-NET' [3] in connection with further international initiatives working on PEDs concept; PED initiative, coordinated by JPI UE [4], aims to develop 'Positive Energy Districts and Neighborhoods for Sustainable Urban Development'; 'IEA EBC Annex 83 – Positive Energy Districts' coordinated by IEA EBC [5] – with the aim of mapping PED relevant experiences and collecting key parameters to characterize these districts and support their uptake around Europe and beyond; the European Energy Research Alliance Joint Program on Smart Cities (EERA JPSC) [https://www.eera-sc.eu/],

whose mission is to contribute to research and innovation in smart cities by promoting actions, at building, district and city level, that facilitate the transformation of the European built environment towards climate neutrality. In this process, a PED Database (PED DB) (https://pedeu.net/map/) is the outcome of this collaborative research.

2.1 PED database

Studies highlight the need for integrated approaches to planning green, healthy, efficient, livable, and resilient districts, aligning with local plans and addressing stakeholder needs [6-10]. Existing tools for characterizing Positive Energy Districts (PEDs) are limited. JPI Urbana Europe's PED Booklet [11] categorizes PEDs as “Projects” (achieving positive energy balance) or “Towards Projects” (adopting innovative solutions). Zhang et al. [12] analyzed these cases, developing a matrix for comparing PED models and defining archetypes. Soutullo et al. [13] mapped PED Labs, identifying strengths, weaknesses, opportunities, and threats through SWOT analysis, emphasizing real-world testing for replicability.

Focusing on Energy Communities (ECs), similar to PEDs [26, 27], the European Commission's JRC [28, 29] reported on 24 communities [30] and is developing an "Energy Communities Repository" [31, 32] with detailed case studies. These resources inform the conceptualization of a PED database. Further PED research includes cataloguing: (1) technologies and solutions [15-17], (2) financing and business models [18, 19], (3) social and community engagement tools [20, 21], and (4) Key Performance Indicators (KPIs) for impact monitoring [22-25].

Several international initiatives promote efficient urbanization and sustainable urban development, including the EU's Strategic Energy Technology (SET) Plan [4], which inspired the goal of deploying 100 Positive Energy Districts (PEDs) in Europe by 2025. A recent publication (Haase et al. 2025) lists initiatives collaborating on a 'PED Database'. Key promoters include COST Action "PED-EU-NET", JPI Urban Europe, IEA EBC Annex 83, and EERA JP Smart Cities. The PED database aims to map, filter, sort, and compare PED experiences, providing an overview of technological and non-technological solutions in various PED projects and case studies. This collaborative effort led to the PED Database, with international PED projects listed in Haase et al.’s recent publication (Clima paper).

The International Energy Agency (IEA) Annexes are collaborative Research and Development (R&D) projects under the IEA's Technology Collaboration Programmes (TCPs). These structured frameworks address specific energy challenges or opportunities, such as renewable energy, energy efficiency, or urban energy systems.

This paper focuses on the crucial internationalization of the PED model by comparing it with other community or district-scale transformation projects. Building on previous research, the PED DB disseminates PED practices via a comprehensive tool which aggregates case studies, projects, solutions, KPIs, policies, and strategies. This supports large-scale development of innovative pilot districts, both new and renovated. This international perspective is essential to identify challenges and key success factors for PED planning and implementation.

3 METHODOLOGY

For this desktop research 98 PEDs from 33 projects were analysed. Fig.1 illustrates the life cycle stages of the PEDs. Among the 98 PEDs recorded in the PED database [7], 40 are in the planning phase, 22 are under implementation, 18 have been completed, and 18 are in operation. Of these, 42 are classified as PED case studies, 18 as PED Labs, and 38 as PED-relevant case studies (see Fig.2).

The database evaluates the effectiveness of strategies and solutions in mapped Positive Energy District (PED) case studies. It is dynamically updatable with new sources and ontologies, maintaining relevance and utility as projects evolve, and enabling the generation of archetypes or "library concepts" for scenario evaluations.

The methodology used to structure the PED database fostered data field harmonization and standardization, resulting in a glossary that ensures PED data interoperability across systems. Detailed case analysis, based on project experiences and insights from PED publications and the EU Energy Community, facilitated the identification of core components, facilitating elements, challenges, and barriers.

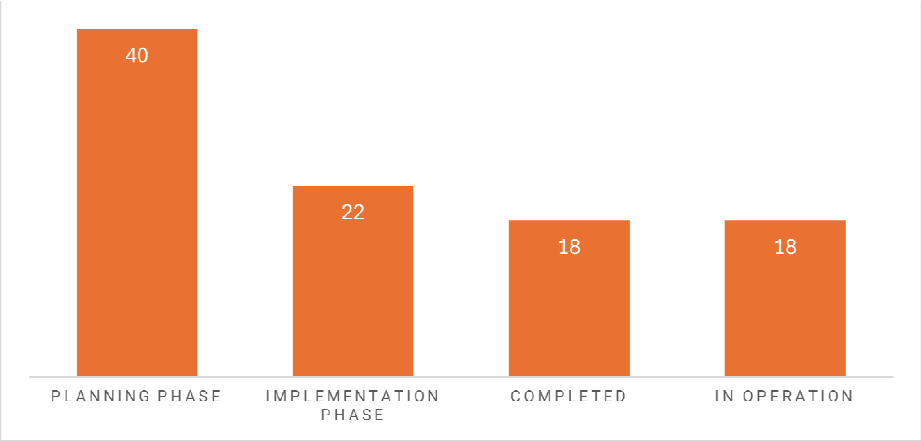

Fig. 1: PEDs from PED database [7].

By capturing detailed parameters and in-depth information, the database provides PED stakeholders with a comprehensive view of prior projects. This comprehensive approach supports the replication of effective practices in future initiatives, as it offers significant insights for deeper PED analysis.

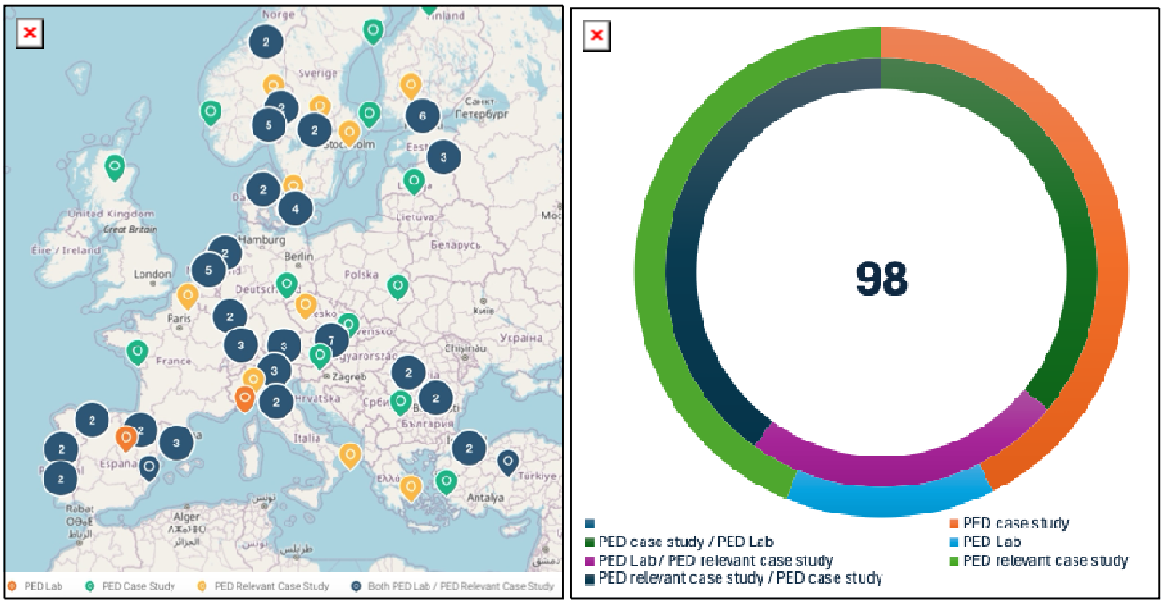

Fig. 2: PED case studies, PED relevant case studies and PED Labs in the PED database (status: Dec 2024).

4 RESULTS

Building on existing frameworks like the Annexes on energy-efficient communities, computational tools, and low-carbon heating, this initiative aims to standardize definitions and develop planning solutions. It collaborates with projects such as the EU Smart Cities Information System, Horizon 2020, and JPI Urban Europe. Annex 83 provides guidance on urban planning, impact assessments, and the economic and social implications of Positive Energy Districts (PEDs). As Annex 83 is ongoing, an evaluation framework is still in development. This framework supports cities, policymakers, and researchers in transitioning to carbon-neutral urban environments, contributing to global energy transition and sustainability goals. Annex 83 partnered with PED EU NET and Urban Europe for the PED DATABASE [26].

The PED database offers comprehensive information on new and refurbished urban environments designed to produce more energy than they consume. Its modular design and online platform enable data, in the form of PED Key Performance Indicators (KPIs), to be sourced from reliable and verified information. Developed through a database development life cycle (DDLC), it began with a scoping phase defining requirements for data collection from demo cases. Following a testing phase, the main conclusions are:

(1) There is no one-fits-all solution for PED implementation. Overall PED framework definitions require further detailing in the local context [27]. The PED Database provides an overview of not only different implementation strategies but also existing different conceptualizations and approaches for the PED concept.

(2) PEDs are still a relatively new concept, but they are gaining traction around the world. As PEDs become more popular, they are likely to play an increasingly important role in the global transition to a clean and sustainable energy future. Overall, PEDs offer a number of advantages over building-level and city-level approaches to sustainable development [28].

(3) PEDs take a holistic approach that considers the needs of the entire community [29].

4.1 PED implementation

Creating a PED is not simply a technical exercise but a complex socio-technical undertaking that requires a holistic and context-specific approach. The PED Database recognizes this diversity and aims to provide a platform for sharing knowledge and experiences across different projects and contexts, enabling stakeholders to learn from each other and adapt best practices to their own unique circumstances. With regard to diverse local contexts these aresummarized in Table 1, while Table 2 provides on averview of varied conceptualizations and approaches and Table 3 summarises the dynamic and evolving nature of PEDs.

Climate	A PED in a hot, sunny climate will have vastly different strategies for achieving positive energy balance compared to one in a cold, cloudy climate. Solar potential, heating/cooling needs, and building design will vary significantly.
Urban Form and Density	Densely populated urban areas may rely on district-level energy solutions and innovative building integration, while suburban or rural PEDs might focus on individual building generation and microgrids.
Existing Infrastructure	The availability and condition of existing energy infrastructure (grids, heating/cooling networks) will influence the feasibility and cost-effectiveness of different PED solutions.
Resources and Industry	Local availability of renewable energy resources (solar, wind, geothermal, biomass) and industrial capabilities will shape the choice of technologies and strategies.
Socioeconomic Factors	Community demographics, energy affordability, and local priorities will influence the acceptance and implementation of PED projects.

Table 1: PED implemantion results with regard to diverse local contexts

Definition of “Positive Energy”	The precise definition of "positive energy" can vary. Some PEDs might aim for net-zero energy annually, while others might focus on specific energy carriers or consider embodied energy.
Scope of the District	The scale of a PED can range from a single building to a neighborhood or even a larger district, each with its own set of challenges and opportunities.
Technology Choices	The mix of renewable energy technologies, energy storage solutions, and energy efficiency measures will depend on the local context and the specific goals of the PED.
Governance and Ownership	PED projects can involve a range of stakeholders, including public authorities, private developers, energy utilities, and community members, each with their own interests and priorities.

Table 2: PED implemantion results with regard to varied conceptualizations and approaches

Technological Advancements	Rapid innovation in renewable energy, energy storage, and smart grid technologies means that PED solutions need to be adaptable and future-proof.
Policy and Regulatory Landscape	Changes in energy policies, regulations, and incentives can significantly impact the feasibility and economic viability of PED projects.
Data and Monitoring	Effective PED implementation requires robust data collection and monitoring to track performance, identify areas for improvement, and adapt strategies over time.

Table 3: PED implemantion results with regard to dynamic and evolving nature of PEDs

4.2 PED concept

Positive Energy Districts (PEDs), while still a relatively new concept, are gaining global momentum and are poised to play a crucial role in the transition to a clean and sustainable energy future. PEDs also offer advantages over building-level and city-level approaches to sustainable development. Table 4 summarises the PED concept results with regard to gaining traction and importantance, Table 5 focuses on advantages of PEDs over Building-Level approaches and Table 6 focuses on advantages of PEDs over City-Level approaches.

Addressing Climate Change	PEDs directly contribute to reducing greenhouse gas emissions by promoting renewable energy generation and energy efficiency at a district level. This aligns with global efforts to combat climate change.
Energy Security and Independence	By generating energy locally, PEDs can reduce reliance on fossil fuels and centralized energy systems, enhancing energy security and independence for communities and nations.
Sustainable Urban Development	PEDs offer a framework for sustainable urban development by integrating energy considerations into planning and design at the district level, leading to more livable and resource-efficient communities.
Economic Benefits	PEDs can stimulate local economies by creating jobs in renewable energy, energy efficiency, and related sectors. They can also reduce energy costs for residents and businesses.
Social Benefits	PEDs can foster community engagement and ownership in the energy transition, promoting social equity and inclusivity.

Table 4: PED concept results with regard to gaining traction and importantance

Economies of Scale	PEDs can achieve economies of scale by implementing energy solutions at a district level, such as shared renewable energy systems, district heating and cooling networks, and smart grids. This can lead to lower costs and greater efficiency compared to individual buildings trying to achieve positive energy balance on their own.
Integrated Planning and Design	PEDs allow for integrated planning and design of energy systems and infrastructure across multiple buildings and land uses, optimizing energy performance and resource utilization.
Flexibility and Resilience	PEDs can create more flexible and resilient energy systems by diversifying energy sources, incorporating energy storage, and enabling peer-to-peer energy trading within the district.

Table 5: PED concept results with regard to advantages of PEDs over Building-Level approaches

Granularity and Focus	PEDs provide a more granular and focused approach to sustainable development compared to city-level initiatives. They allow for tailored solutions that address the specific needs and characteristics of different districts within a city.
Measurable Impact	PEDs make it easier to measure and track progress towards sustainability goals at a district level, providing valuable data and feedback for adaptive management.
Scalability and Replicability	Successful PED projects can serve as models for replication and scaling up to other districts and cities, accelerating the transition to a sustainable energy future.

Table 6: PED concept results with regard to advantages of PEDs over City-Level approaches

4.3 PED approach

Social Equity and Inclusion	PEDs aim to benefit everyone in the community, not just a select few. This means considering factors like affordability of energy, access to clean energy solutions, and potential impacts on vulnerable populations.
Environmental Justice	A holistic approach addresses potential environmental injustices by ensuring that PEDs do not disproportionately burden certain communities with pollution or negative environmental impacts.
Community Ownership and Engagement	Successful PEDs often involve active participation and ownership from community members. This ensures that the projects align with local needs, values, and priorities, fostering long-term support and sustainability.

Table 7: PED approach results with regard to beyond technology

Energy Systems and Infrastructure	PEDs require integrated planning and design of energy systems, including renewable energy generation, energy storage, distribution networks, and smart grids. A holistic approach optimizes these systems for efficiency, reliability, and resilience.
Built Environment and Urban Planning	PEDs consider the built environment as a whole, including building design, energy efficiency measures, land use planning, transportation, and green spaces. This integrated perspective maximizes energy performance and creates more sustainable and livable communities.
Economic Development and Job Creation	PEDs can stimulate local economies by creating jobs in renewable energy, energy efficiency, and related sectors. A holistic approach considers these economic opportunities and ensures that they benefit the entire community.

Table 8: PED approach results with regard to integrate multiple dimensions

PEDs represent a strategic middle ground between individual building efforts and broader city-level plans. They offer a tangible and manageable scale for implementing integrated energy solutions, maximizing benefits while minimizing complexity. It emphasizes a key characteristic of Positive Energy Districts (PEDs) why they are designed in a holistic way. Table 7 summarises the PED approach results with regard to beyond technology, Table 8 focuses on integrate multiple dimensions and Table 9 focuses on long-term sustainability.

Resource Efficiency	PEDs strive to minimize resource consumption and waste generation through strategies like circular economy principles, efficient use of water and materials, and sustainable waste management practices.
Resilience to Climate Change	A holistic approach considers the potential impacts of climate change, such as extreme weather events, and designs PEDs to be resilient and adaptable.
Behavioral Change and Awareness	PEDs often incorporate initiatives to raise awareness about energy consumption and promote sustainable behaviors among community members.

Table 9: PED approach results with regard to long-term sustainability

5 DISCUSSION

The holistic approach to PEDs (Positive Energy Districts) mentioned in the resutls (Table 1 – 9) focus on resource efficiency, resilience to climate change, and behavioral change and awareness:

PED and Resource Efficiency:

- Minimizing Consumption: PEDs prioritize reducing the overall consumption of resources, including energy, water, and materials. This involves strategies like energy efficiency in buildings, promoting sustainable transportation, and reducing waste generation.
- Circular Economy Principles: PEDs can incorporate circular economy principles by designing buildings for disassembly and reuse, using recycled and sustainable materials, and minimizing waste through composting and recycling programs.
- Efficient Resource Management: Smart technologies and data analytics can optimize resource management in PEDs. For example, smart grids can improve energy distribution and reduce losses, while smart water meters can help conserve water.
- Life Cycle Assessment: PEDs can benefit from life cycle assessments that evaluate the environmental impacts of materials and processes throughout their entire life cycle, from extraction to disposal. This helps identify opportunities for resource efficiency improvements.

PED and resilience to Climate Change:

- Risk Assessment and Adaptation: PEDs should conduct thorough risk assessments to identify potential climate change impacts, such as increased temperatures, extreme weather events, and sea-level rise. Based on these assessments, they can develop adaptation strategies to enhance resilience.
- Diversification of Energy Sources: PEDs can diversify their energy sources to reduce reliance on any single technology or fuel. This can include a mix of solar, wind, geothermal, biomass, and other renewable energy options.
- Decentralized Energy Systems: Decentralized energy systems in PEDs can enhance resilience by reducing vulnerability to disruptions in centralized grids. Microgrids and distributed energy resources can provide backup power during emergencies.
- Green Infrastructure: Integrating green infrastructure, such as green roofs, permeable pavements, and urban forests, can help mitigate the impacts of climate change by reducing urban heat island effect, managing stormwater runoff, and improving air quality.

PED and behavioral change and awareness:

- Education and Outreach: PEDs can implement education and outreach programs to raise awareness about energy consumption, climate change, and sustainable practices. This can involve workshops, community events, and online resources.

- Incentives and Rewards: PEDs can offer incentives and rewards for residents and businesses that adopt sustainable behaviors, such as energy conservation, waste reduction, and use of public transportation.
- Citizen Engagement and Participation: Engaging citizens in the planning and implementation of PED projects can foster a sense of ownership and encourage behavior change. Participatory processes can empower communities to take an active role in the transition to a sustainable future.
- Data Transparency and Feedback: Providing residents with transparent data on their energy consumption and environmental impact can motivate them to adopt more sustainable behaviors. Smart meters and energy management platforms can provide valuable feedback and enable real-time monitoring.

6 CONCLUSION

In conclusion, creating a PED is not simply a technical exercise but a complex socio-technical undertaking that requires a holistic and context-specific approach. The PED Database recognizes this diversity and aims to provide a platform for sharing knowledge and experiences across different projects and contexts, enabling stakeholders to learn from each other and adapt best practices to their own unique circumstances.

We found that a holistic approach to PEDs recognizes that energy is not just a technical issue but is deeply intertwined with social, economic, and environmental dimensions. By considering the needs of the entire community and integrating multiple perspectives, PEDs can achieve greater sustainability, resilience, and social equity. This comprehensive view is what distinguishes PEDs from more narrow, technology-focused approaches to sustainable development.

Further, PEDs represent a strategic middle ground between individual building efforts and broader city-level plans. They offer a tangible and manageable scale for implementing integrated energy solutions, maximizing benefits while minimizing complexity.

By addressing these aspects comprehensively, PEDs can create more sustainable, resilient, and equitable communities that are well-prepared for the challenges of the 21st century. They move beyond simply generating clean energy to fostering a holistic transformation of how we live and interact with our environment.

Regarding replication potential we can state that community-centricity can be both a challenge and an opportunity for replication. Because PEDs are designed to meet the specific needs of a community, a direct, cookie-cutter replication might be difficult. Each community has unique characteristics (climate, resources, social structures, etc.) that will influence the PED design. However, the principles of community engagement and a holistic approach are replicable. The process of understanding community needs and tailoring solutions can be replicated even if the specific technologies or designs are different.

Further, the holistic approach suggests a framework that can be adapted. While the specifics will vary, the idea of integrating various aspects (energy, social, economic, environmental) into a PED project provides a replicable framework. Other communities can adopt this integrated planning approach, even if the details of their PEDs are different.

The focus on community needs implies scalability through modularity. If PEDs are designed with a modular approach, where smaller units can be combined or adapted, this improves the potential for scaling up successful elements. This modularity could be replicated in other communities, even if the overall scale of the project is different.

Replication of PED is possible, but it will likely involve adapting the core principles and framework rather than simply copying a PED design from one location to another. The process of community-centered design is replicable; the specific solutions will likely need to be tailored. Information on the availability of resources and technologies needed for PEDs can be found in the PED database. Replication depends on access to necessary resources. To understand the true replication potential, more information is needed, such as:

- Case studies of successful PEDs and attempts at replication. These would provide concrete examples of successful implementation We gathered this information where we could, but more work is needed to better understand what worked and what didn't and why

- Analysis of the costs and benefits of PEDs in different contexts. Economic viability is a key factor in replication potential. This information is very difficult to get and to digest it so that it can become comparable.
- We need more work that focuses on policy and regulatory frameworks that support or hinder PED development. Supportive policies can encourage replication.

1 ABSTRACT

In the face of escalating mobility challenges, active travel is a fundamental and sustainable mode of transport. However, despite its benefits, active travel is often overshadowed by the prioritization of motorized transportation creating continued car dependency.This approach creates environments that are not conducive to active travel. Notably, while Infrastructure is crucial for viable active travel, this paper argues that social realities in most African cities present additional, often overlooked challenges that hinder active travel adoption. Using a mixed method approach, including surveys and secondary data from literature and government reports, this paper investigates these linked dimensions, revealing that just developing infrastructure does not guarantee efficient travel and that the adoption of truly effective solutions is frequently impeded by a failure to address these broader issues. Additionally, policy reforms that regulate the transport planning process and provide incentives are equally important to increase active travel adoption.Ultimately, this study advocates for an integrated and holistic approach considering the broader context of active travel, which is crucial for the future of travel in African cities.

Keywords: Socio-cultural dynamics, Sustainable Development Goals, Non Motorised Transport, African realites, Urban planning

2 INTRODUCTION

Active travel is usually used interchangeably with Non-Motorised Transport (NMT) often including walking and cycling (Prince et al .2022). In this paper, active travel is examined through the lenses ofNMT, precisely walking and cycling. NMT is widely recognized as a cornerstone of physical and health benefits, accessibility, and inclusivity (Litman, 2012; Hunter et al. 2025), Additionally given the current climate crisis, active transport has also been associated with decarbonization initiatives (Moosburger et al. 2024). Although NMT is recognized in policy, the majority of countries in particular, African countries barely include NMT plans in their infrastructural projects (Uzondu and Etika, 2022). In many countries, the majority of the poor rely on walking as their primary mode of transportation. Due to urban design, they often reside on the outskirts of cities and must commute daily to access economic opportunities.

Moreover, many places still lack the required infrastructure, even though there have been major attempts to revive non-motorized transportation (NMT) in cities since the turn of the twenty-first century, and this development has been well documented in the literature. In particular, SDG 11.2, focuses on sustainable cities and communities, SDG 3 focuses on good health &well-being, and SDG 13's call for climate actionall support the use of NMT (Singhai, et al. 2021; Kalaoane et al; 2022; Mulibana et al. 2023; Mahadevia et al. 2023; 2024). The majority of African cities have signed the SDGs agreement and incorporated it into their local plans, but over time, little to no implementation has been done to accommodate these goals (Kalaoane et al; 2022). Therefore this paper investigates the dynamics of NMT adoption in South Africa.

3 NON-MOTORISED TRANSPORT IN AN AFRICAN CONTEXT

A complex and diverse landscape influenced by historical, physical, social, and economic elements may be seen in African cities' Non-Motorized Transportation (NMT). Various factors influence NMT adoption, with social issues playing a significant role. One key obstacle is demographics, where older people are often reluctant to use NMT for traveling (Longar, et al. 2024). Additionally, in most African cultures, walking remains a symbol of poverty(Acheampong et al. 2022) while buying a private motor vehicle is often a symbol of wealth (Jeske, 2016). Even in modern times, people celebrate buying a car through various cultural rituals, while using NMT typically goes uncelebrated. In contrast, many countries from the Global North, specifically European countries offer incentives for either cycling or walking, both in society and the

workplace (Buehler and Pucher, 2023; Karolemeas et al. 2023; Longar, et al. 2024), highlighting a key cultural difference toward NMT adoption. Furthermore, demographics and affordability influence NMT adoption (O'Reilly, et al. 2024). It is estimated that about 68% of people in Africa fall under the poverty line (African Development Group, 2024), forcing the majority to use walking as their primary mode of transport.Because of this contextual variability, one-size-fits-all approaches to NMT policy framework and implementation fail, requiring localized policies that take into consideration the potential and challenges that NMT poses in various cities across the African continent.

4 RESEARCH METHODOLOGY

A combination of qualitative and quantitative methodologies is utilized to create a well-rounded analysis. 300 surveys were administered to analyze the preferred mode of transport among people from different demographics. This study followed a multi-stage sampling technique which did not require a sampling frame (Sharma, 2017). Using this sampling technique, transportation stations in Braamfontein, Johannesburg were divided into different clusters. The commuters from different stations (clusters) were randomly selected to voluntarily participate, a sample size of 300 provided valuable insights while balancing practical considerations and statistical rigor.In addition to survey data, photography and observations were utilized in Johannesburg Central Business District (CBD) to understand mobility patterns. This study also employs secondary data; government reports, journal articles, policies, and legislative frameworks for a broader context of the study focus area. The gathered data from observations, and surveys were coded to identify reoccurring themes, and secondary data was cross-referenced with the survey findings to validate results and provide further insights into NMT adoption.

5 FINDINGS AND DISCUSSIONS

The data analyzed yielded several key findings on NMT adoption in Johannesburg, South Africa highlighting both cultural, policy, and economic challenges.

5.1 NMT Principles

Globally, there is a growing consensus that creating efficient NMT is a fundamental right for all. Efficient NMT is mirrored in global initiatives, specifically, the SDGs and it has been integrated into South African national legislation and policy frameworks, committed to creating a sustainable NMT. The common key principle in these policy initiatives (the Integrated Transport Master Plan (ITMP25) for Gauteng and Johannesburg Master Plan City of Johannesburg integrated Development Plan 2021-2026) and across the literature (Lefevre et al. 2021; Foley et al. 2022; Hunter et al. 2025) are depicted in Figure 1. These principles are intended to guide the planning and integration of NMT in cities.

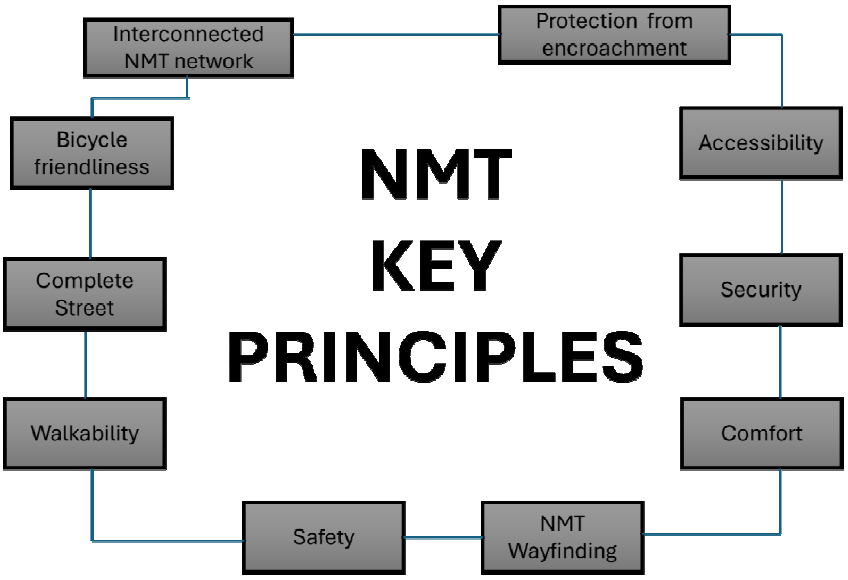

Figure 1: Key principles of NMT. Adopted by Author (2025)

However, the practical implementation of the Integrated Transport Master Plan (ITMP25) for Gauteng and Johannesburg Master Plan City of Johannesburg integrated Development Plan 2021-2026 falls short of the

intended vision. Residents of poorly integrated townships face significant financial burdens due to transportation costs, which can accountfor a significant portion of their monthly expenses (30 percent or more), given the statistics (Development Bank Group, 2024). To mitigate these challenges, the Development Bank established an initiative to construct infrastructure for NMT in South African cities focusing on Johannesburg; Soweto (Figure 2), Durban, and Polokwane.

Figure 2: Soweto NMT infrastructure. Source: Authors (2025)

Figure 2 shows the NMT infrastructure in Soweto that is often not utilized by NMT users attributed to a lack of trees for shade, safety, and security. The underutilization of non-motorized transportation (NMT) infrastructure frequently poses a serious obstacle to its wider adoption. In most cases like the Soweto initiative, NMT implementation partially focuses on one aspect of NMT often infrastructure. Therefore this raises a question; can we truly say that NMT policies are efficient or effective If the full spectrum of needs such as safety, complete streets and interconnectness is not taken into consideration leading to reluctant NMT adoption? These further support the idea that a key issue in many African countries, South Africa included, is the narrow focus on providing infrastructure, yet this focus on transport neglects other crucial elements that are essential for true sustainability and inclusion (Shinde et al. 2023).

5.2 Cultural shifts towards NMT adoption

The majority of the respondents (80%) reported walking due to financial difficulties, however, there is a desire to own a private vehicle. One respondent was quoted as saying;

As soon as I have money, the first thing I will do is to buy a car, so that everyone sees that my status has changed and that I am no longer poor.

Cultural perception also has a big impact on NMT's adoption. Many of these renters expressed frustration, as carownership is culturally regarded as a symbol of wealth and success in Africa. Walking and bicycling are stigmatized, especially among the respondents that identify these forms of transportation with poverty or a lower social standing. Even in cases where NMT is economically advantageous, this cultural view may deter people from implementing it. Walking and bicycling are frequently viewed as less desirable or inferior to motorized transportation.The widespread desire to own a motor vehicle expressed by many respondents suggests that efforts to increase NMT adoption are not having the intended impact, highlighting a critical weakness in the current Soweto initiative and other initiatives across the city of Johannesburg. Even among the respondents interested in cycling, the high cost of bicycles presents a significant barrier, making it difficult to use NMT. This demonstrates that despite people's desire to own a motor vehicle, financial limitations force them to walk or use public transport. Although high-speed rail and Bus Rapid Transit (BRT) systems were designed to solve transportation issues, they are often not accessible to communities. This scenario predicts a potential large rise in car ownership, reflecting South Africa's future mobility.

5.3 Safety and Encroachment

In South Africa, 29% of collisions are caused by cars, with infrastructure and pedestrians walking being two of the main causes, accounting for 22.3% (Road Traffic Report South Africa, 2024).This implies that enhancing safety requires a multifaceted strategy that takes into account not only driving behaviour but also the layout and upkeep of roads and walkways. Additionally, street vendors' invasion of NMT routes, frequently with little consideration for the safety of cyclists and pedestrians, jeopardizes the safety of NMT users (Figure 3). The situation is made worse by the pervasive issue of littering, which makes the NMT infrastructure less usable and creates dangerous conditions. The difficulties in developing accessible and safe transport services for all South Africans are highlighted by these coupled factors (Kalaoane et al. 2023).

Figure 3: Encroachment & littering on the NMT infrastructure in Johannesburg. SOurce: Authors (2025)

Informal trade has also encroached on NMT spaces (Figure 3), with the majority of this encroachment occurring around official business institutions such as offices and universities that are most valued for their convenience.

The significant demand for public space in Johannesburg city, particularly among low-income households that have limited access to formal business spaces, is reflected in the widespread use of NMT spaces. However, this also causes bicycles and pedestrians to compete for space, which lowers the functionality of NMT infrastructure and raises the possibility of accidents. Vendors in these areas frequently push cyclists and pedestrians into the roadway, increasing traffic hazards and decreasing the usefulness of the roads for NMT.

6 IMPLICATIONS FOR POLICY AND PRACTICE

Despite ongoing efforts, there are still many obstacles to overcome to enhance non-motorized transportation (NMT) in African cities. Walking is the most common form of transportation, especially for the underprivileged, which emphasizes the necessity of significant investment in NMT adoption. When combined with current urban planning, the restricted reach of public transport choices like BRT and high-speed rail points to a future rise in automobile ownership, which could exacerbate already-existing traffic and environmental issues. Policymakers are faced with cultural issues as they seek to change public perceptions and increase knowledge of NMT's advantages as a workable solution as well as a sustainable and healthful one. Campaigns for social change, educational programs, and the marketing of cycling as a pastime could all aid in dispelling these myths.

Additionally, road safety is a major concern, these safety hazards are made worse by the presence of litter and the encroachment of street sellers into NMT paths, which also make it more difficult to use NMT amenities. This draws attention to the necessity of integrated urban plans that take informal economic activity and mobility into account. While maintaining the safety and functionality of NMT infrastructure for bikes and pedestrians, urban planners must take into consideration the space needed by street vendors. There are numerous significant ramifications for these findings. First of all, they emphasize the pressing necessity

for thorough transport planning that incorporates NMT with other forms of transit and socio-economic activities. In addition to building infrastructure, this calls for addressing the cultural dynamics in cities and integrating cultural approaches to NMT adoption.

1 ABSTRACT

The paper debates the concept of circular economy in cities through introduction of circular communities composed by materials providers, developers, producers, services, distributors and consumers which all must adopt a holistic and collaborative approach. Therefore, circular development necessitates the socio-ecological transformation of our urban systems. It requires that wasted resources are looped, the ecological regenerative capacity and adaptive capacity of urban systems developed. Therefore, spatial planning potentially has a crucial role to play in the delivery of circular development. The challenge is to integrate a circularity-based approaches into spatial planning practice, and vice versa, and to go beyond the search for temporary solutions, which in spatial terms means temporary spaces for circular experimentation, and to lay the foundations for circular spatial planning thinking and action.

Keywords: spatial planning, circular communities, circular thinking, circular development, circular economy

2 INTRODUCTION

This paper is a discussion based on theoretical knowledge and experiences obtained in many years in spatial and urban planning, built environment development, industrial product design, management and enterpreneurship, and observation of social dynamics. It is encouraging that these observations seem to be finally inline with at least some directions of environmental and socio-economic thinking and recomendations of internationally acnowledged bodies (e.g. UNEP, 2024) and such reasonings are slowly, but not surely, penetrating even into the various EU documents (e.g. EC, 2020; IEB, 2020; Directive (EU) 2024/1799). Discouraging, however, is the fact that a transformation towards global sustainable resource consumption and production is urgently necessary, however, society does still not seem to feel it.

The history of civilisation follows the logic of goods exploitation. People are used to use/exploit resources and when they are exhausted, move on to new teritories to explot and exhaust again. Thus this history shows, that the collapse of settlements and cities coincides with the depletion of resources. These are usually exhausted with the help of a current technology – usually developed at the time and recognized as modern. The current civilisation is also facing the problems of resources exploitation (reflecting the way of the exploitation) as well as with the polution that goes hand in hand with it. Therefore, the UNEP (2024) calls for not merrely a transformation towards global sustainable resource consumption and production as being necessary, but for how to urgently make it happen. Further, the UNEP (2024) document points to insatiable use of resources, which has tripled over the last fifty years, and worrns if we do not change, we could see resource use up by 60% from 2020 levels by 2060.

The pursuit of individual and material profit, which has been extrapolated over the last century, has marginalised the general well-being of our society over the profit-oriented economic activities. It is seen as one of the key elements that has caused the disintegration of local communities. The benefits and well-being of the community were not looked at, but the material gain (profit) of the individual. This paper explores the establishment and strengthening of the circular economy in local communities, as a means of transition towards resource-efficient and sustainable consumption and production, as one of the leverages that may help to revers the process of wellbeing decoupling. Hence, the key to success is a system that links the consumer and the producer – a responsible consumer (user) and a responsible producer (provider). Therefore, both need to be caught in the loop of being mutually dependent and therefore responsible.

The aim of the paper is to pave the way to the cicular community through its logical structure. The logic of the community is presented, based on the logic of economics that takes into account all stakeholders in a balanced way and does not favor or neglect the well-being of any of them, instead of being based on institutions that have become entrenched in society through the implementation of the linear economy model. We will show how certain specific directions/industries/products can be realized with such logic.

The paper firstly elucidates the circular economy concept and introduces accordingly the circular community as a solution that enables systemic socio-ecological transformation (of urban systems) with a special attention to a product as a service business model, where a responsoible consumption is motivated. True, the responsibility and motivation of the consumer (user) towards the product changes the flow of the material, and that is exactly what circular economy is all about, the economy where the value of products, materials and resources is maintained for as long as possible in the economy, and the generation of waste is minimized. The discussion is further elaborated upon DIPSTOR's definition of fully circular product (FCP) and its circular design approach Evolutionary Design (DIPSTOR, 2019), a resource efficiency approach in furniture development and design. These approaches reflect the values and principles of the New European Bauhaus Compas (NEB, 2022; EC, 2019) and are further illustrated with two circularity-based implementations, the slender revitalisation and the circular landscaping. They both are based on the cascaded use approach, such as R-ladder (e.g. Kurilova-Palisaitiene, 2023) and can in the context of urban planning and development contribute to compact, balanced and parhaps quite self-sustained neighbourhoods.

3 CIRCULAR ECONOMY CONCEPT AND CIRCULAR COMMUNITY

Historically speaking, circular economy is a traditional economy of cities and communities. Today, the circular economy is recognised as an innovative model designed to eliminate waste and avoid the contstant use and exploatation resources. Unlike the currently prevailing linear economy, which follows a 'take, make, dispose' approach, the circular economy strives to create a closed-loop system where products and materials are reused, repaired, refurbished, and recycled (even upcycled) for as long as possible. At the heart of the circular economy lie three fundamental principles, designing out waste and pollution, keeping products and materials in use, and regenerating natural systems, being also a fundamental tenant to sustainable urban planning and development. Therefore, this shift not only reduces waste and conserves resources but also fosters sustainable economic growth and resilient communities with quality living environments, and responds by this to United Nations Sustainable Development Goals SDG11 – Sustainable cities and communities and SDG12 – responsible consumption and production, simultanoeusly (UN SDGs, 2017)

3.1 City as a community

"What is the city but the people? True, the people are the city." (Shakespeare, Coriolanus, act 3, scene 1). However, people always act in an environment, therefore the environment matters, and the relation between people and the environment is in reciprocal continuity (Goličnik Marušić and Marušić, 2024). Cities are places of many activities and are their representation, from economic, cultural to criminal, etc., but above all, they are society (Šimunović, 2007). These references call for a reasoning, that people in cities is about communities and networking. However, a community is successful when it works together and complements each other, and so the goods and knowledge start to circulate.

This paper is based on the premise that environments with strong communities having clearly identified and connected activities, adequate capacity and networking, have a better chance of being sustained and having potential for further sustainable development. Historically, in general there are two approaches of city emergence: bottom up and top down. Bottom-up approach reflects evolutionary process of networking of people with complementary interests, including exchange of goods and knowledge; manifested with marketplace and its further organic growth towards towns and cities. Top-down approach usually reflects the intention of the authorities to protect or expand their territories. The key to keeping such territories alive and well is to introduce, build and maintain communities that are socially and economically interconnected. However, the breakdown of socio-economic ties leads to the collapse of communities and, consequently, to the collapse of towns or cities. This was recorded many times in the history of civilisation already, from the very past until today.

Today, with unbridled and extraordinary technological development and society's often uncritical dependence on this technology and its development, we are faced with the breakdown of mutual social and economic ties between the inhabitants of local communities and the consequent disintegration of traditional ways of living and living environments. The concerns already identified decades ago became reality (Mumford, 1961). The narrow specialisation of particular urban areas for certain activities and the loss of the diversity of activities in them has also contributed to this, which is particularly evident in the historical centres of the cities.

Some parts of cities are losing, or have lost, the ability to offer a suitable living environment or a setting for the service and production activities that have traditionally inhabited such environments. These environments are losing their local population and are either emptying and decaying or are being gentrified. This interrupts continuity for many activities and, with it, the flow and transfer of knowledge. The strong point here is that the inhabitants of the city are not socio-economically connected to the city. To illustrate, the people who would traditionally represent the actors in the economic cycles of such a community have largely turned into intermediaries between globally available goods and services and domestic consumers. Some, however, have become merely intermediaries between external goods and services and even external consumers. Production/consumption cycles in the local community thus begin and progress to the break-up of the self-sustaining community. Re-establishing production cycles, especially in the absence of knowledge (crafts, local trade) is usually difficult.

Over the past century, and especially in recent decades, the linear economic model based on resource exploitation and depletion on the one hand, and profit and waste accumulation on the other, has been more intensively transferred from the elites to the general population through globalisation. In doing so, local economy systems that were often based on circular concepts died down. Local cycles also died out as local rural settlements began to empty (after World War II). This process has led to a point where material, energy and cheap labour resources are exhausted, and we are faced with a surplus of waste and a high concentration of wealth among a narrow elite, an unbalanced distribution of goods.

The migration that escalated after the Second World War, which in the rural-urban context meant a shift of the population to the cities for the jobs that were available there, and thus also for the new forms of living in the newly built residential neighbourhoods. Working and living on a farm was considered regressive, while working in industry and in administration was considered better and desirable. On the other hand, as society and technology developed, the educational level of the population rose and the mentality that people with higher education were not destined to live in the countryside, but to work in the cities, in administrative work, took hold. The educated were not returning to rural areas, which, again contributed to the impoverishment of the local community from which they came. Industrialisation has also had an impact on the agrarian community, so that production has increased without maintaining the workforce, even by reducing the workforce.

The process of globalisation that followed seemingly reduced the need for self-sufficiency by offering cheaper products from the global market. All these processes have also had an impact on the demographic picture. Globalisation has led to the drying up of the production that used to attract people to cities. The urban population, however, is at a very low level of self-sufficiency and even faces the problem of securing financial resources. Individuals or some parts of the population (including the highly educated) are emerging to reverse this process. They are returning to the countryside, also moving towards self-sufficiency, and trying to establish different models that have the characteristics of circularity. They are able to do this because today's technology allows them to develop, act and network in their areas of expertise wherever they live. This trend points to the potential for the concept of circularity to become more generally applicable and to become part of the planning and development of cities and their linkages with their rural and peri-urban hinterlands.

However, the process of globalisation has physically emptied villages and impoverished cities in terms of diversity of contents and activities taking place there, and these call for the creation of a model that can improve that situation. Setting up of circular economy models in such environments create the need for different professional profiles, and thus the possibility of introducing a balanced distribution and diversification of the population there. This enables the development of healthy communities and increases their capacity for self-sustainability.

3.2 Circular community model

Although several circular economy business models and related value add via production of goods and services as well as value chain which addresses the activities that provide or receive a value from the activity in a cycle (e.g. developing, producing, distributing, consuming), the current discussion is mostly limited to the physical processes and business models including the way products are developed, promoted or offered to consumers, and there is basically no talk about a community that runs or enables these cycles. This section focusses on setting up of a circular community and showing step by step its possible shaping and

development through its key development phases. A sequence of diagrammatic schemata helps to represent and discuss the circular community model composed by materials providers, developers, producers, services, distributors and consumers; and elucidats the basic relations among them.

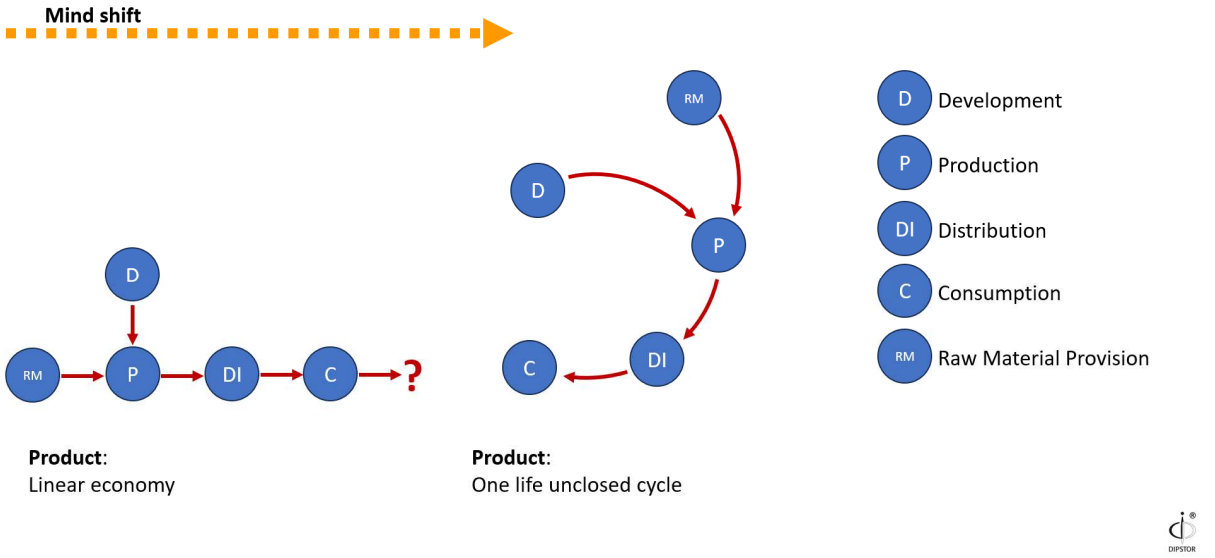

Fig. 1: From linear to basic circular economy model (illustration: authors).

Linear model in general paves the path of raw material through product production, distribution, and consumption toward waste. Development is predominantly in the function of production to serve a consumer's demand for new products. All mentioned cells have no particular need to be physically/territorially close or connected and socially or otherwise interconnected. Basically, the only goal is a profit. The consequences are dislocated production, excessive waste deposition and logistics requirements, only profit-oriented marketing and development and estranged consumption-oriented user having no real influence on quality or affordability of the product or service. The result is excessive need for transportation and waste deposition infrastructure, unbalanced jobs distribution with gravitation towards the lower-cost environments not close or even within the local environment of consumption of products or services. Spatial manifestation is either development of excessive transportation and waste deposition infrastructure requiring large amounts of valuable space or overloaded existing infrastructure or both with constantly growing spatial demand. Since available space is limited, the mind shift that could turn around such trend is essential and inevitable. Figure 1 shows the importance of readiness for as shift away from linear economy concept.

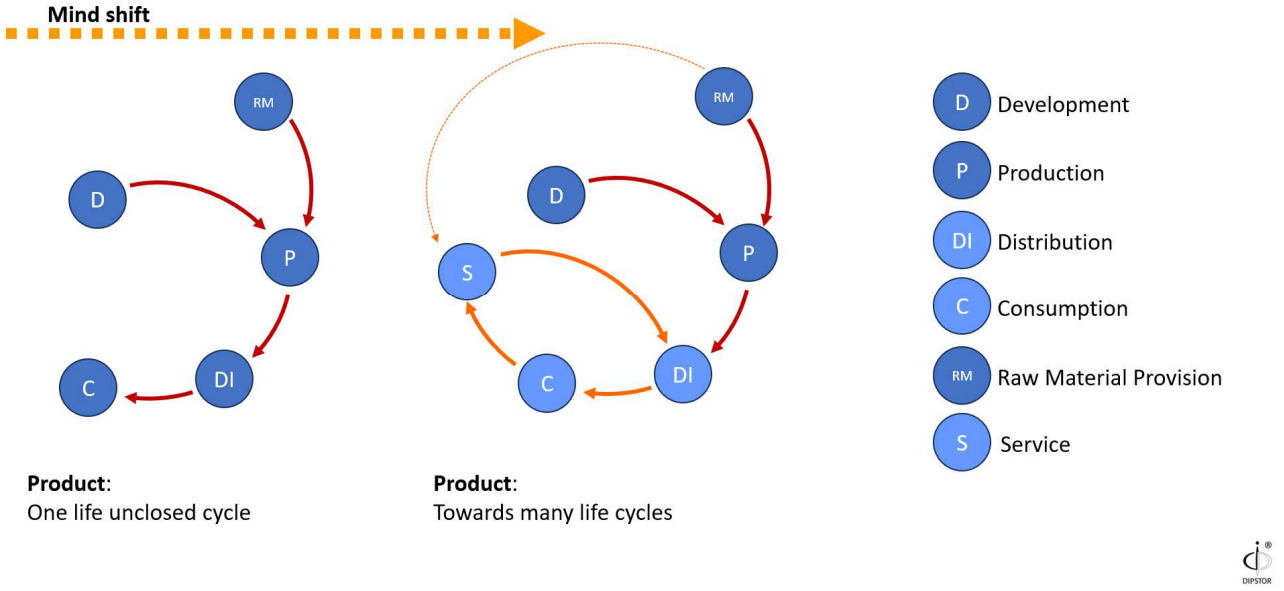

Fig. 2: From linear to basic circular economy model – stakeholders' relations (illustration: authors).

There is a challenge how to "bend the linear process" and which unit of the community could play the crucial role in that. Figure 2 shows that when adding the service in the function of repair, refurbish, or redistribute the used items to be reused, the life of products is prolonged, the need for disposal reduced as well as demand for the raw materials. Service close to consumption reduces logistics demand and provides professional employment in the local environment. Such service in general and certainly in long-term requires less space as it does not accumulate disposed products but circulate them. It also improves professional level and job-diversity in the local environment.

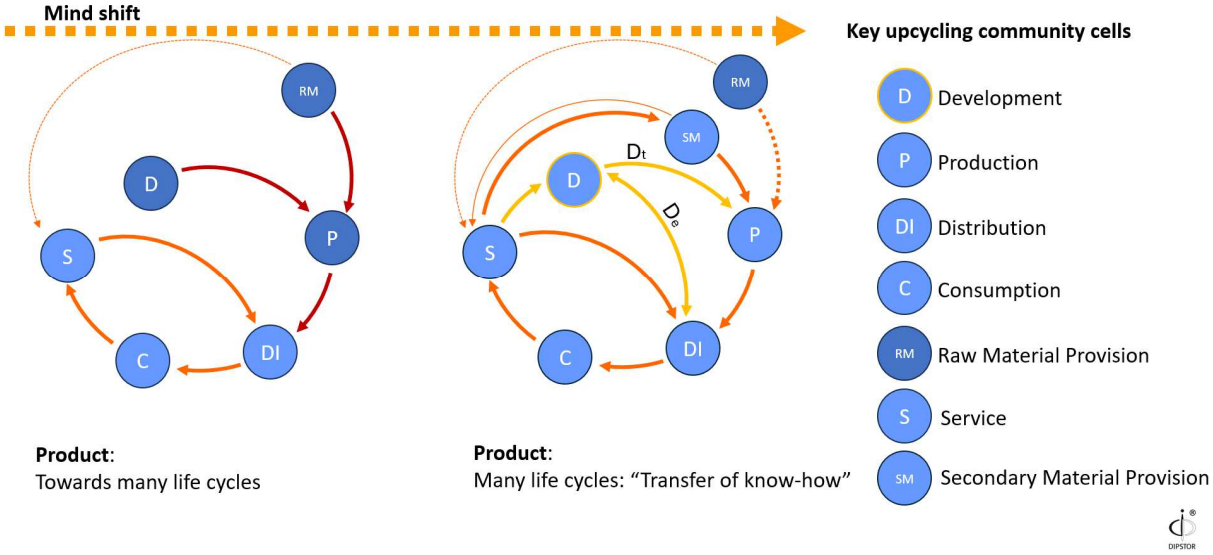

Fig. 3: From basic to advanced circular economy model – development & knowledge transfer as driving forces (illustration: authors).

However, without appropriate development that would follow and fit the contemporary economical and technological needs of consumers the products in the loop after some time (i.e. several loops) exhaust their potential and find the end in disposal. Avoiding such situation and prolongation the life of useful material as long as possible demands further development of this circular community model. As illustrated in Figure 3, Development (D) has to further develop, and interconnect with service (S) and distribution (DI) to offer along with technological development (Dt) also economical development (De) with financial products (e.g. renting, leasing, loans etc.) for both, consumer (C) as well as supplier (e.g. distributer (DI), producer (P)). Such development opens the door to wide spectra of specialisation and jobs within a local community. The products of such model are not any more merely repaired or refurbished old products, but also completely new products, which were developed from the materials of old products entering the cycle as worn-out products from various levels of the value hill R-ladder. Such an approach enables substantial metamorphoses or remanufacture of mass of worn-out products avoiding their substantial degradation (i.e. downcycling) but rather upcycling them into new potentially serial products. Methodology of development and design of industrial products that are able of metamorphosis into new generation of products in the next cycle opens new aspects in development of industrial production with fully circular products (see Section 3.3.1). A vast majority of raw material demand is replaced by secondary material. The space required for disposal of waste material is further diminished. Service (S) takes over another important task such as sorting of collected products or materials according to the value hill and their distribution to relevant units of the model.

This model also addresses the responsibility of final user. Consumer (C) which is involved in such circular process is motivated to act as responsible user as the product he/she is using is perceived as his/her currency, the value he/she will exchange in the next cycle for at least partly covering the costs of the new goods and services, respectively. This whole process suggests the introduction of evidencing and tracking of products and their parts, which can be introduced via digital passport using blockchain technology, especially in larger systems. Such approach not only improves the consumption (C) and distribution (DI) aspects, but also contributes to environmental considerations, such as carbon footprint tracking.

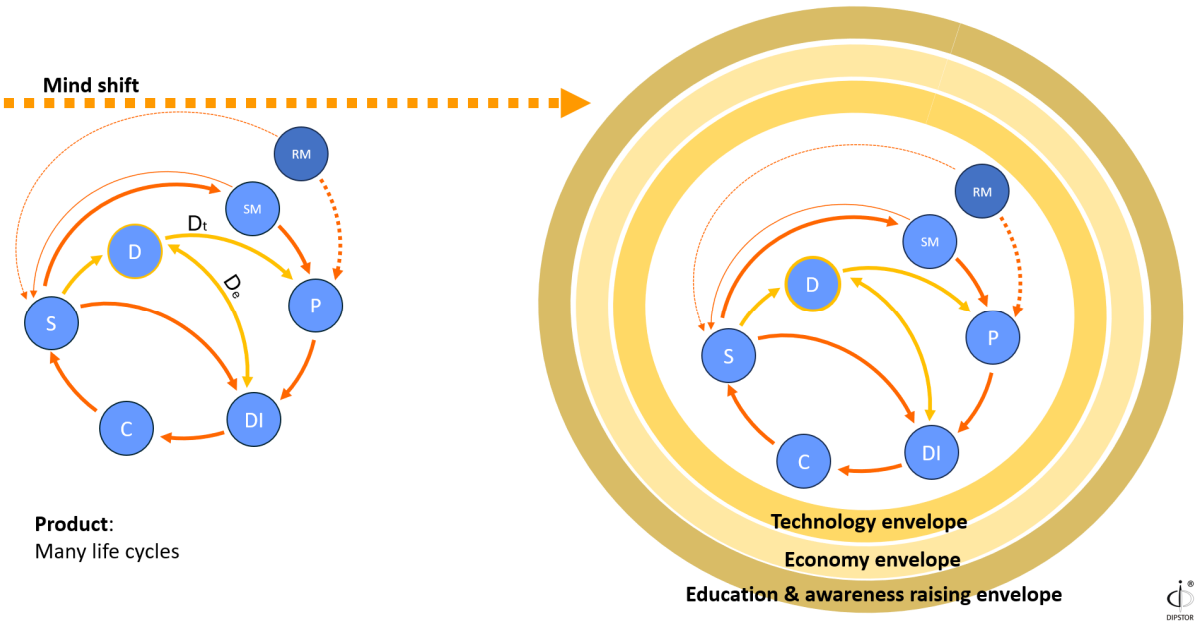

Fig. 4: Circular community model (illustration: authors).

Besides technological knowledge and technical support that every production process needs, a smart circular community to function, must be also supported by adequate economic knowledge and environment. That includes for example, appropriate financial services, presence of adequate individual and collective consumers. However, for community to sustain, it is essential to develop knowledge environment with continuous systematic education and awareness rising programmes for both community members and general public (see Figure 4). Such community is rational and people- and environment-friendly and therefore can be considered a smart community, where high technology is used only to support implementation of these values.

Each such local niche community may consist of several production (P), development (D), distribution (DI), or any other identified units as long as they are supporting each other and looking for synergies in common and shared activities. This means that a local circular community consists of a conglomerate or network of local niche circular communities specialised e.g. for furniture, tourism, gastronomy, fashion, and the like, where each entity/stakeholder can play different roles in different niches, e.g. being producer (P) in one and consumer (C) in another. Such conglomerate can support its members by sharing some common services and even more efficiently circulating the goods.

The market area that may be considered as a local often depends on product or service specifics. The circular model does not imply to extinct the interregional cooperation. On the contrary, development of knowledge network is very important for development of circular economy. Also overlapping and cooperation of neighbouring communities and their markets is important for their sustainability. Therefore, emergence of regional and even global societies and networks supporting circular economy by sharing knowledge is essential. It implies only to reduction of negative environmental impacts and developing sustainable socio-economical local environments. By reduction of transport demand the logistic infrastructure expansion may decrease and its spatial and energetic demand along as well as societal expenses for all that. That would be nice.

3.2.1 Circular product as a service

In the context of fast consumption society, the affordability of high-quality or good-quality products and services is often low. Also, in many fields, it can be observed that the quality of products and services at affordable prices is decreasing. In order to optimize the user experience and use of products, their affordability, material flows and added value in products, the model in which the consumer becomes the owner of a physical product seems not always the most successful. A product-as-a-service (PaaS) business model can offer optimal performance from multiple perspectives in many areas or for many product groups, provided that it is managed in an appropriate environment, such as a functional circular community. Such a service gives the user the opportunity and permission to use, but not the ownership of the object of use.

Responsible consumption is motivated because a responsible consumer benefits from lower service costs. Affordable and incentivized financing options can be developed, including e.g. rental, sharing, leasing, membership, etc. A wide range of products can be included in such services, especially if blockchain technology is introduced to keep records and track products. In practice, this means that one can rent a high-quality product, e.g. furniture, computer, car, etc., for an affordable initial cost and maintain the quality of service for a long time. Such a model supports local niche communities and can be well harmonised with compact neighbourhoods and a city of short distances.

3.3 The material flows

In the linear economy model the raw material extracted from a (natural) source is used in the product and after this use is exhausted, it ends as a waste expanding the infrastructural demand. Often logistic of such product life path is rather demanding as the costs of labour and input (raw) material are reduced by migration into low-cost environments. Disposing of worn-out products takes space and logistics. In somewhat improved economic models, the worn-out products are disassembled and degraded to the level that can be used in the products again. Such process is circular regarding the material flow as the primary material sources are preserved. However, it transforms the product to a very low level at the value hill (downcycling) which often requires substantial energy and the whole production process. Some materials degraded to such a low level cannot be fully recovered. As material is degraded, return to the basic production is required, often not in the local environment. Logistics for that is required, however no jobs for local community growth and reinforcement. In the case of circular models that more intensely include local community capacities and target the higher level of the value hill, efficiency of circular process may be much higher and cover multiple aspects including environmental and social ones, as they seem to be the two sides of the same coin.

Strictly speaking the story of material flows physically starts at the material origins (resources), however it arises by the consumer's need. How this need is developed and does it have a real basis is another story, however, also important in the context of sustainable circular economy. Anyhow, since we are talking about circular economy, we can basically start anywhere to get further and around in the loop. Assume a potential consumer (C) have a need for a certain product. He/she can get it (buy, rent, etc.) at the circular community distribution centre (DI). After some time, for some reason, the product is of no use any more for the given consumer (C). Perhaps it is broke, used up, do not serve the new needs, not attractive to the user anymore, etc. So, consumer (C) brings the product to the circular community service centre (S), reception of which may be at the same spot as distribution centre (DI). Regarding the condition of the used product and the needs/requirements of consumer (C), service (S) and distribution (DI) consult/offer possible solutions to consumer (C) to fulfil his/her new needs. The product brought to the service (S) is assessed and subjected to the treatment according to its condition and market requirements. It can be basically maintained and sent directly from service (S) to distribution (DI) to be reused. If necessary and possible, it can be repaired or even refurbished, if the procedures to do so are simple enough to manage them in the service workshop. Then repaired and simply refurbished products are sent from service (S) to distribution (DI). If more demanding operations are needed for refurbishment, however it is still reasonable to do so, the product is sent to one of the production centres (P). If none of above procedures are appropriate, the product is sent to the secondary material collection centre (SM) to be further treated (probably at least partly decomposed), sorted and redistributed for remanufacture, repurpose or recycle. Some products or their parts are useless for further processing in the form they are due to excessive degradation or inappropriate design, however material stored in them is useful and valuable. For material to be used again, these products have to be severely degraded first and then recycled into some kind of basic material – downcycled in the recycling plant (PRECY). To avoid such situations as much as possible, an introduction of fully circular product (FCP) development/design is needed and applied already in the production phase. Some material from old products is too decayed to be even recycled, however it might be useful for a kind of recovery production (PRECO). However, there might be some leftovers of the worn-out products that are completely useless or even toxic and have to be disposed at the appropriate waste-disposal centres (W). To avoid these situations FCP should be applied in the production of new generations of products. Some products from secondary material collection centre (SM) may be designated for repurpose (PREPU), so they may enter another circular system/loop. Circular production centres (C) get material (products or products' parts) mainly from secondary material collection centre (SM), however, also some from raw material centre (RM). They may

use also some material from recycling plant (PRECY) and other sources (e.g. other circular system/loop). They supply distribution centres with refurbished and remanufactured products. The new generation products may be based on secondary material, but also on new (raw) material, provided that these products are FCP. They also supply circular community service centres (S) with spare parts. The brain of the whole community is development centre or network (D) supporting two important components: technology (Dt) and economy (De). It is responsible for rethink solutions (e.g. FCP), refuse materials and processes harmful to environment and reduce consumption of natural resources within any products, processes and activities in community. Figure 5 shows the material flow in circular community and illustrates the community as a holder of activities which reflects the so-called R-ladder strategies (e.g. Kurilova-Palisaitiene et al., 2023) that can help to readdress concept of waste, and accordingly rethink the consumption patterns and redesign of products, which all finally affect the spatial logistics, uses and activities distribution, and therefore can represent a bottom up circular economy approach to cities and towns planning and development.

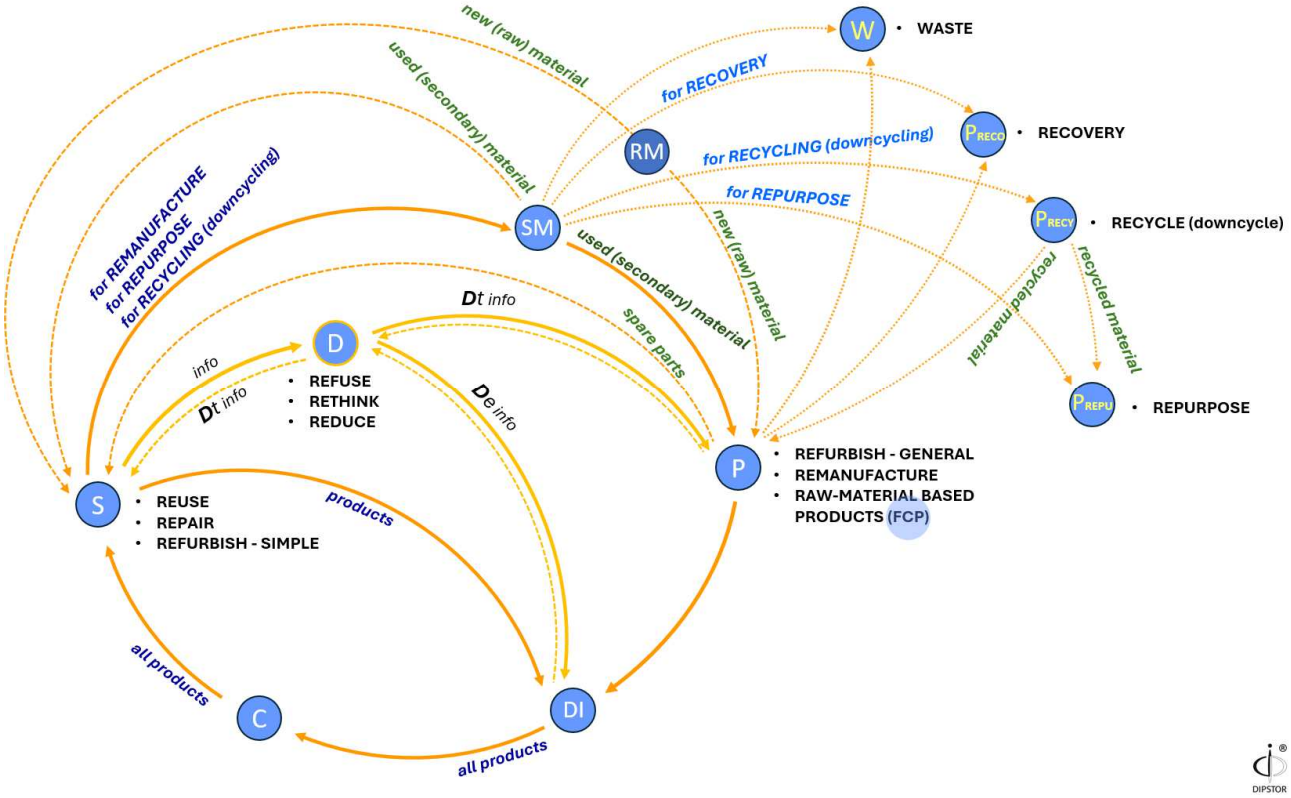

Fig. 5: Material flows in the advanced circular community model (illustration: authors).

3.3.1 Fully Circular Product – Evolutionaty Design

The implementation of circular economy models requires a rethinking of the processes with which the products are managed throughout their life cycle from design to recycle. The methodological approach of evolutionary planning represents a relevant potential for its implementation. This approach is characteristic for not to focus on just one phase of the process but throughout the entire life cycle of a product in each phase of the life cycle (maintain, repair, reuse, refurbish, remanufacture, repurpose, recycle).

Evolutionary Design is an advanced product design-development approach (DIPSTOR, 2019) that continuously generates upgrades or improvements of existing designs and generates new ones, based on success and lessons learnt from parental/related designs simultaneously considering environmental, economic, user experience and societal aspects. It is a concept of development of modular systems that are easy to maintain, repair (e.g. possibility of disassembling and changing parts) and remanufacture (modularity), following the iterative choice of the best characteristics of a product to achieve the best performance, and where each product generates the next development phase and opens new questions and possibilities for further design.

The aim is to adopt a product design-development planning process resulting with Fully Circular Product (FCP), which will, following the Evolutionary Design, move the focus of design process from deterministic

product design of a single product to possibilistic development of product evolution. In such a process the usability readiness of product or its parts for further new designs is prepared. An initial product is subject to an assessment of possible metamorphoses of the initial product via cascades of a product's life cycles.

As well as perpetuum mobile, also a FCP is an ideal, not entirely realistic to achieve. Yet, the bright goal should be to make cities Fully Circular Products (FCP) or as close as possible.

3.3.2 Slender revitalization

An illustrative example of circular process in the urban an environemnt such as a historical city is revitalisation approach where the old building material is treated with care and respect. With careful decomposition and separation of old building materials and parts a substantial share of material can be reused in the new project of revitalization and introduction of some new material is reduced. Due to disposal reduced to the minimum, transportation cost is reduced as well as demand for the landfill. However, some more qualified and careful work is required for such "slender revitalization". Such approach is easier or even possible in the case of built with simple materials rather than with the composite ones, where decomposition and reuse is problematic or even impossible. The natural materials are also often easier to be reused and their decay less harmful to environment than of the synthetic ones. DIPSTOR is currently involved in such a project. Most materials (wood, bricks, roofing tiles, stones, plaster, etc.) are being reused. Some wooden parts that are unable to be used for construction anymore, are used for furniture design, which will be included in furnishing of the renovated building. Such an approach of slender revitalisation also refers to aspects of FCP.

4 CONCLUSION

The presented concept of circular community and a community as a foundation of a city reflects circular economy concept from a bottom-up perspective. It starts on the other end as infrastructural concerns and conceptualisation of industrial symbiosis, water waste or all sorts of waste management, to complement these bigger systems and solutions. The presented model addresses rather small scale and strives towards the shift from product maximisation to provision of human needs, reflecting users' dimensions of circular economy as an instrument for delivering decoupling of economic growth from resource use (waste production) and environmental impacts in practice, as well as a part of the bigger picture of economic, societal, environmental and cultural transformation needed to deliver truly liveable cities.

In the circular model understanding and considering the user needs is addressed by how the material embedded in any product circulates through the product's life cycles or generations of products and their creators. These creators of one generation do not know who and how will create the next generation of products. All they can do is to make their design as wide as possible for the next generation, thus allowing the most probable and/or possible products to be implemented. Unlike linear models, which are deterministic, as the next generation of creators responding to the needs of the community is not actually foreseen, the challenge in designing fully circular products is to cover the needs of the present while allowing for the widest possible possibilities of the future. Thus, products created with circular models are more complex compared to those of a linear model, whether it is the design of a chair or the renovation of a house.

Circular community model discussed in this paper reflects relationships among many actors in it (representative units: P, D, S, DI, C etc.) and when considering them spatially, they all express certain demands about a place but most of all they perform a sort of behaviour pattern which reflects their optimal spatial-temporal relations, and can lay crucial bottom up foundations for optimal locations, spatial dimensions needed for their successful manifestation and the like.

The reasoning in the paper paves the way towards new conceptions of spatial planning in which circularity approach could help spatial planning to move from sectors to systems to address and find solutions for urban systemic inefficiencies and imbalances.

Cities for All: Urban Equity and Cultural Inclusivity in Cosmopolitan Cities: A Case Study of Wadi Hanifa, Riyadh

Dalia Abdelfattah

(Assistant Professor Dalia Abdelfattah, Department of Architecture, College of Engineering, Al Yamamah University, d_fattah@yu.edu.sa)

DOI: 10.48494/REALCORP2025.2077

1 ABSTRACT

The concept of “Cities for All” has become a necessity for addressing the challenges of urbanization, multiculturalism, and social equity in the 21st century. As cities are rapidly evolving anddeveloping increasingly diverse multicultural layers, it became crucial to foster inclusive environments that promote equity, equality, and justice. Yet, challenges persist in developing truly inclusive urban spaces, thisacquires a deep understanding of the interlocking complex relationship between social community needs and urban design parameters.This research explores the dynamics of the multicultural societies in urban spaces.It highlights the challenges faced in accessing equitable public spaces. It examines the role of urban design in fostering social cohesion and reducing spatial inequalities. The research aims to studythe capacity of the outdoor public spaces to accommodate people needs with cultural diversity, including individuals of different nationalities, genders, age groups, and cultural backgrounds, enabling them to practice their activities and express themselves in public without conflict, while fostering mutual acceptance.The research employs a mixed-methods approach, combining qualitative analysisof spatial data with user experiences and perceptions. The study incorporates observational research, annotated mapping techniques, photographing, and looking for traces to provide a comprehensive understanding of space utilization and cultural dynamics. The research conducts systematic observations of public behavior and space usage patterns across different times of the day. This method supported the documentation of how various cultural groups interact with the urban public space, providing insights into the effectiveness of designelements in promoting inclusivity and equity in multicultural settings.The study utilizes annotated maps to visually represent spatial data, and uses qualitative observations topresent the distribution of amenities and facilities across the urban public space to identify the patterns of use by different cultural groups. Theoverlapping between the observational data with the annotated maps creates a powerful tool for analyzing the relationship between urban design of public spaces and social equity in multicultural environments. The study proposes a robust framework for assessing and improving urban equity in diverse public spaces.The research applies its methodology to analyze a case study within the context of Riyadh city (an evolving cosmopolitan city as the capital of Saudi Arabia) with a specific focus on Wadi Hanifa as a study area. This case study concentrates on understanding the concept of urban equity in designing public spaces to promotesocial cohesion, especially in multiculture communities.The research explores the impact of Wadi Hanifa redevelopment project in promoting spatial justice and equity in public spaces, taking into account the varied requirements of the multicultural community in Riyadh. It examines the project's strategy for establishing welcoming public areas that honor local cultural practices while encouraging intercultural harmony, which provide fair access to parks and recreational areas for all groups.The case study analysis of Wadi Hanifa, demonstrates that its strategyaligns with the macro-movement towards creating “Cities for All”. It emphasizes how important it is to accommodate a comprehensive approach that considers culturally-sensitive design. The public spaces of Wadi Hanifa has a flexible design qualities that serve the whole community. The research shows that the Wadi Hanifa project successfully integrates principles of equity and urban justice, resulting in increased public use and improved quality of life for diverse multi-cultural groups. The study concludes its findings by highlighting the importance of such successful projects in promoting social cohesion in cosmopolitan cities that embrace diversity as well as harmony. This approach is aligned with the kingdom 2030’s vision for Sustainable Development, to create safe, inclusive, and resilient communities.

Keywords: Multi-cultural, Equity, Inclusion, Cosmopolitan cities, Public space

2 INTRODUCTION

The significant increasing in populations with the rapid urbanization growth in the 21st century created multicultural communities with challenging needs and unique characteristics. It has become an urgent need

for designing spaces that understand their demands and address their requirements (Gehl, 2010). Urban planning and design guidelines in many countries regulate the concept of "Cities for All" (Alkhresheh, 2012) which was developed to tackle these new challenges of multiculturalism, seeking to achieve social cohesion public spaces (Sinha et al., 2024). This research focuses on the dynamics of the multicultural communities in cosmopolitan cities. It studies the challenges and opportunities of creating public spaces for all (Harris et al., 2023). By examining the relationship between urban design parameters and the needs of diverse cultural groups, the study aims to develop a framework to understand the phenomena, consider the inputs of variables, aided by the case study-based approach for analysis and understanding (Carmona, 2021).The research support the idea that public spaces should be accessible and welcoming to all, regardless of nationality, gender, age, or cultural background, enabling users to engage in communal activities without conflict, and to express themselves freely (Harris et al., 2023).To study the role of urban design in fostering urban equity, an integration of multiple qualitative tools were implemented as observation, documentation, photographing, tracing, and looking for traces (N. Groat & Wang, 2013). On site observations through multiple field trips to examine the inclusivity of public spaces. Focusing on Riyadh, as a rapidly evolving cosmopolitan city (Elsheshtawy, 2021), the research studies Wadi Hanifa project as a case study for a public space. Wadi Hanifa, represents the principles of equity, equality and justice, aligning with the main goal of "Cities for All" (The Royal Commission for Riyadh City, 2025). The study highlights how urban design can promote social cohesion, and enhance quality of life for diverse communities. The study aims to develop a framework for assessing and improving urban equity in multicultural cities, fostering equitable access to public spaces.

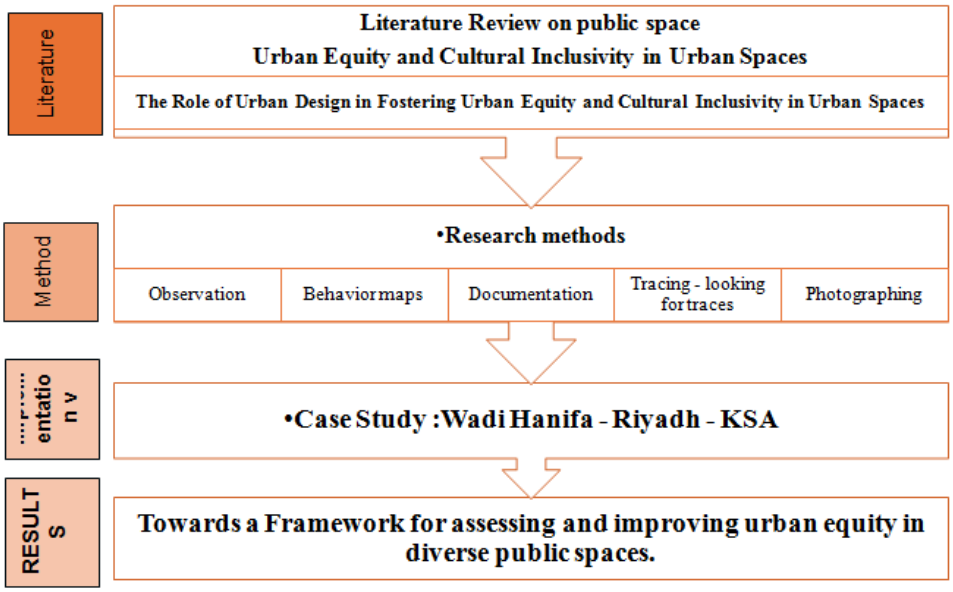

Figure 1: Research Methodology-Source: Author

3 CITIES FOR ALL

For the past decades, Cities have continued to follow a dynamic path of growth and change (Gehl, 2010). It is noticeable that cities become hubs for diversity, as a result of urban populations growth, such differences as language, and gender (Kihato & Massoumi, 2010).Despite the growing emphasis on inclusivity, many cities face substantial challenges in creating equitable and culturally sensitive public spaces (Sevincer et al., 2017). A significant consideration has been dedicated to the concept of "Cities for All" from the urban development perspective, emphasizing the need for inclusive, equitable, and culturally diverse urban spaces, addressing challenges as rapid urbanization, multiculturalism, and social equity (Harris et al., 2023). This research explores the key themes of urban equity, cultural inclusivity, and the role of urban design in fostering social cohesion, with a particular focus on public spaces in multicultural cities (Carmona, 2021). As public spaces play a crucial role in promoting social cohesion and reducing spatial inequalities (Sinha et al., 2024). The research examines the theoretical foundations and practical applications of inclusive urban design. As the implementation of public spaces should consider accessibility for all community members (Abdelfattah & Nasreldin, 2019), cultural sensitivity in design features, and chances for diverse groups to

interact and engage (Harris et al., 2023). Successful public spaces can perform as catalysts for broader urban transformation, positioning cities as models for embracing diversity although maintaining cultural authenticity (Carmona, 2021).

3.1 Urban Equity and Cultural Inclusivity in Urban Spaces

Urban equity is a crucial aspect of creating inclusive cities. The UN Habitat's urban planning principles emphasizes the importance of integrating social equity into urban development to create inclusive, sustainable cities (UN-Habitat, 2013). It defines social equity as the fair distribution of resources, opportunities, and services, addressing differences caused by socioeconomic factors (UN-Habitat, 2013).As, Pratt (2014) explores the evolving role of culture in urban development, highlighting major shifts, he identifies main aspects of differences, including education, technology, and governance, emphasizing cultural inclusivity and equity (Pratt, 2014). He highlights the importance of integrating diverse cultural practices to foster social cohesion and economic growth, aligning with the broader discourse on creating inclusive, equitable cities for multicultural communities. As cultural inclusivity in urban spaces involves creating communities that respect and cherish cultural diversity while fostering mutual understanding and acceptance among different groups. According to (Uitermark, 2012)the pursuit of urban equity is essential to achieving social justice in cities. (Sandercock, 2009) highlights the role of public spaces as sites of cultural exchange and interaction, where diverse communities can coexist and thrive. (Okano & Samson, 2010)highlights the importance of urban cultural diversity in metropolitan cities, suggesting that successful cities should recognize the value of diversity. Correspondingly, Marcuse (2009) discusses that spatial justice and urban equity requires the equitable distribution of public services including green spaces, recreational facilities, and cultural amenities. However, as (Madanipour, 2003) notes, many urban spaces fail to accommodate the multicultural community needs, which might lead to social fragmentation. This highlights the importance to have flexible and adoptable public spaces that consider the values, and preferences of diverse cultural groups, allowing them to practice their culture habits without being judged (Sinha et al., 2024). These sensitive public spaces align with the concept of “Cities for Life”, which places people at the centre of development based on principles of equity and justice (Abdelfattah & Nayer, 2023), and promoting social cohesion (Marcuse, 2009).This research is proposing urban design as a tool to approach more equitable and inclusive open spaces (UN-Habitat, 2014).

3.2 The Role of Urban Design in Fostering Urban Equity and Cultural Inclusivity in Urban Spaces

Urban design plays a critical role to approach equity and justice in public spaces. (Gehl, 2010) highlights the significance of human-centered design principles to create vibrant public spaces. He asserts that well-designed public spaces foster social interaction, and promote cohesion communities. (Carmona, 2010)supports the argument by highlighting the necessity for adaptable and flexible design solutions that can accommodate the changing needs of the multicultural communities of public spaces. Ensuring that their needs and preferences are adequately addressed (Carmona, 2021). In order to foster equitable and resilient communities to create inclusive urban spaces that address social, and economic challenges (Harris et al., 2023) highlights the importance of integrating accessibility into urban design to promote social equity and urban resilience, offers a model for inclusive urban design, aligning with the goals of creating equitable, sustainable cities. On the other hand (Sinha et al., 2024) focuses on how inclusive design and participatory approaches can strengthen social cohesion, ensuring urban spaces benefit all residents and promote equitable, sustainable cities (Nasreldin & Abdelfattah, 2020).

4 THE METHOD

Towards investigating urban equity and cultural inclusivity in public spaces, several scientific methods were adopted. An integration of multiple qualitative tools were implemented, in order to study the role of urban design in fostering urban equity, as observation, documentation, photographing, tracing, and looking for traces (N. Groat & Wang, 2013). On site observations through twelve field trips were applied to examine the inclusivity of public spaces. Six trips were completed on weekends (three trips in the day time and three trips at evening time). The other six trips were conducted on the weekdays (two trips in the day time and two trips at evening time), distributed among the four sessions (summer, winter, autumn and spring).Annotated maps and behavioural analysis were adopted to study the interaction of diverse cultural groups within the public spaces. During the field trips, the research conducted semi-structured interviews (Aboubakr et al., 2020) with

the users and visitors. The interviews tackled criteria related to the frequency of visits, activities conducted during the visits, and their sense of safety and comfort. Information were collected regarding the availability of services and facilities, quality of the set-up, vegetation and shadings, lighting during night visits, availability of parking spaces. Discussions were raised about the ability of the space to accommodate multi-culture communities from different nationalities and their overall sense of comfort, equity and cultural inclusivity in the Wadi Hanifa platform.

4.1 Framework for Inclusive Design: Improving urban equity in diverse public spaces.

The study proposes a robust framework for assessing urban equity and inclusive design to improve the interaction of diverse cultural groups within the public spaces. The framework reviewed the literature related to multiculture societies, urbanization of cosmopolitan cities and culture inclusivity, in order to develop a clear understanding of urban equity, urban equality and urban justice (Norman-Major, 2011). Equality means that everyone is provided with the same opportunities or identical resources, regardless of their individual circumstances or needs. It is based on the premise that everybody is in the same position and needs the same level of support (Minow, 2021). In equality, individuals and groups receive equal resources, regardless of their unique situations. Though, this approach does not take into consider the variations of outcomes, as everyone get advantage from the same level of support, although their different needs (Chu, 2019).On the other hand, Equity focuses on fairness rather than on equality. It takes into account that individuals are different. As Equity as a concept is trying to provide the resources or opportunities necessary to achieve equal outcomes. Equity recognizes these differences and provides unique support to individuals or groups, ensuring that every person receives the needed support to succeed (Lewis et al., 2021). Unlike equality, equity addressing individual needs for fairness, which means that some may require more support than others to achieve the same outcome (Norman-Major, 2011).Justice goes one step further from support, by tackling the fundamental causes of inequality (Lewis et al., 2021). It ensures that everyone's needs are met by removing any barriers and challenges. Justice is all about creating conditions where fairness is integrated and implemented (Minow, 2021). A model that incorporates equity, equality, and justice enhances wellbeing, social cohesion, and finally leads to the creation of inclusive public spaces (Lewis et al., 2021).

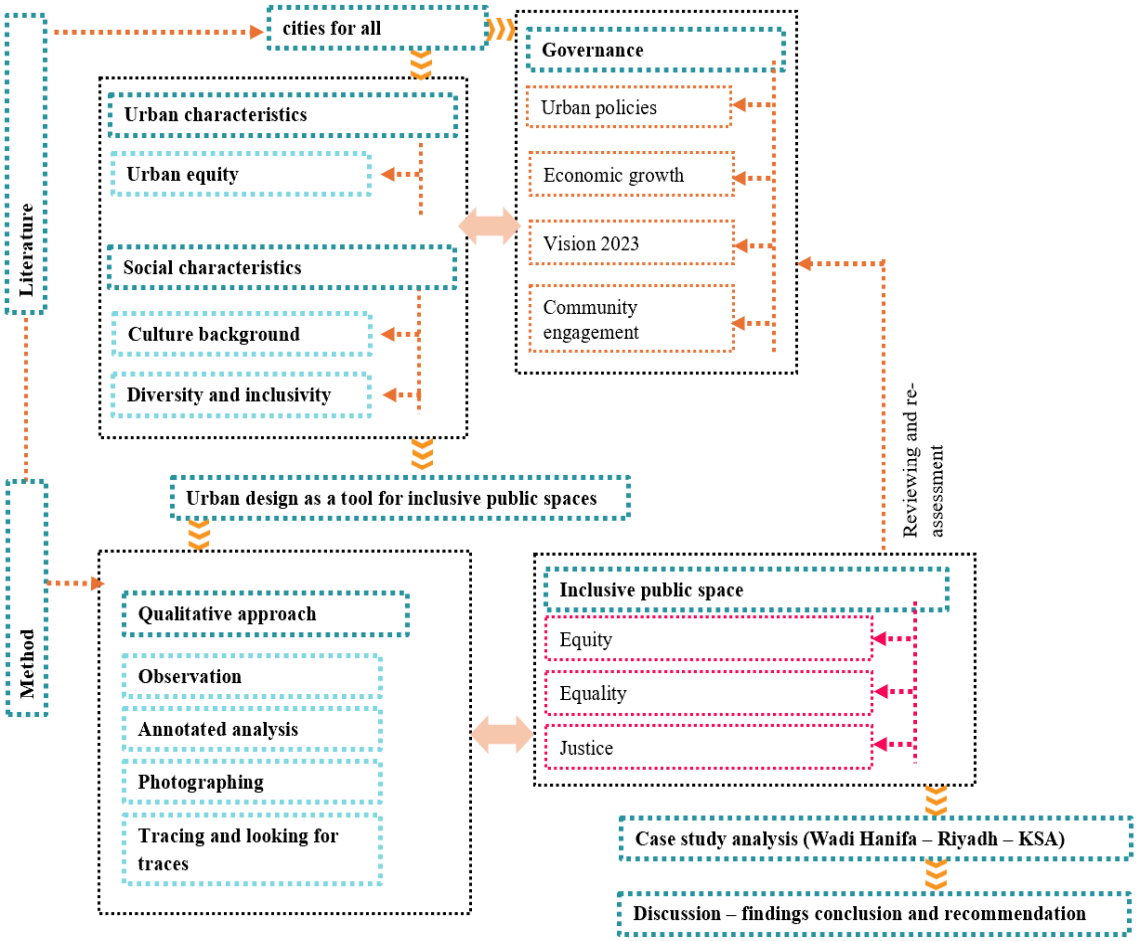

Figure 2: Urban design framework for inclusive public space – Source: Author

5 CASE STUDY: WADI HANIFA, RIYADH:

Throughout its history, Saudi Arabia has developed a cosmopolitan society, due to the free movement of traders and pilgrims, fostering cross-cultural and environmental diversity. Saudi Arabia is known for its multiculturalism, rooted in the coexistence of various national cultures (Al-Hathloul, 2017). This multicultural community includes Muslim Arabs and numerous other groups who have moved to the country for employment, bringing with them their unique cultures and languages. Saudi Arabia's population, exceeding 35 million people, diverse in terms of gender, class, and country of origin, with an estimated 10 million non-Saudis residing in the country (Ahmad Taha & Abdelfattah, 2023).Riyadh city (capital of Saudi Arabia) is considered one of the rapid growing cosmopolitan cities in the middle east and Asia within the past decade (Elsheshtawy, 2021). It is characterized by culture diversity that emphasize values such as equality, and mutual respect. It is becoming a hub for scientific and economic innovation allowing cultural expression and diversity. (Al-Naim, 2008) highlights the importance of preserving cultural identity while accommodating the needs of a diverse population in Riyadh. The concept of multiculturalism in Riyadh city can be recognized on various levels, starting from the top down urban policies that support inclusion, bottom to the daily practice of equity, equality and justice (Al-Hathloul, 2017).Wadi Hanifah represents a natural watershed for the floods and rainwater in an area of 4000 m² in the Najd region, located at the Riyadh Province, in central Saudi Arabia (Fahad & Sulaiman, 2017). The valley runs for a length of 120 km (75 mi) from northwest to southeast, cutting through the city of Riyadh, the capital of Saudi Arabia (Philby, 1920).

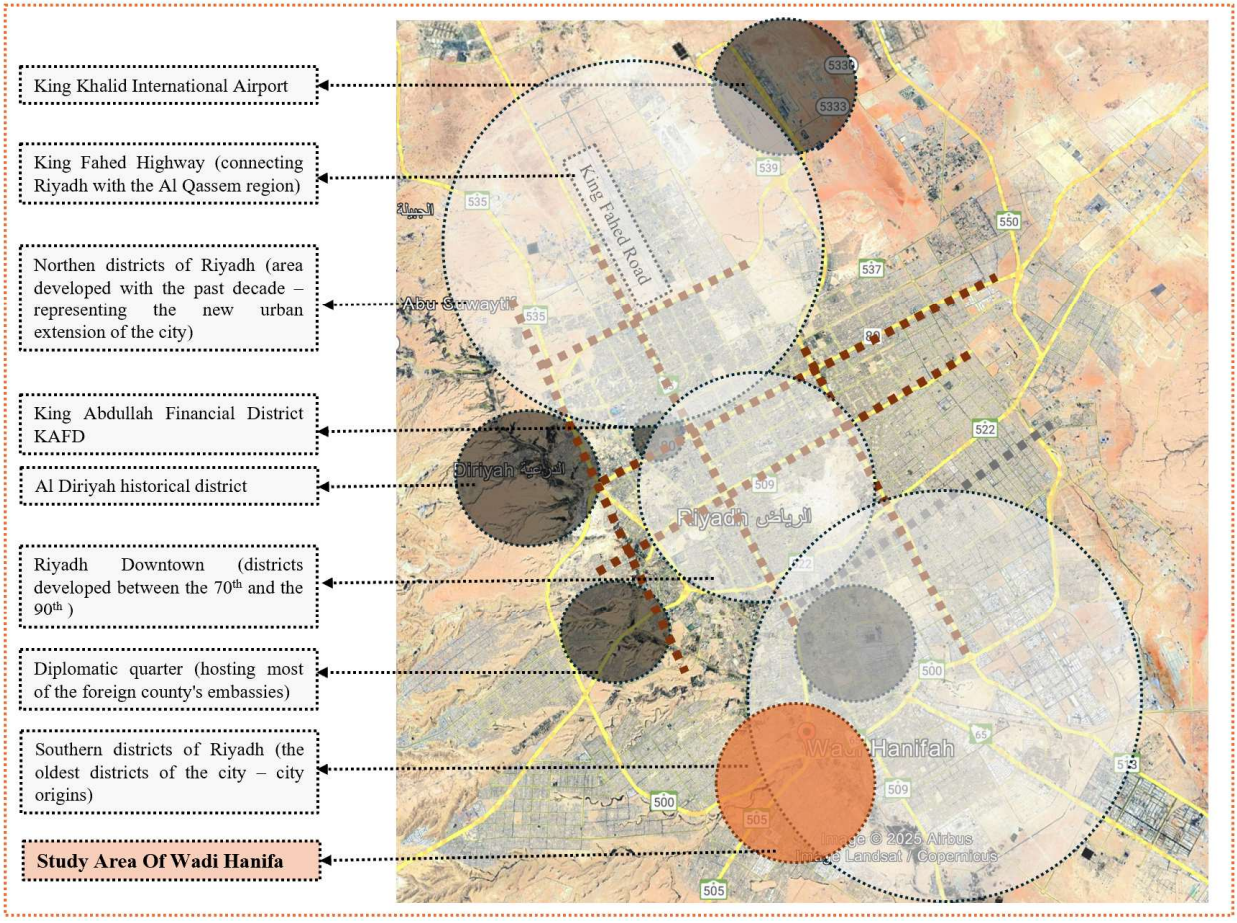

Figure 3: Riyadh City – Source: Google Earth with Author's annotation

The renovation of Wadi Hanifa serves as an example of creating spaces that are inclusive and accommodate accessibility while paying attention to cultural respect and environmental sustainability (Alhathloul, 2022). The Royal Commission for Riyadh City prioritized the conservation and renovation of Wadi Hanifa due to its strategic location and potential investment for Riyadh and its residents (The Royal Commission for Riyadh City, 2025).Back in 1987, Wadi Hanifa was declared as a development area under the direct supervision of the Commission. By 1994, an active renovation plan developed to a comprehensive action

plan. By 2002 Wadi Hanifa comprehensive development plan was approved as the master plan encompassing water resource management, environmental categorization, and land use (The Royal Commission for Riyadh City, 2025).The valley landscapes 47 kilometres of pedestrian walkways, complemented by 7.4 kilometres of rock-paved pathways overlooking rock formations, green spaces, and water canals. The pathways are built to cater to pedestrians as individuals, with strollers and wheelchairs; they also feature seating areas for relaxation and comfort purposes. A two kilometre waterfront promenade runs parallel, to the paths and provides views of the lake dam equipped with palm trees and public amenities. This promenade includes sections where pedestrians and families to picnic and appreciate the lakes beauty, with entry points connecting it to the lake. By incorporating principles of fairness into the design process the initiative has enhanced accessibility. The Royal Commission, for Riyadh City in 2025 provides a blueprint for developing areas in fast growing cities. It shows how careful planning can promote accessibility, to all individuals and communities while also embracing diversity and supporting preservation (The Royal Commission for Riyadh City, 2025).

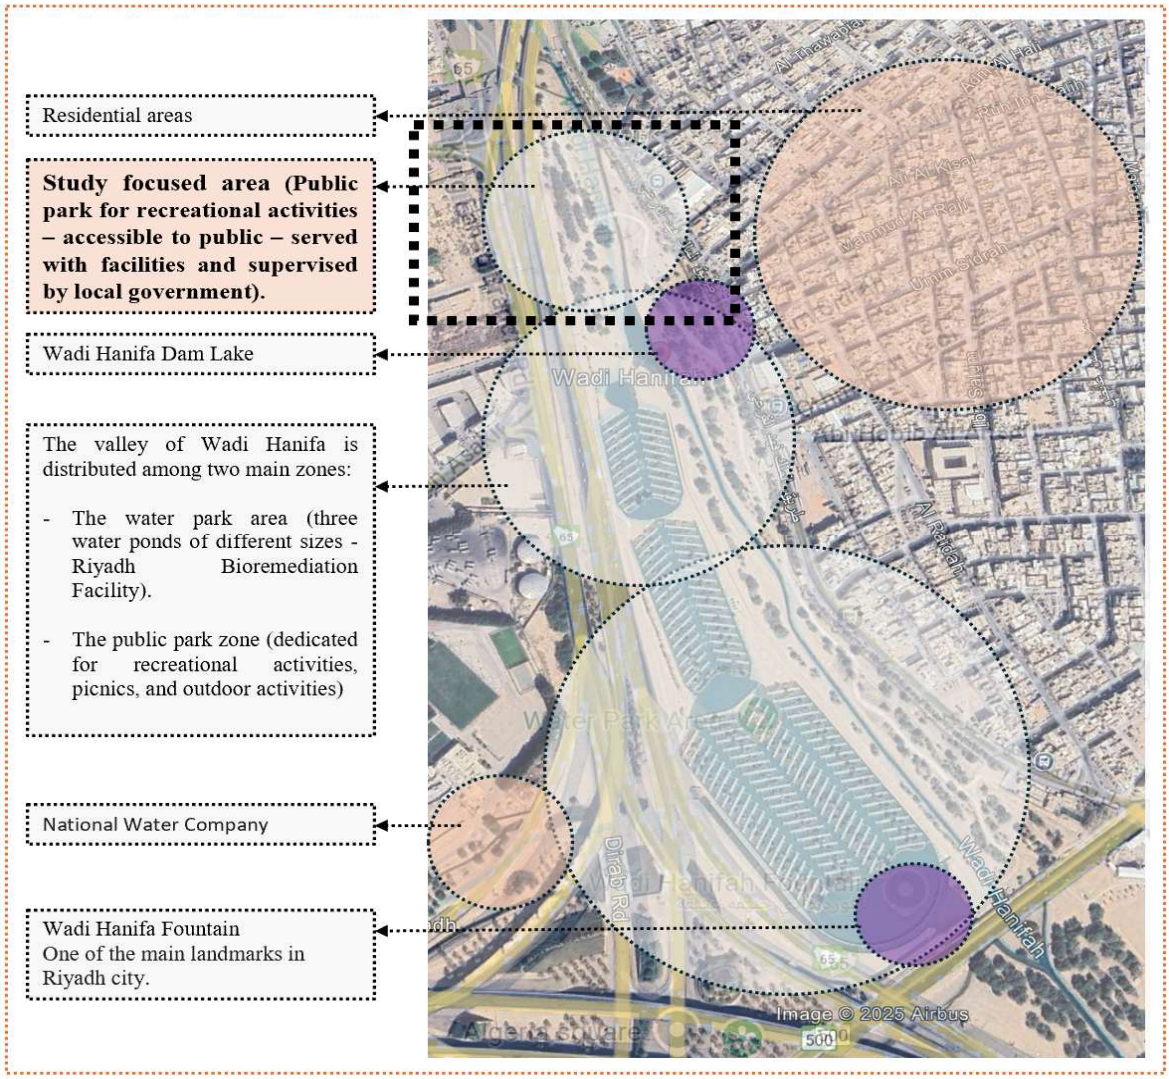

Figure 4: Wadi Hanifa – Source: Google Earth with Author's annotation

5.1 Wadi Hanifa existing conditions documentations and analysis

Documenting the existing conditions contributes a deeper understanding of the layout with insights into the facilities and functions. A layer of analysis has been added in the form of the Annotated maps and behavioural analysis, to explore the potential and determine its variables as an approach for developing a set of guidelines and framework for assessing urban equity in diverse public spaces, targeting further enhancement and improvement. The valley of Wadi Hanifa has One of the main landmarks in Riyadh city, which is the Wadi Hanifa Fountain, located directly before the water parks. The valley of Wadi Hanifa is distributed among two main zones: The water park area (three water ponds of different sizes – Riyadh

Bioremediation Facility), with direct connection to National Water Company, and The public park zone (dedicated for recreational activities, picnics, and outdoor activities). The study focuses on the northern zone of the valley, above the area of the Dam Lake. The area is designed as an urban space for public park and recreational area, where services are allocated, such as toilets and praying areas for both genders, in addition to barbecue area for outdoor cooking activities).

6 DISCUSSION:

The research has investigated Wadi Hanifa as a case study to learn more about public spaces, and its resilience to accommodate various users from multiculture backgrounds. As per the case study documentation of the existing condition, the valley of Wadi Hanifa consists of two main zones: zone one, The water park area (Riyadh Bioremediation Facility) with direct connection to National Water Company, and zone two, the public park zone (dedicated for recreational events, picnics, and outdoor activities). The

research focuses on zone two, where the area is dedicated for public use as park and recreational space. It covered the northern part of the valley, above the area of the Dam Lake. The findings of this research demonstrate the important role of urban design is in the implementation of equity and justice in the use of public spaces, particularly in the growing cosmopolitan city of Riyadh. Studying the case of Wadi Hanifa in Riyadh, the analysis demonstrates how the space is capable of fostering cultural inclusiveness and overcome the challenges of multiculturalism. The semi-structured interviews conducted during field trips to Wadi Hanifa's public park zone (Zone Two) provided valuable insights into how this public space serves a multicultural platform for local community and visitors. The users' feedback stated that the Wadi serves as a public space that promote inclusive community to accommodate different cultural groups, support social cohesion and environmental sustainability. The public space of Wadi Hanifa integrates the specific needs of the multicultural community of Riyadh, the visitors stressed on the ability of the space to provide various amenities and facilities that meet various cultural practices, age, and gender specific needs. Also, they noticed that the design of the public space provides zones or like clusters which are enclosed within rock formations. The use of contextual natural materials promotes the sustainability approaches aligning with the vision 2030. In addition, the majority of women during the interviews focused on the importance of the clusters created to provide a semi-private spots for families especially women to enjoy some freedom, free of restrictions, without being visually exposed to others. Moreover, the space provides prayer areas and water closets for both genders, providing praying carpets, in the outdoor for men, and others in private rooms for ladies. Regarding other activities, the interviews spotted that the Wadi Hanifa visitors usually enjoy outdoor cooking within the picnic areas, using the pre-installed built-in barbeque unites. The space is designed to reflect a deep understanding of the cultural and social dynamics of the community. The direct access to such facilities is directly aligns with the principles of urban equity, which emphasize the fair distribution of resources and opportunities, so that everyone, regardless of their background, can access and benefit from Wadi Hanifa public amenities. The public spaces of Wadi Hanifa contributes to accommodate a wide range of activities, from walking and social gatherings to recreational activities and cultural expressions.

This adaptability ensures the public space design flexibility to be accessible to diverse user groups over time, raising a sense of belonging and mutual acceptance among individuals. This design flexibility can be clearly detected through features like pedestrian walkways, wheelchair-friendly pathways, and seating areas located strategically. These design qualities is emphasizing that the space is inclusive for all, including elderly and individuals with disabilities. This aligns with the core principle of the urban justice, and the right for everyone to enjoy the space freely, with equitable access to outdoor spaces and recreational facilities.

Wadi Hanifa usually hosts one of the important cultural events in Riyadh (the festival of Noor Riyadh: a group of art pieces created by light shades, shiny installations and illuminated pillars). Wadi Hanifah has been one of the significant spots of Noor Riyadh Festival, representing a unique dynamic hub for art and culture. These installations was designed and implemented by both international and Saudi artists. Where Wadi Hanifah has become a shared space for connection and culture interactions, encouraging the dialogue among different culture groups. They highlight the valley's unique role as a bridge between Riyadh's natural heritage and its evolving multiculture urbanism.

The Wadi Hanifa success in encouraging social cohesion proves the significance of urban design in developing the common platform to be accommodated by divers users. It promotes a sense of community. This is remarkably in a cosmopolitan city like Riyadh, where the population includes a combination of locals and expats from diverse cultural backgrounds.

7 CONCLUSION

Urban design contributes to fostering social equity and cultural diversity. The literature emphasizes the importance of urban design in promoting social cohesion, and enhancing the quality of life for diverse individuals. In terms of how urban design can address the challenges of multiculturalism, urban justice, and social equity in rapidly growing cosmopolitan cities. This research aims to study the role of urban design as a tool to enhance inclusive public spaces. Wadi Hanifa's documentation provides a valuable opportunity to explore these principles in practice, highlighting the potential of inclusive urban design to transform public spaces and promote social equity in rapidly developing cities. The semi-structured interviews showed a great integration between the multiculture users and the facilities that meet their requirements. The public spaces provide a pleasant environment with waterfront presence. Offering opportunities for multiple activities,

sufficient to accommodate all age groups and achieve urban inclusivity to all social and culture classes. The space is well designed with a flexibility to accommodate various activities over time, that changes from walking, playing, outdoor cooking, and social gathering activities. One main thing can be highlighted, that sense of nature integration between the multiculture communities to coexistence in harmony, where every group can express his culture freely and enjoy the space.

In conclusion, based on the literature review, the semi-structured interviews and the case study analysis, the research suggests that Wadi Hanifa has been successful in creating a welcoming and attractive environment that promotes a strong sense of place. The observations and annotated maps analysis indicate that Wadi Hanifa has the key factors to become a successful public space. As cities continue to evolve and diversify, the main outcome from Wadi Hanifa to collaborate efforts to create 'Cities for All' where everyone, regardless of their background, can live and flourish.

These results could be utilize in future studies to create recommendations for improving inclusivity in diversity-focused open space. A range of innovative tools could be considered to evaluate public open space inclusivity.

7.1 Limitations and Future Research

This research sheds light and gives valuable insights on the role of urban design in promoting urban equity, and how it can foster cultural inclusivity, however, there might be some limitations. The study focuses mostly on a single case study, which might restrict the generalization of the findings and its applicability to other spaces. Future research could benefit from examining multiple case studies across various cultural and contextual locations, to enrich the understanding of the phenomena. Moreover, the current study mainly utilize the qualitative methods, such as observation, semi-structured interviews and annotated maps. By integrating quantitative approaches, such as user surveys or statistical analyses, researchers could gain a comprehensive understanding of the dynamics of equity, equality and justice in public spaces.

7.2 Declaration

During the preparation of this research, the author used plagiarism checker and Grammarly in order to check grammar and proof reading, After using this tool, the author reviewed and edited the content as needed and take full responsibility for the content of the publication.

1 ABSTRACT

Cities drive the economic growth of any country. In a fast globalising and urbanising world, cities are competing not only to attract investment and lure skilled labour but also to provide solutions to urban and social challenges, as well as create spaces that are liveable for its citizens. The global south has experienced an exponential increase in the number of people living in cities, making it the fastest urbanising region in the world. This presents both challenges and opportunities for the cities. South African cities are not excluded from the current realities of urbanisation and globalisation in that the cities must also position themselves to be global players but also having to deal with past spatial injustices at the same time. Cities are pushed to ensure that they enhance and maintain their unique city advantages to contest in the global arena. This study investigates factors that contribute to city competitiveness within Gqeberha aiming to position the city for global competitiveness. The study examines geographical location, human capital and urban planning as contributing factors to global competitiveness. The research provides insights into the city's strengths and challenges. A comprehensive competitive cities framework for developmental states was developed through this research, that Gqeberha and other developing states can use to set their cities on a path to global competition.

The qualitative research approach was used in the study, and primary data was gathered through semi-structured interviews with nine key informants who are professionals working with land use management, spatial planning and economic development. Furthermore, the study collected secondary data that includes documents, maps and literature. A combination of qualitative data analysis tools that includes, thematic, document and triangulation analysis was employed in the study to analyse collected data. The key findings show that Gqeberha has strategic assets, such as two seaports and Special Economic Zones, but that their influence is hampered by underutilization and a disconnected location. The city also has a human capital shortage, which results from a mismatch between industrial demands and educational attainment and a reliance on foreign expertise. Deficits in urban planning, such as old MSDF and problems with internal collaboration, further hinder development. In addressing these challenges, the study proposes a framework for enhancing competitiveness in Gqeberha and other developing states. The framework highlights that emphasis and priority needs to be placed on infrastructure development, effective urban governance, strategic spatial planning and human capital development. The implication of this study is that by implementing these recommendations Gqeberha can position itself to be globally competitive. In addition, future research should investigate other developing cities' examples of successful urban planning, assess how SEZs affect social and spatial inclusion, identify skills gaps that exist between industry demands and education, and investigate best practices for port management for developing nations.

Keywords: location, human capital, city competitiveness, urban planning, urbanisation

2 INTRODUCTION

2.1 Background

In the rapidly changing landscape of the 21st century, cities have become crucial drivers of the global economy. Economically agile and entrepreneurial people are drawn to the promises and opportunities that cities offer. As a result, many cities are experiencing rapid urbanisation and globalisation (SACN, 2016). It is estimated that Africa, the fastest urbanizing region, has an annual urbanization rate of 3.6%, with some cities growing at an average rate of 5% per year, faster than other global regions. This rapid growth has led to a significant increase in the demand for housing, infrastructure, and basic services (Korah et al., 2019).

Cities are now faced with the challenge of competing for investment and attracting talent while also addressing urban and social issues (Ghahremani et al., 2021). South African cities, including Gqeberha,

formerly known as Port Elizabeth, are not immune to these trends; they must deal with the past consequences of apartheid planning while also dealing with current realities brought about by urbanisation and globalisation.

The State of South African CitiesReport (2016) highlights the following as issues currently faced by South African cities and towns: 'demographic changes, relative strength of metro economies, basic service provision, increasing inequality and exclusivity of cities, understanding of and support for local government' To address these challenges, cities like Gqeberha must focus on enhancing their competitiveness, wherein the city should exploit or create a competitive advantage resulting in sustainable urban environments and economic growth relative to its competitors (Van Noorloos& Kloosterboer, 2018; Porter,2015).

The European Commission defines competitiveness as the "ability of a region to offer an attractive and sustainable environment for firms and residents to live and work" (Rand, 2017). Factors influencing city competition are multifaceted and context-specific, indicating that it's not a one-size-fits-all. This paper investigates factors contributing to city competitiveness in Gqeberha focusing on geographical location, urban planning, and human capital. These aspects have not been thouroughly investigated in previous studies of Gqeberha, which is essential for positioning the city for global competitiveness. The aim of the study is to develop a framework to enhance competitiveness in Gqeberha and other cities in developing countries of the Global South.

3 LITERATURE REVIEW

3.1 Defining city competitiveness

Over the past three decades, cities and urban centres have been increasingly focused on the competitiveness of their economies, firms and labour. This has been motivated by globalisation, which has integrated world economies and created mutual dependence (Jovović, 2017). For cities to be active participants in the global economy, they should adapt to technological advancements that enable interconnectivity and communication among all actors (Porter,2000). Furthermore, cities must reshape their urban spaces to accommodate a new labour force with specialised skills, mobility needs, and demands for lifestyle and social amenities (Guaraldi et al., 2020). The World Economic Forum's Global Competitiveness Report (2016) describes the competitiveness of cities as "'the set of factors – policies, institutions, strategies and processes – that determines the level of a city's sustainable productivity". Sustainability refers to a balance of economic, social, and environmental issues. Productivity is about utilising resources effectively to fuel economic development. According to Villamejor-Mendoza (2020), almost everything matters for competitiveness: schools, roads, financial markets, and citizens.

Although competition is context-specific to a country or city, general factors influence competition across the spectrum (Momaya, 2016). According to Ferreira and Ratten (2017), factors that also influence competitiveness are the resource endowments of a city. These resource endowments are tangible and intangible, including locations near major economic points such as major transportation routes, human capital, and knowledge in a region. The argument is that even if a city is geographically disconnected from other major cities, it can still be attractive and competitive based on its intangible assets, such as good urban planning strategies and policies, skills and knowledge. Baker et al. (2017) state that some of these factors that influence city competitiveness are outside the control of the city government and, by nature, are the mandate of the national government. However, a city's ability to be competitive may be hindered by urban policies that fail to address land management issues, poor business environment, weak infrastructure, low labour skills, and weak governance.

3.2 The Role of location

According to Ferreira and Ratten (2017), location is defined as a place or city with a distinct geographic space. However, it is argued that the determinants influencing location are not solely geographic; they also encompass infrastructure provision and service delivery. The competitive advantage of cities and locations presents a paradox: one might assume that, in an increasingly globalized world with open international markets and the free exchange of ideas and knowledge, location would be less significant. Therefore, when economic activity is carried out in a specific location, it is done with reason (Snowdon & Stonehouse, 2006). Some of those reasons may include soft location factors that a city offers, such as attractive landscapes,

recreational and shopping facilities, universities, and libraries. Such location factors are essential for firms and people who want to move and stay in a city (Gremm et al., 2018).

Gugler (2019), referring to Porter's diamond of four interrelated components of competitiveness, mentions that location comprises inherited and created factors. Inherited factors consist of natural resources found in a specific area, while created factors include efficient infrastructure, such as communication, transport, and energy infrastructure. Bam et al. (2020), elaborate on this by noting that location-related considerations also include natural advantages that comprises geography and climate, as well as the cost of capital, which includes physical capital, financial capital, and land costs.

Additionally, the quality and reliability of infrastructure play a critical role in location decisions. Infrastructure affects competitiveness in two ways. First, businesses depend on global access points such as airports, ports and digital infrastructure, to sell their goods and services both domestically and internationally. Second, a city's competitiveness is influenced by its ability to efficiently connect its people and physical assets for optimal usage (Parilla & Trujiilo, 2018). This indicates that industries tend to conform to pre-existing patterns of people and the resources on the land. Therefore, for cities to attract businesess, they must implement a development and beneficiation policy framework that accurately assesses and addresses the location determinants affecting firms' decisions on where to establish themselves (Bam et al., 2020).

3.3 Human Capital impact of city competitiveness

High levels of human capital provide cities with a competitive advantage. Human capital encompasses various education levels, including primary, secondary, college, and higher education. Universities and colleges serve as key reservoirs of human capital (Debra et al., 2018). The concept of human capital is rooted in the endogenous growth theory, which Paul Romer first advocated in the 1980s. It is defined as the skill sets and abilities of individuals, and can also include labor, skills, talents, and knowledge as forms of productive wealth. This expertise is developed through both formal and informal education (Osiobe, 2019). According to Antonenko (2021, p. 526), cities such as London, New York, Singapore, and San Francisco – considered among the world's most competitive – have achieved their success through clear municipal policies that prioritize human capital, strategic investments, and technological development. This emphasis has transformed them into global economic, social, and cultural hubs, attracting residents and businesses alike. To attract investments and foster a safe environment for all, other cities aiming for growth should prioritize human capital. Albach et al. (2018) argue that for a city to enhance its performance, it must be open to change, continuous improvement, and the adoption of new technologies. Additionally, the accumulation of knowledge is crucial for driving sustainable long-term growth in cities (Jones, 2019; Schilirò, 2019). This is why cities in developed countries tend to grow faster than their less affluent counterparts; they often act as custodians of innovation and technology (Chirwa & Odhiambo, 2018).

In addition to developing its own human capital, a city can also attract and retain talent from outside by offering a high quality of life and diverse opportunities. This concept is supported by Royuela (2014, p. 927), who emphasizes that a city's amenities and lifestyle options play a significant role in influencing the location choices of a highly skilled workforce. According to Katz and Wagner (2014), curriculum modifications that consider industry demands also draw talent and investments, boosting city competitiveness and growth.

Some scholars argue that for cities to effectively harness human capital through innovation and knowledge, they must promote the development of clusters. Clusters consist of interconnected businesses, universities, research institutions, and skilled individuals, serving as vital drivers of economic growth and societal progress. Nurturing and supporting these clusters has become a strategic necessity for cities aiming to succeed in today's dynamic and disruptive environment (Florida et al., 2018). To foster cluster development, cities need to ensure that their educational systems align with industry needs. This alignment helps create a workforce equipped with the critical knowledge and skills necessary for these industries to flourish (Porter, 1998). By facilitating partnerships between industry and educational institutions, cities can enhance workforce readiness and stimulate innovation (Bathelt & Henn, 2014). Additionally, Katz and Wagner (2014) suggest that adjusting curricula to meet industry demands can attract talent and investments, ultimately boosting city competitiveness and growth.

3.4 Urban planning and its influence on competitiveness

Urban planning and related spatial policies are essential tools for cities striving to succeed in an increasingly competitive global environment. The dynamic and transformative demands of the global economy have pushed cities to adopt strategic approaches to enhance their competitive edge. Consequently, urban planning and development have become important frameworks for improving city competitiveness (Yigitcanlar & Bulu, 2015). Urban planning involves the strategic organization of land use, transportation, infrastructure, and public spaces to achieve sustainable and equitable development within urban areas (Bibri et al., 2020). When combined with spatial policies that guide the distribution of resources, investments, and economic activities across a city or region, urban planning can shape both the physical and economic landscape, influencing a city's competitiveness and livability (Todes & Turok, 2018).

Effective urban planning can increase a city's competitiveness by creating efficient and attractive urban environments. This includes promoting compact, mixed-use development that reduces commuting distances and encourages walking, cycling, and the use of public transportation. By prioritizing pedestrian-friendly streets, well-connected public spaces, and diverse mixed-use neighborhoods, cities can attract more residents, businesses, and visitors (Buck et al., 2017). Moreover, cities should adopt spatial policy approaches that enhance urban conditions by leveraging their unique assets, knowledge, and human capital (Todes & Turok, 2018). However, to effectively improve competitiveness through urban planning and spatial policies, strong urban governance is essential. Good urban governance encompasses "the many ways individuals and institutions, both public and private, plan and manage the common affairs of the city. It is an ongoing process that allows for the accommodation of conflicting or diverse interests and facilitates cooperative action" (Nissen, 2021). The collaboration among various urban governance actors can have a positive impact on a city's competitiveness (Parilla & Trujillo, 2018).

Map 1: Gqeberha locality Map. Source: (AfriGIS,2023)

4 CASE STUDY: GQEBERHA

Gqeberha is a port city situated in the Nelson Mandela Bay Metropolitan Municipality. Formerly known as Port Elizabeth, the city has an estimated population of 1.26 million and encompasses a land area of 1,959 km², making it the largest metropolitan municipality in the Eastern Cape province (Cogta, 2020). Gqeberha is home to two significant ports that play a vital economic role in the province: the Port of Port Elizabeth and the Port of Ngura (Nelson Mandela Bay, 2022). Additionally, the city is recognized as South Africa's hub for automobile manufacturing (SACN, 2021). The city hosts major automotive companies such as Volkswagen,

ISUZU, FAW, and BAIC, which play a significant role in its economic growth. Additionally, the city has designated the Coega Special Economic Zone (SEZ) as a hub for industrial development. The SEZ features two ports and a cluster of heavy, medium, and light industries (COGTA, 2020; NMBM, 2021). This advantageous location provides a strong industrial cluster along the coast and key trade routes (see Map 2). Furthermore, the Automotive Industry Development Center (AIDC) offers skills development training and incubation programs for the automotive sector. In 2018, Gqeberha contributed 2.63% to South Africa's Gross Domestic Product (GDP) and was the largest contributor to the GDP of the Eastern Cape Province, accounting for 34.07% of the province's GDP in that same year (COGTA, 2020). The city's economy is primarily driven by four key sectors: manufacturing, community services, agriculture, and finance. The manufacturing industry is particularly diverse, encompassing automobile manufacturing, clothing and textiles, renewable energy, and chemicals (NMBM, 2021). A significant portion of the city's workforce is employed in this sector.

5 RESEARCH METHODOLOGY

This study employed a qualitative research approach to explore the factors that contribute to city competitiveness in Gqeberha and to develop a framework for enhancing that competitiveness. Both primary and secondary data were utilized for data collection. Primary data was gathered through semi-structured interviews with key informants, including professionals in land use management, spatial planning, and economic development. These interviews offered valuable insights into the city's strengths, challenges, and opportunities. Additionally, secondary data was collected from relevant documents, maps, and literature. To analyze the qualitative data, a variety of tools were employed, including thematic analysis, document analysis, and triangulation. This comprehensive set of analytical tools was used to ensure the credibility and validity of the results.

6 RESEARCH FINDINGS & DISCUSSION

6.1 Gqeberha fragmented cluster development

The study results indicated that Gqeberha has substantially developed clusters in Special Economic Zones (SEZs), attracting multinational corporations and foreign direct investment (FDI). These clusters are primarily manufacturing oriented. However, this has not translated into improved socio-economic conditions for local residents, revealing a disparity between corporate benefits and citizen welfare. The geographical isolation of SEZs and inadequate municipal integration contribute to this inequality, leaving surrounding areas underdeveloped.

To tackle these challenges and encourage inclusive prosperity, Gqeberha requires urban transformation. This means the city should become a central hub for addressing current urban issues. Initiatives must focus on incorporating the urban poor into the economic and social framework of the city, ensuring that all residents benefit from its prosperity.

6.2 Strategic location and assets underutilization

Gqeberha, the largest city in the Eastern Cape, boasts a strategic location with two seaports – Port Elizabeth and Ngqura – enhancing trade potential. However, these ports are underutilized due to infrastructure and management issues, limiting the city's urban development and international competitiveness. The city also has an airport in need of significant upgrades to meet global standards. While Gqeberha offers various social amenities, challenges such as high crime rates, housing backlogs, and informal settlements negatively impact liveability, particularly for economically disadvantaged residents.

Rapid urban growth is further straining ageing infrastructure, including power, water, and sanitation systems. Additionally, political instability hampers effective decision-making and development initiatives. Addressing these challenges through targeted strategies and ensuring political stability is essential for Gqeberha to capitalize on its strengths and enhance its standing as a sustainable, competitive city on the global stage.

6.3 Human Capital Deficiencies

The paper investigates the crucial components of human capital necessary for Gqeberha's development as a competitive city, emphasizing the significance of investing in education. It highlights that cities prioritizing education are better equipped to handle global competition. With only 8% of the population holding higher education degrees, and a substantial portion having only primary (69%) or secondary education (25%), Gqeberha faces significant educational challenges (SACN, 2021).

Despite a public university and several educational institutions, the city has launched various workforce development initiatives to address skill gaps, such as internships and community training (Mativenga et al., 2021). Gqeberha boasts a rich heritage and quality of life but struggles with branding and global visibility.

The university plays a role in addressing urban issues and skill development, yet its impact remains unclear. Gqeberha faces hurdles in creating a knowledge-driven economy despite its status as Africa's automotive hub, primarily due to inadequate tailored education programs and reliance on imported skills.

A deficiency in vocational training is evident, exemplified by a local boat manufacturing company that had to import skilled labor from Cape Town, indicating missed opportunities for local workforce development. The city's current initiatives to upgrade skills are insufficient, highlighting the need for enhanced training strategies and closer industry collaboration.

To remain competitive, Gqeberha must invest in human capital, focusing on education and vocational training to build resilience against global competition and ensure sustainable growth.

6.4 Urban planning Challenges

Urban planning is essential for shaping cities and integrating governance, social well-being, economic growth, and environmental sustainability. The findings indicates that Gqeberha's urban governance framework lacks internal collaboration, hindering cohesive development initiatives among various departments. This disconnection limits the city’s ability to enhance competitive advantages and address urban challenges effectively.

In Gqeberha, there is growing demand for densification, evidenced by numerous rezoning applications. However, the city struggles with this demand due to inadequate physical infrastructure and relies on an outdated Municipal Spatial Development Framework (MSDF). The MSDF, crucial for guiding development and investment priorities, needs updating to align with current and future urban needs.

To realize the potential for densification and sustainable development, Gqeberha must enhance its infrastructure and revise its MSDF. The findings highlight both opportunities and challenges for the city, emphasizing the need for proactive strategies and a collaborative approach to foster growth and resilience in Gqeberha.

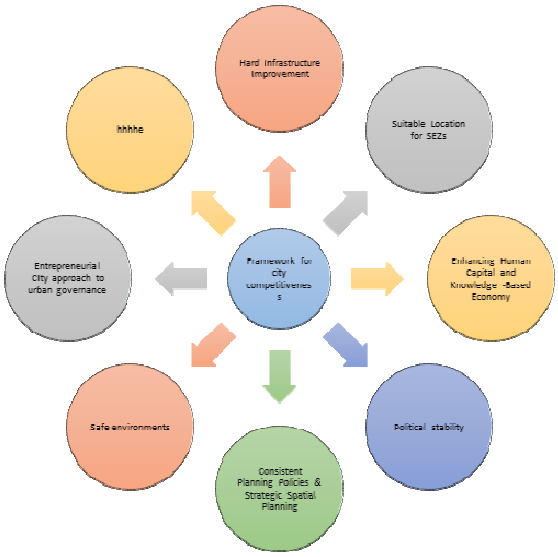

Figure 1: Competitive cities framework for developmental cities. Source: Author.

7 A FRAMEWORK FOR ENHANCING COMPETITIVENESS

Based on the findings, this study proposes a comprehensive framework for enhancing the competitiveness of Gqeberha and other developing cities. The framework focuses on seven key areas: hard infrastructure improvement, consistent planning policies & strategic spatial planning, enhancing human capital and knowledge- based economy, suitable location for SEZ development, entrepreneurial city approach to urban governance, safe environments, and political stability.

7.1 Hard Infrastructure Improvement

According to Eide's (2014) report for the World Economic Forum on the Competitiveness of Cities, urban planning is essential for providing hard infrastructure. Planners must be mindful of how they plan cities, avoiding overplanning or underplanning, which can lead to unpredictable, uneven growth. A balance between planning and organic growth is needed. Additionally, cities should increase their spending on infrastructure to accommodate urbanization demands. Without this, cities may face obstacles to sustainable growth, resulting in sprawl, congestion, pollution, and inadequate public services. However, cities must take a demand driven approach to infrastructure projects that respond to the demands of their local economies rather than a supply side approach that does not consider demand. The Successful implementation of these projects requires careful planning, budgeting, and financial support (Choe and Roberts, 2011).

7.2 Consistent Planning Policies & Strategic Spatial Planning

To thrive competitively, emerging cities must adopt a cohesive approach to development that shapes both public and private investment choices Consistent planning policies are crucial for enhancing city competitiveness for several interconnected reasons. Firstly, such policies establish a stable framework for long-term investment and development, which fosters confidence among businesses and investors. When regulations and zoning laws remain consistent over time, companies can confidently make decisions about where to locate and how to expand, without fear of encountering sudden regulatory obstacles or changes in land use. This stability not only supports local entrepreneurship but also attracts external investment, ultimately driving economic growth and job creation (Kamana et al., 2023).

In addition, a transition needs to be made from conservative spatial planning, which is concerned with preserving order, to strategic spatial planning which is more concerned with dealing with challenges and transformation. Furthermore, this approach is a breakaway from conservative spatial planning that is project orientated rather than being goal orientated. In essence emerging cities need to adopt a strategy that effects change and set good strategic goals instead of the implementation of spatial projects that are effective today and ineffective tomorrow (Albrechts, 2015; Olsen, 2014). Key to strategic spatial planning is the setting out of objectives and the formulation and implementation of strategies to meet those objectives. cities should have a vision for the future assuming that current trends will continue (Salet and Faludi, 2000). Public and private sector coordination and public participation is fundamental in the successful implementation of a strategic spatial plan (Oliveira and Hersperger, 2018). Furthermore, strategic spatial planning appreciates the fact that challenges that are faced by cities that cannot be tackled only by local authorities, as some fall outside the scope of local government, therefore intergovernmental co-ordination is needed (RTPI, 2015).

7.3 Enhancing Human Capital and Knowledge -Based Economy

Cities must acknowledge the growing influence of technologies like AI, big data, and robotics. Thompson and Curella (2021) emphasize the importance of adaptation to these emerging trends. For emerging cities, aligning processes with factors outlined in the Knowledge Economy concept, such as skills development, global competitiveness, and entrepreneurship, is essential (Amo et al., 2017). The initial step for these cities is formulating appropriate policies and strategies. Although specifics may vary, the World Bank's Knowledge Economy Index suggests focusing on themes like education, economic incentives, institutional frameworks, and ICT infrastructure. Additionally, cities should consider factors like Research and Development(R&D), vocational training, government accountability, quality education and investment in innovation and technology as enhancing measure towards their goal (Asongu and Odhiambo, 2020).

The next crucial stage in improving their knowledge economy involves developing partnerships among various stakeholders. These stakeholders include the city government, businesses, research institutions, emerging entrepreneurs, creative individuals, innovators, and residents. Such partnerships serve as platforms

for mutual learning and knowledge exchange, facilitating the pooling of resources for collective advancement (Praharaj et al, 2018).

7.4 Suitable location for SEZ development

The geographical positioning of SEZs plays a crucial role in ensuring broader inclusivity and maximizing their positive impact on local economies and communities. Therefore, a comprehensive approach to SEZ development must incorporate considerations of both regulatory frameworks and spatial planning to foster holistic socio-economic growth which gives a city a competitive edge (Ahmed, 2020; Frick et al, 2019). Thus, the location of SEZs in emerging cities should be orchestrated to serve the collective interests of various stakeholders, including governmental bodies, investors, local enterprises, residents, and workers. The primary objective should be to address pressing socio-economic challenges such as unemployment and poverty. By situating SEZs strategically, cities can harness their potential to stimulate job creation, enhance economic opportunities, and alleviate poverty rates (Ali, 2020).

Cities and national governments need to undertake comprehensive feasibility studies where SEZs are to be located to determine the best suited location that is well connected and has the ability to convert a particular area from rural to urban. Furthermore, the location choice for an SEZ should look at the potential of developing other land uses around the SEZ, such as commercial or residential (Janjua, 2017).

7.5 Entrepreneurial City approach to urban governance

Both theory and practice demonstrate that for a city to be competitive and attract investment, an entrepreneurial approach to city governance is essential. This approach advocates for treating city governance like a business, with the government acting as an entrepreneur to market the city and foster its growth. This involves ensuring fiscal stability and access to financial markets to attract investment and boost investor confidence (Lauermann, 2018).

At the core of this governance approach lies the establishment of Public-Private Partnerships (PPPs) for local government to secure external funding, create employment opportunities, and attract new direct investment (Delmon, 2017). Olsson et al. (2020) refer to these local government initiatives as "entrepreneurial governance," wherein opportunities are identified and assessed, resources are gathered and utilized, and opportunities are exploited.

Furthermore, this city governance model emphasizes the creation of institutions or municipal entities tasked with revenue collection and public service delivery on behalf of the municipality. These entities operate independently from the municipality and mitigate the bureaucratic constraints faced by public entities by adopting private sector delivery models. Although these entities maintain public accountability and transparency, they do not represent full-scale privatization. In addition to revenue collection, these entities are responsible for generating job opportunities across various skill levels (Mabalane, 2019).

7.6 Safe Environments

The UNODC (2016) highlights various factors that contribute to urban crime. Key among these is unregulated urban growth, large income disparities, and inadequate governance. To tackle these issues, cities, particularly those in developing nations undergoing rapid urbanization, need to establish robust regulatory frameworks and enforcement mechanisms. It's essential that these efforts involve active engagement with local communities. Additionally, prioritizing socio-economic inclusion is crucial. This means integrating crime prevention strategies into a range of social and economic policies and programs, including those addressing employment, education, healthcare, housing, and urban planning. By doing so, cities can work towards creating safer and more inclusive urban environments.

Lastly, urban planning approaches in developing cities need to be re-evaluated to ensure the establishment of safe urban spaces. For example, mixed land uses should be encouraged in city development as well a strengthened pedestrian traffic movement. This strategy not only increases the vibrancy of urban areas but also reduces the need for long commutes, which can contribute to safety by decreasing congestion and potential areas for criminal activity. Street layouts design should be in such a way that they deter criminals. This involves careful consideration of factors such as visibility, access points, and lighting to minimize opportunities for crime, while ensuring that housing density standards provide adequate space for community

facilities, natural light, ventilation, and open spaces for residents (Abdul-Kadhum Al-Ghiyadh and Neamah Al-Khafaji, 2021).

7.7 Political stability

Grøn and Salomonsen (2019) contend that the reputation of a city can be adversely affected by political instability. Consequently, it is crucial to proactively address potential conflicts between administrative and political entities. Public managers should also be mindful of their organization's historical reputation, as it could impede their ability to coordinate an effective and unified response when faced with threats to the organization's image. Furthermore, effective management of the discord between politics and administration in Gqeberha is essential to uphold a positive public image and foster collaboration between all actors.

8 IMPLICATIONS OF THE STUDY

The study's findings have important implications for the future of Gqeberha. By adopting the suggested framework, the city can position itself to compete globally while tackling the urgent issues of urbanization and spatial injustice. The framework focuses on key elements related to location, human capital, and urban planning, which are essential for creating a sustainable and competitive city.

Furthermore, the study emphasizes the potential for Gqeberha to become a model for other developing cities that are dealing with similar challenges. By sharing best practices and lessons learned, Gqeberha can contribute to a wider discussion on urban competitiveness in the Global South. The framework outlined in this study provides a flexible blueprint that can be customized to address the distinct challenges faced by different cities.

9 FUTURE RESEARCH DIRECTIONS

Expanding on the findings from Gqeberha, future studies on city competitiveness in developing nations can further explore these several areas:

(1) Assessing the effects of SEZ: Investigate whether the current SEZ model promotes economic inclusion or perpetuates existing disparities.

(2) Enhancing port operations: Study effective port management strategies from prosperous developing countries to identify adaptable solutions for Gqeberha.

(3) Aligning Education Curricula with industry needs: Conduct a skills gap analysis to identify specific mismatches between current educational offerings and industry requirements in Gqeberha.

(4) International promotion: Investigate the impact of global promotion on driving economic growth and competitiveness for Gqeberha.

(5) Urban Governance Collaboration and Spatial Planning: Identify successful instances of collaborative urban planning from other developing cities and evaluate their applicability to Gqeberha.

(6) Contextualizing the competitiveness framework: Refine the proposed competitiveness framework by incorporating specific data and best practices relevant to the South African context.

10 CONCLUSION

In conclusion, the dynamics of competitive cities are shaped by various factors that influence the economic, social, and environmental landscapes. Cities that emphasize knowledge and innovation, allocate resources towards infrastructure, and utilize effective urban planning strategies are more likely to thrive in the global arena. As urban areas face changes in demographics and rapid technological progress, embracing sustainable practices will be crucial for long-term viability. cities must evolve, experiment, and engage in collaboration to create lively and competitive environments that satisfy the needs of their inhabitants.

DOI: 10.48494/REALCORP2025.8015

1 ABSTRACT

Intergenerational childcare, meaning the grandparents helping to take care of the grandchildren, is a common phenomenon in China since we are going through aging population, as well as increasing work pressure on parents. Therefore, the elderly and children, who spend the longest time in the community and use the space and facilities the most frequently, are the group of people that should be prioritized to be satisfied and guaranteed in communities. Considering the physiological and psychological characteristics of the elderly and children, they have special needs for community space and facilities, such as higher demands for diversified service facilities within walking distance and higher demands for safety. However, the community design do not takes their needs into full consideration yet, in terms of inappropriate structural scale, mismatch between service facilities supply and demands, and lacking of engaging and playful space. Therefore, it's urgently needed to have a better undesrstanding of the activity patterns and needs of the elderly and children, as well as the influence mechnism of community space and environment, so as to creat a more inclusive community.

In this regard, this study adopts a human-centered perspective under the guidance of Time Geography and Environmental Behavior theories, focuing on five issuses: (1) what's the spatio-temporal activity patterns of the elderly and children; (2) what's the influence mechanism of the community environment on such activity patterns; (3) what's the differences of the activity patterns and influences mechnisms considering socio-economic property and community catergories; (4) cofiguration and approaches to inclusive community; (5) design and renewal suggestions to creat inclusive community for the elderly and children.

Firstly, 12 typical communities in Tianjin are selected including different house types and geographic location. Spatio-temporal activity of the elderly and children are collected through questionnaire, interview and unmanned aerial photograph, and are imported to ArcGIS for spatio-temporal distribution visualization. Different activity patterns are summarized using cluster analysis. For communities closer to city center, multi-time activities in the community for the elderly with infants, multi-destination activities for the elderly with infants and young children, and afternoon activities for the elderly with young children are typical types. For communities in the suburbs, multi-time activities in the community are more common.

Secondly, a community space index system is establised to calculate the density, scale, accessibility and coverage rate of service facilities and public space within the 15-minute community. Then, correlation and regression are used to analyze the influence of community space index on different activity patterns separately. In general, floor area ratio, road network density, green ratio, accessibility to amenities and education facilities,distance to subway station make a significant impact on the outdoor activity duration, distance and destination of the elderly and children.

Thirdly, heterogeneous mechnisms of space index on different activity patterns are identified. (1) To communities with high floor area ratio, road network density and green ratio, whatever they are located near the city center or in the suburb, the elderly and children spends more time outdoor, and most of their activities are within the community. (2) To communities with high accessibility to education facilities, their activiy reach increases. To communities near the city center with diversified service facilities, the destination of the elderly and children are more varied and the walking distance is longer compared to communities located in the suburb.

Finally, with the aim to promote more diverse and convenient outdoor activities for the elderly and children, three spatial planning and renewal strategies are proposed. (1) The first path is driven by the densification of service facilities within walking distance, which is suitable for newly built communities in suburbs. (2) The second path is driven by the improvement of landscape design of the community's public space, as well as the optimization of the community's space structure and walking routes, which is suitable for older

communities. (3) The third path is driven by increasing the accessibilities of education and recreation facilities within 15-minute community, which is suitable for communities especially in suburbs.

Keywords: space optimization, influence mechanism, spatio-temporal behavior, the elderly and children, inclusive community

2 INTRODUCTION

Against the background of China's aging population and the generalization of dual-income families, the proportion of intergenerational childcare is gradually increasing. Studies show that more than 40% of families with young children between the ages of 1 and 5 years have grandparents involved in childcare, making intergenerational childcare one of the most dominant forms of childcare in China at present1-2. “The 14th Five-Year Plan and the 2035 Vision and Goals Outline clearly propose the implementation of a national strategy to actively address population ageing, and the improvement of the daily life service facilities with a focus on “the elderly and children”. As communities are the basic units of urban governance and residents' lives where they spend approximately 70% of the day, it has become an important issue to optimize community living space with a focus on serving “the elderly and children”, and to solve the mismatch between the demand for integrational childcare and the supply of community living space and service facilities. In the face of the rapidly changing demographic structure and the special physical and mental development needs and activity characteristics of the elderly and children, community living spaces are faced with difficulties as an inappropriate structural scale, a lack of recreational and playing space, and a mismatch of service facilities, making it difficult to effectively satisfy the needs of the “elderly and children” for a shared and inclusive community living space3-4.

To optimize and adjust community living space for the intergenerational childcare, the initail task is to master the daily activity characteristics and patterns of the elderly and children within the community, followed by identifying the elements and mechanisms of community living space on different activity patterns of the elderly and children5. On this basis, targeted spatial design strategies such as spatial index control, service facility configuration, and environment upgrading can be proposed to improve the accessibility of the service facilities, as well as to provide safe and diversified places for recreational and educational activities for the elderly and children.

This study makes comprehensive use of interdisciplinary research paradigms as environmental behavior analysis, spatio-temporal geography, as well as space planning and design, and builds a three-dimensional analysis framework composed of “subject-the elderly and children, object-community space and service facilities, and the link between them-daily activities of the elderly and children within the community”. For the subject, the research focuses on the socio-economic characteristics and demand of the elderly and children for community space and service facilities. For the object, 15-minute walking distance from home is used as the community where most daily activities of the elderly and children take place. 8 categories of POI data are collected and calculated in terms of density, diversity and distance, to analyze and assess the built environment of the community. For the activity, which presents specific patterns in a given community setting, the research focuses on studying the daily activity patterns of the elderly and children, including the activity time, location and events, and whether the patterns vary with their socio-economic characteristics. On this basis, the influence mechanism of the community built environment on the activity patterns is analyzed. So as to identify the key spatial influencing elements and the influencing path, as well as mismatches between the supply of community living space and the demand of the elderly and children. Then more precise space optimization design strategies can be proposed to provide theoretical reference and policy inspiration for the creation of inclusive community for the elderly and children.

3 RESEARCH REVIEW

3.1 Research Theory of Adaptation between Intergenerational Integration and Community Living Space

3.1.1 The theoretical perspective of intergenerational integration wihtin the community

Relevant theories include pluralistic welfarism, social support network, etc., aiming to explain the necessity and feasibility of the integration of the elderly and children from multi-dimensional perspectives of

individual physical and mental development, community governance, and so on. Research has shown that the needs of the elderly and children are common, and the advantages are complementary. Through appropriate environmental design and activity organization, it can help to enhance the communication and interaction between the elderly and children and realize mutual help and assistance.Cohn-Schwartz (2023)6 analyzed under the guidence of Contact theory and concluded that the interaction between the elderly and children can help to promote the elderly group to have more diversified cognitions and attitudes toward aging, and the contact with optimistic people can help to promote more positive attitudes toward aging among older adults. Using the strengths perspective and social support theory, Ta Na and Zhang et al. (2023)7 indicated that the interaction between the elderly and children is not only conducive to providing diversified help and support for the elderly, but also helps to realize mutual assistance and reciprocity between the elderly and children, which is an important way for community cohesion and optimization of community self-governance.

3.1.2 Research paradigm on the adaptation of community living spaces for intergenerational integration

These researches take environmental behavior and hierarchy of needs as the theoretical basis, and takes the interaction behavior of the elderly and children as the starting point to analyze the demand, use, and evaluation of the elderly and children on community living space. Li Han (2021)8 and Lv Yuan (2021)9 take the interaction behavior patterns of the elderly and children as the starting point and analyze the supportive and hindering roles of community space. Other scholars combine social psychology research methods to analyze the relationship between the community physical environment and the subjective feelings of the elderly and children. Jiang Xiaoyan (2022)10 adopts the “anchor point theory” of spatial cognition, pointing out that spatial cognition is a multi-staged and gradual process, and the first to be noticed are the “anchor points” with high relevance and symbolism to the elderly and children, so attention should be paid to pocket parks, Therefore, attention should be paid to the environmental design of community anchors such as pocket parks, community convenience stores, etc., and use them to guide and connect other activity sites.

3.2 Research on the Needs and Interactive Activities of the Elderly and Children in the Community

3.2.1 Needs and activity characteristics of the elderly and children

These researches mainly use on-site observation, questionnaire survey, participatory interviews, etc., to conduct research on the spatio-temporal behavior and the interaction between the elderly and children within the community. Tang et al. (2023)11 pointed out that the activity space of the elderly and children has a high level of residential proximity, which is mainly concentrated in the five-minute walking range, including community public space, service facilities, walking paths, and green space next to the house, and so on. Another study pointed out that to children at different ages, the contents of the interaction between the elderly and children are different, so as their needs to community space. Xu Shuning (2023)12 indicated that for infants within 3 years of age, the interaction between the elderly and children is mainly concentrated within the 5-minute walking range around the house, and the content of the interaction is mainly caregiving and accompanying, with a higher demand for sitting and resting facilities, greening, and safe play facilities; for children aged 4-7, the elderly and children can participate in activities together, including fitness, play, and socialization, with a higher demand for the safety and diversification of the overall community environment.

3.2.2 The influence mechanism of community on the activity and integration of the elderly and children

These researches mainly focus on analyzing the influence of community living space components and spatial organization on the outdoor activities of the elderly and children within the community. Davern et al. (2020)13 pointed out that community land use, population density, and elderly's awareness of community space have a significant effect on the frequency of interaction between the elderly and children.Canedo-García (2021)14 pointed out that face-to-face interactions between the elderly and children have a positive effect on the physical, psychological, and social skills of both age group, yet differences in individual characteristics affect the frequency and satisfaction of interaction. Oetzel (2023)15 pointed out that stable interaction partners and frequency of interaction are crucial, especially when the elderly and children have a higher sense of autonomy of organizing and taking part in the interaction activities, the more conducive to the improvement of interaction satisfaction. Xu Shuning (2023)12 pointed out that the level of interaction between the elderly and children is affected by individual factors and community space. At the individual

level, the extraversion of grandparents and children, more willingness and initiative to interact, as well as higher degree of trust to neighbors have a significant positive correlation with the level of interaction between the elderly and children. In addition, at the community space level, the design and set-up of community center open-space, which can accommodate a variety of activities and residents of different ages, has a positive impact on the interaction and satisfaction of the elderly and children.

3.3 Research on Design Strategies for Elderly and Children-Friendly Community Spaces

3.3.1 Overall design of community space for the integration of the elderly and children

Considering the physiological and psychological characteristics of the elderly and children, safety and composability of community living space are the most important keywords. Zheng Yu (2021)16 proposed the design of all-age parks that can accommodate to resting and playing, delicate pocket parks, and children-friendly parks which are fun and explorable to meet the diversified recreational needs of the elderly and children. Washington et al. (2019)17 suggested transforming vacant spaces and facilities into shared kitchens, vegetable gardens, art spaces, etc. to accomodate diversified activities and promote interaction for the elderly and children. Zhong et al. (2020)18 pointed out that, in addition to the design of community physical spaces such as safe and convenient walking environment and sufficient public activity venues, the organization of coherent activities also has a positive effect on the interaction between the elderly and children.

3.3.2 Refined design of community public activity space for the integration of the elderly and children

Based on the psychology of design, Ma Zhuyi (2022)19 adopted an affective design methodology and proposed that the design of community spaces should be based on three dimensions: form and scale, function and utility, and symbolism and metaphor, to enhance the sense of pleasure and self-identity during the interaction between the elderly and children.Washington et al. (2019) 17 analyzed the interactive activities of the elderly and children in the parks and found that, as children grow older, the interaction between the elderly and children decreased accordingly, but the effective interaction between the elderly and children plays an important role in the development of children's social interaction ability. So it is proposed that the parks should be supplemented with challenging playing facilities, which need the guidance of the elderly to enhance the interaction between the elderly and children.

In conclusion, a large number of researches have been carried out on various aspects of the design of elderly and child-friendly community. Yet the following issues remain to be further explored. Firstly, the outdoor activity patterns and heterogeneity of the elderly and children in different community environments need to be supplemented. Existing researches mainly focus on the elderly and children in a single community or community public space, and few studies have systematically compared and summarized the similarities and differences in the activities and patterns of the elderly and children in different community environments. Secondly, the influence mechanisms of the community space on the elderly and children under different community environments need to be further explored. Existing studies have mainly explored the influence of community public activity space on the integration of the elderly and children, and few studies have systematically considered the influence of the whole elements of community living space at multiple scales. Thirdly, the optimization path of community living space for the integration of the elderly and children needs to be further clarified. Existing researches focus on the elderly and children-friendly space design within a single community, and few studies have clearly proposed different space optimization paths based on differences in community environments for the integration of the elderly and children.

4 METHODOLOGY

4.1 Study area

Tianjin is a mega-city and is planned as a national central city. According to the “Tianjin Urban Renewal Planning Guidelines (2023-2027)”, the core area of Tianjin is densely populated, the quality of living space is in urgent need of renovation and upgrading, and the shortcomings of public service facilities, such as elderly care, childcare and other public facilities, are yet to be replenished. In this background, seven typical communities with different locations, different construction years and complete age structures are selected as the study area (Fig. 1)(Table 1).

Fig. 1: Study Area

Number	Community name	Construction year	Community size (ha)	Population size
1	Ying Jiangli	1985	7.18	4374
2	Hong Shengli	1986	5.13	3306
3	Jia xinli	1995	5.89	3789
4	You Ai Nanli	1988	7.29	7346
5	Bi huali	1997	9.55	4238
6	Han jingyuan	2008	7.3	4638
7	Sunshine 100 International New Town	2004	10.34	6249

Table 1: Overview of the study area

4.2 Data collection

The built environment data of the community is obtained by POI data mining and remote sensing image maps. POI data is obtained from Gaode-map mining in June,2024. According to <Urban Residential Planning and Design Standards> initiated by Ministry of Housing and Urban-Rural Development of China, as well as the spatio-temporal activity characteristics of the elderly and children, 8 categories of POI data are included, namely, commercial services, educational services, health care services, public sports services, public cultural services, elderly care services, public transport station and parks. The image map is obtained through google map and is used to extract the green space and analyze the green ratio.

The daily activities of the elderly and children within the community are obtained by questionnaire, semi-structured interview and on-site observation. The questionnaire consisted of four parts: individual socio-economic characteristics, daily activity time, daily activity space, and activity content. The socio-economic characteristics include age, gender, and educational level of the elderly and children, etc. Activity time includes period, average duration, and frequency of outdoor activities. Activity space includes average walking distance to activity space, and type of activity venues. Activity content includes purpose of the activity, and interaction between the elderly and children (Table 2). The questionnaires were distributed and collected from April to July 2024 in the study area from the elderly and children who were active in the public space during different times of the weekdays and weekends.

4.3 Data processing and analysis

Hierarchical analysis and factor analysis are used to establish a community space index system including density and floor area ratio of residence and service facilities, accessibility of service facilities, green coverage and road network density (Table 3). In these indices, green coverage ratio is calculated using SegNet, the other space indices are calculated within 15-minute walking range, and are normalized and visualized in ArcGIS. The spatio-temporal activity patterns of the elderly and children within the community are analysed using TwoStep Cluster algorithm since the spatio-temporal activity data of the elderly and children includes both categorical variables and continuous variables. In this model, 13 variables as shown in Table 2, which represent the spatio-temporal activity characteristics of the elderly and children, such as outdoor activity period and frequency, activity distance and venues, as well as activity types, etc. were imported to check their contributions to the categorization results (Fig. 2).

Content of the questionnaire				Options
Socio-economic attributes	Gender			Male/Femal
	Age			40-50/50-60/60-70/ 70 years and over
	Education background of the elderly			Elementary school/Junior high school/middle school/ /college/Bachelor's degree and above
	Education background of the grandchild			Infant/kindergarten/elementary school
	Family structure			Live alone/ Cohabitation with spouse/ Co-habitation of elderly and children/ Co-habitation of elderly, middle aged parents and children
Spatio-temporal activity data	Activity time	Period (multiple choices)		6：00-9：00/9：00-12：00/12：00-15：00/15：00-18：00/18：00-21：00
		Duration		0.5h and below/0.5-1h/1-1.5h/1.5-2h/2h and above
		Frequency		Almost daily/ at least 2-3 times a week/1 time a week/barely
		Days		Weekday/weekend/weekday and weekend
	Activity space	Distance (multiple choices)		0-300m(from home)/300-500m/500m-1000m/1000m and above
		Venues (multiple choices)	Within the community	space in front of the house/community path/square and green space/community service center/commercial service facilities/education service facilities
			Outside the community	commercial service facilities/education service facilities/catering service facilities/square/park/public transport station
	Activity content	Purpose (multiple choices)		Leisure/exercise/education/shopping
		Interaction (multiple choices)		Walk with a stroller/ play with children/take care of the children/chat/take exercise

5 RESULT

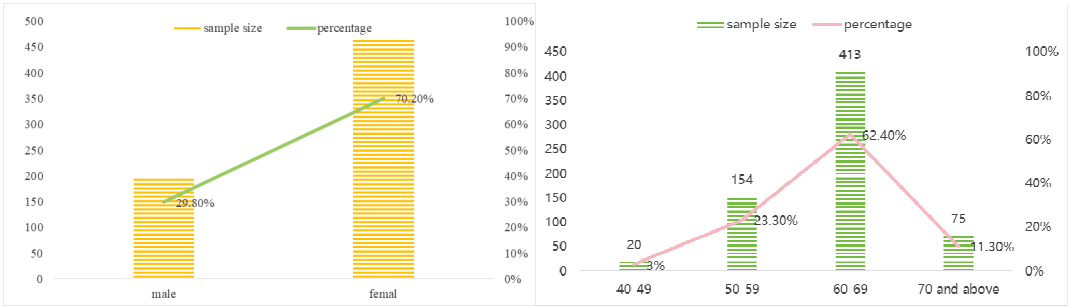
5.1 Descriptive statistics of the elderly and children surveyed

5.1.1 Socio-economic attributes of the survey sample

According to statistical analysis of the returned questionnaires on spatio-temporal behavior of the elderly and children in SPSS 26.0, female elderly accounts for 70.2% of the sample. In the analysis of age structure, the respondent group is mainly concentrated in 60-69 years old, accounting for 62.4%, followed by 50-59 years old, accounting for 23.3%, and there are fewer people over 70 years old and 40-49 years old, accounting for 11.3% and 3% respectively.

In the analysis of the educational background of the elderly interviewed, 41.4% has an educational background of elementary school and below, 29.9% has junior high school, 19.6% has senior high school and middle school, 5.9% has college, and 3.2% has a bachelor's degree or above.

In the analysis of the education level of the children carried, children who had been enrolled in kindergarten and the younger children who are not enrolled in kindergarten are the largestest group, accounting for 38.7% and 33.8% respectively. While elementary school children account for 27.5%. In the analysis of family structure, the respondent group mostly has three generations living together, accounting for 59.1% of all samples, followed by those living with their spouses (28.7%). The group that the elderly and children living together and those living alone account for a small percentage of the sample, which is 11.3% and 0.9% respectively (Fig. 3).



Gender distribution of the sample/Age distribution of the sample

Family structure of the sample/Number of questionnaire of each community

Fig. 3: Socio-economic attributes of the survey sample.

5.1.2 Descriptive statistics of spatio-temporal activities of the elderly and children

(1) Characteristics of the activity time

In terms of time period of activity, the elderly and children are more active between 15:00 and 18:00, accounting for 78.1% of the total number of respondents. The second largestest group are those who chose to be active between 9:00 and 12:00, accounting for 44.1%. Those who chose to be active between 18:00 and 21:00, and between 6:00 and 9:00 are fewer, accounting for 13.4% and 9.8% respectively. While only 1.4% chose to be active between 12:00 and 15:00.

In terms of activity duration, the mostly chosen are 1-1.5h and 0.5-1h, which accounts for 32.2% and 22.5% of the surveyed sample. The proportion of the elderly and children's activity duration as 1.5-2h, and 2h and above are 22.1% and 22.2% respectively. And only 1.1% of the elderly and children usually takes outdoor activities for less than 0.5h. The average activity duration of the old and young population was 1.606h, with a maximum value of 4h, a minimum value of 0.4h, a median value of 1.5h, and a standard deviation of 0.647.

Regarding the frequency of activities, the proportion of elderly and children declines as the frequency of activities decreased. 54.4% of elderly and children are active almost every day, 29.9% are active 3-4 times a week, 15.1% are active 1-2 times a week, and only 0.6% choose the "hardly go" option.

(2) Characteristics of the activity space

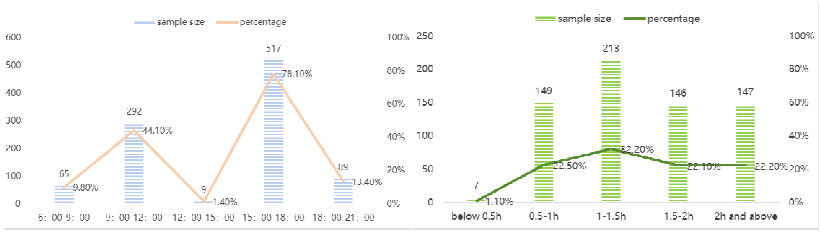
In terms of activity distance, the elderly and children prefer to take activites within short-distance. 93.8% of the surveyed sample choose to take activities within 300 meters from their homes, and the proportion who choose 300-500 meters and 500-1,000 meters from their homes are 41.2% and 24.8% respectively, with only 5.7% choose to take activities at places beyond 1,000 meters from their homes.

In terms of activity venues, the squares and parks within the community are the most chosen option, accounting for 73.3% of the surveyed sample. This is followed by parks and squares outside the community, educational facilities and downstairs space in front of the house, accounting for 59.7%, 58.2% and 55.3% respectively. Catering facilities and shopping facilities were chosen by 33.4% and 20.5% of the surveyed sample respectively. Fewer group choose community stores and canteens, as well as subway stations, accounting for 13%, 4.2% and 0.9% respectively. It is worth noting that 27.5% of the activity venues for the elderly and children involved roads within the community.

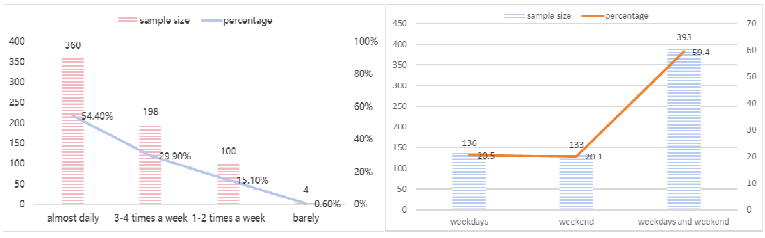
(3) Characteristics of the activity contents

In terms of activity types, those who choose recreational activities, accounting for 95.3% of the total sample. Educational and shopping activities are chosen by 58.9% and 34% respectively.

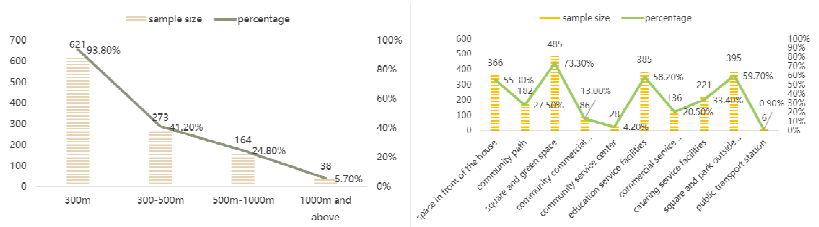
In terms of the interaction between elderly and children, a great portion of elderly choose "looking after children", which accounts for 91.8%. The next most common activity was "chatting and communicating", accounting for 48.3% of the total sample. The proportions of those who choose to "play together with children" and "do fitness activities" are 28.2% and 23.1% respectively, while the proportion of those who chose to "take a walk with a stroller" is 17.8%(Fig.4).



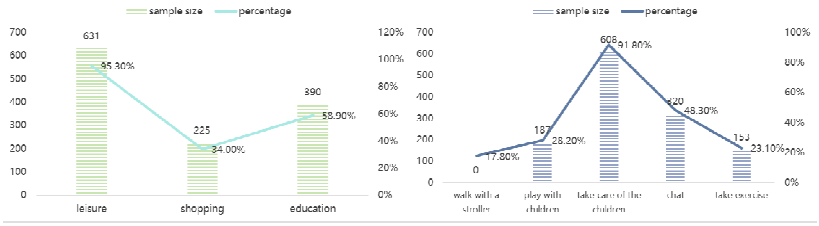
Activity time period/Activity time duration



Activity frequency/Activity days



Activity distance/Activity venue



Activity purpose/Interaction between the elderly and children

Fig. 4: Spatio-temporal activity characteristics of the elderly and children

5.2 Portraits of the elderly and children

The results showed that when three clusters were generated, the centers of each category differed significantly, and the clustering result was significant (Fig.5). According to the variable significance diagram, variables such as activity period, activity frequency, educational activities, activity duration, and activity distance of 500m to 1000m from home are the important variables to distinguish the three categories (Fig.6).

	Statistics
minimum cluster size	120(18.1%)
maximum cluster size	278(42%)
maximum to minimum ratio	2.32

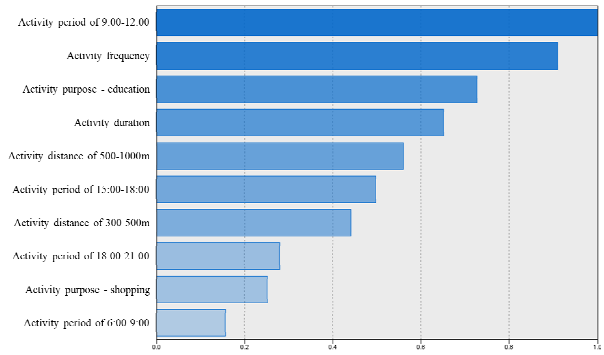


Fig. 5 (left): Cluster size and percentage. Fig. 6 (right): Importance of predictor variables.

5.2.1 The multi-time period and short-distance active group

This group is the most numerous in this research, accounting for 42% of the total research sample. In this group, children are younger, mostly not enrolled in kindergarten. The average outdoor activity duration is 2.01h a day. The activity time is more flexible compared to the other two groups, involving different time period of the day, with a higher concentration in 9:00-12:00 and 15:00-18:00. The weekly outdoor activity frequency is high, as shown in the interviews, the frequency is basically daily if there is no rain or snow. In terms of activity space, the space within five-minute walking distance around home are visited the most frequently, including the park, square and road within the community. Besides, the convenience store, supermarket, shopping mall and parks within 10 to 15-minutes of walking are also frequently visited destinations. The primary purpose of outdoor activity is recreation, followed by shopping and education.

5.2.2 The afternoon short-distance activity group

This is the second largest type of research population, accounting for 39.9% of the whole research sample. In this group, children are mostly in the kindergarten and elementary school enrollment stage, and the elderly mostly pick up the children after school and take outdoor activities on the way back home or around the neighborhood. The frequency of activities is basically once a day, which takes place from 15:00 to 18:00 in general, and the average activity time duration is 1.29h a day. The outdoor activities taks place around the neighborhoods mostly, and there are also some activities that are a little further from home, which mainly

depends on the distance between the school and home. In terms of the type of activity, it's mainly playful and educational.

5.2.3 Low-frequency and multi-purpose activity group

This group accounts for 18.1% of the total research sample, which is the smallest proportion. This group is mostly elderly people with elementary school and kindergarten-aged children. The outdoor activity time is not fixed, which takes place mostly at weekends around 9:00-12:00 and 15:00-18:00 and lasts 1.38h in average. In comparison with the other two groups, this group has a wider outdoor activities range, with both long-distance and short-distance activities involved. The type of activity is mainly amusement, followed by education and shopping.

5.3 Community space influencing factors of elderly and children's spatio-temporal activity

To the multi-time period and short-distance active group, in terms of activity duration, the higher the community greening rate, the longer the activity duration for people especially with infants, while the higher the community floor area ratio and the closer the community is to the subway station, the shorter the activity duration. In terms of activity distance, the higher the educational stage of children, the higher density of the road network and the higher the community floor area ratio, the more medium-distance activities of the baby-carrying population compared to those of the proximity population. In terms of the type of activity, the higher the greening rate, road network density and floor area ratio, the higher the probability that the elderly and children choose to play within the community. The higher the accessibility of play and leisure facilities, and the closer the community is to the subway station, the more diverse types of activities of the elderly and children.

To the afternoon short-distance activity group, in terms of activity duration, the higher the community greening rate and the higher the accessibility of educational and cultural facilities, the longer the activity duration to the elderly especially with school-age children, while the higher the community floor area ratio, the shorter the activity duration. In terms of active distance, the lower the accessibility of community educational and cultural facilities, the lower the community greening rate, and the higher the accessibility of amusement and recreational facilities, the higher the probability of choosing destinations at a greater distance. Regarding the type of activity, the higher the density of the road network, greening rate and community floor area ratio, the higher the probability that the elderly and children choose to play within the community. The closer the subway station, the diverse the type of activities.

To the low-frequency and multi-purpose activity group, in terms of activity duration, the higher the density of the community road network and more diverse the community play and leisure facilities, the longer the activity duration. As regards activity distance, the higher the accessibility of community amusement and recreation facilities, the higher the probability of taking activities within the community. In terms of activity types, the higher the accessibility of amusement and leisure facilities, the diverse the activity types (Table 4).

3 clusters of the elderly and children	Characteristics of spatio-temporal activities	Floor area ratio	Accessibility to education services	Accessibility to recreation services	Road density	Green ratio	Distance to public transport station
multi-time period and short-distance active group	Activity duration	-0.36	–	–	–	0.749	-0.278
	Activity distance	1.578	–	–	2.263	–	–
	Activity type	-3.535	–	3.945	-4.559	-5.615	3.543
afternoon short-distance activity group	Activity duration	-0.167	0.167	–	–	0.321	–
	Activity distance	–	-3.111	2.258	–	-2.158	–
	Activity type	-2.203	–	–	-4.329	-3.076	3.566
Low-frequency and multi-purpose activity group	Activity duration	–	–	0.368	0.424	–	–
	Activity distance	–	–	-5.206	–	–	–
	Activity type	–	–	4.363	–	–	–

Table 4: Influencing factors on spatio-temporal activities within the community of the elderly and children

6 DESIGN STRATEGIES FOR ELDERLY AND CHILDREN-FRIENDLY COMMUNITIES

6.1 Establishing fine-scale and multi-level community outdoor activity space for the elderly and children

According to the analysis of the activity distance and preferred space of the elderly and children, it can be seen that the activity range of the elderly and children is mainly 0-500 meters away from their homes, especially within the range of 300m, and the high green ratio and high road connectivity within this scale have a positive effect on the outdoor activity duration of the elderly and children. In addition, besides parks and squares within the community, the space in front of the house, pathway and corner space in the community are also important parts of the daily activity space, which need to be renovated in terms of safety and enjoyability for the elderly and children. Therefore, on one hand, a finer layers of community scale should be made at the macroscopic level, and the design criteria and key features of each level ought to be proposed. On the other hand, a more refined design of the space in front of the house, as well as the landscape of the community green space and corner space should be carried out at the microscopic level, so as to improve the safety and connectivity of the community roads (Table 5).

Scale level	Service radius (m)	Design specification
residential neighborhood	300	Safety road, diversified playgrounds and rest facilities, versatile landscape, high green ratio
5-minute living area	500	Diversified and accessible recreational, educational and shopping services
10-15minute living area	1000-1500	Safety road, high accessibility to diversified service facilities and public transport

Table 5: Design strategies and specifications for fine-scale community

6.2 Improving the diversity of service facilities for the elderly and children in and around the community

According to the factors influencing the community activities of the elderly and children, the higher the accessibility of playgrounds, educational services and public transport stations, the longer the outdoor activity durations and the more diversified of their activities. Therefore, on the one hand, play and rest facilities can be supplemented to the public activity space in the community, for example, revitalizing vacant and inactive public rooms in the community and transforming them into drawing rooms, chess and cards rooms, reading spaces where the elderly and children can participate and interact together, and making use of the community's marginal space to improve landscape or add play and fitness facilities, in order to provide diversified places for the elderly and children to play and rest.

7 CONCLUSION

In generall, with regard to the characteristics of temporal and spatial activities, the activity time preferred by the elderly and children are 9:00-12:00 and 15:00-18:00, among which, for the elderly with school-age children, they are more inclined to be active from 15:00 to 18:00. The duration of their activities mostly lasts 1-2 hours. The scope of daily activities is mainly within the community, usually within 500 meters from home, especially within 300 meters. Public squares, parks and green spaces within the community are the most important activity places for the elderly and children, followed by parks and squares as well as educational service facilities outside the community, and then dining and shopping service facilities outside the community. For children of school age, public spaces around the school, as well as the path between school and home are also the main activity areas. In addition, it should be noted that the space in front of the house and the community roads are also the main activity places for the elderly and children. In terms of activity content, play and leisure are the main activities, followed by education and shopping. In terms of the interaction between the elderly and children, when the children are at younger ages, the elderly mainly take care of the children, chat and communicate with each other, and take a walk with the baby carriage. As the children grow older, the proportion of the elderly and children taking exercises and playing games together increases.

With regard to the portraits of the community activities of the elderly and children, based on the results of the cluster analysis, they can be summarized into three categories, namely the multi-time period and short-distance active group, the afternoon short-distance activity group, the low-frequency and multi-purpose activity group, which account for 42%, 39.9% and 18.1% of the total research sample respectively. According to the order of importance of the predictor variables, it can be seen that the variables of 9:00-

12:00 activity period, activity frequency, activity duration, educational activities, and 500m to 1000m activity distance are important variables to distinguish the three groups.

Regarding the influencing factors, road network density, green ratio, floor area ratio, distance to subway stations, and accessibility of recreational facilities as well as science and education facilities have a significant impact on the daily spatial and temporal activities of the elderly and children within the community. Specifically, for outdoor activity duration, the higher the green ratio, road network density, and accessibility of recreational facilities, the longer the duration of outdoor activities. In terms of the differences in influencing factors among the three groups, the green ratio of the community has a greater positive influence on the activity duration of the elderly and children who are active in short-distance from home; the density of the road network and the accessibility of recreational facilities have a greater positive influence on the activity duration of the low-frequency and multi-purpose elderly and children; whille the floor area ratio has a negative influence on the outdoor activity duration of the elderly and children who take activities within a short-distance from home, but the level of influence is not high.

For activity distance, high road network density, high accessibility of recreational facilities, and high floor area ratio are associated with a greater activity range and longer distance for the elderly and children, while high accessibility of science and education facilities and high green ratio are associated with a greater tendency for the elderly and children to engage in activities within the community.

As for the types of activities, the higher the accessibility of recreational facilities and the closer the subway station, the more diversified the activities of the elderly and children are, including not only playing in the community, but also carrying out activities outside the community in educational, shopping, catering and other service facilities; whereas, with a high green ratio, a high density of the road network, and a high floor area ratio, the probability that the elderly and children carry out outdoor activities within the community is higher.

8 DISCUSSION

This research focuses on promoting inclusive community sapce for the elderly and children. By taking typical communities in Tianjin as examples, the research follows the analytical steps of “categorizing spatial and temporal behavior patterns of the elderly and children – analyzing spatial influence mechanisms – proposing spatial design strategies”, which provides a science-based method to realize the construction of human-oriented and inclusive community for the elderly and children. However, this study has only considered the spatial elements of the community when analyzing the influencing factors on the community spatial and temporal activities of the elderly and children, and has not given enough consideration to the non-spatial elements of the community such as community governance and interpersonal relationships20. At the same time, the combination of variables affecting the spatio-temporal activities of the elderly and children has not been analyzed in depth, and the path of building an inclusive community for the elderly and children under different environmental and socio-economic conditions is not yet clear.

In future researches, on one hand, non-spatial elements, such as socio-economic and cultural environment, community governance, as well as neighborhood relations have yet to be incorporated into a unified analysis system, so as to comprehensively analyze the effects of the relevant elements on the community activities of the elderly and children in terms of their direct, indirect, and interactive influences. On the other hand, on the basis of analyzing the influencing mechanisms on the activities of the elderly and children in different types of communities, Qualitative Comparative Analysis (QCA) can be used to identify and refine typical paths for the integration of the elderly and children in different community environments, so as to provide more targeted and operational guidence for creating communities that better serve the elderly and children.

1 ABSTRACT

The residential floor area in India is expected to more than double by 2040. Ninety-nine percentof this growth is in Low Income Group segment, proving that affordable housing is the future of residential development. This will lead to high energy consumption and carbon emissions. In 2023-24, the building sector accounted for 13% of the total energy consumption in India, of which 82% came from the residential sector. It is thus crucial to ensure that all new residential building stock, expected to last for the next 5 decades, is built in a climate-conscious manner to reduce energy consumption and carbon footprint of the built environment. However, this can only happen if the needs of the affordable housing segment are addressed.

This paper examines the applicability of India's two of four net zero pathways in affordable housing – energy-efficiency, sustainable materials and construction technologies. It analyses regulatory instruments, policies and schemes, and market instruments through the Availability-Affordability-Quality framework, examining if solutions are available, if solutions are affordable, and if solution favours emission reduction.

Findings show that most instruments are designed for an overall built environment, with no specific focus on low-income groups. Of the specific affordable housing policies, recommendations for achieving affordability is found to compromise with quality, particularly considering GHG emissions. Based on the findings, the paper provides three recommendations – (i) developing a unified definition of green, (ii) consolidating policy implementation through unified regulatory mechanisms, and (iii) procurement reforms to unlock potential of sustainable materials/technologies use, to ensure an affordable net zero future for India.

Keywords: Policy implementation, Operational emissions, Net zero built environment, Embodied emissions, Affordable housing

2 INTRODUCTION

India is at a critical juncture where urbanization and its impact on climate are converging. India's urban population is expected to rise from 31% in 2011 to 38.2% in 2036, accounting for an additional 218 million population(National Commission on Population, 2020). This is expected to lead to an increased demand in infrastructure to house and service the additional urban population, with the highest demand expected to be in residential floor space. The urban residential sector was adding 0.52 billion sqm floor space annually in 2020.By 2050, this is expected to go up by 82%, adding 0.95 billion sqm annually(National Institute of Urban Affairs & RMI, 2022). In a business as usual scenario, energy consumption from this will increase threefold, and carbon emissions will quadruple. Therefore, it is crucial to ensure that all new building stock, expected to last for the next five decades, is built in a climate-conscious manner to reduce energy consumption and carbon footprint of the built environment, especially residential buildings.

Additionally, this has to predominantly address the economically weaker sections (EWS) and low-income groups (LIG). Roy & ML, (2020) estimated the urban housing shortage to be 50 million in 2018, of which 99% belonged to EWS and LIG segments. This implies that the bulk of residential development in Indian cities are required to be affordable in nature. Furthermore, considering that 50% of GHG emissions from the residential sector comes from heating and cooling needs, this segment is also impacted disproportionately by rising energy demands. Dong et al. (2021), highlights that Heating, Ventilation, and Air Conditioning (HVAC) systems are energy and carbon intensive, andunaffordable for low-income households. Studies also show that poorly insulatedaffordable housing units pose a higher risk of exposing inhabitants to prolonged energy poverty (Chen & Feng, 2022).

This paper thus hypothesizes that ensuring sustainable development for all new building stock, and achieving India's target of reducing 45% GHG emissions by 2030 and Net Zero by 2070 (Ministry of Environment, 2024)is only possible if the needs of the affordable housing segment are addressed.

2.1 Net zero pathways in India

Currently the building and construction sector contributes to nearly 40% of annual GHG emissions globally. In India, this number stands at 32% (India Third Biennial Update Report to UNFCCC, 2021). Within this, 60-65% comes from operational emissions – primarily from energy use for heating and cooling needs (National Institute of Urban Affairs & RMI, 2022). Of the 35-40% embodied emissions, the most significant portion comes from using energy-intensive building materials and construction processes. This paper identifies fourpathways of emission reduction in the built environment – reducing operational emissions through (i) clean energy transition, and (ii) energy-efficiency; reducing embodied emissions through (iii) incorporating sustainable materials and construction technologies, and (iv) building retrofit.

While the larger research reviews all four pathways, this paper focuses on the following two pathways.

2.1.1 Pathway 1 – Energy Efficiency

The International Energy Agency (IEA) highlights that energy efficiency is the single largest measure in reducing energy demand at source, leading to significant cost savings for consumers (Energy Efficiency – Energy System – IEA, n.d.). 28% of households in urban India are energy poor. (Khandker et al., 2010). In an affordable housing landscape, energy efficiency, especially through adaptive thermal comfort, supersedes other methods of emission reduction.

2.1.2 Pathway 2 – Sustainable materials and construction technologies

From the 35-40% embodied emissions, 23-34% comes from the product stage, accounting for raw material extraction, transportation to site, and manufacturing. Two-to-four percent comes from the construction process stage accounting for transportation to construction site and installation process. Three-to-six percent comes for the building use stage, with the remaining one-to-six percent coming from the end of life stage (Godrej Design Lab, 2024). This paper thus focuses on the product and construction process stage, accounting for 25-38% of overall embodied emissions.

3 APPROACH AND METHOD

This paper hypothesizes that while numerous solutions exist to mitigate operational and embodied emissions in the built environment in India, none are tailored specifically for the affordable housing sector. The study examines existing the identified pathways for emission reduction through a threefold lens – (a) Availability of existing solutions and policy/regulations/instruments through which solution is made available at scale, (b) Affordability of the solution, including incentivisation for LIG segment, and (c) Quality of solution with respect to emission reduction over complete life-cycle.

The following instruments are reviewed to critically examine the net zero landscape in India, cross examining them with respect to affordable housing policies and national and subnational levels.

Instrument category	Description of instrument	Title of policy instrument	Target sector
National net zero targets	National level climate targets and strategies	Fourth Annual Communication and Initial Adaptation Communication, 2024 National Mission for Sustainable Habitat (NMSH) India Cooling Action Plan	Net zero pathways
Regulatory instruments	Legal tools/regulatory frameworks that guide built environment development	Energy Conservation Act Model Building Bye Laws 2016 Development Control Regulations (state wise) Delhi Schedule of Rates 2021	Built environment Net zero pathways
Building codes	National instruments for regulating building design and construction across the country	National Building Code 2016 Energy Conservation and Sustainable Building Code 2024 Eco Niwas Samhita 2024	Built environment Net zero pathways
Policies and schemes	Guidelines on policy/scheme overview, focus, implementation, and impact	Pradhan Mantri Awas Yojana State Affordable Housing schemes	Affordable Housing
Policy support	Design guidelines and compendiums supporting policies	Innovative Construction Technologies & Thermal Comfort in Affordable Housing (RACHNA) Handbook BMTPC Compendium of Emerging Construction Technologies for Housing & Infrastructure	Built Environment Affordable Housing

Green Building Rating System	Rating and certification systems for greening of projects in the built environment	Indian Green Building Council (IGBC) – Green Affordable Housing IGBC NEST and NEST Plus GRIHA framework Green Pro Ecolabeling	Affordable Housing Net zero pathways

Table 1: Description of policy instruments reviewed

3.1 The Availability – Affordability – Quality (AAQ) framework

The Availability-Affordability-Quality (AAQ) framework is used to analyse regulatory and policy instruments across built environment, affordable housing, and net zero pathways. The AAQ framework was developed to review the efficacy of existing solutions in the context of affordable housing, and exploring if affordability comes at the expense of quality. The study applies a mixed method approach of analysis applied against the AAQ framework. Specific research questions for the AAQ framework along with the type and method of analysis applied to explore those questions are described below.

Framework	Research questions	Type of analysis	Method of analysis
Availability	Is a solution available for a specific pathway? If yes, then how is it made available at scale?	Qualitative	Identification and mapping of regulations, policies, schemes, guidelines, market instruments that solve for the identified pathway
	Does the implementation mechanism of identied solutions converge with affordable housing policies/implementation?	Qualitative	Comprehensive flowchart of implementation mechanisms of the policy/scheme/code/rating system co-examined against implementation of affordable housing policies, schemes, and building byelaws; outlining key stakeholder groups, roles and responsibilities, and existing communication channels between parties.
Affordability	Is the solution affordable to EWS and LIG consumers?	Quantitative	Bill of Quantities comparison of a conventional affordable housing unit vs an affordable housing unit incorporating solutions and strategies recommended in solution pathways. Materials reviewed have been taken from RACHNA handbook.
Quality	What is the quality of the solution with respect to emission reduction?	Quantitative	Comparative analysis of impact metrics for all pathways to identify conflicts in quality of output.
	Does achieving affordability impact the quality of the solution?		

Table 2: The methodology framework

3.2 Boundary conditions for analysis

Establishing boundary conditions was necessary in order to measure the efficacy of existing pathways. The following boundary conditions were identified and applied – housing affordability, typical size and scale of affordable housing unit, and scenarios for analysis. These boundary conditions are primarily applied when comparing Affordability Index with respect to solution pathways, and in determining Quality of solution with respect to emission reduction.

3.2.1 Housing affordability

Housing affordability is a key determinant when reviewing the impact of design recommendations, material, and construction techniques on the overall construction cost.

Affordable housing in India targets three specific income groups, with annual household income as stated (Ministry of Housing and Urban Affairs, 2024)

(1) EWS –up to 3,00,000 INR (3450 USD)

(2) LIG –between 3,00,001 – 6,00,000 INR (3451 – 6900 USD)

(3) Middle Income Group (MIG) –between 6,00,000 – 9,00,000 INR (6901 – 10300 USD)

The scope of this paper is limited to EWS and LIG.

As per the Task Force Report on Promoting Affordable Housing, (Ministry of Housing & Urban Poverty Alleviation, 2012), the desirable housing price to income multiple for affordable housing should not be more than 5. However, housing price is dependent on land price and construction cost. Since land prices are highly variable based on geography, and outside the purview of this paper, this study focuses on affordability of construction cost. The study applies a Bill of Quantities comparison, considering a conventional affordable housing unit of 30 sqm carpet area, with an RCC frame construction, with burnt clay brick walls of 250mm thickness, and unplastered RCC slab roofing. The construction cost for the base case is 1101190 INR (12500

USD) overall, or 25700 INR (300 USD) per sqm. This corresponds with the average cost of construction for a 30 sqm basic unit across India (Construction Cost Calculator for House, n.d.). A construction price to income ratio is also presented as a partial measure of housing affordability, primarily considering capital expenditure for materials and construction.

3.2.2 Scenarios for analysis

As per Ministry of Housing and Urban Affairs, (2024), an affordable housing unit is defined as a unit with carpet area not more than 30 sqm. For analysing efficacy of net zero pathways, we consider two scenarios

(1) An independent housing unit of 30 sqm carpet area; 42.86 sqm of total built-up area (considering carpet area is 70% of built up area (Ministry of Housing and Urban Affairs, 2016))

(2) A mass affordable housing complex of 100 units, 10 units each of 30 sqm carpet area across 10 floors; 4286 of total built up area.

4 RESULTS

4.1 Overall findings for pathway 1 – Energy Efficiency

India's Fourth Biennial Update Report (BUR-4) to UNFCCC, a comprehensive review of India's commitments and progress in terms of it's Nationally Determined Contributions, reveals that Energy Efficiency in the built environment has been a priority focus area of the Union Government (Ministry of Environment, 2024). Initiatives such as ENS has resulted in collective energy savings of 4.84 MU between 2021 and 2023. This section further explores the applicability of such measures in the affordable housing segment.

4.1.1 Availability of Energy Efficiency solutions

In affordable housing, thermal comfort and energy efficiency is primarily solved through four interventions

(1) Change in walling materials and technologies

(2) Change in roofing materials and technologies

(3) Passive design techniques such as natural ventilation, shading, daylighting, building orientation.

(4) Energy efficient appliances

This study critically examines intervention 1-3; energy efficient appliances are outside the purview of this research owing to its limited scope in architecture, design, and planning.

In the overall built-environment, interventions are made available at scale through the following instruments

Instrument category	Title of instrument	Description of instrument
National net zero targets	National Mission for Sustainable Habitat (NMSH) India Cooling Action Plan	National level mission on promoting low-carbon urban growth, achieving India's NDCs through built environment interventions, and building resilient cities. National level cooling action plan identifying strategies and cooling pathways for key sectors including built environment.
Regulatory instruments	Energy Conservation Act Model Building Bye Laws 2016	A law that aims to reduce energy intensity of the Indian economy. A model regulatory framework regulating coverage, height, building bulk, and architectural design and construction aspects of buildings, to ensure orderly urban development.
Building codes	National Building Code 2016 Eco Niwas Samhita 2024	National instrument regulating building construction activities across the country. National level energy-conservation building code for residential buildings.
Policy support	Innovative Construction Technologies & Thermal Comfort in Affordable Housing (RACHNA) Handbook	Thermal comfort design guidelines for affordable housing construction.
Green Building Rating System	Indian Green Building Council (IGBC) – Green Affordable Housing IGBC NEST and NEST Plus	Green building rating systems for affordable housing.

Table 3: Energy efficiency instruments in India

However, only the RACHNA handbook and IGBC green affordable housing, NEST and NEST plus rating systems specifically provides recommendations for the affordable housing segment. All other policy and regulatory target the built environment as a whole – with no targeted recommendations for the affordable housing segment.

Eco Niwas Samhita, a national building code on energy efficiency, is applicable only for residential development with an area of 3000 sqm or above, or with a connected load of 100kw (Bureau of Energy Efficiency, 2024). This renders independent affordable housing units ineligible for the code.

Figure 1shows the implementation mechanisms for energy-efficiency solutions, outlining actors, roles and responsibilities, and existing communication channels.

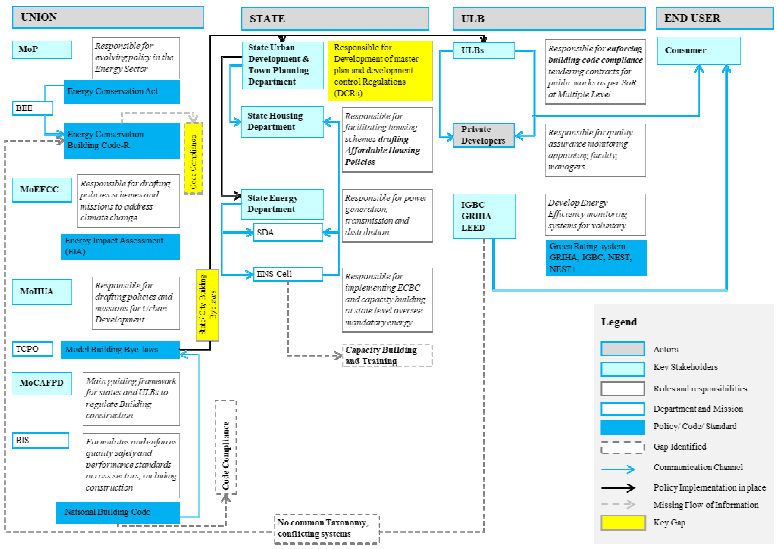

Figure 1: Implementation mechanism for energy efficiency and affordable housing policies

The comparative implementation mechanisms framework of energy efficiency and affordable housing policies reveal that there is currently no convergence between energy efficiency and affordable housing policies directly. Only the parts of the ENS that are incorporated in Model Building Bye Laws (Ministry of Housing and Urban Affairs, 2016, pp. 115-120) are legally applicable to all affordable housing units. ENS itself is not a legally mandated tool; individual state governments are authorised to mandate it across the state. To date, 17 out of 28 Indian states have initiated the notification of ENS (Bureau of Energy Efficiency & Alliance for an Energy Efficient Economy, 2023).

The PMAYhas drafted the RACHNA guidelines focusing on thermal comfort for affordable housing. However, there is limited evidence on its application, currentlyimplemented in only 6 lighthouse projects across India (Ministry of Housing & Urban Affairs, 2022).

4.1.2 Affordability of Energy Efficiency solutions

Based on calculations for standard cost of construction, it is found that walling and roofing materials constitute nearly 60% of the total construction cost. This assessment thus focuses on affordability of these two categories specifically.

In order to measure if existing recommendations are affordable, walling and roofing materials recommended in the RACHNA handbook (Ministry of Housing and Urban Affairs, 2022) or widely used in built construction across India are analysed.Table 2 presents the cost of different walling materials against this base case of an RCC frame structure with burnt clay brick walls and unplastered RCC roof slab.

The comparative construction cost assessment reveals thatmaterials that satisfy the ECBC benchmark of <15W/m2cost significantly higher than the base unit (Case 4 in Table 2). An AAC block with an RCC filler slab that satisfy all thermal comfort benchmarks, cost 31% higher than the baseline.

The construction cost of a unit with AAC walling, and RCC filler slab is 2.8 times the annual income of a EWS consumer, and 0.14 times that of an LIG consumer.

4.1.3 Quality of Energy Efficiency Solutions

The mandatory energy conservation recommendations under ENS consider Openable Window to Floor Area Ratio (WFRop), Visible Light Transmittance (VLT), Thermal Transmittance of Roof (Uroof), Residential Envelope Transmittance Value (RETV) for walls. These mandatory recommendations do not consider thermal emittance as a key criteria; it is provided as an incremental condition in both cases.

Mandatory recommendations for the IGBC green affordable rating system state only U value of roofs ≤ 1.8 W/m2K and glazing ≤ 5.7 W/m2K. The NEST and NEST plus ratings are further relaxed to provide a benchmark of U-value 2.5 W/m2K for walling assemblies. This raises the question of whether the quality of recommendations specifically aimed at the affordable housing sector differs.

Table 4: Construction cost and quality comparison for recommended materials – energy efficiency

This is further exemplified by the fact that there is no direct correlation between the multiple metrics of achieving thermal comfort, and measuring operational energy consumption or emissions. Operational energy is typically measured through Energy Performance Index (EPI), which represents the annual energy consumption per unit area. However, this includes the performance of appliances, in addition to efficiency through materials and passive design. In the lack of an equivalent metric between individual thermal comfort indices and operational energy, it is difficult to isolate the efficacy of each solution. This could potentially lead to difference in quality of output, as seen in the IGBC affordable housing recommendations.

4.2 Overall findings for pathway 2 – sustainable materials and construction technologies

Embodied emissions contribute to 35-40% of overall built environment emissions in India (National Institute of Urban Affairs & RMI, 2022). This share is expected to rise to 50%, as the share of operational emissions decline over time (Jain et al., 2023). A large part of this shifting balance between embodied and operational emissions is due to policy focus skewed largely in favour of operational emissions. Studies show that weightage given to the use of green materials in green building rating systems and building codes is 8-9% (Jain et al., 2023).

4.2.1 Availability of solutions for sustainable materials and construction techniques

This paper explores the availability of solutions across three areas

(1) Market innovation and availability of products and technologies

(2) Regulatory instruments enabling scaling of innovations

(3) Policies and schemes enabling higher market penetration

The following instruments curate and enable the availability of sustainable materials and construction technologies at scale.

The Compendium of Emerging Construction Technologies (Building Materials & Technology Promotion Council, 2023), presents a list of 69 materials and technologies analysed and curated through a third-party assurance system that evaluates materials and technologies based on (a) Structural performance against vertical & lateral loads, (b) Fire resistance, (c) Protection against rain & moisture, (d) Thermal &acoustic behaviour, (e) Ease of fixing services, (f) Quality assurance, (g) Durability /Service Life. The Compendium is prepared under the ambit of the PMAY scheme, implying economic viability of materials to be a key assessment criteria. The Green Pro Ecolabeling adopts an LCA approach to analyse and curate materials(Greenpro | Home, n.d.). NBC 2016 also includes a chapter on sustainable materials, providing alternatives to carbon intensive materials(Bureau of Indian Standards, 2016). However, there is no standard method of impact measurement and reporting in all three documents. Embodied energy calculation and reduction as a specific target is not addressed in any of these documents.

Instrument category	Title of instrument	Description of instrument
Materials compendium	Compendium of Emerging Construction Technologies for Housing & Infrastructure, BMTPC	List of 69 emerging materials and construction technologies
Ecolabeling	Green Pro Ecolabel Directory – 2025 (5th edition)	Ecolabel certification and directory of 9500 green materials
Building codes	National Building Code 2016 Eco Niwas Samhita 2024	*Refer* **Fehler! Verweisquelle konnte nicht gefunden werden.**
Regulatory mechanisms	Schedule of Rates	Standardized rate document for materials, construction technologies prepared for all public works projects

Table 5: Sustainable materials and construction technology instruments in India

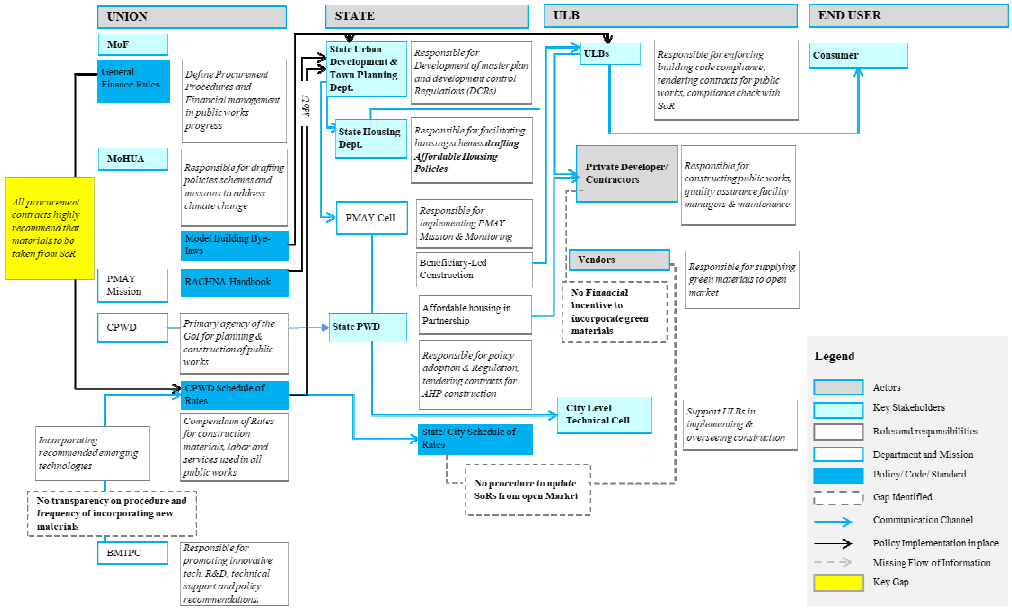

Figure 2: Implementation mechanism for sustainable materials and construction technologies in affordable housing

Finally, none of this instruments serve as mandates to include sustainable materials and construction technologies in the built environment. As per India's procurement regulations, all public works projects,including affordable housing, is recommended to use materials specified in the State Schedule of Rates, adapted from the Delhi Schedule of Rates (DSR) drafted by Central Public Works Department (CPWD). Currently the process of incorporation of sustainable materials and technologies available in the market into the SoR, as well as regular updation, is unknown. In the absence of a regulated system of including recommendations by BMTPC, BIS, and ENS into the CPWD DSR, the process of ensuring the use of sustainable materials and techniques in affordable housing remains arbitrary (refer Figure 2).

4.2.2 Affordability of solutions for sustainable materials and construction techniques

The lack of a standard method of impact measurementpresents a constraint in identifying and thereby measuring affordability of high impact materials.

This paper thus extends the exercise of reviewing recommended/highly used walling and roofing materials to also measure Embodied Energy Value (EEV). The comparative analysis, shown in Table 3, reveals

contradictions when concurrently reviewing cost, thermal comfort, and EEV. CSEB has a lower construction cost as well as significantly lower EEV. However, its RETV values are higher compared to both AAC and Fly Ash blocks. AAC blocks, which are superior in terms of RETV values, cost significantly higher and has a significantly high EEV.

	Case – Wall	Case 1 – Base case	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7	Case 8

Table 6: Construction cost and quality comparison of recommended materials – embodied energy

4.2.3 Quality of solutions for sustainable materials and construction techniques

Table 3 reveals that most recommendations for materials and construction techniques enabling thermal comfort are done without due consideration of embodied energy values. Given that EEV is a measure of energy consumption and thus is strongly linked to energy efficiency in the overall life cycle of a building, not considering EEV while recommending materials aimed at energy efficiency is a significant gap in the current instruments.

Furthermore, measuring the quality of materials against a specific standard become difficult in the absence of a specific target. The Green Pro Ecolabel (Confederation of Indian Industry, 2025), presents the most comprehensive database of more than 9500 products, materials, and technologies from 450+ companies. The ecolabel however uses an 8 part analysis, using a credit system for scoring and selecting green materials. Life cycle assessment is one of the 8 parts, wherein credits are assigned based on performance improvement in emission reduction, and not against a standard benchmark(Confederation of Indian Industry, 2016).

4.3 Synthesis of gaps in the overall ecosystem

The findings reveal the following gaps in the current ecosystem

4.3.1 Lack of a unified/standard method of outcome measurement

The study reveals that currently all net zero pathways operate in isolation. Extensive solutions exist for both energy efficiency and sustainable materials and construction technologies. However, considering the lack of a unified metric of outcome measurement – such as reduction in GHG emissions or energy consumption across the life cycle, it is difficult to measure the overall efficacy of existing solutions. The lack of unified outcome parameter also leads to quality dilution in the case of affordable housing, implying that affordability comes at the cost of quality.

4.3.2 Lack of a comprehensive implementation mechanism for all net zero pathways

The implementation mechanisms for pathway 1 and 2 revealmultiple gaps in communication between actors at the Union, State and City. Multiple solutions exists for both pathways, with no communication between parties, and overlapping roles and responsibilities. The implementation mechanisms also reveal the lack of robust regulatory mechanisms – building codes are not legally mandated in most Indian states and cities. The ENS policy is not mandated but notification is initiated in 17 states. However, this is also not specifically attuned for the affordable housing sector. The applicability of the code rules out independent affordable homes. The limited implementation of RACHNA guidelines in affordable homes built under PMAY further reveals a gap in robust implementation mechanisms of energy efficiency pathways in affordable housing.

4.3.3 Lack of regulatory mechanisms for incorporation/usage of sustainable materials and construction techniques

While solutions exist for pathway 2, implementation of solutions across scale is impacted by the current procurement system, mandating that only materials incorporated in Schedule of Rates be used for public work projects, including affordable housing (refer Figure 2). This implies that most sustainable materials that currently exist in the market are not used in affordable housing projects, unless specifically incentivised.

5 RECOMMENDATIONS

5.1 A unified definition of Green

Multiple recommendations currently exist for categorically reducing operational and embodied emissions in the built environment. However, the lack of a comparative unit of measurement reveals contradictions in recommendations, and subsequently in quality of output.

This paper proposes that there needs to be a unified definition of "Green" that combines operational and embodied emissions of materials and construction techniques, but one that also factors in construction cost. Such a definition will eliminate contradictions in cost, energy efficiency (reducing operational emissions), and embodied emissions. However, considering that units are not equivalent across the three factors, we propose a normalised scoring method, such that

$$Green\ score = -1 * \left(\frac{c_1 - \bar{c}}{\bar{c}} + \frac{o_1 - \bar{o}}{\bar{o}} + \frac{e_1 - \bar{e}}{\bar{e}}\right)$$

Wherein, c_1 = cost of material in consideration;$\bar{c}$ = mean national cost of material
o_1 = operational emission of material in consideration; $\bar{o}$ = mean operational emission of building materials
e = embodied emission of material in consideration; $\bar{e}$ = mean embodied emission of building materials

Considering that the aim is to achieve lower cost of construction and lower emissions, the normalised calculation will provide results wherein lower the score, better the performance. However, for the sake of readability and ease of understanding, the calculations are multiplied by a factor of -1 to lead to a scoring system where higher the green score, better the overall performance and affordability.

This method requires establishing a national mean for operational and embodied emission of materials. This also enables setting standard targets for the building sector in terms of emission reduction.

5.1.1 Considerations for unified measurement metric for operational and embodied emissions

Currently, operational energy is measured through the EPI, representing annual energy consumption per unit area. However, since this also considers the emissions from active cooling systems and appliances, it is imperative to isolate the energy consumption from heat gain through building envelope, and roof, to impart a green score to specific materials, technologies, and passive design techniques.

Bhanware et al., (2020) reveals a strong correlation between the sensible cooling load of a building and ReTV. This enables the extrapolation of cooling load for each climate zone based on ReTV (Qsensible in kWhth/m2). Considering the method of cooling (natural or air conditioning) can provide a comprehensive scenario of electrical units consumed. Multiplying this value with average emissions factor for electricity in India, stated to be 0.716 kg CO_2 per kWh(Central Electricity Authority, 2023), may give the operational emissions from heating/cooling needs for the specific material. Similar methods can be applied for measuring heat gain, and subsequently GHG emissions of roofing materials using U-value. When considering the Green Score of the whole building, EPI is a better metric, but has to be calculated over time and in a consistent manner.

Embodied emissions may be calculated in the same manner from Embodied Energy Value.

5.2 Consolidating policy implementation through unified regulatory mechanisms

Section 4.3.2 highlights the conflicts in the current ecosystem stemming from a lack of convergence in roles, responsibilities, and communication channels in various policies, schemes, guidelines, and market instruments. The gap in implementation mechanisms can be addressed through two regulatory mechanisms

5.2.1 Mandating recommendations through Building Byelaws

Building codes, policies, and schemes are not legally binding. While ENS can be notified state-vide, for implementation the compliance and mandate is integrated into the building permission process through the Building Byelaws (Government of Karnataka, 2018). This paper thus recommends the development of a streamlined process of integrating key clauses of the Eco Niwas Samhita into the Building Byelaws, specifically addressing the low-income housing segment. The latest edition of the Model Building Byelaws gives specific recommendations for Low Income housing in terms of minimum plot area, minimum dimensions for room sizes and layouts, structural requirements, and regulations for land development(Ministry of Housing and Urban Affairs, 2016). However, a specific chapter on "Green Buildings and Sustainability Provisions", incorporating recommendations from ECBC 2007, do not provide targeted recommendations for the Low Income housing segment. This leads to blanket regulations, rendering all plots up to 100 sqm ineligible for any sustainability provisions, and mandating all plots above 3000 sqm (including mass affordable housing) to comply with all 10 provisions (Ministry of Housing and Urban Affairs, 2016, pp. 115-120). This paper recommends a specific segment for affordable housing in the"Green Buildings and Sustainability Provisions", tailored to the recommendations and approach discussed in this paper – to mandate net zero pathways in affordable housing.

5.2.2 Incentivising solutions through Development Control Regulations (DCRs)

DCRs are planning regulations that govern the development of a city through zoning regulations, Floor Area Ratios (FAR), height limitations, set-backs, parking requirements, plot sizes etc. In terms of legal mandates, DCRs supersede Building Byelaws, but are typically implemented in tandem with the later by city governments to guide and regulate development. The provisions in a DCR have been shown to impact housing affordability and influence sustainable development (Niti Aayog, 2021). This paper thus recommends the integration of non-fiscal incentives such as free of cost FAR for mass affordable housing projects that integrate net zero measures, or fiscal incentives such as reduced development fees for projects that meet green building criteria. While this is currently practised through a range of instruments in multiple states across India, there is a need to consolidate these incentives under city-specific regulations to ensure successful implementation on ground.

5.3 Procurement reforms to unlock potential of sustainable materials/technologies use

The findings of this study highlights the procurement challenges in the current landscape of building construction in India – including affordable housing. In order to ensure a sustained integration of sustainable materials/technology in all affordable housing construction, this paper recommends the following

5.3.1 Building a consolidated database of sustainable materials and construction techniques applying a unified measurement metric

Building a consolidated database with a unified measurementmetric is the first step towards procurement reform for sustainable materials/construction technologies. Rawal et al., (2024), and International Finance Corporation, (2017) discuss the development of an embodied energy database for commonly used construction materials using the LCA approach. Such a database provides a clear comparative assessment of all building materials against a unified benchmark. Supplementing this with specific embodied emission reduction targets for the building sector would further strengthen the assessment of building materials/technologies.

The consolidated database of materials should also enable the mapping and curation of manufacturers and suppliers that provide detailed technical specifications of the materials to be used in preparation of construction drawings, tendering, and estimation.

5.3.2 Developing a Green Schedule of Rates (SoR)and Analysis of Rates (AoR)for affordable housing

Such a database can be used to identify cost-effective, high impact materials for affordable housing. This paper recommends the preparation of a Green Schedule of Rates providing standardised rates of materials, technologies, and construction processes/services. The Green SoR should further provide the following information to ensure holistic decision-making in selecting green materials/technologies for construction

- What is the embodied carbon savings of the material?
- What is the operational emissions/utility cost savings over the lifetime of the material?
- How is its overall performance over life time compared to a conventional material it aims to replace?

The Green SoR should be supplemented with a detailed Analysis of Rates of items and services, providing a comprehensive cost analysis for each item. This ensures transparency and accuracy in the costing process. The AoR should further provide a rate comparison between sustainable and conventional materials, to further enable data driven decision making in selection of materials.

Developing a Green SoR that serves as a standardised rate document ensures all public works projects including affordable housing are built using sustainable materials and technologies.

6 DISCUSSION

This paper first examines the applicability of two net-zero pathwaysin the affordable housing segment. The Availability-Affordability-Quality framework applied here aims to comprehensively capture the gaps in the current ecosystem with respect to the affordable housing segment. The analysis reveals gaps that are addressed through three recommendations – 1) having a unified definition of "Green", (2) consolidating multiple instruments and ensuring implementation on ground through two regulatory instruments, building byelaws and development control regulations, and (3) addressing the building construction procurement system through having a consolidated database of low embodied energy materials and preparing a standardised rate document for the same. The implications of this study are discussed further

6.1 Critically considering the affordable housing segment in designing and implementing net-zero pathways

This study highlights that current net-zero pathways do not necessarily consider the needs for the affordable housing segment. Most instruments examined in this study are designed for an overall built environment, with no specific focus on low-income groups. Of the specific affordable housing policies, recommendations for achieving affordability is found to compromise with quality, particularly in terms of overall emission impact. Given that the significant proportion of new building stock is estimated to house EWS and LIG segments, it is crucial to examine and ensure the affordability of recommendations and solutions.

A framework is needed for comprehensively measuring affordability and quality of solutions, which ensures that achieving affordabity does not compromise quality. The study thus draws focus on the process of identifying and developing pathways, proposing that the needs for this segment are considered from the onset of policymaking, and not as an afterthought.

6.2 Developing a unified metric for measuring impact

The comparative analysis of recommendations analysed highlights inconsistencies in the output due to differing objectives. A material that achieves high thermal comfort may have significantly high EEV and construction cost. This thus highlights the need for a unified objective and method of measuring impact.

One potential metric is introduced. A method of developing a green score that combines operational and embodied emissions, and construction cost is discussed. However, the authors acknowledge that there may be other optimal ways of measuring impact that combines different objectives into a unified output. Furthermore, the unified metric method discussed here needs to be developed in collaboration with a wider quorum of technical experts and stakeholders – to ensure that differing objectives and needs are addressed at the onset.

6.3 Developing a consolidated implementation framework

Numerous solutions exist for each pathway discussed. While that implies a strong focus on addressing the issue, the intent may not always result in effective implementation and success on ground. The comprehensive implementation framework reveals that there are significant gaps in policy framing and policy implementation on ground. Actors responsible for drafting and implementing the multitude solutions be aligned. The intent of one policy/regulation can negate the impact of another – ultimately lessening the impact on ground. Thus, a consolidated framework of implementation, new communication channels between actors, and identification of streamlined pathways for on-ground implementation are necessary.

The paper presents an examination of two net zero pathways in the context of affordable housing in India, identifies critical gaps, and provides recommendations to ensure an affordable net zero future for India.

1 ABSTRACT

Das DREAMS-Projekt (finanziert durch das Forschungsprogramm Driving Urban Transitions to a sustainable future, https://dutpartnership.eu/) untersucht Entwicklungspfade zu barrierefreien, nachhaltigen und integrativen 15-Minuten-Quartieren in urbanen Randlagen in europäischen Städten und Regionen. Dabei werden 6 europäische Stadtquartiere außerhalb der dichten Stadtzentren als Living Labs herangezogen (Budapest, Brüssel, München, Paris, Utrecht und Wien). In einem ersten Schritt wurde die Ausgangslage untersucht, inwieweit die Mobilität der Einwohnerinnen und Einwohner schon heute dem Konzept der 15 Minuten-Stadt entspricht und wo die Defizite zu Tage treten. Hierbei wird nach verschiedenen Bevölkerungsgruppen und Verkehrszwecken unterschieden. Analysen des Mobilitätsverhaltens in den 6 Living Labs zeigen, dass der höchste Anteil an Wegen innerhalb von 15 Minuten bei Einkaufswegen (45%-81%) besteht, gefolgt von Freizeit (33%-58%) und Ausbildung (32%-49%). Im Vergleich zu Zentren nahen Quartieren sind die Ausbildungswege länger (wegen der geringeren Dichte an Ausbildungseinrichtungen), die Wege zur Freizeit hingegen kürzer (wegen dem besseren Naherholungsangebot bei den Quartieren an den Stadträndern). Von einem ausreichend hohen Anteil kann man im Ist-Zustand jedoch bei keinem Verkehrszweck sprechen. Auch bei unterschiedlichen Bevölkerungsgruppen (z.B. Alter, Geschlecht, Bildungsstand, Einkommen) gibt es Unterschiede und erreicht in keiner der untersuchten Gruppen einen Idealzustand.

Es zeigt sich außerdem, dass die Stadtstruktur bei vielen Verkehrszwecken eine wesentliche Rolle spielt. Wenn die Stadt sehr monozentristisch aufgebaut ist, sind viele Bewohnerinnen und Bewohner der Randlagen gezwungen, Wege in die Stadtzentren zu unternehmen, um ihre grundlegenden Bedürfnisse befriedigen zu können. Ähnlich verhält es sich, wenn Städte monofunktional aufgebaut sind, also Wohnquartiere weit von Einkaufsmöglichkeiten, Arbeitsplätzen, medizinischen und Ausbildungseinrichtungen entfernt sind (auch wenn sich diese in den Randlagen befinden). In diesen Fällen wird es schwierig, Wege mit aktiven Mobilitätsformen (primär zu Fuß oder Fahrrad) innerhalb von 15 Minuten zurückzulegen.

Einerseits kann man nun die Definition der 15-Minuten-Stadt aufweichen. Vielleicht reicht auch eine 20 oder 30 oder x Minuten Stadt an den Stadträndern? Sollen (umweltverträgliche) motorisierte Verkehrsmittel (Mikro-ÖV, E-Bike, Car-Sharing, etc.) miteinbezogen werden, um die Reichweiten innerhalb der 15-Minuten-Grenze zu vergrößern? Andererseits können Stadtstrukturen analysiert werden und Defizite bei Angeboten im Stadtquartier erkannt und verringert werden (auch durch finanzielle Beiträge des öffentlichen Sektors, wenn aufgrund der geringeren Nachfrage Angebote nicht marktwirtschaftlich betrieben werden können). Realistischerweise wird es wohl ein Mix aus diesen Ansätzen für Stadtquartiere in Randlagen geben, eventuell auch abgestuft nach den Verkehrszwecken.

Ausgehend von den vorliegenden Analysen werden daher in diesem Projekt auch neue Geschäftsmodelle und Governance-Ansätze für Mobilitätsdienste (einschließlich Mikromobilität, Carsharing, bedarfsgesteuerter Verkehre) und mit Mobilität in Zusammenhang stehenden Aktivitäten und Angeboten (z. B. Pop-Up Stores, kulturelle Aktivitäten im Stadtteil) in diesen Gebieten mit geringer/mittlerer Dichte entwickelt und getestet. Es wird analysiert, inwieweit diese Interventionen geeignet sind, sich dem Konzept einer 15-Minuten Stadt anzunähern.

Keywords: Mobilitätsverhalten, Stadtrand, 15-Minuten-Stadt, Planung, Städtebau

2 EINLEITUNG

Das DREAMS-Projekt fokussiert sich darauf, wie Co-Creation von Angeboten im Stadtteil und nutzerzentrierte Shared-Mobilitätsdienste zu barrierefreien, nachhaltigen und integrativen 15-Minuten-Quartieren in urbanen Randlagen in europäischen Städten und Regionen beitragen können. Für das Projekt DREAMS werden dazu sechs Stadtteile beforscht, jeweils in Budapest, Brüssel, München, Paris, Utrecht und Wien. Zunächst wird für DREAMS eine umfassende und vergleichende Analyse des 15-Minuten Lebensstils in diesen Städten und Stadtteilen durchgeführt. Die Ergebnisse dieses Arbeitsschritts werden im folgenden Paper diskutiert. Im Gegensatz zu den angebotsbezogenen Erreichbarkeitsanalysen (Moreno 2016, 2021) wird in diesem Paper die Nachfrageseite beleuchtet, also wie weit Individuen tatsächlich unterwegs sind um ihre Ziele für Arbeit, Bildung, Einkaufen oder Freizeit zu erreichen, ungeachtet davon, welche Möglichkeiten es im 15 Minuten-Umfeld gegeben hätte. Das bedeutet, es werden hier die Präferenzen der Individuen mitberücksichtigt, welche eine Mischung aus dem tatsächlichen räumlichen Angebot an Möglichkeiten und den bevorzugten Zielen aus einer Auswahl von Möglichkeiten darstellt, z.B., wenn eine Person lieber auf einem Markt statt im Supermarkt einkauft oder lieber die Staatsoper als in eine lokale Kultureinrichtung bevorzugt.

In weiterer Folge wird im Projekt DREAMS neue Geschäftsmodelle und Governance-Ansätze für Mobilitätsdienste (einschließlich Mikromobilität, Carsharing, bedarfsgesteuerter Verkehre) und mit Mobilität in Zusammenhang stehenden Aktivitäten in Gebieten mit geringer/mittlerer Dichte entwickelt und getestet, um die Autoabhängigkeit zu verringern. Im Projekt DREAMS werden die Effekte auf Mobilität, Erreichbarkeit und die weitergehenden gesellschaftlichen Aspekte der neuen Mobilitätsdienste und damit in Zusammenhang stehende Dienstleistungen untersucht. Final wird es politische Empfehlungen für Wege zur Schaffung einer nachhaltigen und integrativen städtischen Mobilität in 15-(oder X-)Minuten-Quartieren in städtischen Randlagen durch die Nutzung von durch Co-Creation geschaffenen und benutzerzentrierten neuen Mobilitätsdiensten und damit in Zusammenhang stehende Dienstleistungen sowie für neue Governance-Geschäftsmodelle geben.

3 METHODE

Für die vorliegende Analyse wurden vorhandene Mobilitätserhebungen von den sechs Fallstädten verwendet. Dabei wurde die Stadt in ihrer Gesamtheit und ein konkretes Gebiet am Stadtrand ausgewertet. Dadurch ist es möglich, nicht nur die Unterschiede zwischen den sechs Städten und Stadtteilen, sondern auch jene zwischen dem Stadtteil in Randlage und der Stadt im Gesamten zu vergleichen. Dafür wurden nationale oder regionale Mobilitätserhebungen herangezogen. Um die Daten vergleichbar zu machen wurde vorab Informationen zu den Erhebungen gesammelt: (1.) Allgemeine Informationen zur Erhebung (z. B. Name, Jahr, Stichprobengröße, Beschreibung der Verkehrszwecke, Definition eines Weges); (2.) Datensatzinformationen (z. B. Verfügbarkeit, Formattyp, Sprache); (3.) Informationen zu den Attributen von Haushalten und Personen; (4.) Informationen zu den Attributen der berichteten Wege. Darauf aufbauend wurden die Datensätze in einem weiteren Schritt harmonisiert. Das Ziel der vergleichenden Analyse besteht darin, die bestehenden Mobilitätsmuster und -verhaltensweisen von Personen zu vergleichen und zu verstehen. Daher konzentrierte sich die Analyse auf das Mobilitätsverhalten von Personen in ihrer lokalen Umgebung. Dementsprechend wurde eine spezifische Methode implementiert. Jede Datenbank wurde nach folgenden Kriterien gefiltert: (1.) Alle berichteten Wege haben als Ausgangspunkt den Wohnbezirk des Befragten. (2.) Alle berichteten Wege haben als Ziel dasselbe Land, um lange Wege zu vermeiden, die das Endergebnis der Analyse beeinflussen könnten. (3.) Der Zweck der berichteten Wege ist Arbeit, Bildung, Einkaufen oder Freizeit. (4.) Das Fortbewegungsmittel der gemeldeten Fahrten ist zu Fuß, mit dem Fahrrad, mit dem Auto (Fahrer oder Beifahrer) oder mit öffentlichen Verkehrsmitteln. Aufgrund des Seitenlimits für dieses Paper werden die detaillierten Ergebnisse exemplarisch für den Verkehrszweck Einkaufen dargestellt. Im Arbeitsbericht des Projekts sind auch die Ergebnisse für die anderen Verkehrszwecke dargestellt, siehe https://www.dreams15mc.eu/publications.

4 WIEN

Aus dem Datensatz „Österreich Unterwegs 2013/14“ wurde eine Liste von Variablen ausgewählt, die dabei helfen sollen, die Merkmale der Bewohner sowohl auf Stadtebene als auch auf Bezirksebene abzubilden und

zu verstehen. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets (Wien oder Liesing).

4.1 Die Gesamtstadt

Die Wiener Wohnbevölkerung legt im Durchschnitt kurze Wege (16,5 Minuten) zurück, um ihre Einkäufe zu erledigen. 70% der Einkaufswege werden innerhalb von 15 Minuten erledigt, was auf ein dichtes Netz an Einkaufsmöglichkeiten in ganz Wien hindeutet. Zu Fuß wird am häufigsten eingekauft (47,2%), mit einer durchschnittlichen Dauer von 13 Minuten, während über 80% der Wege bis zu 15 Minuten dauern. Darüber hinaus sind Einkaufswege mit dem Auto (20,7%) oder öffentlichen Verkehrsmitteln (20,6%) in der Stichprobe etwa gleich stark vertreten, mit einer durchschnittlichen Fahrtdauer von 16 bzw. 26 Minuten (siehe Tabelle 1, Abbildung 1).

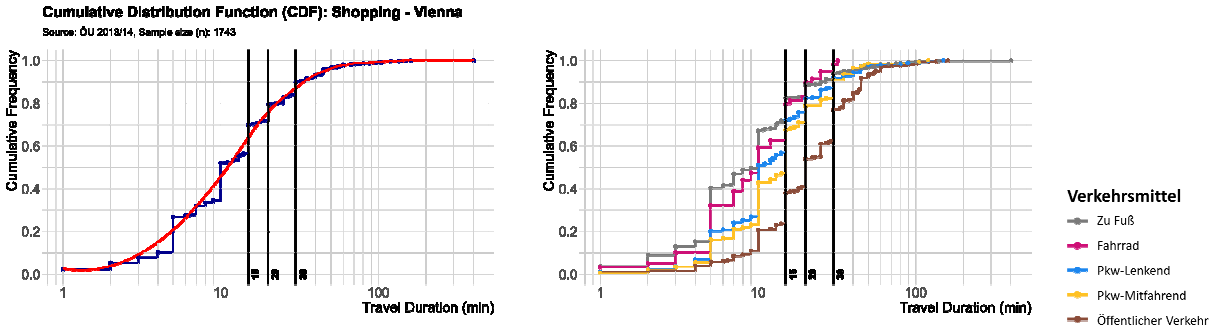

Abbildung 1: Kumulative Verteilung der Einkaufswege nach Dauer – Wien. Links: Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**52,1%**	**69,9%**	**79,5%**	**90,1%**
Zu Fuß	**67,3%**	**82,5%**	**88,7%**	**94,2%**
Fahrrad	**59,3%**	**79,7%**	**89,8%**	**98,3%**
Pkw-Lenkend	**51,1%**	**72,2%**	**82,5%**	**91,9%**
Pkw-Mitfahrend	**43,0%**	**67,6%**	**78,9%**	**90,8%**
Öffentlicher Verkehr	**20,6%**	**38,2%**	**54,0%**	**77,2%**

Tabelle 1: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Wien

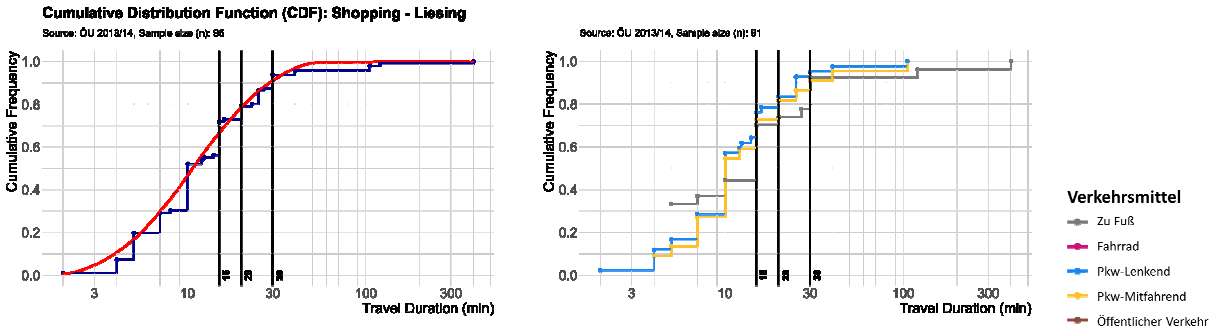

Abbildung 2: Kumulative Verteilung der Einkaufswege nach Dauer– Stadtteil Liesing. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**52,1%**	**71,9%**	**79,2%**	**93,8%**
Zu Fuß	**44,4%**	**70,4%**	**74,1%**	**92,6%**
Fahrrad	**Zu geringe Fallzahl**			
Pkw-Lenkend	**57,1%**	**76,2%**	**83,3%**	**95,2%**
Pkw-Mitfahrend	**54,5%**	**72,7%**	**81,8%**	**90,9%**
Öffentlicher Verkehr	**Zu geringe Fallzahl**			

Tabelle 2: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Stadtteil Liesing

4.2 Der Stadtrand: Liesing

In Liesing beträgt die durchschnittliche Wegedauer 21 Minuten, wobei im Gegensatz zur gesamten Stadt das Auto das am häufigsten gewählte Verkehrsmittel ist (43,8%). Zu Fuß zu gehen ist für diesen Fahrtzweck mit einem Anteil von 28,1% vertreten. Allerdings sind Gehwege deutlich länger als in Wien gesamt (32 Minuten gegenüber 16,5 Minuten). Die Kombination aus Verkehrsmittelwahl und Fahrtmerkmalen lässt darauf schließen, dass die Nähe zu Einzelhandelseinrichtungen in Liesing geringer ist, was wiederum die Nutzung motorisierter Fahrzeuge begünstigt (siehe Tabelle 2, Abbildung 2). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

5 UTRECHT

Für die deskriptive statistische Analyse für die Stadt Utrecht und die Region Overvecht wurde der Datensatz „Onderweg in Nederland 2021“ verwendet. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets (Utrecht bzw. Overvecht).

5.1 Die Gesamtstadt

Im Durchschnitt fahren die Einwohner von Utrecht etwa 12 Minuten und 3,4 Kilometer zum Einkaufen. Das beliebteste Transportmittel ist das Fahrrad (33,2%), gefolgt vom Auto (29,5%) und dann zu Fuß (28,9%). Einkaufswege mit dem Fahrrad dauern im Durchschnitt 11 Minuten und fast 87% davon bis maximal 15 Minuten. Wie erwartet dauern Fahrten mit dem Auto etwas länger (13 Minuten) und es werden viel größere Entfernungen zurückgelegt als zu Fuß oder mit dem Fahrrad. Personen, die sich für den Einkauf mit dem Auto entscheiden, suchen tendenziell Einkaufszentren außerhalb des Stadtzentrums auf. Im Allgemeinen sind Einkaufswege in Utrecht meist kurz und 84% von ihnen dauern bis maximal 15 Minuten. Dieses Ergebnis zeigt eine gute Ausstattung mit Einkaufsmöglichkeiten (siehe Tabelle 3, Abbildung 3).

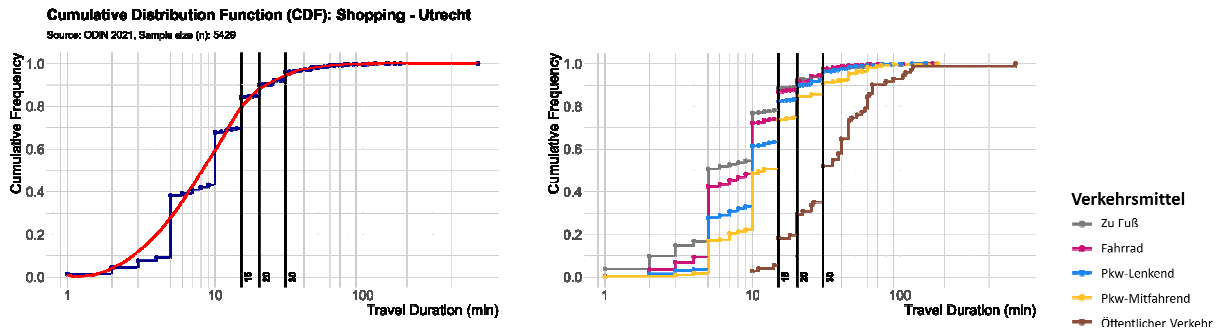

Abbildung 3: Kumulative Verteilung der Einkaufswege nach Dauer– Utrecht. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**67,8%**	**84,1%**	**90,0%**	**96,1%**
Zu Fuß	**76,9%**	**88,4%**	**92,5%**	**97,3%**
Fahrrad	**72,2%**	**86,8%**	**91,8%**	**97,6%**
Pkw-Lenkend	**61,5%**	**82,4%**	**89,6%**	**96,4%**
Pkw-Mitfahrend	**48,6%**	**73,6%**	**84,8%**	**91,2%**
Öffentlicher Verkehr	**2,8%**	**18,3%**	**29,6%**	**52,1%**

Tabelle 3: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Utrecht

5.2 Der Stadtrand: Overvecht

In Overvecht dauern Einkaufswege durchschnittlich 11 Minuten. Das beliebteste Transportmittel zum Einkaufen ist das Gehen (40,3%), gefolgt vom Fahrrad (31,9%). Einkaufswege zu Fuß oder mit dem Fahrrad dauern ungefähr 10 Minuten, während der Anteil der Wege, die bis zu 15 Minuten dauern, 89% bzw. 78% beträgt. Insgesamt werden mehr als 80% der Einkaufswege in Overvecht in weniger als 15 Minuten erledigt. Diese Zahlen zeigen, dass die Menschen in Overvecht im Gegensatz zur Gesamtstadt eher lokal einkaufen und nachhaltigere Verkehrsmittel bevorzugen (siehe Tabelle 4, Abbildung 4). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

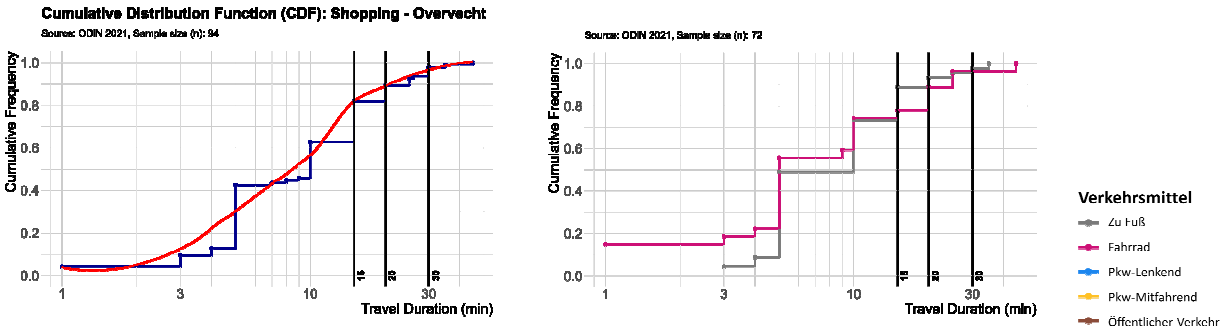

Abbildung 4: Kumulative Verteilung der Einkaufswege nach Dauer– Stadtteil Overvecht. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

6 BRÜSSEL

Für die deskriptive statistische Analyse für die Stadt Brüssel und die Region Brüssel-Stadt wurde der Datensatz „Onderzoek Verplaatsingsgedrag (OVG) 2021“ verwendet. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets (Brüssel bzw. Heembeek und Haren). Die deskriptive statistische Analyse liefert eine wertvolle Perspektive auf die demografischen Merkmale der Bevölkerung von Brüssel und der Stadt Brüssel. Was den Autobesitz betrifft, besitzt die Mehrheit der Haushalte in beiden Regionen mindestens ein Auto.

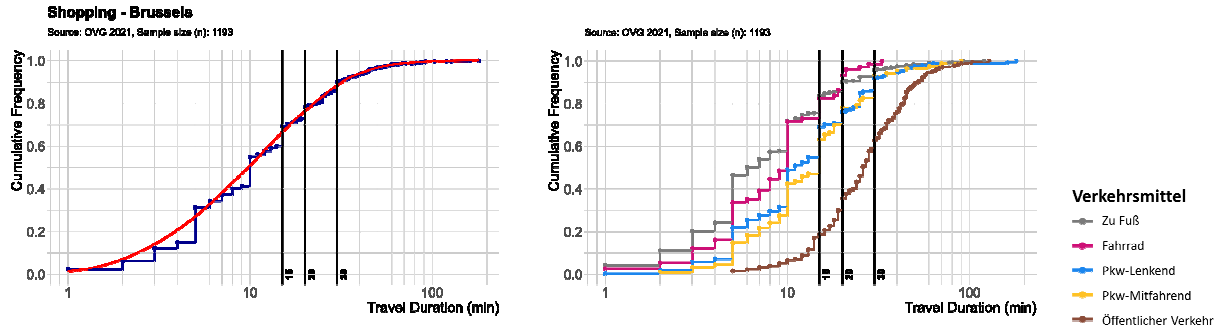

Abbildung 5: Kumulative Verteilung der Einkaufswege nach Dauer – Brüssel. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**55,0%**	**69,3%**	**78,3%**	**90,0%**
Zu Fuß	**72,0%**	**84,0%**	**90,4%**	**96,0%**
Fahrrad	**71,6%**	**82,4%**	**93,2%**	**98,6%**
Pkw-Lenkend	**49,0%**	**69,1%**	**76,1%**	**91,9%**
Pkw-Mitfahrend	**42,5%**	**63,2%**	**78,2%**	**93,1%**
Öffentlicher Verkehr	**6,7%**	**18,9%**	**35,6%**	**62,8%**

Tabelle 5: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Brüssel

6.1 Die Gesamtstadt

Einkaufswege in Brüssel dauern im Durchschnitt 15,4 Minuten, wobei fast 70% davon bis maximal 15 Minuten dauern, was auf gute Einkaufsmöglichkeiten im Umfeld hindeutet. Das beliebteste Transportmittel zum Einkaufen ist zu Fuß (49,7%), gefolgt vom Auto (21,7%) und dann den öffentlichen Verkehrsmitteln (15,1%). Im Durchschnitt gehen die Brüsseler 11 Minuten zu Fuß zum Einkaufen. Darüber hinaus dauern 84% dieser Fußwege weniger als 15 Minuten. Einkaufswege mit dem Auto dauern im Durchschnitt etwas

länger als Fußwege und es werden dabei längere Distanzen zurückgelegt. Fahrten mit öffentlichen Verkehrsmitteln dauern im Durchschnitt am längsten (30 Minuten), nur ein kleiner Prozentsatz (19%) davon dauert weniger als 15 Minuten (siehe Tabelle 5, Abbildung 5).

6.2 Der Stadtrand: Heembeek und Haren

Im Durchschnitt dauern Einkaufswege in den Stadtteilen Heembeek und Haren etwa 17 Minuten und umfassen fast 2,9 Kilometer. Das Gehen ist das vorherrschende Transportmittel für Einkaufswege (62,8%). Fußwege sind kurz und ein großer Teil davon (80%) wird innerhalb von 15 Minuten zurückgelegt. Dies zeigt, dass die Menschen die meisten ihrer Einkäufe vor Ort erledigen können. Einkaufswege mit öffentlichen Verkehrsmitteln (Anteil von 17,4%) sind sowohl in Bezug auf die Entfernung als auch die Zeit viel länger als Fußwege. Insgesamt zeigen die Ergebnisse, dass Einkaufswege in der Brüsseler Stadtteilen Heembeek und Haren mit nachhaltigeren Verkehrsmitteln wie zu Fuß und mit öffentlichen Verkehrsmitteln unternommen werden als in der Gesamtstadt (siehe Tabelle 6, Abbildung 6). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

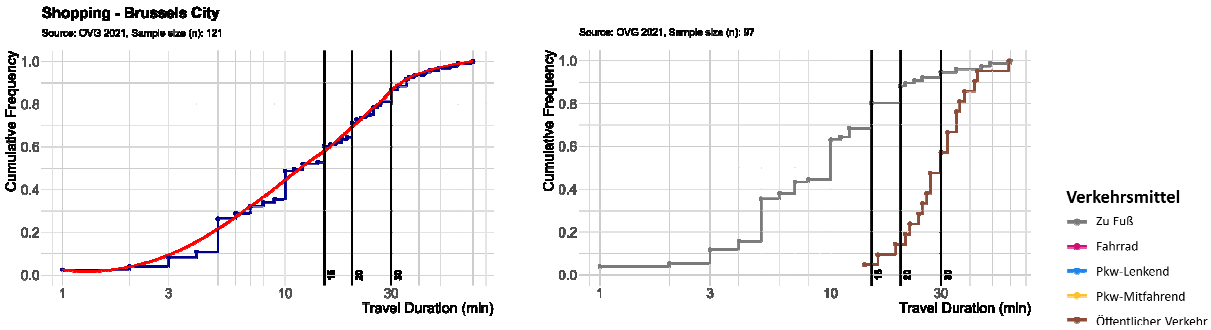

Abbildung 6: Kumulative Verteilung der Einkaufswege nach Dauer – Stadtteile Heembeek und Haren. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten

7 BUDAPEST

Für die deskriptive statistische Analyse der Stadt Budapest wurde der Datensatz „Unified Macroscopic Modelling Household Survey 2019“ verwendet. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets.

7.1 Die Gesamtstadt

Einkaufswege in Budapest dauern durchschnittlich 20 Minuten, wobei 55% davon innerhalb von 15 Minuten erledigt sind. Das am häufigsten genutzte Verkehrsmittel für Einkaufswege in Budapest ist zu Fuß (36,6%), gefolgt vom Auto (29,6%) und öffentlichen Verkehrsmitteln (27,2%). Fußwege zu Einkaufsmöglichkeiten dauern durchschnittlich 11,8 Minuten und fast 82% davon maximal 15 Minuten. Darüber hinaus sind Autofahrten zu Einkaufsmöglichkeiten im Durchschnitt länger als Fußwege, und die hohe Varianz in der Stichprobe zeigt, dass Autofahrten für Einkaufsziele bevorzugt werden, die weit vom Wohnort entfernt sind. Gleiches gilt für Einkaufswege mit öffentlichen Verkehrsmitteln. Allerdings werden nur 24% der Fahrten mit öffentlichen Verkehrsmitteln innerhalb von 15 Minuten erledigt, verglichen mit 48% der Autofahrten (siehe Tabelle 7, Abbildung 7).

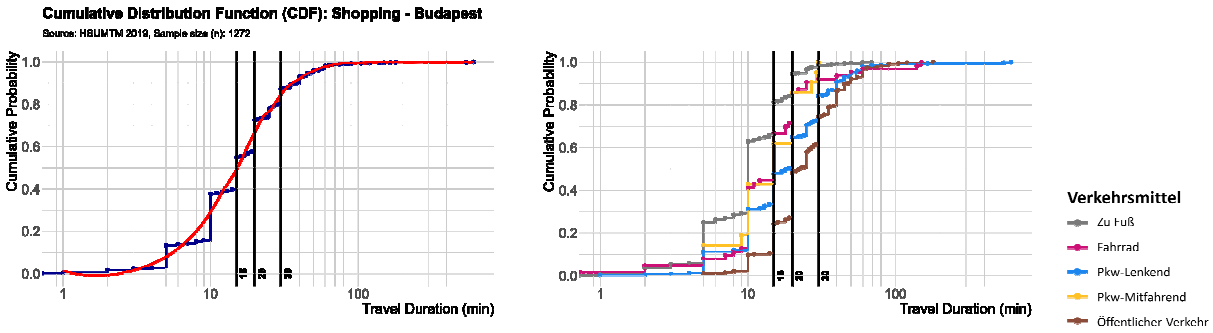

Abbildung 7: Kumulative Verteilung der Einkaufswege nach Dauer – Budapest. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**37,7%**	**55,0%**	**72,6%**	**87,4%**
Zu Fuß	**62,9%**	**81,5%**	**94,4%**	**98,5%**
Fahrrad	**41,3%**	**66,7%**	**85,7%**	**92,1%**
Pkw-Lenkend	**31,1%**	**47,9%**	**64,9%**	**84,3%**
Pkw-Mitfahrend	**42,9%**	**61,9%**	**85,7%**	**100,0%**
Öffentlicher Verkehr	**9,8%**	**24,3%**	**48,3%**	**74,3%**

Tabelle 7: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Budapest

7.2 Der Stadtrand: 16. and 17. Bezirk

Die durchschnittliche Dauer von Einkaufsfahrten im 16. und 17. Bezirk von Budapest beträgt 22 Minuten, und fast 45% dieser Fahrten werden innerhalb von 15 Minuten erledigt. Bewohner der Bezirke 16 und 17 verbringen einen größeren Teil ihrer Zeit damit, zum Einkaufen zu gelangen, als Bewohner des gesamten Stadt Budapest. Die Analyse zeigt, dass das Auto das vorherrschende Verkehrsmittel für Einkaufsfahrten ist (41,4%), was auf eine hohe Abhängigkeit von motorisierten Verkehrsmitteln hindeutet (siehe Tabelle 8, Abbildung 8). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

8 PARIS

Für die deskriptive statistische Analyse der Regionen Paris, Île-de-France und Essonne wurde der Datensatz „Enquête Globale Transport (EGT) 2020“ verwendet. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets (Paris, Île-de-France bzw. Stadtteil Essonne).

8.1 Die Gesamtstadt

Im Durchschnitt dauern Einkaufswege in der Region Île-de-France etwa 16 Minuten, wobei eine Distanz von 3 Kilometern zurückgelegt wird. Das vorherrschende Fortbewegungsmittel ist das Gehen (47,6%), gefolgt vom Auto, lenkend (31,4%) und öffentlichen Verkehrsmitteln (12,2%). Im Durchschnitt gehen die Menschen in der Region Paris, Île-de-France 10 Minuten zu Fuß, um zu Einkaufsmöglichkeiten zu gelangen, wobei fast 90% dieser Fahrten bis maximal 15 Minuten dauern. Autofahrten hingegen sind vergleichsweise lang, wobei auch größere Distanzen zurückgelegt werden. Der hohe Anteil an Fahrten, die innerhalb von 15 Minuten erledigt werden, unterstreicht die gute Ausstattung an Einkaufsmöglichkeiten in der Region Paris, Île-de-France (siehe Tabelle 9, Abbildung 9).

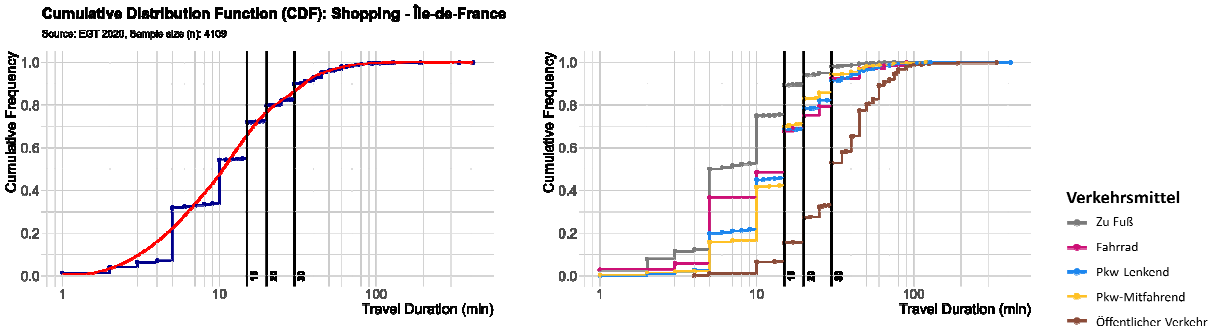

Abbildung 9: Kumulative Verteilung der Einkaufswege nach Dauer– Paris Île-de-France. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**54,4%**	**72,0%**	**79,9%**	**90,1%**

Pkw-Mitfahrend	**41,7%**	**69,8%**	**83,1%**	**94,2%**
Öffentlicher Verkehr	**6,6%**	**15,6%**	**27,3%**	**52,9%**

Tabelle 9: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – Paris Île-de-France

8.2 Der Stadtrand: Essone

Die durchschnittliche Dauer von Einkaufsfahrten in der Region Essonne beträgt etwa 17 Minuten, wobei eine Entfernung von fast 4 Kilometern zurückgelegt wird. Das vorherrschende Verkehrsmittel für Einkaufsfahrten ist das Auto lenkend (52,9%), gefolgt vom Gehen (28,3%). Im Vergleich dazu sind zu Fuß zurückgelegte Wege kurz, wobei ein erheblicher Anteil (83%) innerhalb eines Zeitrahmens von 15 Minuten zurückgelegt wird. Im Gegensatz dazu sind Einkaufsfahrten mit dem Auto durch eine längere Dauer und größere zurückgelegte Entfernung gekennzeichnet. Die Analyse zeigt, dass die Mehrheit der Einkaufswege in der Region Essonne innerhalb von 15 Minuten zurückgelegt wird (69,3%), was auf eine ebenfalls auf eine gute Ausstattung mit Einkaufsmöglichkeiten hindeutet (siehe Tabelle 10, Abbildung 10). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

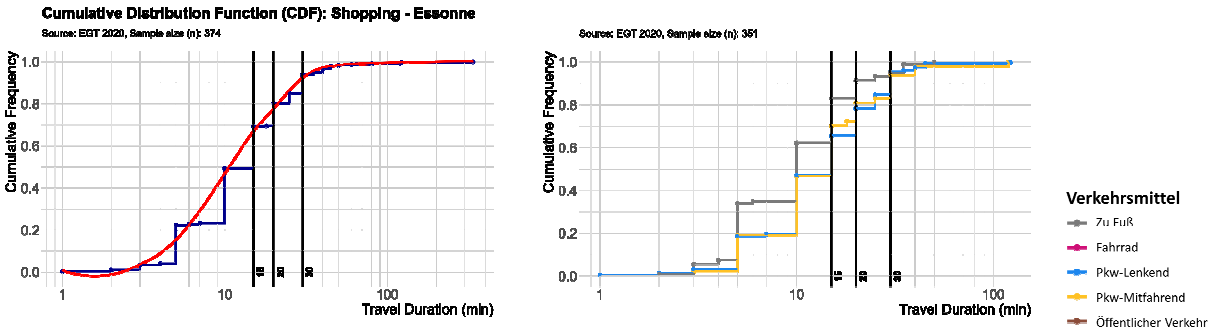

Abbildung 10: Kumulative Verteilung der Einkaufswege nach Dauer– Stadtteil Essonne. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

9 MÜNCHEN

Für die deskriptive statistische Analyse für München wurde der Datensatz „infas, DLR, IVT und infas 360 (2018), Mobilität in Deutschland (im Auftrag des BMVI)“ verwendet. Die für diesen Teil der Analyse verwendete Stichprobe ist die gesamte Wohnbevölkerung innerhalb des Gebiets.

9.1 Die Gesamtstadt

Im Durchschnitt dauern Einkaufswege in München etwa 17 Minuten, wobei eine Distanz von 3,7 Kilometern zurückgelegt wird. Das vorherrschende Fortbewegungsmittel ist das Gehen mit 35%, gefolgt vom Auto lenkend (26%) und Fahrrad (20%). Im Durchschnitt gehen die Menschen in München 14 Minuten zu Fuß, um zu Einkaufsmöglichkeiten zu gelangen, wobei fast 80% dieser Wege maximal 15 Minuten dauern. Autofahrten (lenkend) hingegen sind vergleichsweise lang, wobei dabei größere Distanzen zurückgelegt werden (siehe Tabelle 11, Abbildung 11).

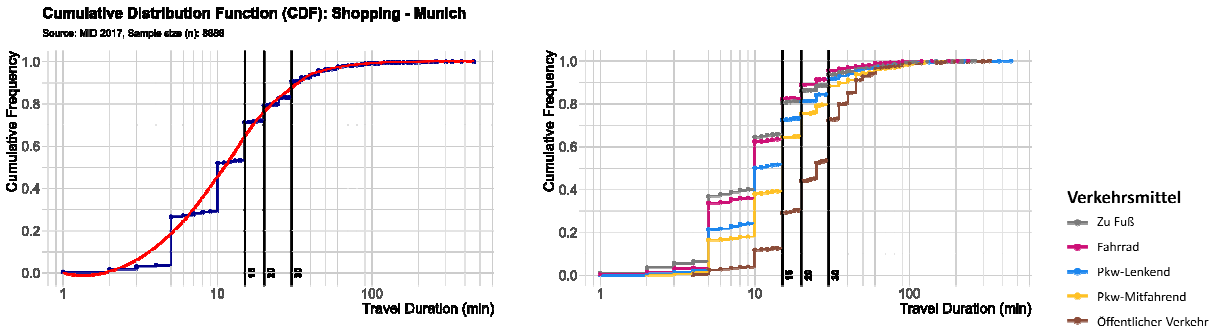

Abbildung 11: Kumulative Verteilung der Einkaufswege nach Dauer– München. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**52,1%**	**71,3%**	**79,4%**	**90,6%**
Zu Fuß	**64,6%**	**80,4%**	**86,1%**	**93,7%**

Öffentlicher Verkehr	**11,8%**	**29,0%**	**43,8%**	**72,5%**

Tabelle 11: Anteil (%) der Einkaufswege innerhalb einer definierten Wegedauer je Verkehrsmittel – München

9.2 Der Stadtrand: periphere Stadtregionen Münchens

Im Gegensatz zu den anderen Fallstädten wurden aufgrund der Rahmenbedingungen der Stichprobe nicht ein konkreter Stadtteil ausgewählt, sondern anhand von räumlichen Rahmenbedingungen die Teilstichprobe gefiltert. Die durchschnittliche Dauer von Einkaufsfahrten in dieser Region beträgt etwa 15 Minuten, wobei eine Entfernung von 5 Kilometern zurückgelegt wird. Das vorherrschende Verkehrsmittel für Einkaufswege ist das Auto, lenkend (53%), gefolgt vom Fahrrad (19%). Im Vergleich dazu sind zu Fuß zurückgelegte Wege kurz, wobei ein Anteil von 68% innerhalb eines Zeitrahmens von 15 Minuten zurückgelegt wird. Im Gegensatz dazu sind Einkaufsfahrten mit dem Auto durch eine längere Dauer und größere zurückgelegte Entfernung gekennzeichnet. Die Analyse zeigt, dass ein Anteil von 77,3% der Einkaufswege in periphere Stadtregionen Münchens innerhalb von 15 Minuten zurückgelegt wird (siehe Tabelle 12, Abbildung 12). Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet.

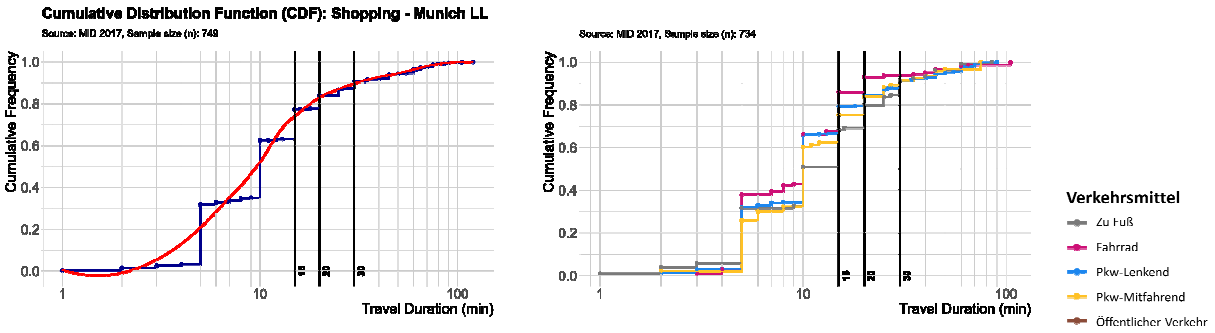

Abbildung 12: Kumulative Verteilung der Einkaufswege nach Dauer– Stadtteil periphere Stadtregionen Münchens. Links: Summenlinie Wegedauer, alle Verkehrsmittel, rechts: Summenlinie Wegedauer je Verkehrsmittel.

Verkehrsmittel	Anteil der Wege mit weniger als x Minuten			
	10	15	20	30
Alle Verkehrsmittel	**62,3%**	**77,3%**	**83,9%**	**90,7%**
Zu Fuß	**50,9%**	**68,3%**	**79,8%**	**91,3%**
Fahrrad	**66,2%**	**85,9%**	**92,9%**	**93,7%**
Pkw-Lenkend	**66,1%**	**79,2%**	**84,3%**	**91,4%**
Pkw-Mitfahrend	**60,2%**	**75,3%**	**83,9%**	**91,4%**

Tabelle 14: Vergleich der Wegzeiten in Minuten nach Geschlecht (M=Männer, F=Frauen) auf Stadtteilebene

10 VERGLEICH DER STÄDTE

Tabelle 13 zeigt den Vergleich der durchschnittlichen Wegzeiten nach Geschlecht, Verkehrsmittel und Wegezweck aller Fallstädte. Für jeden Wegzweck je Verkehrsmittel wurde jeweils der Minimalwert (blau) und Maximalwert (orange) farblich hervorgehoben. Bei der bloßen Betrachtung der durchschnittlichen Wegzeiten erkennt man, dass bei den Fußwegen der Mittelwert innerhalb von 15 Minuten liegt. Einzige Ausnahme bilden Freizeitwege, da hier in den meisten Städten auch Wege ohne Ziel (also einfaches "im Kreis" Spazierengehen) mitabgebildet sind. Wege mit dem Fahrrad liegen im Mittelwert bereits etwas über der 15 Minuten Schranke (auch hier der Effekt bei den Freizeitwegen, dass auch das Radfahren zum Selbstzweck im Datensatz erhalten ist). Bei den Pkw-Wegen und öffentlichen Verkehrsmitteln liegen die Mittelwerte deutlich über der 15-Minuten-Dauer. Frauen weisen tendenziell kürzere Wegdauern auf als Männer. Tabelle 14 zeigt diese Werte für die Stadtteilebene, wobei wegen der geringeren Stichprobengröße die Verkehrszwecke nicht mehr ausgekreuzt werden konnten. Wenn bei der Auswertung bei den Verkehrsmittelklassen weniger als 20 Datensätze (Wege) vorhanden waren, wurden diese nicht ausgewertet. Wie erwartet weisen die Wege auf Stadtteilebene größere Fahrtdauern auf als auf Gesamtstadtebene, wobei dies stärker bei Fußwegen und Radwegen durchschlägt. Pkw-Wege, lenkend und Wege mit öffentlichen Verkehrsmitteln dauern nur geringfügig länger im Vergleich zur Gesamtstadt. Die Unterschiede zwischen Männern und Frauen auf Stadtteilebene ergeben ein sehr heterogenes Bild, es ist kein Trend ablesbar, ob Frauen oder Männer tendenziell längere Wegzeiten aufweisen.

11 SCHLUSSFOLGERUNGEN

Die Ergebnisse zeigen, dass sowohl auf Gesamtstadtebene als auch auf Stadtteilebene in den gewählten Fallstädten die 15-Minuten-Stadt bei Analyse des Mobilitätsverhaltens nicht realisiert ist. Es besteht also Handlungsbedarf, die planerischen Ziele mit dem Verkehrsverhalten der Einwohnerinnen und Einwohner in Gleichklang zu bringen. Prinzipiell gibt es dazu 2 Hebeln, die Verdichtung der Ausstattung und Gelegenheiten, Ziele in einem näheren Umfeld zu erreichen und das Umdenken der Personen, ihr Verkehrsverhalten zu ändern, auch wenn dies eventuell ihren hedonistischen Präferenzen (bezügliche Verkehrsmittel und gewähltem Ziel) entgegensprechen. Im Rahmen des Projekt DREAMS möchte man in den Living Labs entsprechende Aktivitäten setzen. Parallel dazu ist für Stadtränder zu diskutieren, inwieweit die planerischen Ziele etwas weiter gefasst werden müssen, zum Beispiel bezüglich der Zielvorgaben der Wegzeiten oder auch der Hereinnahme (nachhaltiger) motorisierter Verkehrsmittel in den Verkehrsmittelmix. Die Ursprungsidee der 15-Minuten-Stadt war ja die ausschließliche Verwendung von nicht motorisierten Verkehrsmitteln. Im Rahmen des Projekt DREAMS werden wir prüfen, inwieweit Verkehrsmittel wie Mikro-Mobilität, Car-Sharing oder bedarfsgesteuerte Verkehre wie Anrufsammeltaxis) für die Erreichung einer 15-Minuten-Stadt – besonders in den Randlagen – zulässig und erstrebenswert ist.

1 ABSTRACT

Schutz und Entwicklung unbesiedelter/unbebauter Freiräume innerhalb und außerhalb von Siedlungsbereichen werden als fundamentale Handlungsfelder des natürlichen Klimaschutzes und der Anpassung an den Klimawandel betrachtet. Zugleich gilt der Freiraum als multifunktionaler Träger von Biodiversität und Ökosystemleistungen. In der Raumplanung werden mit Unterstützung des Instruments der Umweltprüfung bereits bisher für Klima und Umwelt wertvolle Freiräume gesichert sowie raumbeanspruchende Vorhaben auf ihre Klima- und Umweltverträglichkeit geprüft und optimiert. Mit der UVP-Änderungsrichtlinie der EU von 2014 wurde das „Schutzgut Fläche” in den Schutzgüterkatalog der Umweltprüfung zusätzlich aufgenommen. Damit sollen weitergehende Fortschritte bei der Reduzierung des sog. „Flächenverbrauchs“ für Siedlung und Infrastruktur erreicht und entsprechende Freiraumverluste begrenzt werden. In diesem Kontext geht der Beitrag der Frage nach, inwiefern das Schutzgut Fläche als Impuls und Unterstützung für die Eindämmung des Flächenverbrauchs und zugleich für einen multifunktional begründeten Freiraumschutz genutzt werden kann. Eine Analyse der aktuellen Praxis der Umweltprüfung zeigt im Hinblick auf die Bearbeitung des Schutzgutes Fläche im Ganzen erhebliche Defizite, in einzelnen Fällen aber auch innovative, über das Thema des quantitativen Flächenverbrauchs hinausgehende Ansätze eines qualitativen Freiraumschutzes auf. Bisher werden die Auswirkungen auf das Umweltschutzgut Fläche aufgrund fachlicher Unsicherheiten wie auch fehlender Bewertungsmaßstäbe nur selten einer fundierten Bewertung unterzogen. Verbindliche Flächenkontingente und Dichtewerte einerseits sowie planerische Festlegungen zu einer stärker multifunktional begründeten Freiraumsicherung und -entwicklung andererseits werden deshalb als Umweltziele für die Umweltprüfung mehr als bisher benötigt.

Keywords: Flächenverbrauch, Raumplanung, Umweltprüfung, Freiraumschutz, Planung

2 FLÄCHENVERBRAUCH UND FREIRAUMVERLUST ALS PERSISTENTE PROBLEME DER RAUM- UND UMWELTENTWICKLUNG

Siedlungs- und Verkehrsflächen in Deutschland, in Österreich wie auch darüber hinaus in ganz Europa haben sich in den letzten Jahrzehnten zu Lasten ökologisch wertvoller Freiräume und nicht zuletzt auch von landwirtschaftlich genutzten Flächen kontinuierlich ausgedehnt (Destatis 2023; EEA 2023; ÖROK 2023). Das Erfordernis eines Gegensteuerns gegenüber diesem sog. „Flächenverbrauch“ war offensichtlich, eine um den Faktor vier verbesserte Flächeneffizienz erschien erstrebenswert und zumindest längerfristig machbar. In Deutschland wurde mit der 2002 erstmals herausgegebenen Deutschen Nachhaltigkeitsstrategie der Bundesregierung (DNS) das sogenannte 30-ha-Flächensparziel, bezogen auf das Jahr 2020, etabliert (BReg 2002, S. 99 f.).

In den letzten 20 Jahren ist zwar die Flächenneuinanspruchnahme für Siedlungs- und Verkehrszwecke, also der Flächenverbrauch, in Deutschland kontinuierlich zurückgegangen, jedoch mit Werten zwischen 50 und 60 ha pro Tag erheblich über der definierten Zielmarke geblieben und zuletzt sogar wieder leicht angestiegen (Destatis 2023). Mit der Aktualisierung der Nachhaltigkeitsstrategie der Bundesregierung Ende 2016 wurde das Flächensparziel um 10 Jahre „gestreckt“ und als „30 ha pro Tag minus X“ für das Zieljahr 2030 proklamiert (BReg DE 2017). Die „Weiterentwicklung 2021“ der DNS bekräftig dieses fortgeschriebene „30 ha-Ziel“ und ergänzt: „Bis zum Jahr 2050 wird eine Flächenkreislaufwirtschaft angestrebt. Das heißt, es sollen netto keine weiteren Flächen für Siedlungs- und Verkehrszwecke beansprucht werden“ (BReg DE 2021, S. 269).

Auch in Österreich haben sich Bund, Länder, Städte und Gemeinden im Rahmen der Österreichischen Raumordnungskonferenz auf das Ziel verständigt, „die Zunahme der Flächeninanspruchnahme durch

Siedlungs- und Verkehrsflächen und das Ausmaß neu versiegelter Flächen bis 2030 substanziell zu verringern“ (ÖROK 2023, S. 6).

Die Europäische Union (EU) hat sich der Problematik des Flächenverbrauchs ebenfalls in vielfältiger Weise angenommen und mit ihrem „Fachplan für ein ressourcenschonendes Europa“ (EU KOM 2011) „Land und Böden“ als zu schonende Ressourcen herausgestellt. Landverbrauch und Land- bzw. Bodenversiegelung sollen weiter reduziert werden; bis 2050 soll netto kein Land mehr verbraucht werden (ebd., S. 18). Neuste Montoringergebnisse der Europäischen Umweltagentur (European Environment Agency – EEA) zeigen, dass die Mitgliedstaaten der EU in Sachen Netto-Null-Flächenverbrauch in den letzten Jahren eher nicht auf der Spur sind („likely off track“) (EEA 2025, S. 82-83).

Flächenverbrauch im Kontext der DNS bezeichnet die Umnutzung von freien, bisher unbesiedelten Flächen in Siedlungs- und Verkehrsflächen. Er wird über die jährliche Zunahme der statistisch erfassten Siedlungs- und Verkehrsflächen berechnet. Da diese in beachtlichem Umfang auch Grün- und Freiflächen umfassen, ist der Flächenverbrauch nicht mit Bodenversiegelung gleichzusetzen (Bay LfU 2019, S. 59). In Österreich sind beim Flächenmonitoring darüber hinaus auch Ver- und Entsorgungsflächen, die nicht zu den Siedlungsflächen zählen, miterfasst (ÖROK 2023, S. 77).

Die Fläche ist eine knappe, grundsätzlich nicht vermehrbare natürliche Ressource. Sie hat damit im Kontext der Ressourcenschutzpolitik eine im wörtlichen und übertragenen Sinne „tragende“ Bedeutung: Denn die Fläche übernimmt eine „Trägerfunktion“ nicht nur für die Siedlungs- und Infrastruktur, sondern auch für die natürlichen Ressourcen im Freiraum. Auf unbesiedelten, insbesondere unversiegelten Flächen außerhalb der Siedlungsbereiche wie auch in urbanen Freiräumen innerhalb der Siedlungsbereiche entfalten sich ihre ökologischen Funktionen und freiraumbezogenen Nutzungen. Die Raumplanung ist seit Langem der Umweltvorsorge und insbesondere dem Ressourcenschutz verpflichtet.

Abb. 1: Fläche im Kontext aktueller flächenrelevanter Umweltpolitiken (Eigene Darstellung)

Wie Abbildung 1 veranschaulicht, nimmt die Fläche als Träger von Flächen- bzw. Freiraumfunktionen und -nutzungen eine zentrale Rolle innerhalb aktueller Umweltpolitiken ein. Im breiteren Kontext flächenrelevanter Umweltpolitiken ist die Reduzierung von Flächenverbrauch und Freiraumverlust (im Folgenden auch als Flächen- und Freiraumschutz bezeichnet) nicht allein zur Umsetzung des quantitative definierten 30-ha-Flächensparzieles der DNS zu verstehen, sondern wesentlich umfassender im Kontext der immer vielfältiger werdenden umweltpolitischen Ziele, welche Flächen- und Freiraumqualitäten adressieren:

- Energiewende und Klimaschutz (insbes. energieeffiziente Siedlungsstrukturen, Flächeneffizienz bei Erzeugung, Speicherung und Transport erneuerbarer Energien),
- Anpassung an die Folgen des Klimawandels (insbes. Flächenvorsorge und -steuerung zur Wasserretention in der Fläche und zum Schutz vulnerabler Siedlungs- und Infrastrukturen vor Hochwasser, Sturzfluten und Massenbewegungen, aber auch Flächenvorsorge für klimaökologisch und lufthygienisch bedeutsame Frei- und Ausgleichsflächen),
- Urbaner Umweltschutz (insbes. durch kompakte und gemischt genutzte Siedlungsstrukturen mit attraktiven Wohnumfeldern und grüner Infrastruktur, Förderung einer „doppelten" bzw. „dreifachen" Innenentwicklung),
- Nachhaltige Mobilitätsentwicklung (insbes. durch Ansätze „Stadt/Region der kurzen Wege" bzw. „15 Minuten-Stadt" und integrative, den Verkehrsaufwand reduzierende und Flächen sparende Mobilitätskonzepte; im urbanen Raum als dritte Komponente einer „dreifachen Innenentwicklung"),
- Erhalt und Entwicklung der Biodiversität (insbes. Flächenvorsorge für Schutz, Pflege, Entwicklung und Wiederherstellung von Natur und Landschaft, Kompensationsflächenmanagement).

Bei alledem sind die Wechselbeziehungen zwischen den verschiedenen Raumstrukturen und Flächennutzungen, insbesondere die vielfach thematisierten Flächennutzungskonkurrenzen, als Hintergrund bzw. Auslöser vielfältiger direkter und indirekter Flächeninanspruchnahmen zu berücksichtigen.

3 FLÄCHEN SPAREN UND FREIRAUM SCHÜTZEN MIT DEM INSTRUMENT DER UMWELTPRÜFUNG

Ein wichtiges Instrument einer ressourcenschonenden, vorsorgenden Umweltpolitik ist seit den 80-er Jahren die Umweltprüfung (Töpfer 1989). Mit ihr werden mögliche Umweltauswirkungen von Planungen und Vorhaben einschließlich der Inanspruchnahme der natürlichen Ressourcen vor ihrer Verwirklichung ermittelt, beschrieben, bewertet und im Zuge ihrer Annahme bzw. Genehmigung gemäß bestehender Umweltziele und -standards berücksichtigt (grundlegend Bunge 2008).

Nach ersten, rechtlich unverbindlichen Anfängen in Deutschland und anderen Ländern wurde die Umweltverträglichkeitsprüfung für Projekte (UVP) in 1985 (UVP-RL vom 27.06.1985) und die Strategische Umweltprüfung für Programme und Pläne (SUP) in 2001 (SUP-RL vom 27.06.2001) europaweit eingeführt. Mit zunehmendem Flächenverbrauch und Freiraumverlust in dem Territorium der EU war es nicht überraschend, dass die EU-Kommission auch die Umweltprüfung als Instrument der Umweltvorsorge dazu einsetzen würde, den weiteren Flächenverbrauch und Freiraumverlust einzudämmen. Entsprechend wurde mit der sog. UVP-Änderungsrichtlinie von 2014 (UVP-Änd-RL vom 16.04.2014) die Fläche in den Schutzgüterkatalog der Umweltprüfung aufgenommen.

Die Umsetzung der UVP-Änderungsrichtlinie erfolgte in den Mitgliedstaaten der EU auch im Bezug auf das hinzugekommene Schutzgut Fläche vor dem Hintergrund der jeweiligen nationalen Besonderheiten des Planungs-, Zulassungs- und Umweltrechts unterschiedlich. Dieser Beitrag fokussiert im Folgenden auf die Umsetzung in Deutschland, die sich in rechtlicher Hinsicht drei Jahre später durch Gesetzesnovellierungen im UVP-Recht wie auch im Raumordnungs- und Bauplanungsrecht (BauÄndG vom 4.05.2017; ROÄndG vom 23.05.2017; UVP-ModG vom 20.07.2017) manifestierte.

In der Umweltprüfung, die mit der europaweiten Einführung der Strategischen Umweltprüfung (SUP) nicht zuletzt auch für Raumordnungs- und Bauleitpläne durchzuführen ist (Jacoby 2000), sind nun also neben den bisher bereits offensichtlich flächenrelevanten Schutzgütern auch die Umweltauswirkungen auf das Schutzgut Fläche zu prüfen (siehe Abbildung 2). Der Freiraum ist zwar nicht als eigenständiges Schutzgut der Umweltprüfung benannt, nimmt aber selbstverständlich im Umweltbezug als der Raum mit den ökologisch besonders wertvollen und schützenswerten Flächen eine hervorgehobene Bedeutung bei der Durchführung von Umweltprüfungen ein.

Die Einführung des neuen Schutzgutes Fläche wirft zahlreiche rechtliche und vor allem fachlich-methodische Fragen für die Umsetzung in der Praxis der Umweltprüfung auf. Dies hat nicht zuletzt mit der Begrifflichkeit „Fläche" zu tun, die in der bisherigen Praxis der Umweltprüfung als einer der wichtigsten Indikatoren mit unterschiedlichen Begriffsderivaten (Flächeninanspruchnahme, Flächenverlust u. a.) bei der Ermittlung der Umweltauswirkungen für den Großteil der Schutzgüter verwendet wurde. Auch enthalten

weder die UVP-Änderungsrichtlinie von 2014 noch die diesbezüglichen rechtlichen Anpassungen des deutschen Planungs- und Umweltrechts in 2017 klare und aussagekräftige Hinweise zum Bedeutungsgehalt des Schutzgutes Fläche und seiner Bearbeitung bei der Erstellung von UVP- bzw. Umweltberichten.

Abb. 2: Schutzgüter im Sinne des deutschen UVP-Gesetzes (Stand 2023) (eigene Darstellung).

Neben der Hinzunahme von „Fläche“ in die Auflistung der maßgeblichen Schutzgüter (siehe insbesondere § 2 Abs. 1 Nr. 3 UVPG) wird im UVP-Gesetz nur an einer Stelle der Bedeutungsgehalt des Schutzgutes Fläche angesprochen, wenn auch nach Auffassung der Verfasser sehr verkürzt. So ist in der Anlage 4 UVPG in einer Tabelle die „mögliche Art der Betroffenheit“ ausgewählter Schutzgüter beschrieben. Zum Schutzgut Fläche wird dabei als mögliche Art der Betroffenheit lediglich das Schlagwort „Flächenverbrauch“ genannt.

Nun ist der Aussagegehalt der genannten Tabelle nicht überzubewerten, da zum einen die Auflistung keinen Anspruch auf Vollständigkeit hat und zum anderen bei weiteren Schutzgütern die Beschreibung der möglichen Art der Betroffenheit ebenfalls begrenzt und wenig aussagekräftig ist. Dennoch hat die eingeschränkte Sicht auf den Flächenverbrauch im Kontext der DNS, die sich auch in den Begründungstexten der Umsetzung der EU-Änderungsrichtlinie in das deutsche Recht zeigt, dazu geführt, dass die rechtliche Auslegung und praktisch Handhabung des Schutzgutes Fläche in der Umweltprüfung bisher vor allem und häufig nur auf den Wirkungsbereich Flächenverbrauch bezogen wird. So heißt es in einem Kommentar zum UVPG: „Eine eigene Legaldefinition zu der Frage, was genau unter dem Begriff „Fläche“ zu verstehen sein soll, enthält das UVPG nicht“ (Hamacher 2018, Rn. 17). Und weiter: „Sein Bedeutungsgehalt erschließt sich jedoch ohne Weiteres aus seinem natürlichen Wortsinn und vor dem Hintergrund der aktuell geführten umweltpolitischen Diskussionen“ (ebd.). Das Schutzgut Fläche erweise sich „gewissermaßen als „spin off“ aus dem bereits zuvor in den Schutzgutkatalog aufgenommenen Schutzgut „Boden“ […]“ und fokussiere sich auf die Problematik des „Flächenverbrauchs“ (ebd.).

Wie allerdings „Flächenverbrauch“ rechtlich auszulegen sei und in der Praxis der Umweltprüfung zu handhaben wäre, bleibt an dieser Stelle offen. Insbesondere muss auch hinterfragt werden, ob das von der EU über die UVP-Änderungsrichtlinie von 2014 neu eingeführte Schutzgut Fläche vom Sinngehalt her mit der Fläche im Kontext des Flächensparziels der DNS vollständig übereinstimmt. Schließlich bezieht sich die EU-Richtlinie mit dem Schutzgut Fläche nicht auf ein einzelnes nationales Flächensparziel, sondern vor allem auf die europäische Perspektive des Flächenressourcenschutzes. In den bisherigen Ausgaben der DNS spielt zudem das Instrument der Umweltprüfung und ihr neues Schutzgut Fläche keine Rolle. Eine Verknüpfung von Flächensparziel der DNS und Schutzgut Fläche der Umweltprüfung fehlt.

Zum Schutzgut Fläche in der Umweltprüfung sind bisher neben der Aufnahme in Gesetzeskommentaren nur vereinzelt wissenschaftliche Untersuchungen durchgeführt worden (Kuhlmann; Lintzmeyer und Wilts 2014;

Alsleben 2015; Repp und Dickhaut 2017; Karrenstein 2019; Jacoby und Binder 2023). Arbeitshilfen oder Leitfäden für die Bearbeitung des Schutzgutes Fläche liegen in Deutschland bisher nicht vor. In Österreich hat das Bundesministerium für Klimaschutz, Umwelt, Energie, Mobilität, Innovation und Technologie (2023) einen „Leitfaden für die Schutzgüter Fläche und Boden in der Einzelfallprüfung und in der Umweltverträglichkeitsprüfung“ herausgegeben, der nach Auffassung der Autoren noch zu eng an dem rein quantitativen Flächensparziel orientiert ist. Was die Praxis der Umweltprüfung und die hierbei verfolgten Ansätze zur Behandlung des Schutzgutes Fläche angeht, fehlt es bisher an einer umfassenden Analyse. Vor diesem Hintergrund hat das deutsche Umweltbundesamt (UBA) das mit Bundesmitteln finanzierte Forschungsvorhaben „Fläche als Schutzgut des Gesetzes über die Umweltverträglichkeitsprüfung – Erarbeitung von Praxisempfehlungen“ beauftragt. Die Forschungsergebnisse sollen 2025 publiziert werden.

Ergeben nun die UVP-Änderungsrichtlinie von 2014 und das entsprechend novellierte deutsche UVPG keine näheren Hinweise, was unter dem Schutzgut Fläche im Einzelnen zu verstehen ist und welche möglichen Umweltauswirkungen diesbezüglich zu ermitteln, zu beschreiben, zu bewerten und bei Planungsentscheidungen und Vorhabengenehmigungen zu berücksichtigen sind, so kann ein Blick in die Entstehungsgeschichte und Begründung der UVP-Änderungsrichtlinie der EU weiterhelfen. Die den Artikeln der EU-Richtlinie vorangestellten Erwägungsgründe geben hier bereits einen etwas besseren Einblick in die mögliche inhaltliche Bedeutung des Schutzgutes Fläche. So wird im neunten Absatz dieser Erwägungsgründe auf die Mitteilung der Kommission vom 22. September 2006 „Thematische Strategie für den Bodenschutz“ und den „Fahrplan für ein ressourcenschonendes Europa“ verwiesen, mit denen gegen die „nichtnachhaltige fortschreitende Ausweitung von Siedlungsflächen (Flächenverbrauch)“ vorgegangen werden soll. Darüber hinaus wird auf die Abschlusserklärung der UN-Konferenz über nachhaltige Entwicklung im Juni 2012 in Rio de Janeiro abgestellt. Damit zeigt sich einerseits die fachliche Nähe des Schutzgutes Fläche zur natürlichen Ressource Boden, andererseits ein klarer Zusammenhang mit dem internationalen Nachhaltigkeitsprinzip. Und der in der Richtlinie angesprochene „Flächenverbrauch“ wird bei diesem Erwägungsgrund als „nichtnachhaltige fortschreitende Ausweitung von Siedlungsflächen“ näher beschrieben, was allerdings nicht als normative Eingrenzung des Schutzgutes Fläche auf das Siedlungsflächenwachstum, sondern lediglich als eine beispielhafte bzw. bedeutsame Form des Flächenverbrauchs zu interpretieren ist („insbesondere“).

In der Begründung des Gesetzes zur Modernisierung des Rechts der Umweltverträglichkeitsprüfung vom 13.03.2017 (BTag 2017) finden sich weitergehende Hinweise auf den Bedeutungsgehalt des Schutzgutes Fläche. Zunächst heißt es: „Als eigenständiges Schutzgut wurde auch „Fläche“ aufgenommen“ (ebd., S. 57). Damit wurde Diskussionsbeiträgen, welche Fläche nicht als ein eigenständiges Schutzgut betrachten wollten, entgegengetreten.

Unter der Zwischenüberschrift „Nachhaltigkeitsaspekte“ wird in der Begründung ausgeführt, dass der Gesetzentwurf die Verwirklichung der Ziele der Deutschen Nachhaltigkeitsstrategie 2016 fördere und die positive Wirkung der UVP für die Förderung einer nachhaltigen Entwicklung weiter verbessere (ebd. 2017, S. 62). Auch mit Blick auf die in der Nachhaltigkeitsstrategie definierten Indikatoren zu den Nachhaltigkeitszielen, die sich in ihrer Systematik an den Sustainable Development Goals der Vereinten Nationen orientieren, sei der Gesetzentwurf für die Zielerreichung förderlich, unter anderem auch in Bezug auf den „Anstieg der Siedlungs- und Verkehrsfläche (Flächenverbrauch)“ (ebd.).

Und weiter heißt es in diesem Abschnitt der Gesetzesbegründung: „Dem Aspekt der nachhaltigen Flächeninanspruchnahme (Indikator Nummer 11.1.a -11.1.c) wird in dem Entwurf dadurch in besonderer Weise Rechnung getragen, dass das Schutzgut Fläche ausdrücklich in den Katalog der Schutzgüter des § 2 Absatz 1 aufgenommen wird. Damit wird deutlich, dass auch quantitative Aspekte des Flächenverbrauchs in der UVP zu betrachten sind. Der besonderen Bedeutung von unbebauten, unzersiedelten und unzerschnittenen Freiflächen für die ökologische Dimension einer nachhaltigen Entwicklung wird auf diese Weise Rechnung getragen“ (ebd., S. 63). Als ein Beispiel für eine umwelterhebliche Inanspruchnahme der Ressource Fläche durch ein Vorhaben wird an anderer Stelle der Gesetzesbegründung „eine extensive Flächeninanspruchnahme“ (ebd., S. 112) genannt, welches die Art der Inanspruchnahme (baulich oder anderweitig) offen lässt.

Hiermit wird zunächst klargestellt, dass Fläche nicht nur (wie bisher) ein Indikator für andere Schutzgüter wie insbesondere Boden, Wasser; Klima, Tier- und Pflanzenwelt darstellt (Verlust von diesbezüglich

schutzwürdigen Flächen), sondern als quantitatives Merkmal im Hinblick auf eine nachhaltige Entwicklung insbesondere von Siedlungs- und Verkehrsflächen eine eigenständige Bedeutung erhält. Dass es allerdings nicht nur um den quantitativen Flächenverbrauch gehen kann, zeigt allein die Vorgabe in Anlage 3 Nr. 2.2 UVPG, wonach bei der Beurteilung der Qualität und Schutzwürdigkeit eines von einem Vorhaben betroffenen Gebietes „Qualitätskriterien“ wie „Reichtum, Verfügbarkeit, Qualität und Regenerationsfähigkeit der natürlichen Ressourcen“ heranzuziehen sind und dabei auch die Ressource Fläche explizit genannt wird.

Betrachtet man das 30-ha-Flächensparziel der DNS genauer, so wird unter der weit gefassten Zielsetzung des Sustainable Development Goals (SDG) Nr. 11 „Städte und Siedlungen inklusiv, sicher, widerstandsfähig und nachhaltig gestalten“ als Indikator (Nr. 11.1.a) die „Flächeninanspruchnahme“ mit drei verschiedenen Teil-Indikatoren und Zielgrößen definiert:

- Anstieg der Siedlungs- und Verkehrsfläche in ha pro Tag – Zielgröße: Senkung auf durchschnittlich unter 30 ha pro Tag bis 2030 (also das weit bekannte „30-ha-Flächensparziel“),
- Freiraumverlust – Zielgröße: Verringerung des einwohnerbezogenen Freiflächenverlustes,
- Siedlungsdichte – Zielgröße: keine Verringerung der Siedlungsdichte.

Die Indikatoren Freiraumverlust und Siedlungsdichte waren in der ersten Fassung der DNS noch nicht enthalten, jedoch waren im Kapitel 3 unter dem Titel „Flächeninanspruchnahme – Freiräume erhalten“ neben dem konkreten, quantitativen 30-ha-Ziel auch die Erfordernisse des Freiraumschutzes aufgrund seiner wertvollen Funktionen und Nutzungen herausgestellt (BReg 2002, S. 99 ff.). Die Forderung nach kompakten Siedlungsstrukturen und damit einer flächensparenden Siedlungsdichte weist bereits auf Nachhaltigkeitsprinzipien der Flächeneffizienz und -suffizienz hin.

Trotz dieser verschiedenen begrifflichen und fachlichen Annäherungen an das Schutzgut Fläche sollte mit einem grundlegenden Verständnis für den erforderlichen Flächenschutz deutlich sein, worum es bei dem Schutzgut Fläche im Wesentlichen geht, das heißt, welche Umweltqualitäten überhaupt unter dem Stichwort „Fläche“ zu schützen sind: unbebaute bzw. unbesiedelte, unzersiedelte und unzerschnittene Freiräume/Freiflächen (als nicht anthropogen geprägte, naturnahe Freiräume und -flächen) als knappe natürliche Ressourcen, die insbesondere für die ökologische Dimension einer nachhaltigen Entwicklung von besonderer Bedeutung sind. In der bundesdeutschen Raumordnung ist in diesem Kontext die Flächenkategorie „großräumig zusammenhängender Freiraum“ und insbesondere die entsprechende Ausweisung von „Regionalen Grünzügen“ bekannt, den es aufgrund seiner multifunktionalen Nutzbarkeit und vor allem ökologischen Qualitäten vor Besiedlung zu schützen gilt. Die Sicherung und Entwicklung großräumig regionaler, stadtregionaler und nicht zuletzt urbaner Freiräume gewinnt gerade auch vor dem Hintergrund des Klimawandels und seiner Folgen immer mehr an Bedeutung (Domhardt et al. 2025; Jacoby et al. 2025).

Auf der Ebene der EU wurde bisher keine Arbeitshilfe oder Erläuterung zum Schutzgut Fläche veröffentlicht. Mit den neueren Leitfäden der Europäischen Kommission für das Screening und Scoping bei der UVP werden allerdings auch Fragestellungen in Bezug auf das Schutzgut Fläche formuliert, welche – über das in Deutschland fokussierte Problemfeld „Flächenverbrauch“ hinausgehend – weitere Betrachtungsperspektiven aufzeigen (EU COM 2017b, 2017c):

- Werden durch den Bau, den Betrieb oder den Rückbau eines Projektes physische Veränderungen der Flächennutzungen ausgelöst?
- Werden durch den Bau und den Betrieb eines Projektes natürliche Ressourcen wie die Fläche, insbesondere Fläche als nichterneuerbare begrenzte (knappe) Ressource, in Anspruch genommen?
- Verursacht ein Projekt einen Verlust an unbesiedeltem Freiraum (Freiraumverlust)?
- Werden durch ein Projekt vorhandene oder geplante Flächennutzungen (Wohnflächen, Grünflächen etc.) unmittelbar (durch Umnutzung der Fläche) oder mittelbar (randlich/im räumlichen Umfeld) beeinträchtigt?
- Werden durch ein Projekt besonders empfindliche Flächennutzungen (z.B. Krankenhäuser, Schulen etc.) beeinträchtigt?

Ein Teil dieser Fragestellungen lässt sich sicherlich schwerpunktmäßig anderen Schutzgütern wie Menschliche Gesundheit, Boden, Wasser, Tier- und Pflanzenwelt etc. zuordnen, ein anderer Teil, nämlich Fläche als knappe Ressource und als unbesiedelter Freiraum, wäre demgegenüber unter dem Schutzgut Fläche vertiefend zu betrachten. Fläche als eine (natürliche) Ressource soll demnach nicht nur geschützt werden im Sinne einer Nichtinanspruchnahme der Ressource, sondern soll in ihrer Verfügbarkeit für die Aktivitäten bzw. Nutzungen des Menschen möglichst erhalten bleiben, in dem neue Projekte so weit wie möglich nachhaltig und flächeneffizient geplant und realisiert werden (EU Com 2017a, S. 46). Der Nachhaltigkeitsindikator Siedlungsdichte ist von wesentlicher Bedeutung, da er sowohl direkte als auch indirekte Flächeninanspruchnahmen adressiert und neben der Effizienz der Flächennutzung auch die Suffizienz inkludiert.

4 FACHLICHE KONKRETISIERUNG DES SCHUTZGUTES FLÄCHE

Fasst man UVP-Änderungsrichtlinie der EU und das in Deutschland entsprechend novellierte UVPG einschließlich der Begründungstexte sowie aktuelle Dokumente der EU-Kommission und Ansätze aus der Fachdiskussion und -literatur zusammen, so lassen sich erste inhaltliche Konturen des Schutzgutes Fläche erkennen. Drei umweltbezogene Zieldimensionen des Schutzgutes Fläche wurden herausgearbeitet: das „quantitative Flächensparen“ (Reduktion des Flächenverbrauchs und damit des Freiraumverlusts), der „qualitative Freiraumschutz“ und eine „nachhaltige Flächenressourcennutzung“:

Abb. 3: Inhaltliche Konturen des Schutzgutes Fläche in der Umweltprüfung in Form von drei Zieldimensionen (Eigene Darstellung).

- „Quantitatives Flächensparen“: Klarer, aber nicht ausschließlicher Bezug zum Nachhaltigkeitsziel „Reduzierung der Flächenneuinanspruchnahme für Siedlungs- und Verkehrszwecke auf 30 ha minus X bis 2030“. Dieser sog. „Flächenverbrauch“ wird insbesondere in Anlage 4 Nr. 4 lit. b UVPG explizit angesprochen.
- „Qualitativer Freiraumschutz“: Deutlicher Bezug zum korrespondierenden Nachhaltigkeitsziel, unbebaute bzw. unbesiedelte, unzersiedelte und unzerschnittene Freiflächen bzw. -räume mit hohen funktionalen Qualitäten und Leistungen, die für die ökologische Dimension einer nachhaltigen Entwicklung von besonderer Bedeutung sind, von Bebauung bzw. Besiedlung freizuhalten.
- „Nachhaltige Flächenressourcennutzung“: Möglicher weitergehender Bezug zum allgemeinen umweltpolitischen Ziel des Ressourcenschutzes, nachdem die Fläche als begrenzte natürliche Ressource für alle Arten von Flächennutzungen sparsam und schonend zu nutzen bzw. zu

bewirtschaften und nach den Prinzipien der nachhaltigen Entwicklung (Effizienz, Konsistenz, Suffizienz) auch als dauerhaft und umweltverträglich nutzbar zu erhalten ist.

Mit dieser Konturierung wird auch erkennbar, dass das Schutzgut Fläche nicht von vorneherein auf das Thema „Flächenverbrauch“ im Sinne von Flächenneuinanspruchnahme für Siedlungs- und Verkehrszwecke reduziert werden kann. Sowohl UVP-Änderungsrichtlinie als auch UVPG weisen einen umfassenderen Begründungszusammenhang (Ressourcenschutz und Freiraumschutz im Sinne einer ökologisch orientierten nachhaltigen Entwicklung) auf. Schließlich verlangt das UVPG in Anlage 4 Nr. 4 lit a) auch eine (umfassende) Beschreibung nicht nur der direkten, sondern auch der „etwaigen indirekten, sekundären, kumulativen, grenzüberschreitenden, kurzfristigen, mittelfristigen und langfristigen, ständigen und vorübergehenden, positiven und negativen Auswirkungen des Vorhabens“. Auch temporäre Flächennutzungen, die Wiederherstellung des ursprünglichen Zustands temporär genutzter Flächen oder ihre mögliche andere Nachnutzung sind in der UVP zu behandeln (EU COM 2017a, S. 91).

5 ZUR PRAXIS DER UMWELTPRÜFUNG IN BEZUG AUF DAS SCHUTZGUT FLÄCHE

In der Planungs- und Gutachterpraxis herrscht bisher eine weit verbreitete Unsicherheit bezüglich der fachlichen Bearbeitung des Schutzguts Fläche vor allem aufgrund einer fehlenden, allgemein anerkannten Schutzgutdefinition, fehlender Arbeitshilfen/Leitfäden und Schwierigkeiten in der Abgrenzung von anderen bereits zuvor zu berücksichtigenden Schutzgütern (insbesondere Boden und Landschaft). Die bisher vorherrschende, weiter oben beschriebene eingeschränkte Auslegung des Bedeutungsgehalts des Schutzgutes Fläche (Prüfung des „Flächenverbrauchs“) führt in Verbindung mit weitgehend fehlenden fachgesetzlichen Standards zum Schutzgut Fläche im engeren Sinne dazu, dass in der Praxis seit 2017 zunächst vielfach das Schutzgut Fläche bei der Bearbeitung von UVP- bzw. Umweltberichten entweder ganz „vergessen“ wurde, nur randlich beim Schutzgut Boden mit erwähnt wurde und häufig auch nicht durchgängig zusammen mit den anderen Schutzgüter bei den verschieden Kapiteln eines Umweltberichts (Umweltzustand, Status-Quo-Prognose, Wirkungsuntersuchung, Bewertung) behandelt wurde.

Im Rahmen des weiter oben erwähnten UBA-Forschungsvorhabens zum Schutzgut Fläche wurden in den letzten Jahren unter anderem anhand von über 100 Fallbeispielen aus Deutschland, die mindestens das Schutzgut Fläche explizit erwähnt hatten, die Herangehensweisen in der Praxis in Bezug auf die Bearbeitung dieses Schutzgutes im Rahmen von Umweltprüfungen genauer untersucht.

Obwohl die Fläche als eigenständiges Schutzgut im UVPG definiert ist, wurde in ca. 30 % der untersuchten Fälle (mit Bearbeitung ab 2017) das Schutzgut Fläche komplett in das Schutzgut Boden eingebettet oder zusammen mit diesem Schutzgut (Abschnitt „Boden und Fläche“) geprüft. Diese Zusammenlegung ist zwar rechtlich nicht zu beanstanden, zeigt aber den geringen Stellenwert des Schutzgutes Fläche, speziell in diesen Fällen, in denen unter der Überschrift „Boden und Fläche“ im Wesentlichen nur die Bodenfunktionen nach Bundesbodenschutzgesetz behandelt werden. Auch eine Verlagerung in nachfolgende Planungsverfahren (Abschichtung) konnte vereinzelt festgestellt werden.

Bei den untersuchten Fallbeispielen wurde die quantitative Zieldimension des Schutzgutes Fläche („Flächenverbrauch“ für Siedlungs- und Verkehrszwecke) deutlich am häufigsten bearbeitet und auch teilweise mit methodischen Ansätzen bewertet. Für die qualitative Zieldimension (Auswirkungen auf ökologische Qualität und Leitung von Freiräumen/Freiflächen) wurden bei den Fallstudien nur vereinzelt Ansätze, aber keine tatsächliche Bewertung der Auswirkungen auf das Schutzgut Fläche gefunden. Die Zieldimension einer nachhaltigen Flächenressourcennutzung klang zwar etwas häufiger an, war jedoch ebenfalls nicht Gegenstand einer methodisch fundierten Bewertung.

Neben dem weitbekannten „30-ha-Flächensparziel“ der DNS, welches als Umweltqualitätsziel für die Umweltprüfung relevant, aber bisher über einen einfachen Abwägungsbelang hinaus nur sehr begrenzt zu planungs- oder gar zulassungsrelevanten Umweltstandards konkretisiert werden konnte, und den überwiegend qualitativen Zielen, Grundsätzen und Festlegungen der Raumordnung und Bauleitplanung in Bezug auf kompakte Siedlungsstrukturen und den Schutz wertvoller, unbesiedelter Freiräume gibt es bisher kaum Normen, die auf das Flächensparen bzw. eine Flächennutzungseffizienz abzielen.

Je weniger Normen bzw. Umweltstandards für einzelne Schutzgüter der Umweltprüfung herangezogen werden können, desto wichtiger wird die Alternativenprüfung, die zwar bei der UVP für Projekte kein zwingender, bei der SUP für Programme und Pläne jedoch ein obligatorischer Baustein der Prüfung ist und

eine wesentliche Optimierungsfunktion im Hinblick auf die Berücksichtigung des Schutzgutes Fläche übernehmen kann. Auch hier zeigt die bisherige Praxis der Umweltprüfung, dass das Potenzial der Alternativenprüfung für die Steigerung der Flächeneffizienz als wesentlicher Aspekt einer nachhaltigen Flächennutzung nur selten genutzt wird.

Auffällig bei der Untersuchung der Bewertungspraxis war auch die uneinheitliche, nicht-standardisierte Verwendung flächenbezogener Begriffe. Hier sind als Beispiel vor allem „Flächen(neu)inanspruchnahme", „Versiegelung", „Flächenverbrauch" oder „Flächenverlust" zu nennen. Oft wurden viele unterschiedliche Bezeichnungen benutzt, um das gleiche Thema zu behandeln. Zwischen dem Schutzgut Fläche und der Fläche als Indikator für die Beschreibung und Bewertung von Betroffenheiten der verschiedenen (anderen) Schutzgüter wird bisher kaum begrifflich klar und konsistent unterschieden. Dadurch wird die Nachvollziehbarkeit bei der Betrachtung des Schutzgutes Fläche und so letztlich auch dessen Berücksichtigung im Sinne einer wirksamen Umweltvorsorge bei der planerischen bzw. behördlichen Entscheidung erschwert. Eine einheitliche Nomenklatur wäre für Büros und Behörden sehr hilfreich.

Obwohl die Raumordnungs- und Bauleitplanung seit Langem flächenbezogenen Zielen und Grundsätzen des Umweltschutzes verpflichtet ist (Flächenspargrundsatz, Bodenschutzklausel, Schutz natürlicher Ressourcen etc.), spielt auch in der Umweltprüfung von Raumordnungs- und Bauleitplänen das Schutzgut Fläche im Vergleich zu den anderen Schutzgütern meist nur eine untergeordnete Rolle. Selbst vorhandene flächenbezogene Umweltziele für die Ausweisung neuer Siedlungsflächen wie Flächenkontingente oder Dichtewerte, ob als verbindlich zu beachtende Ziele oder nur abwägungsrelevante Grundsätze der Raumordnung, werden in der Regel nicht adäquat bei der Bewertung der Umweltauswirkungen im Rahmen der Umweltprüfung berücksichtigt.

Nachfolgend soll an einem Beispiel aus der Praxis der Umweltprüfung aufgezeigt werden, dass Ansätze über das rein quantitative Flächensparziel hinaus möglich sind. 2021 wurde erstmals ein Raumordnungsplan des Bundes für den länderübergreifenden Hochwasserschutz aufgestellt. Der hierzu erstellte Umweltbericht (Bosch & Partner GmbH 2020) enthält eine breiter angelegte Zusammenstellung der für die Betrachtung des Schutzguts Fläche maßgeblichen Umweltziele (siehe Abbildung 4).

Fläche	• Sicherung und Schutz der prägenden Vielfalt des Gesamtraumes und geeigneter Flächen vor allem im besiedelten und siedlungsnahen Bereich (§ 1 Absatz 4 Nr. 2 BNatSchG und § 2 Absatz 2 Nr. 2 ROG) • Großflächige, weitgehend unzerschnittene Landschaftsräume sind vor weiterer Zerschneidung zu bewahren (§ 1 Absatz 5 S. 1 BNatSchG) • Vermeidung von weiterer Zerschneidung der freien Landschaft und von Waldflächen sowie Flächeninanspruchnahmen im Freiraum (§ 2 Absatz 2 Nr. 2 S. 6 ROG) • Ausführung zulässiger Vorhaben in einer flächensparenden Weise (§ 1a Absatz 2 S. 1 2. Hs. BauGB, § 35 Absatz 5 BauGB) • Reduzierung der Zunahme der Siedlungs- und Verkehrsflächen in Deutschland von 70 ha/Tag auf 30 ha minus x /Tag bis 2030 (Nachhaltigkeitsstrategie der Bundesregierung Aktualisierung 2018; Die Bundesregierung 2018) • Netto-Null-Flächenverbrauchsziel der Europäischen Kommission (Europäische Kommission 2011) • nachhaltige Sicherung oder Wiederherstellung des Bodens in seiner Nutzungsfunktion als Fläche für Siedlung und Erholung (§ 2 Absatz 1 und 2 BBodSchG)

Abb. 4: Umweltziele zum Schutzgut Fläche im Umweltbericht zum länderübergreifenden Raumordnungsplan des Bundes für den Hochwasserschutz (Bosch & Partner GmbH 2020, S. 12).

Hervorzuheben ist bei dieser Zusammenstellung, dass zunächst die gesetzlichen Ziele bzw. Grundsätze (Abwägungsbelange) des Naturschutzrechts sowie des Raumordnungs- und Bauplanungsrechts genannt werden, die sich primär auf den Freiraum- und Landschaftsschutz beziehen und als qualitative Zielkriterien für die Bewertung von Umweltauswirkungen auf das Schutzgut Fläche herangezogen werden können.

Umweltauswirkungen möglich?	**Ja**	Nein	**Raumbezug?**	**Ja**	Nein
Umweltprüfung Stufe 2: Abschätzung der Auswirkungen auf die Schutzgüter					
Schutzgut	**Betroffenheit**	**Mögliche Auswirkungen**			
Me	↑	Bestehende bau-, anlage- und betriebsbedingte Auswirkungen in Bezug auf das Schutzgut Menschen bzw. menschliche Gesundheit werden durch den Rückbau der Einrichtungen tendenziell reduziert und neu hinzukommende Auswirkungen unwahrscheinlicher. Der hochwassergerechte Umbau senkt das Schadensrisiko und die dadurch hervorgerufenen Auswirkungen auf die Gesundheit.			
Ti, Pf, bV	↑	Bestehende bau-, anlage- und betriebsbedingte Auswirkungen in Bezug auf die Schutzgüter werden durch den Rückbau der Einrichtungen tendenziell reduziert und neu hinzukommende Auswirkungen unwahrscheinlicher.			
Fl	↑	Bestehende bau-, anlage- und betriebsbedingte Auswirkungen in Bezug auf das Schutzgut Fläche werden durch den Rückbau der Einrichtungen tendenziell reduziert und neu hinzukommende Auswirkungen unwahrscheinlicher.			

Abb. 5: Ausschnitt des Prüfbogens zur Abschätzung der Auswirkungen auf die Schutzgüter (Bosch & Partner GmbH 2020, S. 67).

Das quantitative Flächenschutzziel der DNS („30 ha-Ziel“) und das längerfristig angelegte Netto-Null-Flächenverbrauchsziel der Europäischen Kommission kommem hinzu. Ergänzend wird auch das Bodenschutzrecht im Kontext der Altlastenbeseitigung angesprochen. Diese Zusammenstellung weitet den Blick auf die vielfältige Ressource Fläche und unterstützt auf diese Weise eine umfassende, nicht nur quantitativ begründete Schutzgutbetrachtung und -bewertung. Abbildung 5 stellt aus diesem Umweltbericht ein Beispiel für die Abschätzung der Auswirkungen auf das Schutzgut Fläche dar. Für die Ebene der Bundesraumordnung erscheint eine rein verbal-argumentative Betrachtung angemessen.

6 SCHLUSSFOLGERUNGEN

Bei der Verfolgung des Nachhaltigkeitsziels „Reduzierung der Flächenneuinanspruchnahme für Siedlungs- und Verkehrszwecke“ (30 ha minus x bis 2030/Netto-Null bis 2050) geht es seit der Deutschen Nachhaltigkeitsstrategie von 2002 bis zur aktuellen Fassung von 2021 in der Zielperspektive darum, mit der Begrenzung des sog. „Flächenverbrauchs“ die Verluste an Freiräumen zu reduzieren, in dem die Innenentwicklung (mit Nachverdichtung etc.) Vorrang vor der Außenentwicklung erhält und damit Freiräume außerhalb der Siedlungsräume in quantitativer Dimension (ohne Betrachtung ihrer einzelnen Funktionen) stärker geschützt werden. Urbane Freiräume als Grün- und Freiflächen innerhalb der Siedlungsräume bleiben bei diesem quantitativen Flächensparziel außen vor.

Das mit der UVP-Änderungsrichtlinie der EU von 2014 in das Recht der Umweltprüfung hinzugenommene Schutzgut Fläche wird bisher vor allem im Hinblick auf diese quantitative Dimension des Flächenverbrauchs und Freiraumverlusts diskutiert bzw. in der Praxis der Umweltprüfung umgesetzt, obwohl die EU-Richtlinie von 2014 nicht auf die nationale Deutsche Nachhaltigkeitsstrategie abstellt und im deutschen UVP-Gesetz neben anderen Schutzgütern auch die Fläche als qualitatives Kriterium und natürliche Ressource beschrieben wird. Die Betroffenheit von Freiraumfunktionen und -qualitäten bzw. Flächenwertigkeiten ist deshalb beim Schutzgut Fläche hinsichtlich ihrer quantitativen und qualitativen Dimension außerhalb und innerhalb von Siedlungsräumen zu prüfen. Fläche ist dabei nicht zuletzt als Träger von sich räumlich überlagernden Freiraumfunktionen (Multifunktionalität) und als natürliche Ressource im Hinblick auf ihre Entwicklungsmöglichkeiten in Bezug auf die einschlägigen Nachhaltigkeitsprinzipien (Effizienz, Konsistenz, Suffizienz) zu betrachten.

In der Praxis der Umweltprüfung wird das Schutzgut Fläche einerseits als nicht vermehrbare Ressource und wegen seiner multifunktionalen Trägerfunktion für andere Umweltschutzgüter bzw. verschiedene Freiraumfunktionen und -nutzungen zunehmend auch als wichtiges, ja als ein zentrales Schutzgut verstanden. Andererseits ist die rechtliche Einführung des Schutzgutes Fläche in das deutsche Umwelt- und Planungsrecht in Umsetzung der UVP-Änderungsrichtlinie von 2014 sehr „zurückhaltend“ und ohne fachliche Differenzierung erfolgt, weshalb bisher auch in der Praxis nur selten eine differenzierte Ermittlung der Umweltauswirkungen auf das Schutzgut Fläche vorgenommen wird. Insbesondere wird aufgrund der fachlichen Unsicherheiten wie auch fehlender Bewertungsmaßstäbe nur selten eine fundierte Bewertung der Auswirkungen von Planungen und Projekten auf das Schutzgut Fläche durchgeführt, sodass die Bearbeitung des Schutzgutes Fläche in der Praxis der Umweltprüfung in der Regel keine erkennbare Wirkung auf die umweltbezogene Planungsoptimierung bzw. umweltfreundliche Genehmigungsentscheidung zeigt.

Bei genauerer Betrachtung der diesbezüglich einschlägigen Rechtsvorschriften sowie ihren Herleitungen und Begründungen wird deutlich, dass in dem Schutzgut Fläche mit den drei Zieldimensionen

- Quantität (des Flächenverbrauchs reduzieren),
- Qualität (der Flächen- bzw. Freiraumfunktionen und -nutzungen erhalten), und
- Ressource (Fläche nachhaltig im Sinne von Effizienz, Konsistenz und Suffizienz nutzen/entwickeln)

ein großes, bisher noch zu wenig ausgeschöpftes Potenzial für eine wirksame Umweltvorsorge liegt, welches mit Hilfe von Umweltprüfungen gehoben werden könnte. Bisher sind allerdings mit der Einführung des Schutzgutes Fläche kaum Impulse für das Flächensparen in Richtung Netto-Null-Ziel, für einen wirksameren, multifunktional begründeten Freiraumschutz und einen nachhaltigeren, insbesondere effizienteren, konsistenteren oder gar suffizienteren Umgang mit der begrenzten Ressource Fläche in der Planungs- und Zulassungspraxis erkennbar.

Da sich in Verbindung mit einem weiter steigenden „Druck auf die Fläche“ formelle und materiell-rechtliche Anforderungen an die Prüfung und Umsetzung des Flächensparziels verschärfen werden und mit dem Netto-Null-Ziel für 2050 eine Flächenkreislaufwirtschaft erforderlich wird, jedoch die Einführung einer eigenständigen „Flächensparprüfung“ – vergleichbar mit anderen umweltbezogenen Prüfverfahren – mit Blick auf die angestrebte Planungsbeschleunigung und Verfahrensvereinfachung nicht opportun erscheint, besteht die Chance, das vorhandene, EU-weit vorgegebene Instrument der Umweltprüfung für Programme, Pläne und Projekte durch differenzierte Bearbeitung des Schutzguts Fläche für die dringender werdenden Aufgaben des Flächensparens und multifunktionalen Freiraumschutzes gezielt zu nutzen. Auch das Instrument eines „Freiraumchecks“, das vor dem Hintergrund des Ansatzes der doppelten Innenentwicklung bei städtebaulichen Projekten und informellen Planungen der Stadtentwicklung zur Sicherung der urbanen Freiräume mit ihren klimatischen Ausgleichsfunktionen empfohlen wird (BDLA 2022, S. 3), ließe sich ohne Probleme in die Umweltprüfung integrieren.

Zur Wirksamkeit der Umweltprüfung bedarf es neben einer frühzeitigen Integration in die Planungsprozesse möglichst verbindlicher Umweltziele und -standards für die Bewertung der Umweltauswirkungen von Planungen und Projekten. In Bezug auf das Schutzgut Fläche spielen die Festlegungen der Raumordnung und Bauleitplanung zur quantitativen Reduzierung der baulichen Flächenneuinanspruchnahme und zu Schutz und Entwicklung von Freiraumfunktionen entsprechend ihrer datengestützten Wertigkeiten eine entscheidende Rolle. Neben der raumordnerischen Festlegung von Flächenkontingenten und Dichtewerten für die Siedlungsentwicklung sind deshalb auch weiterentwickelte Strategien und verbindliche Instrumente mit Festlegungen zur raumordnerischen Sicherung von Freiraumfunktionen und -nutzungen gerade auch im Hinblick auf die Multifunktionalität/Mehrfachnutzung von Freiräumen erforderlich. Kommunale Strategien einer kompakten Siedlungs- und Freiraumentwicklung, insbesondere dreifachen Innenentwicklung, mit kommunalpolitisch beschlossenen baulichen Dichtewerten und urbanen Freiraumqualitäten, stellen neben den möglichen raumordnerischen Flächenkontingenten zukünftig wichtige Umweltziele für die Umweltprüfung in der Bauleitplanung dar.

Für die künftige Gutachter-Praxis erscheint zudem wichtig, das Schutzgut Fläche einerseits definitorisch und fachlich-methodisch so klar wie möglich von den anderen Schutzgütern abzugrenzen, andererseits die zweifelsfrei existierenden, fachlichen Überschneidungen, insbesondere mit Boden, Landschaft und dem Schutzgut Wechselwirkungen, zu adressieren und mit Hilfe von Schwerpunktsetzungen wie auch Verweisungen auf andere Schutzgüter ohne größere Redundanzen in den Berichten zu bewältigen. Gleichzeitig sind die Potenziale der Alternativenprüfung für eine effizientere Flächennutzung stärker zu nutzen und die Möglichkeiten der Abschichtung bei der Bearbeitung des Schutzgutes Fläche auf den verschiedenen Ebenen der Umweltprüfungen (SUP/UP/UVP) sorgfältig zu prüfen.

7 ACKNOWLEDGEMENTS

Der Beitrag basiert insbesondere auf Erkenntnissen des vom deutschen Umweltbundesamt (UBA) mit Bundesmitteln finanzierten Forschungsvorhabens „Fläche als Schutzgut des Gesetzes über die Umweltverträglichkeitsprüfung – Erarbeitung von Praxisempfehlungen“ sowie des Arbeitskreises „Freiraumsicherung und -entwicklung in der äumlichen Planung” der Akademie für Raumentwicklung in der Leibniz-Gemeinschaft (ARL). Did we Build Enough? Pleadings based on Statistics and Technologies for the Building Stock

Ulrich Pont

(Senior Scientist Dipl.Ing. Dr.techn. Ulrich Pont, Research Unit of Building Physics and Building Ecology, TU Wien, Karlsplatz 13, 1040 Vienna, Austria, ulrich.pont@tuwien.ac.at)

DOI: 10.48494/REALCORP2025.1184

1 ABSTRACT

This contribution wants to argue for a fundamental transformative change for future development of the built environment in Austria (and generally Central Europe). Thereby, innovative technologies to update and adapt the existing building stock play a fundamental role, to improve comfort and energy performance of existing buildings and built structures. This contribution is based on a talk the author held two years ago about innovative technologies for building stock improvement in view of we built enough as a statement.

When we address the existing building stock, we find buildings and structures that can be considered of high value for European cities appearance. However, an even larger fraction of existing buildings might not be considered as "beautiful" or "identification landmark" for European cities. While the replacement of the sooner would mean an immense loss of identity, the latter might in part be considered as "the ugly child", but still provides a sink of past Greenhouse Gas (GHG) emissions. If we would demolish and replace these buildings by new ones, huge energy consumption and GHG emissions would be the consequence, connected with the demolition, depositing of old materials, and material movements and utilisation of the new buildings, as circularity concepts in the AEC (Architecture – Engineering – Construction) – Domain are not yet well established. Cities are expanding, which can be explained by rising numbers of population, but on the other side also with a increased space consumption of inhabitants. These expanision tendencies on the one hand require extensive overwork of public infrastructure and accelerate sealing of surfaces and loss of natural resources and green-blue infrastrucutres, and on the other hand seem strange, given that we face empty built infrastructures e.g. on groundfloor level in many residential districts.

Toward this end, the present contribution advocates for holistic view of the update possibilities of the building stock, while at the same time critically warns against romantification of the building stock in view of outdated perspectives of the past. Rather, research, technologies and approaches are presented and discussed that have been worked upon in the past 10–15 years and directly address the existing building stock. These efforts all tried to balance out the difficult relation between heritage protection on the one hand, and comfort and energy performance improvements on the other hand.

As such, this contribution tries to utilise the concept of imperial lifestyle as critically brought up by scientistst from environmental political science and maps it on the AEC-domain.

Keywords: Building Stock, Space consumption, technologies for retrofit, pladoyer, vacuum glazing

2 INTRODUCTION

In recent years the role and responsibility of the built environment regarding climate change shifted from being an issue discussed majorly amongst scientists and domain experts to a convolute of topics perceived and discussed in media and the broad public. This might be due to the fact that the effects of climate change cannot any longer be neglected, especially during Summers in the cities. One example for these topics is urban sprawl, which euphemistically often is named Verhüttelung in German (denoting the sprawl of a large number of detaches houses instead of more condensated forms of dwelling), and the associated issue of surface sealing (WWF 2021). Planning sciences for decades have scientifically worked on the topics and reasons for urban sprawling effects. In Austria, the situation is complex, given the relation between the country administration and its federal states that involves different responsibilities, economic interests and policies, leading to a strange culture that not only not hinders urban sprawl, but provides fruitful grounds for this development (Umweltbundesamt 2001, p147, Bröthaler 2020). Parallely, Austrian Cities, especially Vienna, experience population rises after times of stagnation leading to increased demand for urban dwellings, and at the same time – paradoxically – face large real estate vacancies (Kadi et al. 2020, Plank et al. 2022): Up to one fifth of all residential units in Vienna are considered to be vacant/unused. At the same e time, the AEC (Architecture-Engineering-Construction) sector is subjected to tightening regulations

stipulated by national and supranational administration bodies. This is due to the key role the built environment plays in approaches to fulfill ambitious, but increasingly unlikely to be achieved emission cuts, as defined by the Paris climate targets (UN 2015) and initiatives such as the as the 'European Green Deal' (European Commission 2019). The focus on the built environment seems logical, given the large percentage of climate-damaging emissions that are directly or indirectly related to buildings. This percentage varies in studies due to different geographical or temporal scope. A frequently mentioned statement is that the built environment is responsible for up to 40% of the end energy demand (Weber and Zucker 2022, p18). As a result of the European Building Directives of 2002 and 2010, Austria already has very "harsh" requirements for the thermal-energetic quality of buildings (OIB 2023a, OIB 2023b). While it seems easy to design new buildings to be energy efficient, i.e. with low or almost zero operational energy consumption and climate-damaging (gas) emissions, the existing building stock is often "forgotten" on the one hand, and on the other hand is seen in the literature as the key to energy-saving measures (Weber and Zucker 2022, p3). Buildings should clearly be designed or refurbished in such a way that it is practically possible to minimise the energy required for operation (e.g. to create a high level of thermal comfort for users). comfort for the users) as low as possible in order to minimise as low as possible so that as few or no negative emissions are caused. If the occupants of such buildings behave in a correspondingly "sensible" way, then the low energy consumption might be realizable. However, the everyday experiences illustrate that this is not necessarily the case (see Housez et al. 2014, discussed later in this paper). Moreover, many so-called retrofits conducted in recent years have pursued the goal of preserving (or at least beautifying) existing buildings, but not necessarily improving them thermally/energetically. In 2013, the German Federal Environment Agency assumed that 40 percent of building retrofit did not or barely include any thermal improvements (DENA 2013).

This article aims to highlight innovative technologies and approaches to improving the existing building stock that go into borderline areas where, for various reasons, such as the protection of the ensemble or the preservation of the architectural and aesthetic quality, "conventional" thermal improvements (such as the application of thermal insulation panels) are not possible or not possible without further ado. At the same time, the article aims to show that "all that glitters is not gold". To this end, the article is structured as follows: Firstly, Section 2, under the heading "Everything used to be better", looks at building traditions and their role in today's discourse, as well as the danger of (rather useless) glorification. Section 3 discusses the concept of the existing building stock and the challenges associated with it using a number of examples. Section 4 is dedicated to the concepts of "rebound" and "prebound" as well as the problem of energy performance certificates as a supposedly reliable indicator of building quality. Section 5 looks at which construction measures still appear necessary and sensible despite the 'build enough' paradigm. Section 6 focuses on innovative technologies for the refurbishment/optimisation of existing buildings and illustrates this using current research projects as examples. Section 7 discusses the available and necessary instruments and tools that are required to identify sensible measures for existing buildings and to provide evidence. Section 8 takes stock of the previous chapters and attempts to answer the question: 'Haven't we already built enough?

3 "EVERYTHING USED TO BE BETTER" OR THE DANGER OF ROMANTICISING PAST BUILING STOCK

For centuries, people used to employ locally available materials and constructed residential and other buildings by low energy, majorly manual work. As an example: The arrangement of Mbaru Niang roundhouses from the village of Wae Rebo, Flores, in West Manggarai, Indonesia, shown in Figure 1, demonstrates such a low-energy, high-performance architecture from a long 'trial and error' tradition. In the case of this village, which even today can almost only be reached on foot due to its location in a remote high valley/volcano caldera, these houses were built with the material that could be obtained from the surrounding countryside within walking distance with reasonable, machine-free effort. It was used to withstand the local rigours of nature in the form of strong sunshine, storms, or heavy rainfall. These are renewable raw materials (e.g. the draining, quick-drying roof covering made of lontar palm thatch) or materials that were used as found (stone material underneath the uprights) and combined in such a way that they offered the users (comparatively) pleasant living conditions or a comfortable living centre (e.g. storage tanks in the pitched roof, elevated construction to prevent water ingress in the event of heavy rain). Needless to say, these buildings offer pleasant living conditions all year round without heating or cooling, as many other local building traditions offer passivly. The author of this article is always tempted to show this image when

someone from the architecture scene comes along with a design for a ‘sustainable’ detached house in Vienna's suburbs and praises it with excessive fervour as ‘sustainable architecture’.

Fig. 1: Traditional Mbaru-Niang-Buildings, Wae Rebo, Flores, West-Manggarai, Indonesia (Image by the Author)

But does this mean that we “only” need to look at and copy architectural traditions in order to create “sustainable buildings” for the present day? Not at all. First of all, the traditional houses in this village have been disappearing over time because the inhabitants of the village built houses next to them in the 20th century using materials such as concrete and corrugated iron, where they “preferred” to live (Some of the depicted buildings have been reconstructed for touristic purposes). This also has something to do with the fact that eight families, usually of three to four people, lived together in each of the buildings, which no longer fits in well with today’s requirements in terms of privacy and cohabitation of the residents. The comfort requirements, both in terms of living habits (e.g. eating at a table instead of on a mat on the floor, sleeping in a bed instead of on a mat) and in terms of building physics parameters (temperature, room acoustics, daylight), have also changed over time and can only be met to a limited extent by the buildings shown in the illustration. Instead, the comfort requirements are – energy-intensively, powered on site primarily by diesel generators – fulfilled in newer homes not shown in the illustration. The traditional buildings have been reconstructed from a cultural-historical point of view, some of them rebuilt from scratch and now serve as a main source of income for the village, tourism – as a tourist, you can stay overnight “traditionally” in the village. The fact that the village’s main source of income used to be a different one, mainly from agriculture through coffee cultivation, is only mentioned here in passing, as is the fact that a 1:1 transfer of this building tradition would not even work within Indonesia, as the habitus of the users, other microclimatic conditions, other available materials and other requirements for the buildings would be different. These traditional buildings, just like traditional buildings from Austria, would not fulfil requirements such as “watertightness” (i.e. “sealed” instead of “draining” roofs) or ‘airtightness’ (no convective heat loss through structures). So what can we take away from this example? Taking inspiration from traditional building forms and principles is certainly advisable. This is important for the reactivation of the existing buildings and with regard to the discourse on Haven’t we already built enough?; romanticising the forms and presenting them as the ideal ideal solution is certainly not expedient. At the same time, however, it should also be questioned whether certain requirements that we place on today’s buildings due to “building preservation” and and “comfort requirements” really make sense. For instance, Central European building regulations demand a high degree of air tightness, but such envelopes are usually perforated by pipes of technical systems for ventilation. Another example is the assumption that all rooms of residential units are heated at all times during Winter. We should thus ask ourselves if such requirements make sense or should rather be seen as results of self-made construction problems and false ideas of comfort?

4 CHALLENGES RELATED TO THE BUILDING STOCK

According to Statistics Austria (2023a) (reference year 2021), the building stock in Austria consists of around 2.4 million buildings, of which around 93 per cent are predominantly used for residential purposes.

Figure 2 shows the development of the Austrian building stock over time in terms of the total number of buildings (buildings and buildings with predominantly residential use).

It is striking that the total number of buildings has increased by over 85 per cent within fifty years (1971-2021, Figure 2). In contrast, the population has only increased from 7.5 million to 8.9 million people between 1971 and 2021, which is an increase of 18.7 per cent. In purely mathematical terms, there were 5.85 people per building in 1971; in 2021, there were only 3.75 people per building. This consideration makes comparatively little sense without taking into account the flats or number of residential units per building, but nevertheless shows the trend towards "fewer residential units per residential building". Boom phases of growth were apparently between 1971 and 1981 (+ 23.9 per cent) and between 1981 and 1990 and 1991 and 2001 (14 per cent and 13.1 per cent respectively). So at least the 'growth rate' has fallen somewhat, even though the total number of buildings has risen.

Figure 3 shows the composition of the building stock from different building ages in absolute figures. With regard to the age composition of the buildings, it is striking that between 1971 and 2021 the number of Gründerzeit buildings (built up to 1918) fell by 40 percent, the number of buildings erected between 1919 and 1945 fell by 17 per cent and the number of buildings erected between 1945 and 1960 fell by 15 percent. This contrasts with a large number of buildings erected between 1961 and 1980, which have "only" declined by 5 per cent since 1981. The loss of building fabric, most of which has been replaced by new buildings, has therefore particularly affected the oldest building stock. In a lecture in 2022, civil engineer Andreas Kolbitsch pointed out that, compared to the 13 per cent of buildings from the Gründerzeit period in Austria as a whole, a quarter of Vienna's buildings date from the period up to 1919 (Kolbitsch 2022).

Fig. 2: Absolute number of buildings in Austria 1971 – 2021 (Source: Statistik Austria 2023, illustrated by the author)

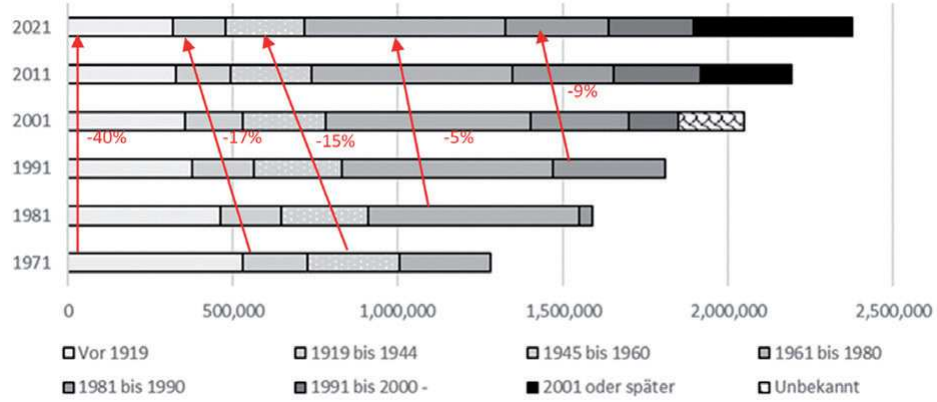

Fig. 3: Age distribution and development of number of buildings in Austria 1971 – 2021 (Statistik Austria 2023, illustrated by the author)

Basically, it should be noted that the "image" of a Central European city is largely constituted by its existing buildings. This applies to cities such as Vienna, Prague, Bratislava, Brno and many others and can be confirmed by looking at cities in Germany that were destroyed and rebuilt during the Second World War: Those cities where efforts were made to "rebuild" the old stock are today perceived as "more attractive" compared to those where reconstruction was carried out purely through new construction. Today, however,

the old stock includes not only the Gründerzeit and the interwar period (as evidenced, for example, by the imposing and architecturally valuable buildings of "red Vienna" to this day), but also the post-war period and the "off-the-peg" buildings of the period between 1945 and 1980. The fact that the question of the value of even relatively "new" architectural icons often depends on the urban planning and utilisation-specific context can be seen when studying the work of some former professors of the TU Wien, Vienna, who held chairs in high-tech architecture, construction and installation (Seidel and Steixner 2020).

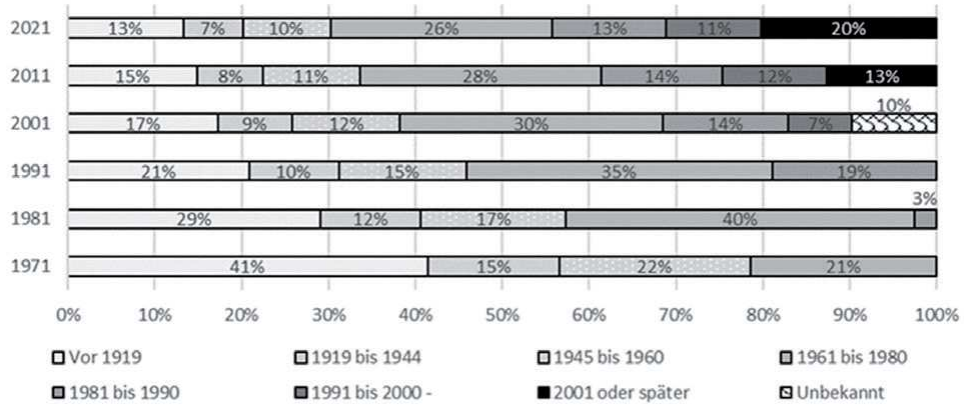

Fig. 4: Relative distribution of different building ages in Austria between 1971 and 2021 (Statistik Austria 2023, illustrated by the author)

The construction of the so-called Juridicum by Ernst Hiesmayr is still considered a milestone among the university buildings that belong to the University of Vienna, even though a Gründerzeit inner-city block was demolished on its site. Hiesmayr's successor at the TU Wien, Helmut Richter, is internationally recognised for the school on Kinkplatz (14th district of Vienna) and for the residential complex on Brunner Straße (23rd district of Vienna). While Brunner Straße is a popular residential building for residents despite a number of adaptations and its difficult location (the building is situated in industrial surroundings along a busy road), the glass and steel icon of the Kinkplatz Computer Science Secondary School, built in the 1990s, is today affected by disuse and slow decay despite its significance for recent Austrian architectural history and was long threatened with potential demolition (the school has since been listed as a historical monument). As far as existing buildings are concerned, one has to accept the idea that a black-and-white approach is not expedient. Looking at social housing from the post-war period up to the 1960s, one will find supposedly low-quality off-the-shelf buildings that are hardly considered adequate in terms of current thermal or acoustic requirements. Nevertheless, a huge proportion of residential units in Vienna is made up of/situated in these buildings. Buildings from the Gründerzeit of 1850–1918 (and even older buildings), which have been set under special protection recently due to certain incidents (deliberate decay to enable demolition), certainly have qualities that should not be underestimated; however, if they are not cared for and fall into disrepair, every building will eventually "come to an end". If this is accepted wilfully by the building owners in order to achieve technical readiness for demolition, the idea that can be found behind is very often that a new building could possibly generate more profit through lower storey heights (which just meet the minimum requirements of the building regulations). From a building ecology perspective, it should be noted that a building that stands for 100 or 150 years represents a certain degree of sustainability, despite possibly poorer thermal-energetic parameters. Bricks that form the construction material of such buildings have a lifecycle that outnumbers the predicted lifespan of today's new buildings by a factor 4 to 5. Replacing the (historic) building stock with new buildings is neither advisable nor expedient; numerous studies and theses have shown that the ecological footprint of existing buildings is significantly lower than that of new buildings over a long service life (Padayhag et al. 2016, Schmidt 2020). Furthermore, the loss of the architectural value cannot be quantified. The endeavour to replace the existing building stock with new buildings would take up to a century at today's new construction rates and would leave an enormous ecological footprint as well as a cultural black hole.

Challenges that the (historical) building stock must cope with today include, in addition to the usual maintenance work that every structure requires, aspects of adaptation to climate change. Urban heat islands in inner-city areas, which often lack sufficient green-blue infrastructure, pose a challenge to users. The fact

that there are often no simple solutions available in densely built-up urban areas will be addressed later in this article.

5 (P)REBOUND, ENERGY CERTIFICATES OR "DO YOU GET WHAT YOU DEMAND?"

This section describes two research efforts that deal with the Key Performance Indicators (KPIs) often used to evaluate buildings. However, before that, two terms will be introduced that occur in the context of such energy metrics in the building sector, as well as generally in the "measurement" of any kind of "performance"'

5.1 Rebound Effect

The term rebound or rebound effect refers to the phenomenon where a specific target (e.g., the potential savings from efficiency improvements in construction) is not or not fully achieved – despite careful attempts. An example of this would be that a building is thermally and energetically upgraded through construction measures, but the energy savings are negated by changed user behavior – such as prolonged showering, the use of additional energy-consuming appliances, or excessive ventilation in winter, etc. It is important to consider the systemic perspective here: a rebound effect could also occur if the saved heating costs are then invested in a vacation trip by airplane, which may cause even higher greenhouse gas emissions.

5.2 Prebound Effect

In contrast to the rebound effect, there is the prebound effect: a 'worse' performance is expected than what actually occurs. An example of this would be heating demand calculations (HWB calculations) for historic buildings that determine much higher heating demands than what is actually evidenced by energy bills. Reasons for this could include differing user behavior, such as heating only one or two living spaces instead of the entire apartment, or overly simplified assumptions regarding the thermal envelope quality of buildings, where default values are used in the HWB calculation instead of real constructions (Sunikka-Blank and Galvin 2020).

5.3 Is it all done with the renovation?

Housez et al. (2014) analyzed the renovations of seven existing residential buildings, mostly apartment buildings for older adults with multiple units. In this study, the actual energy performance before and after the renovation was assessed using data from bills and compared with calculations and simulations of the status quo as well as the planned renovations. The buildings were constructed between 1968 and 1985 and were renovated between 2005 and 2009. The planned target values for the specific heating demand after the renovations, which were designed for high energy efficiency, ranged according to the standards for energy certificate calculations at that time from 6.7 to 17 kilowatt-hours per square meter of gross floor area per year (abbreviated: $kWh.^{m\text{-}2.a\text{-}1}$). These values were and are extraordinarily low energy metrics for residential buildings. The actual specific heating demand (determined from energy bills) was only close to the planned value for one building; for the others, the determined values ranged between 40 and 55 $kWh.m^{-2}.a^{-1}$, meaning in some cases four to five times higher than the anticipated energy performance. Subsequently, parametric estimates were conducted to find out how the deviation occurred: higher indoor temperatures and differing real weather data were quickly ruled out as strong influencing parameters, as the available measurements of indoor temperatures and weather records showed that there were no significant deviations. In terms of adjusting ventilation behavior, it became evident that increased air exchange through more extensive ventilation (e.g., consistently "tilting" windows) served as a very good explanation. Interestingly, in the building where the anticipated and actual performance largely matched, the users directly paid the energy cost bills, while in the other properties, the energy costs were proportionally allocated to the units based on their floor area, meaning that the users could not recognize whether their behavior was causing the "worse" energy performance.

5.4 Building Energy certificates – the solution or the box of Pandora?

In another research effort, the practical creation of energy certificates was examined. Although there are a number of laws (EAVG 2012), guidelines from various institutions (guidelines from the Austrian Institute of Construction Technology, Ö-Normen from Austrian Standards International), and supporting documents for this purpose, there remains a significant interpretive degree of freedon regarding how to handle existing

buildings. Since the issuance of energy certificates is not particularly well compensated and there are no clear training requirements for issuers, the lack of accuracy in energy certificates is likely to be quite high. As part of a research project (see Sommer and Pont 2017, Pont et al. 2016), it was shown that there are significant differences in the results of energy certificates. Two groups of previously identically trained issuer groups each calculated the energy certificates for buildings. The differences in the results were sometimes enormous – at times, the difference in heating demand results was 100 $kWh.^{m-2.a-1}$ (!). Upon closer examination of the calculations from the two groups of issuers, differences in the assumed calculation data were identified: While both groups similarly determined gross floor areas and gross volumes, as well as area calculations and glazing ratios, there were striking differences in the assumed U-values (thermal transmittance coefficients) of the building components. Apparently, components that were not accurately described in the existing building documentation were approximated using default values according to the OIB guideline 6. Unfortunately, there is a significant interpretive degree of freedom for these default values, which means that the described deviations could arise "to the best of the issuers' knowledge and belief." It should also be noted that the energy certificate would certainly be an excellent idea for comparing different buildings if the aforementioned problems did not occur. However, it is fundamentally advisable to refrain from assuming that the energy certificate accurately reflects the actual behavior of occupants (e.g., regarding heating, internal gains from the presence of people, operating devices, artificial lighting, or ventilation behavior). In another project, it was investigated (Pont et al. 2019) how the energy certificate procedure can be used in evaluating large real estate portfolios and making decisions with limited budgetary scope to find the "best" renovation option that can achieve maximum savings effects. What has been described should be kept in mind when conducting the thermo-energetic assessment of the building stock. In short: just because a certain energy key performance indicator (KPI) is assumed for an existing building through a calculation, it does not necessarily reflect reality. Besides the fact that the calculation or simulation is based on sometimes rough assumptions (especially regarding user behavior), the manner in which the calculations or simulations are conducted is also significant, as it is subject to a variety of uncertainties.

6 WHAT WOULD WE BUILD ANYWAY?

Until now, this article has primarily dealt with aspects of proof for buildings, innovative retrofitting technologies, and similar topics. This leads directly to the question: "Should nothing more be built anew?" This can be answered relatively simply, but it unfolds into a series of partial answers. First: It will definitely be necessary to create additional (or altered) residential spaces as the population grows, but this should only be accompanied by measures that make better use of existing structures or sensibly expand them. In a project aimed at reorganizing living space, it was shown that – no matter how absurd a reorganization may sound at first – a win-win situation for residents and energy performance could be achieved with the same or improved living comfort in the existing building stock through organizational and (small-scale) structural modifications in the (historic) building stock (Mahdavi et al. 2012). Of course, legal and ownership-related aspects are significant hurdles here, but the project demonstrates the vast potential of this approach. The idea of sufficiency, meaning a limitation of, for example, living space per person, also comes to mind. Improved utilization of the 'still' available urban area is another aspect that is conceivable in the context of 'new' building. Assuming that many building regulations today have developed prescriptively from a long cascade of evolutionary steps, it is unlikely that the existing "negative space" that still exists will actually be efficiently utilized through core densification. In the course of another project (Pirstinger et al. 2017), it was investigated which core densification potentials could be unlocked with which methods.

A major theme for new buildings will be measures for climate change adaptation. Historical, urban areas with their very limited offerings of green-blue infrastructure and conditionally available root space for trees could benefit from 'artificial' structures for shading and cooling.

As part of a recently completed research project, the essential aspects of artificial tree structures (dubbed Smart & Urban Trees) were examined for urban cooling purposes. It is important to note that such structures do not compete with trees and plantings but are intended to complement areas where natural plantings cannot be implemented or are difficult to implement for technical or organizational reasons. Figure 5 shows result visualizations from this project. The corresponding structures were also examined for their shading effects and cooling potentials through numerical simulations and were confirmed in their effectiveness. The multitude of legal, organizational, technical, and socio-economic questions associated with such structures

indicates that new construction in the future may need to be conceived in a much more holistic and integrative manner than is currently the case.

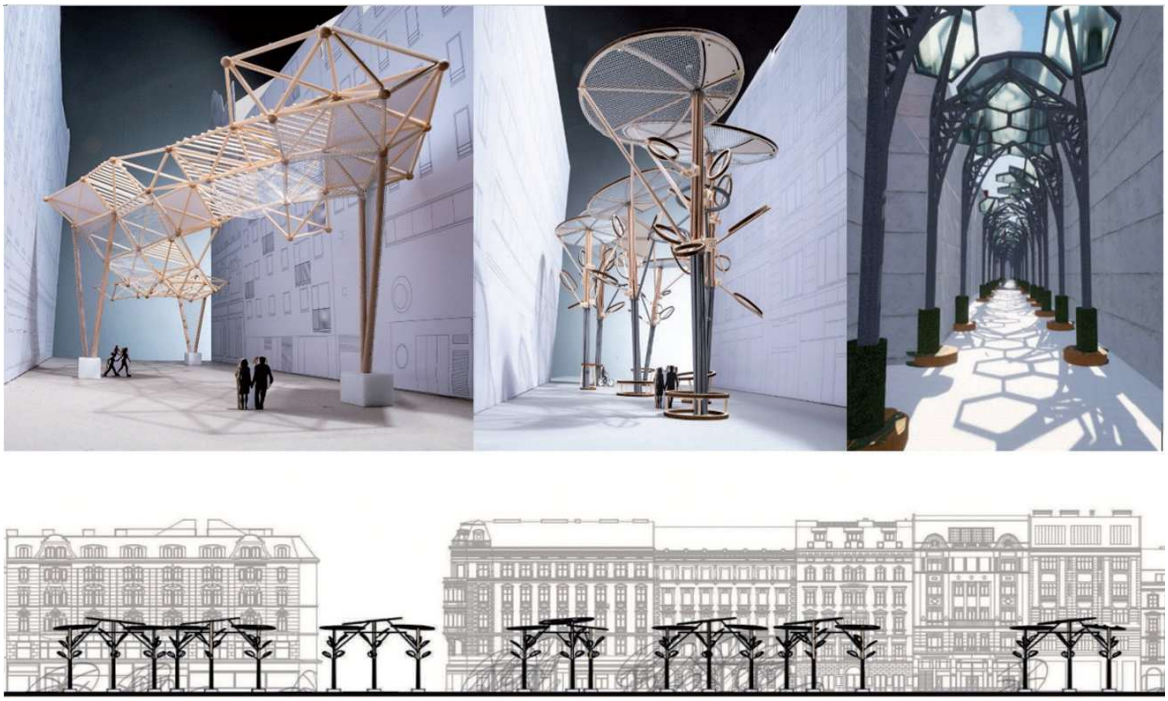

Fig. 5: Visualisations of artificial tree structures for urban cooling (Pont et al. 2025)

7 INNOVATIVE TECHNOLOGIES FOR IMPROVING THE THERMO-ENERGETIC PERFORMANCE OF THE BUILDING STOCK

It has already been suggested that the city, as the largest manifestation of building stock, may also require new organizational approaches for densification and expansion. Therefore, the following will address a whole range of research and development efforts on the topic of 'innovation in optimizing existing structures. When asked how to energetically upgrade existing buildings, the standard response is always “insulation”. What is typically meant by this is the additive (external) application of insulating materials. While this may seem feasible for the unadorned facades of post-war buildings – though even here, a sometimes questionable cultural impact is often hard to deny – this solution often appears not readily applicable to richly decorated cultural heritage buildings. As an alternative, aside from no intervention, internal insulation is mentioned. However, from the perspective of the Central European winter climate, this poses problems: the temperature drop is shifted to the interior side of the load-bearing components, making condensation and mold formation likely, which must be avoided, for example, through diffusion-tight membrane materials or capillary-active insulating materials. The interior ceilings that connect to the load-bearing exterior walls become thermal bridges, and the altered temperature characteristics in this detail area can lead to the rotting of wooden beam ceilings, resulting in a shortened lifespan of the structures and potentially leading to collapse. The significant reduction of interior spaces due to corresponding insulation thicknesses should also be noted as an economic and living space issue.

7.1 Thermal insulation made with Aerogel Plasters and Subtracive Insulating

For the innovative external insulation of culturally significant buildings, plaster systems with insulating characteristics are suitable, provided that the exterior plaster does not represent the preservable cultural asset. In a research project (AGelFa), the insulation potential of the still relatively expensive aerogel plasters was demonstrated (Proskurnina et al. 2015). Aerogels are solid, highly porous gel structures (with up to 97 percent air pore content) that are highly insulating even at low thicknesses. Not only was the benign nature and durability of the material for top plaster systems explored through extensive monitoring, but it was also shown that for average Gründerzeit facades, with an appropriate offset of the facade structure and plaster system thickness, and with accompanying measures on other components (e.g., window upgrades, avoidance of thermal bridges in ceiling connection areas), savings of up to 70 percent in heating energy demand can be achieved. This makes Gründerzeit buildings 'competitive' in terms of heating energy demand (cf.

Proskurnina et al. 2015). Figure 6 shows a test area for aerogel plasters as produced and observed in this project.

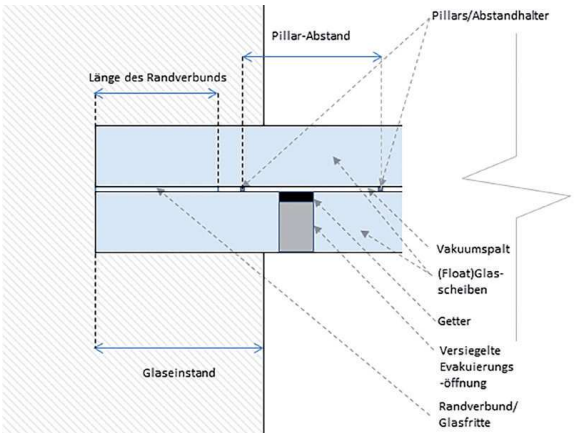

Fig. 6: Aerogel-plaster test surfaces (Image by the Author), fig. 7: Schematic Constituents of vacuum glazing products (Image by the Author)

Another approach regarding the "insulation" of opaque parts of existing facades was recently explored in a preliminary project: The idea here is to insulate "subtractively", meaning to thermally improve the static reserve of Gründerzeit walls by introducing suitable drill holes (and corresponding "caps") with insulating, standing air inclusions. The U-values of Gründerzeit walls could be improved by up to twelve percent concerning the thermal transmittance coefficient (U-Value). In combination with other concepts, such as phase change materials (PCM), the characteristics of heat transfer, especially during cold winter nights, could be positively manipulated. Moreover, an interesting approach to renovation is that it should not be carried out as usual by construction workers on scaffolding, but rather that autonomous robots should gradually upgrade the facade whenever resources (energy, money, time) are available. Future music? It is certainly true that such highly innovative concepts must reach a level of maturity and face challenges (robot technology, appropriate modeling of the facade to clarify where "drilling" is allowed, suitable drill heads/drilling techniques). However, it has become evident, especially in recent years, that such ideas are no longer mere science fiction with the advent of digitalization (Sommer et al. 2021).

7.2 Historic casement windows and their retrofit via innovative glazing products

Buildings are not only made up of opaque components but also of transparent elements like windows. Windows are still considered a weak point in building envelopes, through which a significant amount of heat is lost during the cold season. The existing building stock is often characterized by very elegant window constructions, which, however, do not necessarily meet the current standards for thermal insulation. Unfortunately, the unsustainable practice of "window replacement" has become the primary form of renovation for windows. In this way, and under the false argument of an alleged lack of alternatives regarding improved thermal building performance, thousands of box window constructions are unnecessarily lost each year, and the appearance of the valuable building stock is often negatively altered.

The old casement window constructions represent fundamentally well-thought-out and high-quality window designs that utilize an air cushion between the inner and outer sashes for thermal insulation. However, due to leaks and the high thermal conductivity of float glass compared to multi-pane insulating glass, the thermal insulation effect is often limited. While adjusting the windows and fittings, adding seals, and maintaining the windows can generally counteract leaks and drafts, the heat losses through float glass are difficult to modify. Heavy double or triple glazing with several millimeters of gas inclusions is not feasible as a glass alternative due to the delicacy of box window constructions (often very thin wooden strips as muntins and delicate beams for the window frame). Since box windows also represent an excellent construction from a circular economy perspective (easy separability of materials, durability), a glass alternative would be a great opportunity to make box windows 'fit' for the present time. In fact, there have been durable vacuum glass products for about ten years that meet the requirements regarding glass thickness and weight (vacuum glasses are available from about five millimeters of glass thickness) for box windows. Vacuum glasses are highly insulating due to the thin, less than one millimeter thick vacuum gap, which largely eliminates the heat transport mechanisms of conduction and convection (see Figure 7).

The author has been leading several research and development projects in recent years that focus on the use of vacuum glass in new and existing window constructions. Due to the characteristics of vacuum glass, which have a significant “thermal bridge” at the edge connection of the glass, it was necessary to pull out all the stops regarding the evaluation of the performance of box windows reinforced with vacuum glass: Not only through simulations and laboratory tests, but also through monitoring under real conditions in buildings, it could be demonstrated that box windows reinforced with vacuum glass do not show any tendency for condensation or mold even under harsh winter conditions. In six heritage-related objects, box windows with vacuum glass were implemented for demonstration purposes and subjected to intensive performance monitoring for over a year using high-end measurement equipment. In each of the objects, a control window in its original state was monitored alongside two reinforced windows that were sensorily observed. For the reinforced windows, one window had its outer layer of float glass replaced with vacuum glass, while the same was done for the inner layer.

Ultimately, it was demonstrated that box windows, when carefully planned for structural renovation (in addition to glass replacement, also correct adjustment of fittings and, if necessary, adding seals in the rebate), can achieve a significant performance improvement compared to the original. The use of vacuum glass can be planned so that the windows do not show any signs of condensation or ice formation. If the vacuum glass is used for the inner sash, the energy performance of the renovated window is better; if the vacuum glass is installed in the outer sash, a slightly poorer thermal insulation property results in a warmer space between the panes (thus protecting against condensation formation). With such a minimally invasive renovation option (sash replacement, adjusting the window and fittings, adding a sealing layer), a 10 percent reduction in heating energy demand was found in Gründerzeit houses without large construction sites. The window U-value for box windows reinforced with vacuum glass could be reduced from 2.5 $W \bullet m^{-2}K^{-1}$ to below 1.0 $W \bullet m^{-2}K^{-1}$ (Pont et al. 2016).

8 WHAT INSTRUMENTS DO WE NEED FOR IMPROVING THE BUILDING STOCK?

This article described concepts and showcased exemplary projects that either address the meaningful enhancement of built space for additional effects (e.g., mitigating summer overheating) or focus on the innovative improvement of existing structures with minimally invasive measures. It should be noted that these projects – although often with a built 'demonstration character' – have largely utilized digital tools: For example, numerical thermal bridge simulations were employed for the development of vacuum glass box windows, as well as light and temperature simulations. The use of such technologies plays a key role in the success of evaluations of the potential of ideas, especially given the impossibility of experimentally testing a multitude of variants. Verification and validation of results through monitoring, as in the case of box windows, is also of utmost importance.

In fact, the digital tools available today do not represent the “ceiling” for supporting planners, end users, or decision-makers. A decision support system for renovations was developed ten years ago, aimed at making the overwhelming amount of information for stakeholders involved in renovation processes more “manageable” through “multi-objective optimization” and semantic web technologies (Heurix et al. 2013). The enormous amounts of information needed for building renovations (e.g., building material/product data, subsidies, legislative information, zoning regulations, etc.) often have to be painstakingly compiled manually. This overload often leads to the seemingly 'simplest' but not necessarily “most sensible” path being taken. This problem resulted in the tool SEMERGY (2023), which can still be used today for planning building renovations while considering the parameters of energy performance, ecological footprint, and costs, evaluating several hundred thousand variants regarding optimal performance in typical renovation projects (cf. Pont 2014). In times of artificial intelligence, robotics, and other disruptive technologies, such tools will likely be expanded and utilized even better for the purposes of optimizing existing structures, provided there is the political will to focus on much more efficient and sufficient optimization of existing buildings.

9 CONCLUSIONS

This article presented different approaches to optimizing the existing building stock. They highlighted various points: (a) A holistic approach is required for the optimization of existing buildings, with the involvement of as many relevant stakeholders as possible. It is of no use, for example, if the renovation of

windows through minimally invasive measures is only scientifically proven to be sensible. The industry (small and medium-sized carpentry businesses and guilds) as well as the administration (moving away from funding regimes that only support window replacement as a sole measure) must be involved here – just as civil society must be willing to participate. (b) The existing building stock is somewhat like an 'undiscovered' land: In fact, we still do not know many details about the existing building stock today, particularly concerning thermal building envelope qualities, etc. Further research, development, demonstration, and communication are required. What we do know suggests that the existing stock can do much more than is often acknowledged. (c) The existing building stock must be recognized as a valuable asset that needs to be maintained and improved. The cultural significance of the existing stock already constitutes a large part of the identity, image, and quality of life in many cities. At the same time, we must move away from romanticizing it. Just as in the area of new construction, there are areas where the existing stock has weaknesses: It is necessary to find technologies and approaches that allow for optimization. There is also a building stock that may not be as "presentable" as the historic city centers from the Gründerzeit. Improvements can address the aesthetic and technical problems that may exist there. (d) While a respectful approach to the (historical) existing building stock is a conditio sine qua non, one should remain open to new technologies and methods for its improvement. In times of digitization, 'assemble to order' custom manufacturing, and high-tech materials, addressing the existing stock can not only help rapidly reduce energy consumption and emissions but can also be used to bring the somewhat outdated construction industry into the present and compensate for economic losses due to reduced new construction activity.

No matter how you look at it: Yes, we have already built enough, even in a growing world, and yes, it is necessary, in the spirit of Karl Polanyi (1944), to initiate a 'Great Transformation': The existing building stock can play a key role in this.

10 DISCLAIMER AND ACKNOWLEDGEMENTS

This article is based on a recently published contribution to a book in German language (Pont 2024) that is the written and extented form of a presentation held in 2022. The research presented in this article is always a co-production with colleagues from the fields of building physics and building ecology at TU Wien, as well as from partner institutions in academia and industry. Notable contributors include Magdalena Wölzl and Matthias Schuss from TU, Peter Schober and his team from Holzforschung Austria, Bernhard Sommer and his team from the University of Applied Arts, as well as numerous companies that have particularly collaborated on projects directly related to structural elements. Without the generous support of the Austrian Research Promotion Agency, the projects on which this article is based could not have been carried out.

1 ABSTRACT

Der menschengemachte Klimawandel führt zu einer Erhöhung der durchschnittlichen Lufttemperaturen. Dies hat insbesondere Auswirkungen auf die dicht besiedelten und versiegelten urbanen Räume durch eine Intensivierung des städtischen Wärmeinseleffektes. Ein wichtiges Instrument zur Anpassung an den Klimawandel und die damit einhergehenden Temperaturveränderungen ist die Entwicklung, Erhaltung und Etablierung innerstädtischer Grünflächen. Zur Bestandsaufnahme und Weiterentwicklung der Grünflächen ist die Schaffung einer Grünflächenkartierung essenziell. Die Heterogenität und diffuse Verteilung von Grünflächen im räumlichen Kontext erschweren eine entsprechende Kartierung jedoch maßgeblich. Vorweg ist es notwendig, den Begriff der Grünflächen zu definieren. Anschließend kann bezugnehmend auf die Herausforderung einer vollständigen Kartierung aller Grünflächen vor Ort untersucht werden, inwiefern solche Flächen mithilfe des Einsatzes einer Künstlichen Intelligenz identifiziert, voneinander abgegrenzt und als lokal klimaaktiv bilanziert werden können.

Die initiale Definition der Grünflächen findet aufgrund der heterogenen Ausstattung und Eigenart der Flächen vorerst auf allgemeiner Ebene statt. Hierfür werden verschiedene fachwissenschaftliche/rechtliche Abgrenzungen hinzugezogen. Sie können darauf aufbauend in Gras- bzw. Strauchflächen, Wasserflächen, große Strauchflächen und vegetationslose Bodenflächen sowie vorhandener Baumbestand klassifiziert werden.

Die Analyse der definierten Grünflächen findet mithilfe eines vortrainierten Deep Learning Modells zur Identifikation der allgemeinen Landbedeckungen statt. Hierfür ist im Rahmen der Anwendung der Künstlichen Intelligenz die Nutzung/der Einsatz sehr hochaufgelöster Luftbilder Grundvoraussetzung für eine ausreichend gute Prognose der Lokalisation von Grünflächen und es sollte so eine Identifikation ebendieser Flächen möglich sein.

Die Anwendung dieses vortrainierten Deep-Learning-Algorithmus kann eine Identifikation der grünen Flächen, basierend auf den allgemeinen Landbedeckungen, leisten. Die besten Werte werden hierbei für innerstädtische Lagen erreicht. Die außerhalb der baulichen Strukturen befindlichen Grünflächen werden jedoch aufgrund ihrer Eigenart oftmals falsch abgegrenzt und als Wasserflächen ausgewiesen, sodass durch das vortrainierte Modell eine Gesamtgenauigkeit von lediglich 46 % erreicht wird. Nach Beurteilung der Ergebnisse soll zur potenziellen Verbesserung des Modells ein Nachtrainieren des Deep Learning Algorithmus stattfinden. Das Nachtrainieren des vortrainierten Deep Learning Modells mittels „Transfer Learning“ führt zu einer allgemeinen Verbesserung der Gesamtgenauigkeit auf 78 %. Dabei besitzt das nachtrainierte Modell einen höheren Detailgrad bei der Beurteilung außerstädtischer Grünflächen – innerstädtische Grünflächen hingegen werden im Vergleich zum vortrainierten Modell schlechter identifiziert. Eine sich daran anschließende Kombination aus der Modellierung des vor- und des nachtrainierten Deep Learning Algorithmus führt schließlich zu einer Gesamtgenauigkeit von 86 %.

Darauf aufbauend wird unter Zuhilfenahme der Kombinationsmodellierung die Klimaaktivität der Grünflächen bestimmt. Diese ist charakterisiert durch die potenzielle Kühlleistung der identifizierten Grünflächen mithilfe der Verschattungsanteile, der Bodenoberflächen sowie der absoluten Flächengröße. Hierbei sind die Grünflächen mit niedriger Klimaaktivität in den stark verdichteten und versiegelten innerstädtischen Lagen vorzufinden. Mit einer Zunahme an unversiegelter Fläche nimmt die absolute Flächengröße und damit einhergehend die Klimaaktivität von anfänglichen Kühlleistungen < 1 K in stark versiegelten Gebieten bis zu > 3 K im unversiegelten Bereich außerhalb der Siedlungsräume zu, welche aufgrund der hohen Kühlkraft zudem auch eine Transferwirkung über die eigentliche Grünfläche hinaus besitzen.

Keywords: Urbane Grünflächen, Stadtklima, Klimaanpassung, Künstliche Intelligenz, Blau-Grüne Infrastruktur

2 EINLEITUNG

Prognostizierte Temperaturveränderungen aufgrund des menschengemachten Klimawandels führen zu einer generellen Zunahme der Lufttemperatur. Urbane Räume sind hierbei durch vorhandene bauphysikalische und raumstrukturelle Eigenschaften besonders betroffen. Dies führt dazu, dass die städtische Überwärmung, überdurchschnittlich – ausgelöst durch den Klimawandel – zunimmt. Aufgrund dessen ist es wichtig, neben den Maßnahmen zur Mitigation des Klimawandels auch Maßnahmen zur Adaption an den Klimawandel vorzunehmen.

Eine zentrale Maßnahme zur Anpassung an den Klimawandel stellt die Etablierung, die Erhaltung und die Optimierung innerstädtischer Grünflächen dar. Grünflächen besitzen verschiedene Eigenschaften, welche dabei behilflich sind, das Stadtklima in stark versiegelten und besiedelten urbanen Räumen zu beeinflussen und zu verbessern (IPCC 2023).

Aufgrund der besonderen Stellung von Grünflächen als Bestandteil der Klimaanpassung in urbanen Räumen ist es essenziell, diese bestmöglich zu kartieren. Eine Kartierung fand in der Vergangenheit überwiegend in persona statt und setzte einen hohen zeitlichen und personellen Aufwand voraus. Für die Schaffung einer nachhaltigen Grünflächenkartierung gilt es deswegen zu untersuchen, inwieweit eine (teil-)automatisierte Identifikation von Grünflächen durch den Einsatz der Künstlichen Intelligenz möglich ist. Neben einer bloßen quantitativen Identifikation der Grünflächen (Wo? und Wieviel?) ist es auch Ziel der Forschungsarbeit zu eruieren, welche qualitativen klimaaktiven Effekte (Wie hoch ist die Kühlleistung der Grünflächen?) die jeweiligen (innerstädtischen) Grünflächen aufweisen und inwiefern diese bilanziert werden können.

3 STAND DER FORSCHUNG

Die Identifikation und anschließende Auswertung von Grünstrukturen als Teil der allgemeinen Landbedeckung findet oftmals durch die Auswertung von Fernerkundungs- und Multispektraldaten statt. Die jeweiligen Oberflächen werden bei diesen Verfahren mithilfe ihrer elektromagnetischen Strahlungseigenschaften identifiziert und klassifiziert. Für eine allgemeine Oberflächenklassifikation stehen hierbei verschiedene Klassifikationsmethoden zur Verfügung, welche grundlagentechnisch sowohl auf der Verwendung eines Trainingsgebietes zur Klassifikation der Oberflächen aufbauen (überwachte Klassifikationsverfahren) als auch solche, welche keine zusätzlichen Informationen zur Klassifikation voraussetzen (unüberwachte Klassifikationsverfahren).

Auswertung und Klassifikation finden grundsätzlich bereits mit Methoden des Maschinellen Lernens als Unterbereich der Künstlichen Intelligenz statt. Hier wird mit statistischen Verfahren wie dem Random Forest Algorithmus oder auch die mit der Häufigkeitsverteilung arbeitende Maximum Likelihood Methode in Verbindung mit Maschinellem Lernen gearbeitet (De Lange, 2020) .

Als Unterbereich des Maschinellen Lernens bietet sich zudem die Verwendung des auf die Muster- und Bilderkennung spezialisierten Teilbereichs des „Tiefen Lernens“ (engl. Deep Learning) für die Identifikation und Klassifikation von Grünflächen an. Hierbei wird auf künstliche neuronale Netze zur Identifikation zurückgegriffen. Grundlagendaten für die Bestimmung der Grünflächen sind dabei oftmals Satellitenbilder mit relativ geringer Auflösung (Albert et al., 2017; Nguyen & Chidthaisong, 2022; Zhao, 2022). Neben der Untersuchung der Grünflächen mithilfe der neuronalen Netze findet eine kleinteiligere Untersuchung unter Hinzunahme von Straßenbildern und dem aus dem Nahinfrarot ableitbaren NormalizedDifference Vegetation Index (NDVI) statt (Sun et al., 2021; Wang et al., 2021).

Hinsichtlich vorhandener Literatur bestehen dementsprechend bereits Ansätze zur Identifikation und Klassifikation von Grünflächen sowohl auf übergeordneter Ebene durch Satellitenbilder in Verbindung mit neuronalen Netzen als auch kleinräumigere Untersuchungen unter Zuhilfenahme von Multispektralbildern. Die Forschungsarbeit soll eine Kombination aus beiden Ansätzen untersuchen und eine kleinteiligere Identifikation der Grünflächen mithilfe künstlicher neuronaler Netze eruieren. Hierbei wird auf schon vorhandene Deep Learning Modelle zur allgemeinen Identifikation von Landbedeckungen zurückgegriffen (ESRI, 2024a).

4 UNTERSUCHUNGSGEGENSTAND

Voraussetzung für die Identifikation von Grünflächen mittels neuronaler Netzwerke ist die Auswahl eines passenden Untersuchungsgebietes. Es bietet sich hier an, aufgrund der Voraussetzungen zur Ausführung des Deep-Learning-Modells, ein Gebiet auszuwählen, welches gute Datengrundlagen für eine anschließende Modellierung frei zur Verfügung stellt. Aufgrund der sehr guten Datenverfügbarkeit und der gesamtstädtischen Lokalisation wurde deswegen die Stadt Jena (Thüringen, Deutschland) als Untersuchungsgebiet ausgewählt.

Für eine erfolgreiche Identifikation von Grünflächen ist es zudem wichtig, diese hinreichend zu definieren. Es handelt sich bei den Grünflächen um Flächen, welche sowohl mit natürlicher als auch mit menschengemachter Vegetation ausgestattet sind (L. Li & Pussella, 2017). Sie decken zudem eine breite Anzahl an Ökosystemleistungen ab (Odini & Mhangara, 2012). Arabi et al. (2014) unterteilen Grünflächen in öffentliche, halböffentliche und private Grünflächen sowie in Straßen(begleit)grün (Arabi et al., 2014). Einen anderen Ansatz zur Definition von Grünflächen wählen Yang et al. (2017). Diese differenzieren Grünflächen in sog. angehängte, Straßen- und Parkgrünflächen, produktive Grün- sowie andere Grünflächen (Yang et al., 2017). Wie diese kurze Auswahl aus der Fachliteratur aufzeigt, werden die jeweiligen Arten von Grünflächen bereits differenziert definiert und unterschiedlich abgegrenzt. Allgemein handelt es sich bei diesen Flächen um sehr heterogene Räume ohne scharfe Abgrenzung. Jede fachwissenschaftliche Disziplin grenzt diese unterschiedlich ab (Harasimowicz, 2018).

Auch bei Betrachtung der Definition von Grünflächen im stadtklimatischen Kontext wird deutlich, dass keine allgemeingültige Definition der Grünfläche besteht. Allgemein werden die Ökosystemleistungen aufgegriffen und mit der Speicherung von Kohlenstoff, der Sicherung des Bodens durch das Verhindern der Versiegelung, das Verbessern der Luftqualität sowie der Speicherung von Wasser in Verbindung gebracht. Die stadtklimatische Definition der Grünfläche ist zudem von der Eigenschaft ebendieser geprägt, dass sie angrenzende sowie umliegende Strukturen durch die Prozesse der Evapotranspiration sowie durch eventuell vorhandene Verschattungseffekte abkühlt (klimaaktive Kühlleistung). Diese Eigenschaft haben sowohl großräumige Flächen als auch Einzelbepflanzungen in verschiedenem Maße inne (Bowler et al., 2010).

Weitergehende Attribute, welche die Klimaaktivität einer Grünfläche beeinflussen, sind die Größe und die Lage der Grünfläche, die Form und die Vitalität der Vegetation, die Verbindung mit Wasserflächen sowie exogene Ursachen (z. B. Straßenorientierung, angrenzende Bebauungsdichte) (Bao et al., 2016; Huang et al., 2008; Jaganmohan et al., 2016; Z. Li et al., 2024; Oliveira et al., 2011).

Aufgrund der Heterogenität der Grünflächen sowie deren unterschiedliche Ausstattung ist eine allgemeine Definitionsfindung schwer. Für die weitere Untersuchung werden daher Bestandteile der verschiedenen Definitionen dahingehend kombiniert, dass relativ klar abzugrenzende Grünstrukturen identifizierbar sind. Außerdem handelt es sich bei den Grünflächen zum Zwecke der Identifikation mit Deep Learning Modellen deshalb grundsätzlich um alle Flächen jeglicher Größe, welche den Klassen Gras- /kleine Strauchflächen, große Strauchflächen,unversiegelte Bodenflächen, Baumbestand sowie Wasserflächen zuzuordnen sind.

5 METHODIK

Die Grundlage der Identifikation der Grünflächen stellt ein vortrainiertes Deep Learning Modell mit ursprünglichen Trainingsdaten aus Nordamerika zur allgemeinen Identifikation von Landbedeckungen in Verbindung mit sehr hochauflösenden Luftbildern dar (ESRI, 2024a). Diese werden in ein geographisches Informationssystem (GIS) eingebunden. Mithilfe des Deep Learning Modells sowie der Datengrundlage kann eine Modellierung der Landbedeckungen des Untersuchungsgebietes stattfinden. Nach Entfernen der Landbedeckungen ohne Grünflächenbezug verbleiben die Grünflächenklassen des Modells, welche den entsprechenden Grünflächen zugewiesen werden können. Es kann daran anschließend eine subjektive sowie objektive Analyse und Abschätzung der Genauigkeit stattfinden. Anschließend wird das bereits vortrainierte Modell unter Anwendung von Transfer Learning im GIS mit zentraleuropäischen (deutschen) Landbedeckungen nachtrainiert. Unter dem Hinzuziehen der Modellierungen findet abschließend eine Untersuchung der Klimaaktivität auf Grundlage der durch das Deep Learning Modell identifizierten Grünflächen unter Rückgriff auf eine abgewandelte Methode von Zardo et al. (2017) statt. Hierbei wird die Kühlleistung der verschiedenen Grünflächen mithilfe sogenannter „coolingpoints“ klassifiziert und baut auf den jeweiligen klimaaktiven Eigenschaften der Grünflächen auf. Dabei behandelte Eigenschaften der

Grünflächen, welche die Kühlleistung beeinflussen, sind der Verschattungseffekt, die potentielle Verdunstungsleistung der Fläche, die Art der Bodenbedeckung sowie die absolute Flächengröße (Zardo et al., 2017).

6 MODELLIERUNG MITHILFE DES VORTRAINIERTEN DEEP LEARNING MODELLS

Die Modellierung der Grünflächen in Abbildung 1 mithilfe des vortrainierten Deep Learning Modells zeigt eine sehr heterogene Durchmischung der Grünflächen im Stadtgebiet Jenas auf. Die Analyse der Prognosen der Modellierung lässt sich schwerpunktmäßig sowohl in den stark versiegelten Siedlungsbereich Jenas als auch in den weniger bis gar nicht versiegelten Bereich außerhalb der Siedlungsräume aufteilen.

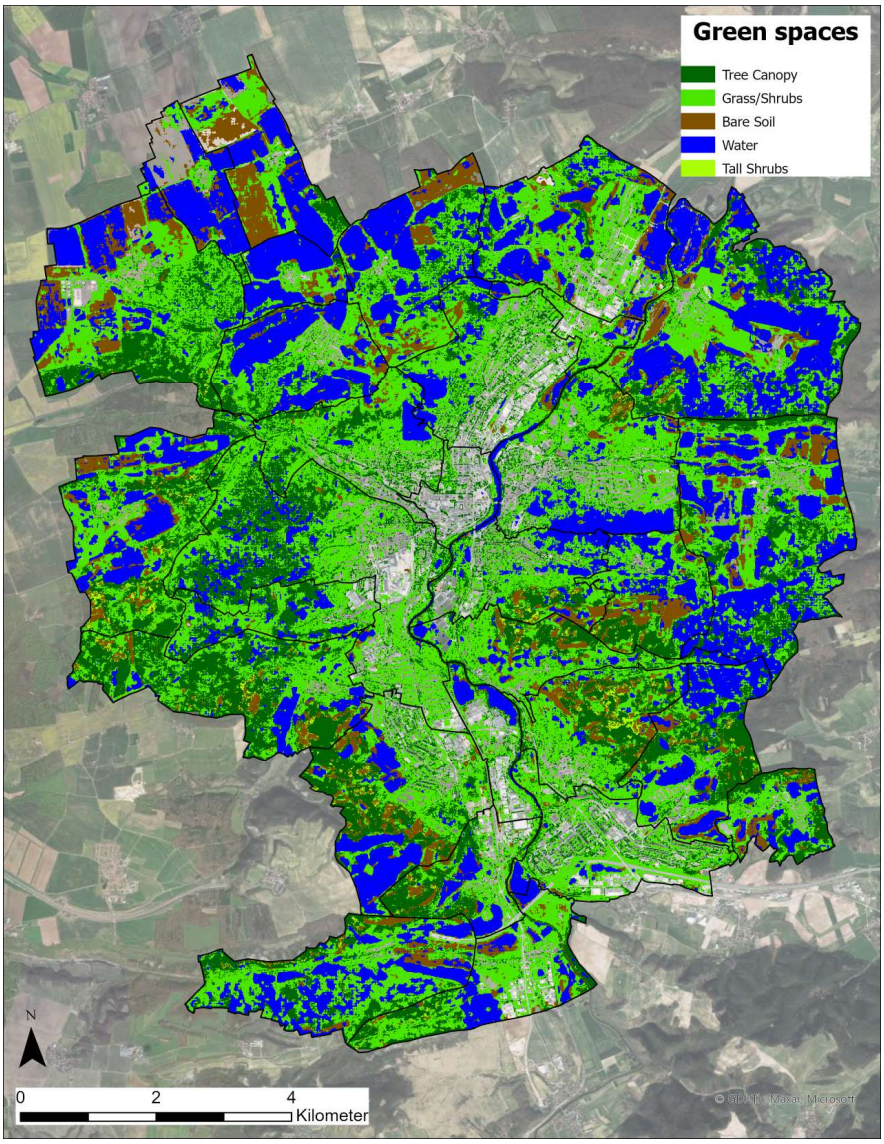

Abb. 1: Modellierung der Grünflächen des Stadtgebietes von Jena mithilfe des vortrainierten Deep Learning Modells (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft und Layer Grünflächen)

Die Untersuchung der peripher gelegenen Bereiche Jenas zeigt eine durchmischte Modellierung von Grünflächen auf. Hervorzuheben ist ein sehr hoher Anteil an (fälschlicherweise) ausgewiesenen Wasserflächen in den Bereichen, bei denen es sich um großflächige heterogene Flächen handelt (z. B. Wälder und Wiesen). Diese werden durch die Modellierung aufgrund ihrer Struktur, ihrer Heterogenität sowie der geringeren Auflösung der verwendeten DOPs als Wasserflächen ausgewiesen.

Bei Betrachtung der Modellierung des innerstädtischen Bereiches wird deutlich, dass es hier im Großen und Ganzen zu einer Ausweisung von Gras- und Strauchflächen sowie von Baumflächen kommt. Wasserflächen werden auch in innerstädtischem Kontext vereinzelt (fälschlicherweise) ausgewiesen, aber es zeigt sich, dass

eine deutlich verbesserte Identifikation der Grünflächen in innerstädtischer Lage im Vergleich zu außerhalb der Siedlungsstrukturen zu verortenden Grünflächen stattfindet.

Insgesamt kommt es bei der Modellierung des vortrainierten Deep Learning Modells zur Identifikation der Grünflächen unter dem Hinzuziehen einer Konfusionsmatrix mithilfe des Vergleiches von Referenzwerten (Ground Truth Werten) zu einer Gesamtgenauigkeit von ca. 46 %.

Zur Verbesserung der Genauigkeit bei der Identifikation und Klassifikation kann das vortrainierte Deep Learning Modell mittels Transfer Learning im GIS mit verhältnismäßig wenig Aufwand nachtrainiert werden (Wallace, 2023). Hierbei wird das vortrainierte Deep Learning Modell mithilfe ausgewählter Trainingsdaten dahingehend nachtrainiert, dass es mit den zur Verfügung stehenden Grundlagendaten (20 x 20 cm Bodenauflösung, zentraleuropäische Vegetation) eine erhöhte Genauigkeit im Vergleich zum ursprünglichen Modell aufweist.

7 MODELLIERUNG MITHILFE DES NACHTRAINIERTEN DEEP LEARNING MODELLS

Die Modellierung des mit Transfer Learning nachtrainierten Deep Learning Modells in Abbildung 2 weist insbesondere bei den außerhalb der Siedlungsräume liegenden Strukturen eine subjektiv deutlich akkuratere Ausweisung von Grünflächen auf.

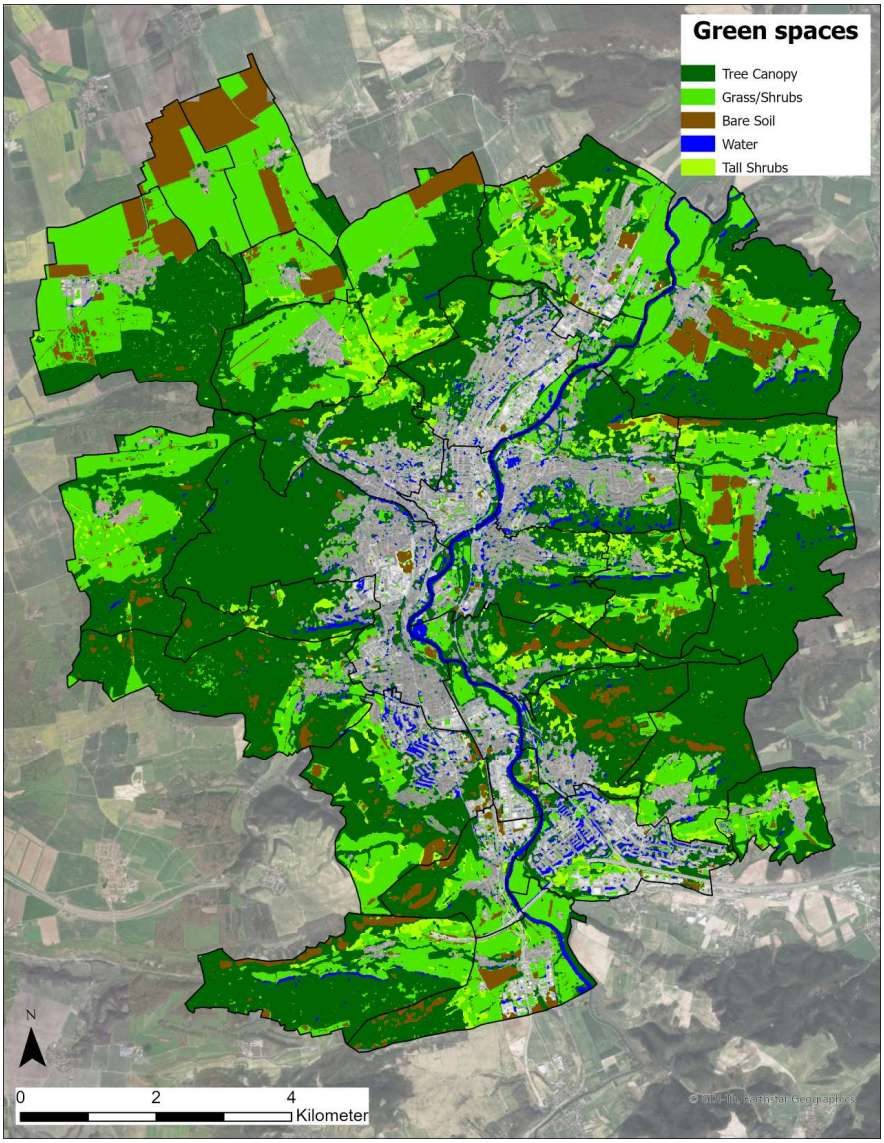

Abb. 2: Modellierung der Grünflächen des Stadtgebietes von Jena mithilfe des nachtrainierten Deep Learning Modells (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft und Layer Grünflächen nachtrainiertes Modell)

Es kommt im Vergleich zu der Modellierung des vortrainierten Modells in den periphereren Gebieten zu einer hauptsächlichen Ausweisung von Gras- und Strauchflächen, Baumflächen sowie Flächen mit großen

Sträuchern. Leider zeigt sich in der nachtrainierten Version aber auch, dass, wenn die Genauigkeit der Identifikation von Grünflächen in den äußeren Gebieten Jenas in subjektiver Betrachtung zugenommen hat, deutlich weniger Grünflächen in innerstädtischer Lage identifiziert werden. Dies ist vermutlich darauf zurückzuführen, dass die Auswahl der Trainingsdaten – insbesondere in innerstädtischer Siedlungsstruktur – aus sehr diversen und heterogenen Strukturen besteht. Dies führt dazu, dass keine eindeutig abzugrenzenden Strukturen entstehen. Infolgedessen wird von dem nachtrainierten Modell ein Großteil der innerstädtischen Grünflächen einer grünflächenfremden Landbedeckung (i. d. R. baulichen Strukturen) zugeordnet.

Allerdings zeigt sich alles in allem, dass die differenzierte Ausweisung von Grünflächen im Vergleich zur vorherigen Untersuchung der vortrainierten Deep Learning Modellierung zu einer Gesamtgenauigkeit des nachtrainierten Modells von ca. 78 % führt. Somit besitzt das nachtrainierte Modell eine deutlich höhere Gesamtgenauigkeit im Vergleich zum vortrainierten Modell – systematische Schwächen bestehen jedoch in der Ausweisung von Grünflächen in innerstädtischer Lage.

8 HYBRIDMODELLIERUNG

Für eine optimierte Ausweisung der Grünflächen sowohl in innerstädtischer als auch in peripherer Lage bietet es sich an, die Grünflächenmodellierung des vortrainierten Modells in innerstädtischer Lage und die Modellierung der Grünflächen des nachtrainierten Modells außerhalb der dicht besiedelten Bereiche zu verschneiden und eine Hybridmodellierung durchzuführen, die die Stärken beider zuvor eingesetzten Modellierungen vereint.

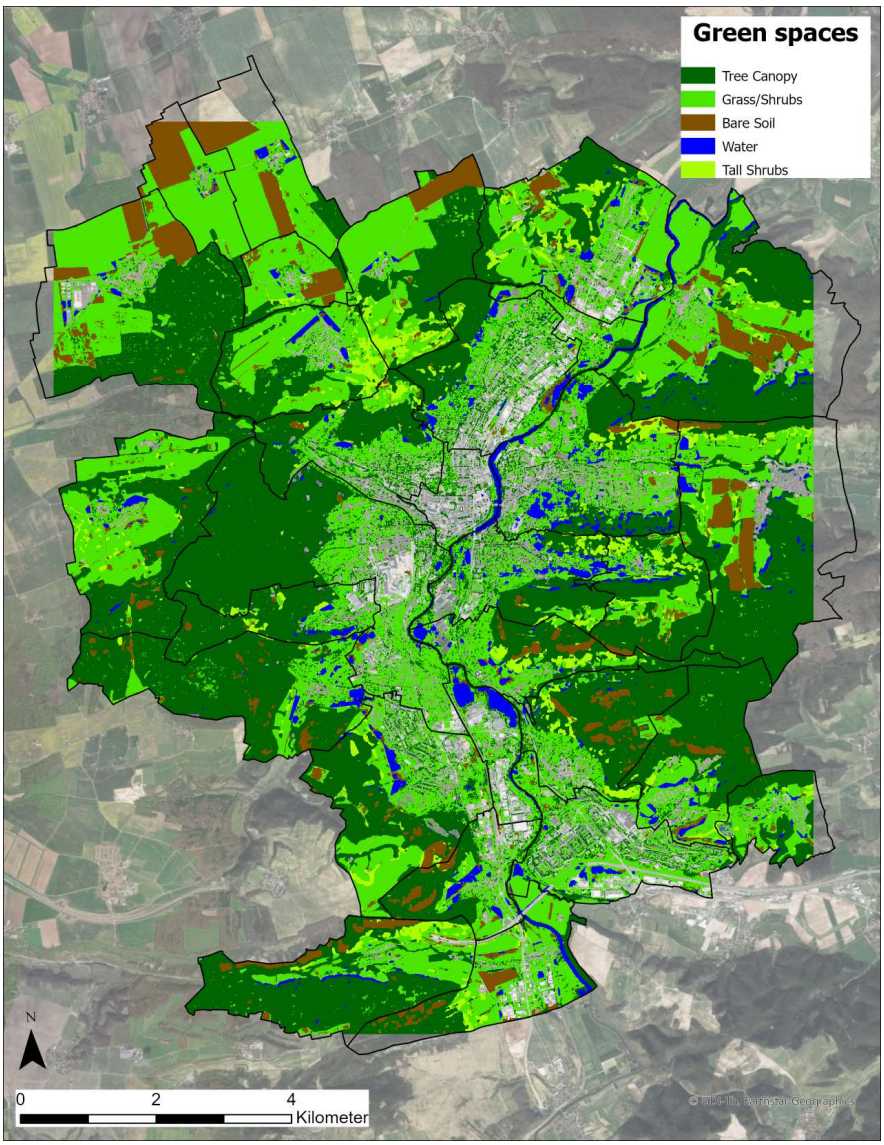

Abb. 3: Hybridmodellierung der Grünflächen des Stadtgebietes von Jena mithilfe der Kombination des vortrainierten sowie des nachtrainierten Deep Learning Modells (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft und Layer Hybridmodellierung Grünflächen)

Die Hybridmodellierung in Abbildung 3 zeigt insgesamt ein deutlich einheitlicheres Bild bei der Identifikation der Grünflächen im gesamten Stadtgebiet auf. Die Grünflächen werden subjektiv sowohl innerhalb als auch außerhalb der Siedlungsräume überwiegend identifiziert und korrekt klassifiziert. Mithilfe der Kombination der beiden ursprünglichen Modellierungen kann mit der Hybridmodellierung eine Gesamtgenauigkeit von ca. 86 Prozent erreicht werden, was als ein mehr als ausreichendes Ergebnis für die initiale Identifikation von Grünflächen bezeichnet werden kann. Auf Grundlage der durch die Hybridmodellierung identifizierten Grünflächen muss anschließend eine grundlegende Bestimmung der Klimaaktivität der zu differenzierenden Flächen erfolgen.

9 KLIMAAKTIVITÄTSBESTIMMUNG

Die Klimaaktivität der Grünflächen kann je nach unmittelbarer Kühlleistung in verschiedene Klassen eingeteilt werden. Es handelt sich hierbei um Grünflächen mit sehr geringer Kühlleistung (< 1 K), Grünflächen mit geringer Kühlleistung (> 1 K < 2 K), Grünflächen mit einer hohen Kühlleistung (> 2 K < 3 K) sowie Grünflächen mit einer sehr hohen Kühlleistung (> 3 K) (Zardo et al., 2017).

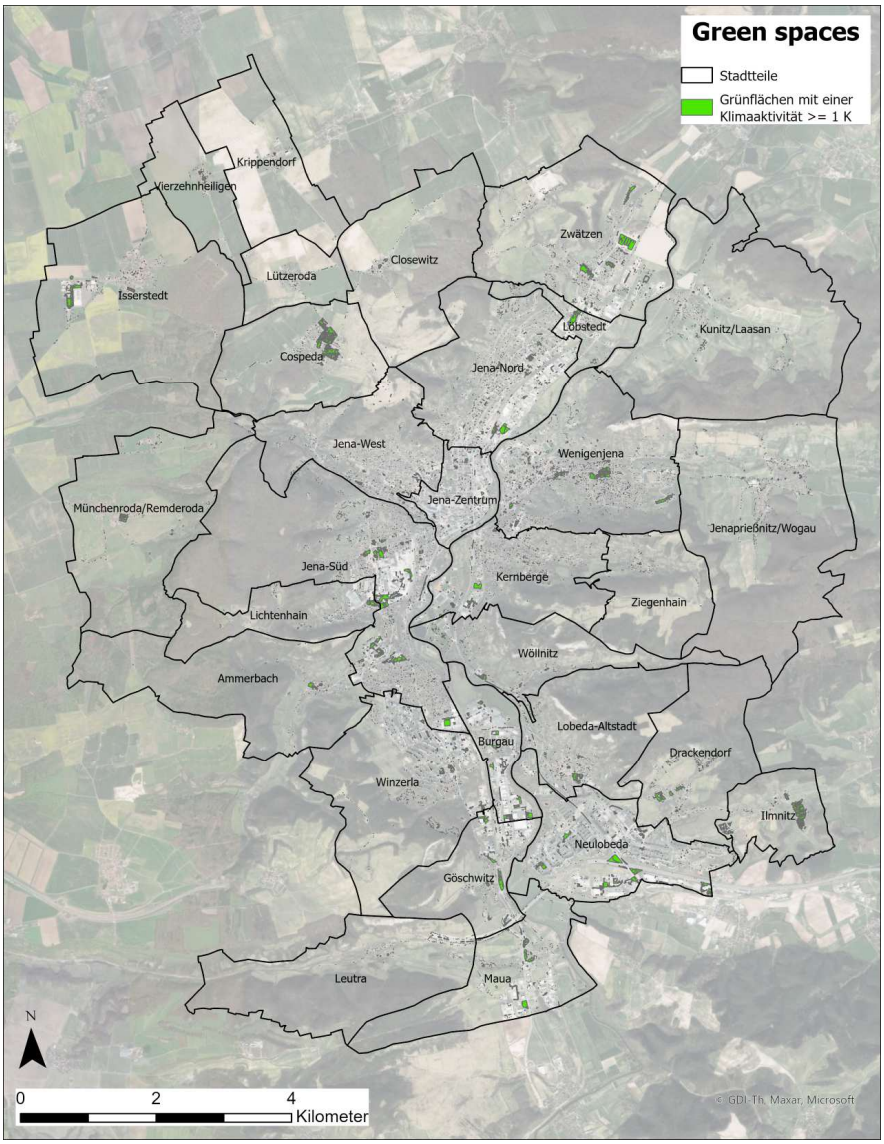

Abb. 4: Klimaaktive Grünflächen mit einer sehr geringen Kühlleistung < 1 K innerhalb des Untersuchungsgebietes von Jena (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft, Stadt Jena, dl-de/by-2-0 (http://www.govdata.de/dl-de/by-2-0), URL: https://opendata.jena.de/dataset/ortsteile und Layer Grünflächen mit einer Klimaaktivität >= 1 K, Stadtteile)

Bei der Betrachtung der klimaaktiven Grünflächen mit einer sehr geringen Kühlleistung in Abbildung 4 wird ersichtlich, dass diese insbesondere in den dicht versiegelten Bereichen im Stadtgebiet von Jena vorzufinden sind. Es handelt sich bei diesen Flächen mit sehr geringer Klimaaktivität um Bereiche mit einer absoluten Flächengröße < 2 ha sowie einem anteilsweise geringen Baumbestand. Flächen, welche dieser

Klimaaktivitätsklasse zugeordnet werden können, sind kleine zusammenhängende Gartenstrukturen, kleinere Abschnitte von Straßenbegleitgrün sowie einzelne Grasflächen.

Die darauffolgende Klasse hinsichtlich der Klimaaktivität aufgrund ihrer abrufbaren Kühlleistung definiert sich durch eine absolute Flächengröße < 2 ha, allerdings mit einem deutlich höheren prozentualen Baumbestand innerhalb der Fläche im Vergleich zur vorherigen mit sehr geringer Klimaaktivität.

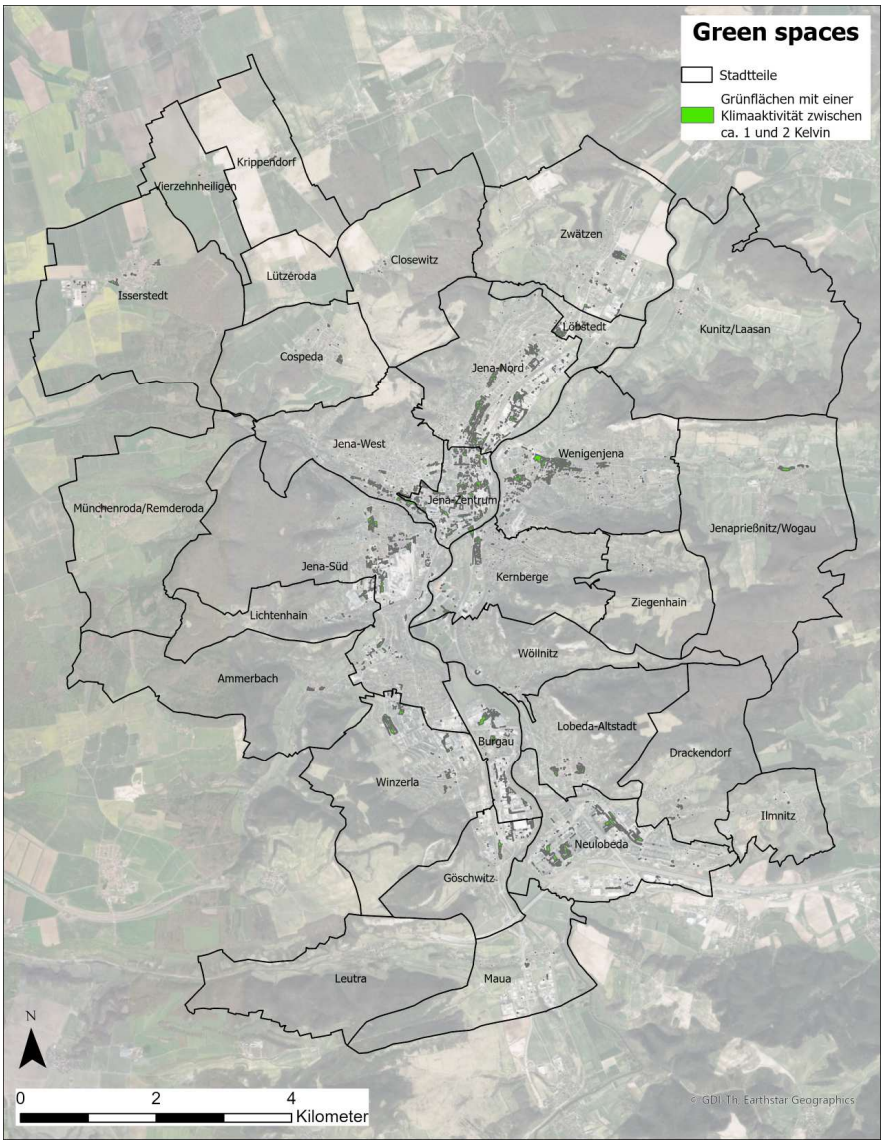

Abb. 5: Klimaaktive Grünflächen mit einer geringen Kühlleistung (> 1 K < 2 K) innerhalb des Untersuchungsgebietes von Jena (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft, Stadt Jena, dl-de/by-2-0 (http://www.govdata.de/dl-de/by-2-0), URL: https://opendata.jena.de/dataset/ortsteile und Layer Grünflächen mit einer Klimaaktivität zwischen ca. 1 und 2 Kelvin, Stadtteile)

In Abbildung 5 wird deutlich, dass Grünflächen mit einer geringen Klimaaktivität subjektiv aufgrund ihres höheren Baumanteils an der absoluten Flächengröße tendenziell größere Bereiche einnehmen, als dies bei den Grünflächen mit einer sehr geringen Klimaaktivität der Fall war. Sie sind noch immer in den dicht besiedelten und versiegelten Räumen vorzufinden, haben sich jedoch hinsichtlich ihrer räumlichen Verteilung in Richtung der Kernstadt (insbesondere Jena-Zentrum sowie Jena-Nord) verschoben. Aufgrund ihrer Standorte und ihren zuordenbaren Eigenschaften handelt es sich bei diesen Flächen beispielhaft um bepflanzte Innenhöfe von Blockbauten, Straßenalleen sowie kleineren Stadtparks. Daher lässt sich insgesamt festhalten, dass die Grünflächen mit sehr geringer und geringer Klimaaktivität überwiegend in den Siedlungsräumen vorzufinden sind. Sie tragen zur Kühlung der unmittelbaren Umgebung nur in geringem Maße bei und stellen einen untergeordneten Teil des Siedlungsraumes dar.

Die Flächen mit einer hohen und sehr hohen Klimaaktivität mit Kühlleistungen von > 3 K werden mithilfe des Deep Learning Algorithmus grundsätzlich den außerhalb der Siedlungsräume liegenden Grünflächen zugewiesen (Gesamtstadt Jena exkl. Jena-Zentrum, Jena-Nord, Jena-Süd sowie Wenigenjena).

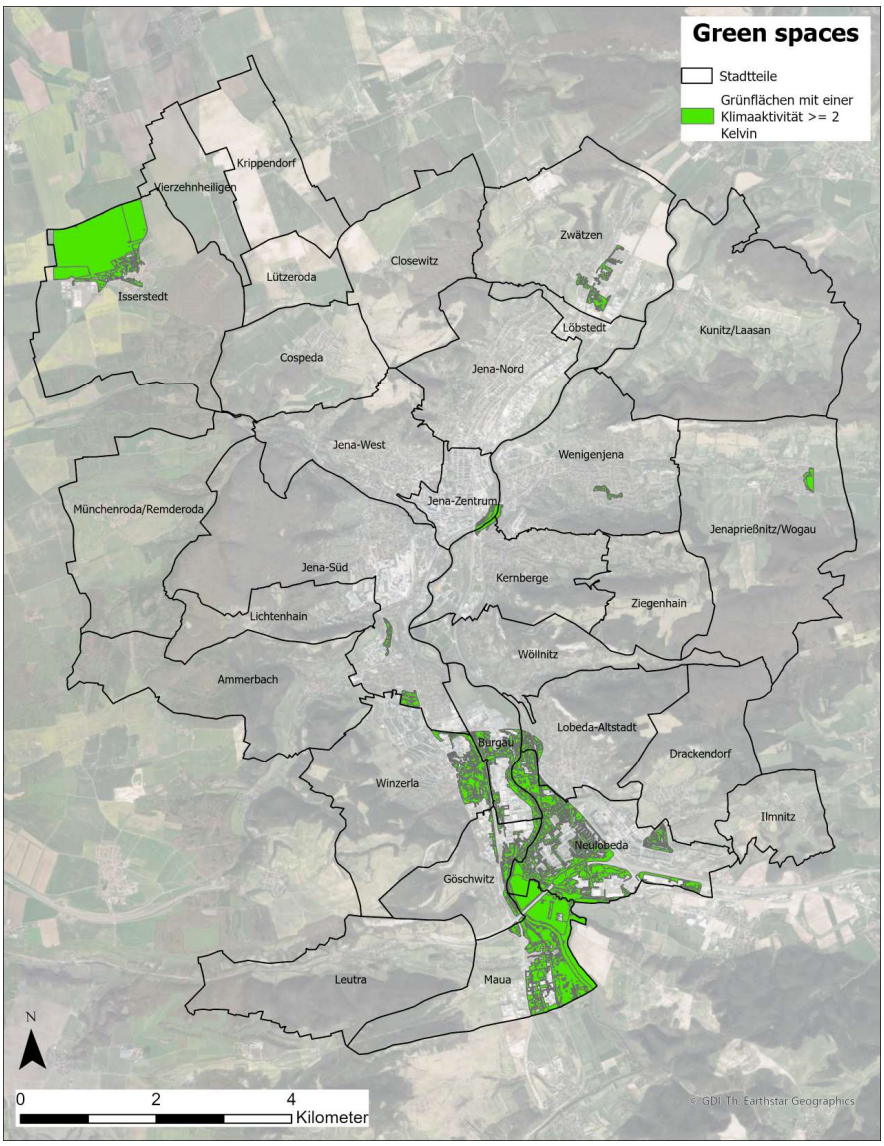

Abb. 6: Klimaaktive Grünflächen mit einer hohen Kühlleistung > 2 K < 3 K innerhalb des Untersuchungsgebietes von Jena (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, Maxar,EarthstarGeographics, Microsoft, Stadt Jena, dl-de/by-2-0 (http://www.govdata.de/dl-de/by-2-0), URL: https://opendata.jena.de/dataset/ortsteile und Layer Grünflächen mit einer Klimaaktivität >= 2 Kelvin, Stadtteile)

So ist in den Abbildungen 6 und 7 erkennbar, dass die Grünflächen mit einer hohen sowie sehr hohen Klimaaktivität größtenteils außerhalb der Siedlungsbereiche liegen. Diese sind in ihrer absoluten Fläche größer als zwei Hektar und besitzen einen anteiligen Baumbestand zwischen 0 und 40 % (Flächen mit einer hohen Kühlleistung) respektive über 40 % an der Gesamtfläche (Flächen mit einer sehr hohen Kühlleistung).

Die außerhalb der Siedlungsräume liegenden Grünflächen ziehen sich durch Grünverbindungen bis in den Siedlungskern hinein. So ist es möglich, dass Flächen, welche ursprünglich keine bzw. eine deutlich geringere Kühlleistung aufweisen, durch die Verbindung mit anderen Grünflächen, in Summe eine höhere Kühlleistung abrufen können.

Bei den Flächen mit sehr hoher Klimaaktivität, welche in Abbildung 7 zu erkennen sind, handelt es sich um sehr große, außerhalb der Siedlungsräume zu lokalisierende Grünräume in Form von Wiesen, Feldern und Wäldern – aber auch große innerstädtische Grünräume wie Stadtparks.

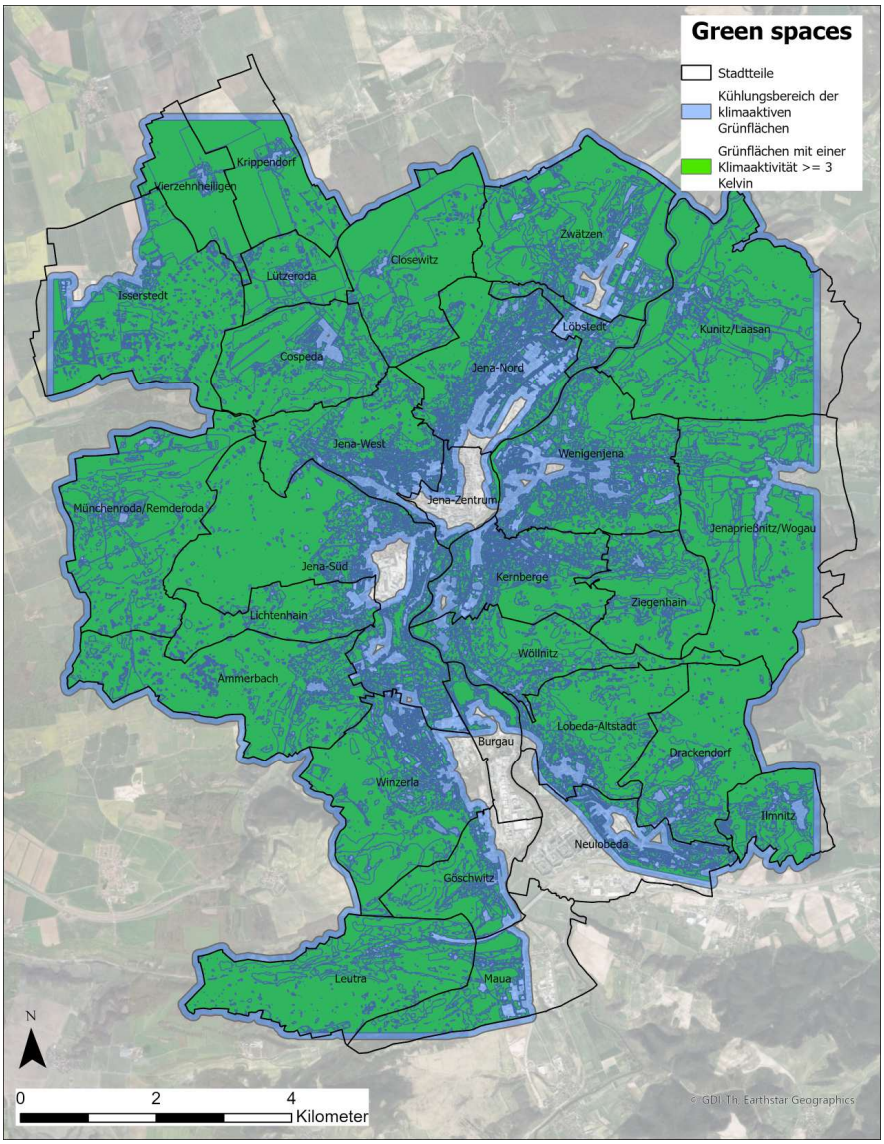

Abb. 7: Klimaaktive Grünflächen mit einer sehr hohen Kühlleistung > 3 K sowie einer Transferkühlleistung von 100 Metern über die eigentliche Grünfläche hinweg, innerhalb des Untersuchungsgebietes von Jena (Eigene Darstellung in ArcGIS Pro in Verbindung mit den Deep Learning Libraries (Version 3.3), Datengrundlage: © GDI-Th, Esri, EarthstarGeographics, Maxar, Microsoft, Stadt Jena, dl-de/by-2-0 (http://www.govdata.de/dl-de/by-2-0), URL: https://opendata.jena.de/dataset/ortsteile und Layer Kühlungsbereich der klimaaktiven Grünflächen, Grünflächen mit einer Klimaaktivität >= 3 Kelvin, Stadtteile)

Es handelt sich bei den Flächen mit sehr hoher Klimaaktivität um Bereiche, die eine unmittelbare Kühlleistung auf ihre nähere Umgebung aufweisen, aber auch Transferkühlleistungen erbringen. So kommt es zu Transferkühlleistungen von ca. 110 Metern um großangelegte Parks. Die unmittelbaren Kühlleistungen von Grünräumen mit einem hohen Anteil an Bäumen, wie beispielsweise Wälder, weisen Transferkühlleistungen von ca. 190 Metern auf. Unter Berücksichtigung der siedlungsstrukturellen Besonderheiten wie beispielsweise der Blockade der unmittelbaren Kaltluft wird hier mit einer Kühltransferleistung von 100 Metern in Form eines Puffers um die klimaaktiven Grünflächen gearbeitet (Jaganmohan et al., 2016; Syrbe et al., 2024).

10 AUSBLICK UND HERAUSFORDERUNGEN

Insgesamt kommt es zu einigen Herausforderungen bei der Modellierung von Grünflächen sowie deren Klimaaktivität. Sie liegen in der Schwierigkeit bei der Definition einer allgemeinen Abgrenzung für eine solche Fläche, in der generellen Arbeit mit Künstlicher Intelligenz im Allgemeinen und Deep Learning Modellen im Speziellen sowie den damit verbundenen Grundlagendaten für die Berechnung der Modellierung bzw. deren Verfügbarkeit.

Wie bereits erwähnt, handelt es sich bei der Begrifflichkeit der Grünfläche keinesfalls um eine allgemeingültige sowie universal anerkannte. Je nach Situation, Ziel sowie anderen Rahmenbedingungen

wird diese subjektiv definiert. Dies macht es schwierig, die „eine“ Grünflächendefinition zu finden. Für die Identifikation dieser Räume mithilfe des Instrumentes der Künstlichen Intelligenz wird mittels einer Kombination aus verschiedenen Abgrenzungen für Grünflächen eine subjektiv definierte Begrifflichkeit für die weiteren Untersuchungen formuliert.

Eine weitergehende Herausforderung besteht in der Abhängigkeit bei der Auswahl des Deep Learning Modells und den damit verbundenen ursprünglichen Trainingsdaten bzw. dem ursprünglichen Trainingsgebiet. Im konkreten Fall handelt es sich um einen Algorithmus, der mithilfe sehr hochauflösender (10 x 10 cm Bodenauflösung) Luftbilder aus dem nordamerikanischen Raum initial trainiert wurde. Er funktioniert dementsprechend mit diesen Inputdaten am besten. Wird nun ein mitteleuropäischer Raum mit den frei zur Verfügung stehenden Luftbildern mit einer sehr hohen Auflösung (20 x 20 cm Bodenauflösung) durch den Algorithmus modelliert, kommt es aufgrund verschiedener geometrischer Auflösung, Landbedeckungsarten bzw. unterschiedlicher Vegetation auch zu differenzierten Prognosen, mit – im Endeffekt – einer Verschlechterung der Ergebnisse.

Für die bestmögliche Modellierung der Grünflächen ist es demnach nötig, so nah wie möglich an die für das ursprüngliche Training verwendete Daten hinsichtlich ihrer Eigenschaften (z. B. Auflösung, Landbedeckungs-/Grünflächenarten, etc.) zu gelangen. Es besteht dementsprechend eine Abhängigkeit in Bezug auf die Grundlagendaten.

Ebenso ist die korrekte Identifikation bodennaher Grünflächen mit Fernerkundungsdaten in Verbindung mit der Identifikation von ebendieser mithilfe Künstlicher Intelligenz eine weitere Herausforderung. Dies wird insbesondere dann zum Problem, wenn Landbedeckungen verschiedener vertikaler Ausdehnung übereinanderliegen und hierdurch durch das Luftbild nicht ausreichend dargestellt werden. Eine korrekte Bilanzierung der Grünflächen wird somit deutlich erschwert. Abhilfe geschaffen werden kann hier mit der Anwendung von Interpolation.

Insgesamt lässt sich feststellen, dass eine grundsätzliche Identifikation von Grünflächen mithilfe Künstlicher Intelligenz möglich ist. Differenziert werden muss dahingehend – aufgrund der unterschiedlichen Eigenschaften – zwischen dem Siedlungsraum und dem unbesiedelten bzw. weniger dicht besiedelten (oftmals peripheren) Raum. Aufbauend auf der Identifikation der Grünflächen ist es zudem initial möglich, eine Bestimmung der Klimaaktivität, definiert durch die abrufbaren Kühlleistungen der Grünflächen, vorzunehmen. Die Identifikation (klimaaktiver) Grünflächen unter der Zuhilfenahme von Künstlicher Intelligenz stellt dahingehend ein Instrument mit sehr hohem Potenzial dar, welches für eine Kartierung sowie Optimierung der Grünflächen innerhalb des Bestandes genutzt werden kann.

1 ABSTRACT

The "World Social Report 2023: Leaving no one behind in an ageing world" by the United Nations describes the ageing of the world's population as an irreversible global trend. This trend is particularly significant in Japan. Here, the ageing processes have progressed much further than in other countries, also driven by two age cohorts with particularly high birth rates, known as the baby boom, followed by decades of a baby bust (Nennstiel 2011; Reher 2015). This has fundamental social and spatial implications (Pauly and Pallagst forthcoming).

Digitalization processes are being strongly promoted in Japan. As part of the Japanese government's Society 5.0 program, all areas of life are to be digitalized as an approach to overcome social challenges. Cyberspace and physical space are to be merged (Hitachi-UTokyo Laboratory 2018; Pallagst et al. 2024).

This raises the question of how the Japanese approach to digitalization actually addresses the social and spatial challenges posed by ageing processes. At national level, the PLATEAU project must be mentioned in this context, in which the Japanese government is developing a national digital twin in which around 500 cities are being modeled (Seto et al. 2023, MLIT n.d.) as well as a national big data analysis tool for strategic benchmarking purposes (Matsuura 2020). On the local and regional level, on the other hand, there is a focus on the development of platforms that create a digital space designed to overcome barriers caused by physical limitations and social isolation. Metaverse environments of communities with use cases like avatar cafés, for example, are emerging. (Pauly and Pallagst forthcoming).

The mentioned digital approaches at different levels in Japan are discussed in this contribution and linked to ageing-related challenges that were derived as part of the research project "Ageing Smart – Designing Spaces Intelligently". Interviews with experts and stakeholders on site in Japan in 2024 provided important insights in this regard.

Keywords: Digitalization in Spatial Planning, Social and Spatial Challenges, Ageing Society in Japan, Digital Twin, Metaverse

2 INTRODUCTION

In Japan, there is a strong affinity for new digital technologies. The Japanese national government often plays a key role in technology development, creating strategic plans and funding their implementation with significant financial resources. One example of this is the Society 5.0 vision in the "Science and Technology Basic Plan" y the Japanese government. Through this funding program, digital innovations are being developed to address social and societal challenges (Hitachi-UTokyo Laboratory 2018; Pallagst et al. 2024).

A major example of social and societal challenges is population ageing. It is by no means a phenomenon that is limited to a few regions in the world. Rather, it is a global trend that emerged in the middle of the twentieth century and is considered irreversible (United Nations 2023a, p. 18). In 2022, 9.7% of the world's population were 65years oldor older, and 16.4% are projected for 2050 (United Nations 2023b, p. 8). More developed countries have generally been confronted with the ageing process for many decades, while for many less developed countries it is a new phenomenon and they are still in transition (United Nations 2023a, p. 18). The ageing of the population and resulting population decline are the crucial characteristics of demographic change. It is a trend that has not lost its relevance, but on the contrary, is becoming increasingly important. Demographic change is a topic that has global effects and requires in-depth investigations and an international search for solution strategies.

Ageing populations sometimes lead to drastic problems that pose significant challenges for countries and their municipalities. An ageing society has very specific demands on services and infrastructure, which must

therefore be adapted. While there is an increasing demand for personnel in the healthcare and elderly care sectors, the number of people in the working age population simultaneously decreases (OECD 2019, p. 19; Swiaczny et al. 2008, p. 200; Yu and Lee 2017, pp. 442-444). The phenomenon of social isolation is increasingly spreading in society, and more spaces with homogeneous age structures and 'ghost towns' are emerging (Interview with Dimmer 2024).

However, social and spatial issues arising from ageing are influenced by various factors. They do not solely result from population development but also from path dependencies that differ depending on the country's context. Cultural and governance-structural issues can play a role, among others. Therefore, it is necessary to consider ageing problems and potential approaches for solutions within a specific country context.

As part of the research project "Ageing Smart – Designing Spaces Intelligently", the ageing processes in three countries – the USA, Finland and Japan – were compared with each other. Japan was identified as an extreme example where population ageing is particularly advanced (Pauly and Pallagst forthcoming). This finding is taken up in this article and used as an opportunity to take a more focused look at ageing in Japan and the resulting problems and approaches to solutions at various levels.

The aim is to look beyond the German context in which the research project is situated. Japan represents an extreme example in this regard. Age-related problems have been particularly pronounced here for at least two decades and have a significant impact on civil society. Studying a country where demographic change has been recognized as particularly advanced for a longer period offers distinct advantages for the research and learning opportunities. The investigation makes it possible to identify solution strategies that could also be applicable to other contexts around the world. The findings can provide valuable information for countries and municipalities that are increasingly confronted with demographic challenges and are looking for strategies to address them.

This contribution first examines indicators that describe the ageing processes in Japan. For this purpose, population data is used and analyzed. Then, the social and spatial challenges Japan faces due to its demographic developments are described. Building on this, the digital solution strategies Japan is implementing to address these challenges are explored. For the investigation of the social and spatial implications as well as possible digital solution strategies, guided interviews were conducted on-site in Japan. These interviews involved experts from the academic field in Japan, as well as stakeholders from public administration. On the academic side, interviews were conducted with a researcher from Waseda University in Tokyo and with representatives from the German Institute for Japanese Studies. On the administrative side, interviews took place with officials from the Tokyo Metropolitan Government and the city administration of Takamatsu. Additionally, on-site walks were conducted in Tokyo and Takamatsu.

3 POPULATION AGEING IN JAPAN

As part of an international comparison, Pauly and Pallagst (forthcoming) have carried out an analysis of population data that is suitable for describing ageing processes in a country. This analysis is taken up and summarized here for the specific case of Japan.

The ageing of a population is strongly linked to the number of births in that population. If the number of births declines, the proportion of older people in the population slowly increases over time. The crude birth rate is the ratio of the number of births to the total population and thus provides information about the fertility of a society. However, these factors are closely linked to mortality, for example indicated by the number of deaths in each period.Inward and outward migration also influences the structure of the population and thus ageing processes.Another influencing factor is life expectancy. If life expectancy increases, this means that the people in society tend to get older. Such a trend alone would already lead to ageing. In combination with falling birth rates, this is an aggravating factor. Looking at the composition of the population by age or age group reveals how large the proportions of people of certain ages are. If the development is observed over several decades, trends in the population composition can be identified. Finally, the factor of the proportion of people aged 65 and over indicates how large the proportion of the older population actually is.

In terms of population development, it can be observed that Japan experienced strong population growth in the twentieth century. Since the end of the 1970s, this growth has continued to slow down. In 2009, the

population peaked at just over 128 million inhabitants. Since then, negative population growth has been observed. By 2021, the population had shrunk by almost 3% to less than 125 million inhabitants.

Fig. 1 shows a comparison of the population trend with the trend in live births and deaths. It illustrates that live births have fallen almost every year since the 1970s. At the same time, the number of deaths has been steadily increasing since the 1980s. In 2005, the number of deaths exceeded the number of live births for the first time. This trend has continued up to the latest available data and can explain the population development with initially weaker growth from the 1970s until the peak was reached in 2008 and the subsequent population shrinkage. What is striking about net migration is that it has alternated between a positive and a negative migration balance over the course of history, without appearing to have a significant influence on population development. Since 1988, net migration has always been above zero, meaning that there is more immigration than emigration in Japan. Net migration reached its highest level in 2019. Nevertheless, it should be noted that the positive migration balance is not able to compensate for the population decline caused by the negative natural population balance.

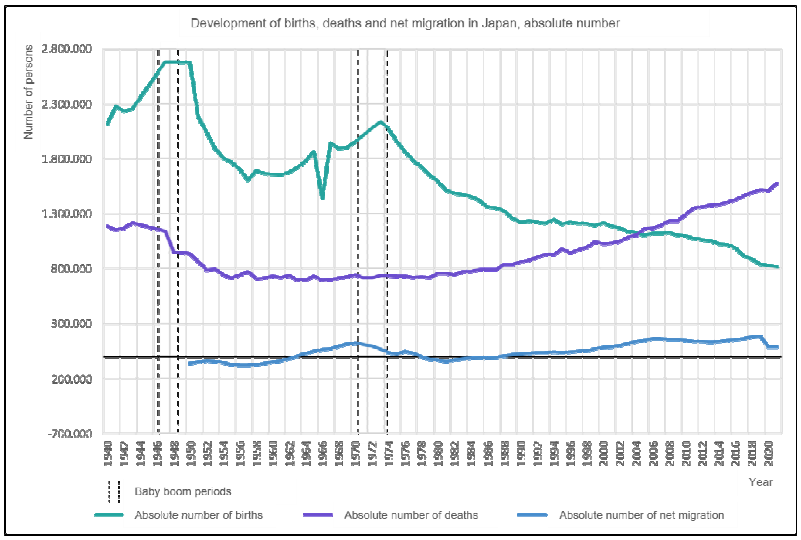

Fig. 1: Development of Births, Deaths and Net Migration in Japan, Own Representation, Data: United Nations, Department of Economic and Social Affairs, Population Division 2024, National Institute of Population and Social Security Research n.d., Statistics Dashboard, Statistics Bureau, Ministry of Internal Affairs and Communications n.d.

Even in the first half of the 20th century, the number of live births was already at a high level. After the Spanish flu, then concerns about the social consequences of overpopulation and the prospect of war caused a decline in births in the previous decades, social policy in the late 1930s and early 1940s led to marriage and childbearing being strategically promoted in the context of military conflicts, resulting in an increase in births (Nennstiel 2011, p. 334). The effects of the Second World War also caused the birth rate to fall in 194 and 1946. Very quickly after the end of the Second World War, however, the number of births rose again, leading to a first baby boom from 1947 to 1949. Remigrants from former overseas territories and war returnees were factors influencing this development (Nennstiel 2011, p. 335). A subsequent renewed decline in births can be explained by eugenics policy and the associated reduction in legal barriers to abortions (Nennstiel 2011, p. 336). In 1966, the graph shows a strikingly sharp decline in live births. This can be explained by the myth about the Year of the Fire Horse, which recurs every 60 years and states that people born in these years are considered to be particularly aggressive (Nennstiel 2011, p. 330). The second baby boom in Japan took place between 1971 and 1974, with a direct connection to the first baby boom generation, as the people who were born during the first baby boom became parents themselves in the early 1970s (Nennstiel 2011, p. 339).

The decline in births in the following decades up to the present cannot be unambiguously explained. Influencing factors discussed include the increased employment of women, but also a decreasing tendency to marry and start a family due to the risk of social demotion against the background that the income of a male single earner is no longer sufficient for the living costs of a family (Schad-Seifert 2006, p. 34-35).

It can be stated that the baby boom in Japan has a statistically detectable effect. There is the peculiarity that two different cohorts are associated with the baby boom:

- 1st baby boom 1947 to 1949
- 2nd baby boom 1971 to 1974

The crude birth rate, which indicates how many live births there were per 1000 inhabitants within a survey year, can be used to make a statement about fertility. If the crude birth rate falls in the sense of a long-term trend, this inevitably means that the population is getting older, as the age group distribution is changing. In theory, this effect could only be compensated by particularly strong and young migration and/or the occurrence of particularly young mortality with falling life expectancy, but this is unlikely to occur in practice.

For Japan it can be observed that the crude birth rate is falling rapidly, which indicates a significant ageing of the population. While the birth rate was particularly high at the beginning of the period under review in 1950 with over 28 births per 1,000 inhabitants, it was extremely low in 2021 with less than 7 births per 1,000 inhabitants. The high birth rates of the 1940s and 1950s are due in particular to the first baby boom. After the subsequent fall in the birth rate, however, the trend is initially positive again, culminating in a second baby boom from 1971 to 1974. This is followed by another negative trend, which continues to the present.

Life expectancy is another factor in connection with the ageing process of a population. If life expectancy were stable in its development, a falling birth rate alone would cause the proportion of older people in a population to rise, ignoring migration effects. This makes it clear that life expectancy, which in reality is not stable but actually increasing, is an additional driver for ageing.

In Japan life expectancy has risen sharply. In 1950, it was just over 59 years, whereas in 2021 it was almost 85 years. This clearly shows that rising life expectancy is continuing to push the ageing population forward.

In order to better illustrate the characteristics of ageing processes in Japan, fig. 2 analyzes the population according to age groups and the statistically surveyed genders male and female. Four points in time were selected with an interval of 20 years. The observation period was chosen so that the population distribution is shown over several generations.

In Japan, the baby boom of the years 1947 to 1949 is very clearly visible in 1960. This is illustrated in the age groups 10-14 and 15-20, which represent the largest groups in the population in 1960. It is noticeable how small the population proportions of the older age groups are. This makes it clear that the population in Japan was very young at this time.

Twenty years later, in 1980, the baby boom cohorts are still visible as particularly large age groups of 30-34- and 35–40-year-olds. It is also clear that there were fewer births in the following years. However, the second Japanese baby boom of 1971-1974 can now be seen in the 5-9 and 10-14 age groups. Both baby booms are now clearly visible and form the two largest population cohorts in Japan.

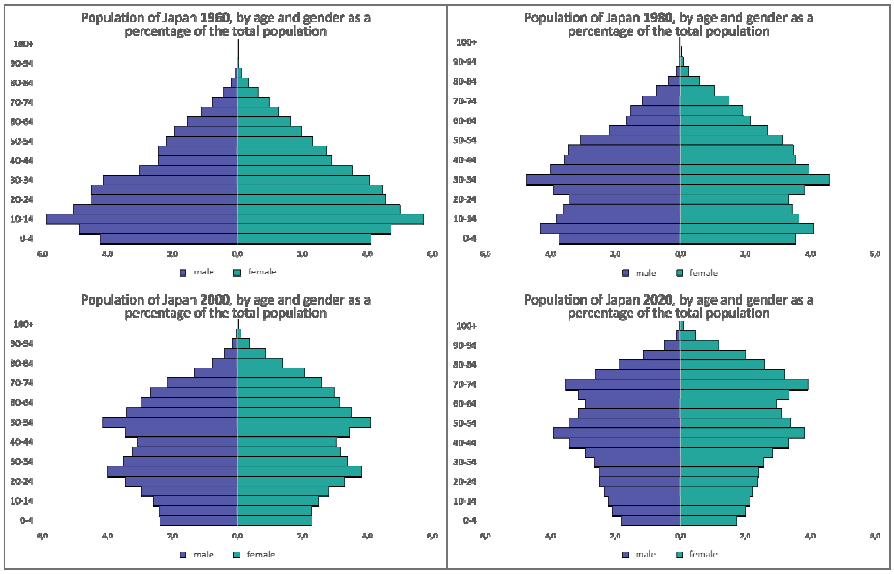

Fig. 2:Population Development in Japan by Age and Gender, Own Representation, Data: United Nations, Department of Economic and Social Affairs, Population Division 2024.

This is still the case in the year 2000. It can be seen that the cohorts of the two baby booms are now each 20 years older. In the cohorts after the second baby boom, there are now significantly fewer births and the percentage of young age groups in the total population is shrinking considerably. Ageing has therefore already visibly set in at this point.

In 2020, it can be observed that thetwo boom generations have become another 20 years older. The cohorts of the first baby boom in the 70-74 and 75-80 age groups are still very much in evidence. The same applies to the cohorts of the second baby boom in the 40-44 and 45-50 age groups. The older population groups dominate the younger generations with their percentage of the population. The population share of the younger age groups has decreased once again.

Overall, the composition of the population in 2020 is completely the opposite of that in 1960. The population has aged considerably and will continue to age in the coming years.

In addition to population development by age and gender, the group of 65-year-olds and older as a proportion of the total population can also be used as an ageing indicator. The same observation years were used for this purpose.

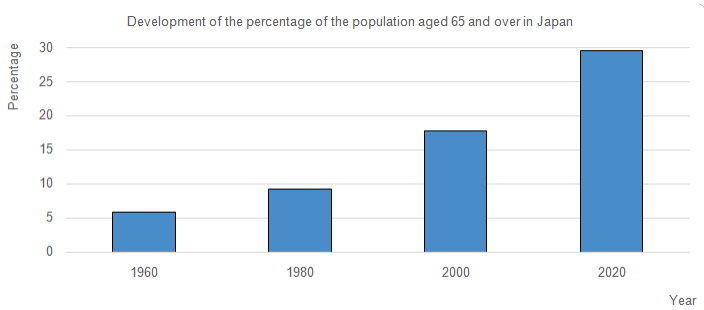

Fig. 3:Development of the proportion of people aged 65 and over, Own Representation, Data: United Nations, Department of Economic and Social Affairs, Population Division 2024

It is evident that the population trends mean that the proportion of people aged 65 and over is continuing to rise and was already almost 30% in 2020. Furthermore, the increase is to be classified as very extreme and proves that the issue of ageing is not new to Japan. An international comparison also shows that Japan is an extreme case. If you compare the indicator of the proportion of people aged 65 and over Japan certainly stands out.

SDGRegion	2022 (percentage)	2050 (percentage)
Worldwide	*9,7*	*16,4*
Sub-Saharan Africa	3,0	4,7
North Africa and West Asia	5,5	12,5
Central and South Asia	6,4	13,4
East and Southeast Asia	12,7	25,7
Latin America and the Caribbean	9,1	18,8
Australia/New Zealand	16,6	23,7
Oceania	3,9	8,2
Europe and North America	18,7	26,9

Table. 1:Proportion of people aged 65 and over in a global comparison in the year 2022, Own Representation based on United Nations (2023b, p. 8)

Japan is assigned to the East and Southeast Asia SDG region. This is one of the regions in which ageing is currently strongest and where, in view of projected future trends, a very sharp increase inthe ageing process is to be expected.Japan, where the proportion of people aged 65 and over was almost 30% in 2020, is an extreme example not only internationally but also within the region, which is also strongly characterized by ageing.

Looking at the population data, it is clear that Japan is affected by ageing to an extreme degree. The country was also affected by the resulting challenges earlier than other countries. At the same time, it is foreseeable that the trend will continue, and the population will become even older. This situation is not expected to change until the people born during the second baby boom have passed away. How birth rates will develop between now and then, however, remains an unknown factor. It is therefore difficult to predict the future population development.

4 SOCIAL AND SPATIAL IMPLICATIONS

Ageing processes in society bring with them various social and spatial challenges. From an economic perspective, the value produced by both the very young and the elderly is lower than their consumption. Between these age groups, however, people produce more added value than they consume (United Nations 2023a, p. 50). If this principle is applied to a society's public system and the related public services, this means that children, young people and older people receive education, health services, social security, pensions, elderlycare, etc. from the proportion of society that is of working age. This working generation, at the time, consumes less of the public services. As a society ages, these age groups shift. On the one hand, this can lead to many more people using the existing services of the public system than before and, on the other hand, to a reduction in the group of people who support the public system (United Nations 2023a, p. 50).

It can be concluded from this that ageing processes demand the adaptation of public services. The associated public infrastructure must be adapted to new conditions too – both quantitatively and in terms of new needs. At the same time, it is becoming difficult to provide public services and infrastructure economically, both financially and in terms of human resources. This means, in practical terms, that it will be more difficult to provide the necessary level of healthcare, and elderly care pensions, for example, which will be even more heavily utilized due to an ageing society (OECD 2019, p. 19; Swiaczny et al. 2008, p. 200).

The changing demands in public services can also give rise to issues of where they should be located. This makes it clear that, in addition to social challenges, specific spatial issues also arise. The topic of 'housing' seems particularly important here. On the one hand, forms of housing must be adapted to the changing conditions associated with an ageing society (Yu and Lee 2017, pp. 442-444) and, on the other hand, cities are often confronted with the fact that older people occupy a disproportionately large living space, which conflicts with the effort to achieve compact urban development (Nelson 2020, p. 480).

However, social and spatial problems arising from ageing are caused by different factors. Various interviews were conducted for the country-specific context of Japan. The interviewees are stakeholder from Japanese-based scientific institutions and public administration. Additionally, on-site walks took place to better understand spatial effects. The findings are now used as the first step to illustrate the implications of an ageing population.

Social Implications

First of all, the social challenges that are perceived in connection with ageing in Japan will be described here. One major issue that is also a major topic of debate in society is the loneliness and isolation that many people face. Older people are particularly affected by this (Interview with Dimmer 2024). In this context, the 'hikikomori' phenomenon must be mentioned, which describes the situation in which an “individual has left the group and is isolated” (Kato et al. 2019, p. 427). The term 'kodokushi' is also often used in this context to describe the solitary dying of people living alone and in isolation (Toyama and Poudyal 2021, p. 2). Both are major media phenomena, which sheds light on the fact that many people are no longer involved in social life and very rarely leave their own homes. This also means that fewer people are visible in public spaces on top of that. Spaces in which people communicate and interact with each other are becoming fewer (Interview with Dimmer 2024). Although older people may be more affected by these phenomena, it is also impacting the society as a whole, if only because of the statistically dominant significance of the older population.

This is also reinforced by the fact that both densely populated urban districts, mostly in outlying areas, and villages in rural regions have a less mixed age structure. This means that older population groups are usually concentrated in one place. This exacerbates the negative social and societal consequences (Interview with Dimmer 2024; Interview with Waldenberger et al. 2024).

Another obvious problem has already been mentioned. The challenges associated with the need for care are a major consequence of ageing in Japan. The individual life situation of a person in need of care can vary greatly. For a person who is socially and familiarly well integrated, care can often be provided by relatives. However, given the trend towards isolation and loneliness, care as a service is becoming increasingly important. Due to the rapid ageing of the population, more and more capacity is needed in this service area, while at the same time care workers are already in short supply (Interview with Dimmer 2024).

Spatial Implications

In addition to the social challenges, there are also significant spatial challenges resulting from ageing. These are presented below. While large metropolitan areas such as Tokyo are confronted with settlement pressure in city centers and areas close to city centers, there is a vacancy problem in rural regions. While many people of working age move to the metropolitan areas to work, it is usually the older generations who stay behind in rural areas. This results in areas that are ageing and affected by strong shrinkage trends. This also has an impact on the public infrastructure in rural areas. Local public transport and the provision of important shopping facilities, such as grocery stores, are no longer viable. As infrastructure is being scaled back, and people are not adequately supplied, these rural areas become even less attractive as residential locations (Interview with Dimmer 2024; Interview with Waldenberger et al. 2024).

At the same time, however, it can also be observed that people who once moved to the city move back to the countryside, for instance after they reach retirement age. They usually return to their own family home, which was inherited after the death of their parents, for example, or move back to their parents to care for them.Those city-dwellers for whom moving is not an option are encouraged by the Japanese government to buy a second home in the countryside.There is also a market specifically for foreign clients, where properties in the countryside with traditional Japanese architecture are specifically promoted (Interview with Waldenberger et al. 2024).

Many (single family) homes in Japan have a very short lifespan of about 30 to 40 years (Komatsu 2008, p. 2202), as they are often demolished and rebuilt generation by generation. When used properties are sold, their value has often fallen sharply and they are in need of renovation, despite their young age (Barlow and Ozaki 2005, p. 11). The renovation of houses with traditional architecture or the construction of a second home is therefore associated with a high financial burden. The undersupply of infrastructure and services further contributes to these properties beingunattractive as potential living spaces. As a result, both approaches to reruralization movements do not have a major effect overall, so that the shrinkage and vacancy trends are not being relativized (Interview with Dimmer 2024).

In contrast, there is high settlement pressure in the city centers and adjacent districts of metropolitan areas. Despite this pressure, there is a measurable ageing of the population and the emergence of vacancies here too. However, the spatial effects are different.If older buildings in inner-city locations in metropolitan areas, often with only one residential unit, become vacant, they are usually demolished plot by plot and replaced by a much denser new-built project with many residential units.Although this creates a higher population density in inner-city locations, buildings that once characterized the neighborhoods also fall victim to this development, while new buildings dominate the cityscape.However, these new buildings, like the single-family homes mentioned above,are often built cheaply for a short life cycle, also with an awareness that new construction is not intended to last for centuries, but that there is a possibility that in a few decades urban transformation could place new demands on the use of the land. This leads to a constant process ofsuccessive, fragmented transformation and revitalization of the city with a lot of construction activity (Interview with Dimmer 2024).

A different development can be observed inurban peripheries. Many suburban regions have been developed as New Towns. These are mostly large-scale housing complexes on the periphery of the city, which were developed in Japan in the 1960s and 1970s and in which there is a strong functional dependence on the city center (Tanabe 1978, p. 39). At that time, mostly young people of the same generation moved into these areas, resulting in a homogeneous age structure. Nowadays, the same generation still lives in the New Towns, making ageing effects particularly visible here. As this generation is ageing, it will also reach the end of their life expectancy together, which means that deaths accumulate over the course of a few years leading to major social changes in the districts. In this way, systemic vacancy arises very quickly (Interview with Waldenberger et al. 2024). Colloquially, one can speak of the emergence of 'ghost towns' in less attractive locations.

It can be summarized that the social and spatial implications of ageing processes in the country-specific context of Japan largely correspond to the general problems outlined at the beginning. Nevertheless, there are some special characteristics in Japan. On the one hand, the issue of loneliness and isolation plays a significant role and, on the other hand, the strongly homogeneous age structures, both in rural and suburban areas, are particularly noticeable. In contrast, the difficulties in providing infrastructure and services, the need for elderly care and the rise in vacancies are more general and typical implications of ageing.

5 APPROACHES AT DIFFERENT LEVELS

In connection with the implications described above, various problems arise for Japan. There are approaches at various administrative levels to deal with the problems. From an administrative perspective, Japan is highly centralized, and the national government generally acts as the main actor in the country's development (Pallagst et al. 2018, p. 7; Martinez-Fernandez et al. 2016, p. 13). Therefore, the approaches from a national perspective are discussed here first. Local and regional approaches will be outlined afterwards.

National Level

At a national level, the Society 5.0 initiative should be mentioned first. Society 5.0 expresses the Japanese governments vision of pushing forward digitalization in all policy areas with the aim of merging cyberspace and physical space (Deguchi et al. 2020, p. 2; Cabinet Office Japan 2017; Pallagst et al. 2024, p. 138). This can be classified as a kind of funding program aimed in particular at researching and testing new technical possibilities. It originated from a Japanese development instrument, the “Science and Technology Basic Plan”, which is updated every five years, has received a lot of media attention and was seen as a response to Germany’s “Industry 4.0” (Interview with Waldenberger 2024).

One specific digitization project that has been developed and implemented at the national level is the “Project PLATEAU” of the Japanese Ministry of Land, Infrastructure, Transport and Tourism (MLIT). The project aims to develop a national digital twin to support urban development tasks and aims to have developed 3D CityGML models in around 500 Japanese cities by 2027 (Seto et al. 2023, p. 202; MLIT n.d.a) Although there is little information about how the project is organized, the MLIT itself offers some insights (MLIT n.d.b, Uchiyama and Ishimaru 2022, p. 15). With the ministry, the highest administrative body at national level is the main actor in the project. This approach to the governance structure corresponds to the top-down, centrally organized administrative system in Japan. Although this is a project that requires large-scale implementation, it is not surprising that development is nevertheless being steered by a higher-level body. However, the technical implementation is not being carried out by the MLIT alone. A consortium has been formed with various participating institutes, organizational units and local authorities. According to MLIT, these come from the fields of science, industry and local administrations. The Association for Promotion of Infrastructure Geospatial Information Distribution is responsible for the provision, creation and maintenance of geographical and other spatial data. Nonetheless, the specific roles of the various stakeholders are not always clear in detail and are difficult to categorize independently. However, it is clear from the MLIT's explanations of the more specific use cases within 'Project PLATEAU' that industry and research institutes play a leading role in their development in particular (MLIT n.d.c).

The overall aim of “Project PLATEAU” is to provide a data platform for geodata, building data, geographical data and other spatial urban data relating to the built environment and to make this available as open-source data. In addition to static data, dynamic camera and sensor data are also used in individual applications (Uchiyama and Ishimaru 2022, p. 13). In this context, Seto et al. (2023, p. 202) found that in spatial planning practice in Japan, data relating to population, settlement areas, land use, traffic and landscapes must be collected and mapped every five years. In many local authorities, however, these maps are still only available in paper form. This makes it clear that the development of digital twins as part of 'Project PLATEAU' is primarily understood as a spatial planning tool. It should make it possible to visualize urban data and thus gain knowledge. MLIT also places the project in the context of the Society 5.0 vision and the associated goal of solving the country’s social and societal problems. It is referred to as the “digital transformation of urban planning” and is intended to connect various actors involved in spatial development, such as administration, private companies, researchers, engineers, etc., via the data platform in the form of digital twins to enable more efficient collaboration. The MLIT aims to model around 500 Japanese cities (MLIT n.d.a). In a first step, 56 Japanese cities have already been modeled, including particularly populous cities (Uchiyama and Ishimaru 2022, p. 7). It is clear that the PLATEAU project is unprecedented in the world due to its intended scale. With regard to other digital twins in an urban planning context, such as that of the city of Helsinki in Finland, the national digital twin in Japan with its formulated goals appears to be very ambitious, but at the same time a logical consequence and comprehensible approach in view of the Japanese government’s policy.

The basic functionalities in the CityGML model, which can be accessed via the “PLATEAU View” application, include, for example, any perspective view within the model, including pedestrian view, the

shadowing by the built environment based on specific date and time input and also the possibility for users to add geometric objects to the built environment and works therefore like a scenario visualization. With regard to building modeling, each building can be selected individually or in combination with other building units in order to obtain specific information associated with the objects. This also includes information relevant to spatial planning, such as building heights, usage typology and information on built-up areas (MLIT n.d.d). In addition, there are special use cases for certain functionalities, some of which have been developed by local administrations for specific problems.

Mayer et al. (forthcoming) took a closer look at two of these use cases and concluded that they hold great potential for spatial planning. Work processes can be made more efficient and the functionalities also offer new opportunities for spatial planning. As the project was developed with the intentionthat various stakeholders can design and implement more specific use cases based on the linked CityGML models and the basic functionalities, it is also possible to thematically address general trends and crises that are shaping spatial planning. This means that there is also potential for age-related problems. So far, however, there is no use case that deals exclusively with this topic, although general planning-related use cases involving locations for infrastructure and the organization of land use naturally have important cross-references for ageing problems. Mayer et al. (forthcoming) consider the project to have great potential for strategic spatial development but also note that there is a need for greater transparency regarding the processing of the data used. Through national implementation, municipalities benefit from the tool that is made available to them without having to incur high development costs themselves.However, due to the aforementioned short lifespan of many buildings and the constant fragmented transformation of the city, high maintenance costs are to be expected. And although there is a risk that local specific needs are not taken into account during development, this can be counteracted by the expandability based on local use cases.

A similar project at national level that should be mentioned in this context is the “RESAS Portal”. The name is an acronym that stands for “Regional Economy Society Analyzing System”. It is a tool for big data visualization, that brings together large amounts of regional data that make it possible to compare regions and municipalities in Japan with each other using selected indicators. “RESAS” is thus used for regional benchmarking in Japan (Interview with Waldenberger et al. 2024). The system was developed by an international company from the private sector, which also has a head office in Tokyo. The commissioning party is the Japanese 'Ministry of Economy, Trade and Industry',which is strongly committed to promoting regional economic policy (Takram Japan Inc. n.d.). This once again illustrates the typical steering system in Japan, where it is the Japanese national government that develops and implements concrete policies and takes action.

The aim of the “RESAS” tool is explicitly related to economic development with special emphasis on the support of regional economic policies. Among other things, it makes specific reference to the challenges associated with demographic change (Takram Japan Inc. n.d). Population declines and ageing, as well as unequal demographic development in rural and urban regions and the resulting economic weakness in certain regions are seen as problems that the instrument is intended to support (Matsuura 2020, p.3-4). It was designed for a broad user group and is not only available to public administrations at all levels, but also to the private sector, citizens and educational institutions. (Takram Japan Inc. n.d.; Matsuura 2020, p. 3).

The tool offers users two main views. Firstly, a geographical image of Japan, which is viewed from a bird's eye perspective, and secondly, a breakdown of specific information on an indicator under consideration, in which regulators can also refer back to the geographical view. Both views can be controlled interactively. In addition to the national borders, the geographical view further shows the borders of other administrative units, such as prefectures and municipalities, but also other vector-based elements at local level, such as the road infrastructure of a city, which enable better orientation. Various methods are used for data visualization. Among other things, areal and octal representations are used, but also different forms of diagrams, some of which are assigned to polygons on the geographical view. In addition, there are network visualizations in which relationships can be established from one polygon to other polygons (Takram Japan Inc. n.d.). Overall, the interactive functionalities are very versatile. And so is the data that the tool can visualize. There is a clear focus on economically relevant data. For example, there are indicators relating to the regional economy suchas the production of certain goods and their distribution, the cultivation of food in agriculture, the economic structure by sector, the labor market and employment figures, energy use, consumption of goods by certain population groups, tourism by overnight stays and accommodation destinations and much

more. However, there are also indicators on other topics, e.g. population development, municipal finances, taxes and healthcare. In addition, there is a separate category for relevant indicators in urban planning, which includes urban structures and some types of public services, such as education (Cabinet Office Regional Revitalization Promotion Office n.d.).

“RESAS Portal” is an outstanding tool that can provide and analyze exceptional amounts of data. For the strategic development and planning of cities and regions, it can thus provide important support for decision-making and help to ensure that decisions are made based on facts and free from intuitive evaluations. The competitive approach can incentivize structurally weak regions to become more competitive. However, as the tool is also explicitly aimed at the private sector and location issues are examined for economic viability, there is also a risk that decisions made based on economic interests may not always preserve the overall view of Japan’s development. The question therefore remains as to how much the tool contributes to solving social and regional problems.

Both projects described show that the national level plays a key role in the development and implementation of digital tools und innovations. It can be observed that the government has an affinity fordrawing up large-scale plans that are then rolled out acrossthe country. In these processes, participatory approaches are often lacking and future users or consumers, where the needs lie, are rarely included in the processes (Interview with Waldenberger et al. 2024). At the same time, however, this ensures fast development times in which coordination requirements are kept to a minimum.

The potential arising from the tools presented for the ageing problem is huge. The basic functionalities alone make it possible to visualize specific spatial distributions of relevant indicators, provided the data is available to the tool. This could serve as decision-making support for spatial planning, which could, for example, help to make age structuresmore heterogeneousin certain areas and strategically determine locations for public services and infrastructures that play a role for an older population, as well as counteract gaps in services.However, this potential applies to all sectoral topics with spatial relevance for which data can be provided. In this respect, it is striking that there are no specific use cases related to ageing so far.

Local and Regional Level

Although national government policies and instruments set the standard and projects at local and regional level are much smaller in scale, digital platforms still play a major role here too.

As part of the smart city Initiative in Japan, many municipalities have developed smart city strategies. The authors talked to responsible people from the administration in Tokyo and the much smaller city of Takamatsu. It emerged that both smart city strategies have great potential to provide a supportive tool for finding solutions to ageing-related problems. Both strategies already include implemented map-based platforms that can be used to visualize certain data on a pointwise or area basis (Interview with Masashige and Asad 2024; Interview with Munenori and Mitsuhiro 2024). This could be used to better coordinate locations for certain services and infrastructures that are needed according to the needs of an aged population, and to analyze the residential distribution of the older population to make it more heterogeneously through spatial planning.

In both Tokyo and Takamatsu, however, the smart city platforms are mainly used for operational issues such as traffic control and many more. So far, there is no approach to planning use or to making strategic decisions about the development of space. There is also no specific link to ageing issues (Interview with Masashige and Asad 2024; Interview with Munenori and Mitsuhiro 2024).Nevertheless, there are indirect links between smart city strategies and ageing issues. The topic of mobility and transportation is central to the Japanese smart city initiative and represents important use cases for the two strategies described above, too (KANTEI n.d., p. 10). This can benefit accessibility to important facilities for an elderly population. In addition, smart city strategies have the potential to make administrative tasks more efficient (Narmeen and Jawwad 2015, p. 9). Since fewer and fewer people are of working age due to ageing processes, this provides an important contribution that can help to maintain important administrative structures.

Metaverse platforms are a development that addresses the problems of loneliness, isolation and unattractive rural areas. These are projects at a local level. Here, certain environments of places are graphically recreated digitally. The target group is citizens. The development usually takes place in the private sector, with citizens taking on the role of consumers. They can use avatars to move around the recreated environments and interact with each other. Virtual reality hardware is also used in some cases. In many cases, metaverse

platforms are used to entertain users or to advertise products or businesses. In some cases, it is also used to impart knowledge, for example in museums (Interview with Waldenberger et al. 2024).

However, it is also seen as an approach to create new meeting and opportunity spaces against the background of many people's loneliness and isolation. People who normally find it difficult to leave their own homes due to physical disabilities, whether caused by illness or ageing, can also participate. In rural areas, metaverse platforms are also used by municipalities affected by population decline to promote them as residential locations with their digital image and increase residents' identity with their town. Users then have the opportunity to explore and get to know the municipality digitally (Interview with Waldenberger et al. 2024).

Another avatar-based approach, which takes place without the use of metaverse but is instead intertwined with physical space, are avatar cafés. In these cafés, robots that resemble humans are able to move within the premises. People who are unable to leave their homes can visit the café remotely via an avatar. The digital avatar takes on the appearance of one of the robots in the café. This allows for interpersonal interactions within the café, where some visitors participate physically and in human form, while others are represented by the robot avatars (Interview with Waldenberger et al. 2024).

The impact of such projects is difficult to assess. In general, however, a great affinity with new technologies can be observed in Japan. People base their actions strongly on pop-cultural imaginaries and also identify themselves as part of them. New technologies and manga graphics are key components of this (Interview with Waldenberger et al. 2024). In this respect, the social and spatial effects that could be triggered by this should not be underestimated. At the same time, this raises the question of whether such approaches could actually be transferred to societies with other cultures.

There are many other digital approaches that are being applied at the local or regional level. These include, for example, ideas for providing peripheral areas with goods using drones. This can be particularly advantageous when municipalities are located on islands, where quick delivery of essential goods may not always be possible, such as in the case of medications. Another example addresses the issue of transportation infrastructures being reduced in rural, shrinking regions. At the same time, it addresses the problem that many people in retirement age remain willing to work. Therefore, Japan places a strong emphasis on volunteer work in sectors that would otherwise not be able to operate due to lack of profitability. This also applies to the transportation sector in rural areas. Such projects are supported by digital technologies, such as platforms where individuals can register for transportation services, and volunteer drivers are then notified and assigned the task of providing the transport service (Interview with Waldenberger et al. 2024).

These types of digital solutions seem to have greater international transferability, as they are less tied to pop culture and imaginary contexts in Japan. The practicality of the solutions appears to be evident, as they directly address existing issues in a very immediate way.

6 CONCLUSIONS

The paper shows that Japan can be a very pertinent example in terms of researching the effects of ageing in the population. Ageing in Japan is particularly advanced compared to other countries. Effects from the decline in births and fertility coupled with a simultaneous increase in life expectancy have a statistically high significance that can explain the ageing process. The baby boom cohorts are a particularly strong driver of ageing.

Generally, insights on demographic trends in Japan and their spatial and social impacts can be transferred well to other countries, especially to developed countries, where ageing processes are evident too. A key difference, however, that needs to be highlighted, is the factor of migration. In many developed countries, there is a clearly positive migration balance. In Japan, the migration balance is also positive, but it is rather small and not statistically significant compared to the total population. For Japan, this means that this mitigating factor for the ageing effect does not apply. Nevertheless, the effects of ageing which are more advanced in Japan than in other countries can serve as an example from which lessons can be learned.

The social and spatial impacts of ageing pose enormous problems for Japan and force the government and administrations to find solutions.

Varioussuch solution approaches have been presented here. It has been noted that the national government plays a special role in Japan. This is due to the centrally organized governance structure. Development and

implementation at the national level, as in the cases of Project PLATEAU and the RESAS Portaloffer several advantages. The development and implementation process can be organized by a single body. The need for coordination among different stakeholders is minimized. In addition, powerful platforms are provided to local governments throughout Japan. Even small, structurally weak municipalities have the opportunity to benefit from digital innovations and are dependent on their own finances and do not depend on the possibility's local efforts.

At the same time, the centralist approach also carries risks. For example, local specificities and interests may not be sufficiently taken into account. The processes are less transparent and leave no room for participation. Another criticism is that national strategies are being rolled out across the country and local authorities may be unprepared. Furthermore, actual local problems cannot always be addressed by these policies.

Applied to other countries' contexts, it can be noted that the centralist approach has both advantages and disadvantages. Coordination in a central body at the national level and funding from that body is an approach that is transferable to other countries, although this could mean that local administrations may have to give up authority fields. However, it would be necessary to implement well-functioning participatory processes, with both actual local needs and specificities forming the basis for the development of digital solutions.

In contrast, the local and regional approaches to the metaverse and avatar platforms are difficult to transfer. Yet, the reliance on Japan-specific pop cultural imaginaries makes adaptation in a different cultural context unlikely. Thus, this approach to solving age-related problems is questionable.

In contrast, the approach of allowing willing retirees to work as volunteers in sectors that provide essential public services and infrastructure, which are increasingly difficult to maintain due to population ageing, seems highly transferable. It is considered worthwhile conducting further research in this area to explore through case studies how digital solutions can provide support in this context.

In the approaches examined at various levels, it is notable that there is rarely a direct connection to real, existing problems related to ageing. Although indirect connections exist, and the potential becomes apparent, further research is needed to determine the extent to which the implemented solution strategies contribute to a transformation process in addressing these challenges.For this purpose, it is assumed that examining path dependencies through empirical case studieswill help describe the synergies related to supporting solutions to aging-related challenges through new technologies.

1 ABSTRACT

Durch die Änderung des Bayerischen Denkmalschutzgesetzes ist es in der Denkmalpflege nun möglich, Denkmäler zu schützen und erneuerbare Energien zu fördern. Der Art. 6 (2) BayDSchG (Bayerisches Denkmalschutzgesetz BayDSchG 2023) erlaubt es Eigentümern von Baudenkmälern, erneuerbare Energien zu nutzen, sofern keine überwiegenden Gründe des Denkmalschutzes entgegenstehen. Das Bayerische Landesamt für Denkmalpflege betont dabei die Bedeutung einer denkmalverträglichen Energieversorgung, die Denkmalschutz und Klimaschutz vereint.

Ein Solarrahmenplan ist ein Planungsinstrument für Kommunen mit historischer Bausubstanz, das Potenziale und Anforderungen für erneuerbare Energien definiert. Grundlage ist eine Analyse von Einsehbarkeit, historischen Raumqualitäten und Gestaltungskriterien. Ziel ist es, Transparenz zu schaffen und die Entscheidungsfindung zu unterstützen.

Der Beitrag stellt die Erarbeitung eines Solarrahmenplans für die Altstadt Landsberg am Lechs vor. Der Digitale Zwilling des mFUND-Projekts „TwinCity3D“ wird genutzt, um Sichtachsen zu analysieren und sensible Bereiche zu identifizieren. Die Studie liefert methodische Ansätze, zentrale Erkenntnisse und einen Ausblick auf die Umsetzung.

Keywords: Simulation, Denkmalschutz, Solarkataster, Digital Twin, Photovoltaik

2 HINTERGRUND

Am 01.07.2023 ist eine Änderung des Bayerischen Denkmalschutzgesetzes in Kraft getreten. Mit dieser Änderung will das Gesetz Denkmäler schützen, Energiepotenziale nutzen und Kommunen unterstützen. In Art. 6 (2) BayDSchG heißt es „Dient die Maßnahme der Gewinnung erneuerbarer Energien überwiegend für den Energiebedarf im Baudenkmal oder zu einer energetischen Verbesserung, kann die Erlaubnis […] nur versagt werden, soweit überwiegende Gründe des Denkmalschutzes entgegenstehen und diesen nicht durch Nebenbestimmungen zur Art der Umsetzung Rechnung getragen werden kann.“ Der Gesetzgeber möchte also Eigentümern von Baudenkmälern grundsätzlich die Möglichkeit geben, erneuerbare Energien zu nutzen. Auf der Homepage des Bayerischen Landesamtes für Denkmalpflege ist hierzu Folgendes aufgeführt: „Solarenergie im Ensemble und im Baudenkmal: Eine in denkmalfachlicher Sicht verträgliche Versorgung von Baudenkmälern mit bezahlbarer regenerativer Energie dient auch dem Denkmalerhalt und ist gerade heute von ganz besonderer Bedeutung. Denkmalschutz und Klimaschutz sollen Hand in Hand gehen und ihre Belange verantwortungsvoll verbunden werden. Denkmäler sollen dabei aber natürlich ihre besondere Eigenheit als einzigartige, identitätsstiftende und höchst wertvolle Zeugnisse der bayerischen Geschichte behalten. Für die Vereinbarkeit von Denkmalpflege und Solarenergienutzung bietet das Bayerische Landesamt für Denkmalpflege Lösungen für städtebauliche Konzepte zur Energieversorgung im Ensemble und Möglichkeiten am oder in der Nähe eines Baudenkmals an.“

Ein Solarrahmenplan ist ein informelles Planungswerkzeug, dass sich speziell an Kommunen mit einem umfangreichen historischen Baubestand richtet. Solch ein Rahmenplan soll die Möglichkeiten der Nutzung erneuerbarer Energien im Ensemble differenziert betrachten. Dafür wird der öffentliche Raum auf der Grundlage einer städtebaulich-denkmalpflegerischen Analyse kategorisiert, um für die einzelnen Bereiche abgestimmte Gestaltungsanforderungen formulieren zu können. Der Plan kann so als Werkzeug für die

Verwaltung dienen, um entsprechende Anträge auf Solaranlagen im Denkmalbereich zu bearbeiten und eine Transparenz für die Eigentümer herzustellen. Ziele der Stadt bei der Erstellung eines solchen Plans sind:

- Klarheit und Transparenz für den Umgang mit Solaranlagen für alle Beteiligten
- Defintion von Gestaltungsqualitäten für die Dachflächen als 5. Fassade im historischen Kontext
- Informelle Planung als Werkzeug für die Untere Denkmalschutzbehörde (UDB)

Für die Erstellung eines Rahmenplans sind drei Fragestellungen denkmalfachlich zu untersuchen und zu bewerten:

- Einsehbarkeit und Sichtachsen
- Analyse der historischen Bedeutung von städtischen Räumen
- Gestaltungsanforderungen für die Anlagen

Als Ergebnis soll eine digitale Karte entstehen, die Auskunft über die denkmalpflegerischen Werte und Qualitäten von Räumen, Einzelgebäuden, Straßen- und Platz-, sowie Stadtansichten gibt, die Einsehbarkeit vom öffentlichen Raum beschreibt sowie die Potenziale und Anforderungen zur Integration von EE-Anlagen darstellt.

Mithilfe des virtuellen 3D-Stadtmodells von Landsberg am Lech sollen diese Arbeitsschritte durchgeführt werden. Mithilfe der Sichtachsenanalyse werden die betroffenen (Teil-)Dachflächen abgeleitet und kategorisiert. Durch die Auseinandersetzung mit der historischen Bedeutung des Stadtraums findet eine weitere Einstufung sensibler Bereiche innerhalb des Altstadtgefüges statt. Aus der Überlagerung der angefertigten Analysen werden anschließend Gestaltungsanforderungen abgeleitet, die dachflächengenau Aussagen zur möglichen Verwendung von PV-Modulen liefert.

Im Rahmen eines Forschungsseminars an der Professur für Stadtquartiersplanung des KIT wurden diese Arbeitsschritte 2024/2025 in Zusammenarbeit mit dem BLfD und der Stadt Landsberg am Lech mit den zuständigen Referaten der Technischen Bauaufsicht als Untere Denkmalschutzbehörde und dem Referat Digitaler Zwilling, Klimaschutz und Mobilität (DZKM) durchgeführt, die nachfolgend näher beschrieben werden.

3 STAND DER FORSCHUNG

3.1 PV-Anlagen und Denkmalschutz bisher

Vor der Gesetzesänderung 2023 konnten gewichtige Gründe für den Erhalt des bestehenden Zustands die Genehmigung erneuerbarer Energien verhindern. Nun müssen überwiegende Denkmalschutzgründe vorliegen, sofern diese nicht durch Auflagen zur Umsetzung berücksichtigt werden können (Bayerisches Denkmalschutzgesetz BayDSchG 2023). Dies bedeutet, die Frage lautet nun nicht mehr „ob“ erneuerbare Energien am Denkmal erlaubnisfähig sind, sondern „wie“. Dabei soll die Substanz des Baudenkmals soweit wie möglich erhalten bleiben während eine möglichst denkmalverträgliche Integration in das Erscheinungsbild angestrebt wird. Maßgebend ist, dass vorrangig der Energiebedarf im Baudenkmal abgedeckt werden soll.

Das Staatsministerium für Wissenschaft und Kunst (STMWK) hat hierzu das Stufenmodell als Handlungsanweisung herausgegeben, wonach zunächst Nebengebäude und nicht einsehbare Flächen zu Belegen belegen sind. So sind auf Flächen, welche nicht vom öffentlichen Raum einsehbar sind, regelmäßig auch herkömmliche Anlagen erlaubnisfähig (Bayerisches Staatsministerium für Wissenschaft und Kunst 2023).

Bei vom öffentlichen Raum aus einsehbaren Dachflächen wird unterschieden in Ensemble und Einzeldenkmäler. Bei Ensembles gilt: Mit dem Erscheinungsbild denkmalfachlich vereinbare Anlagen, z. B. in die Dachfläche integrierte Anlagen, sind regelmäßig erlaubnisfähig. Bei Einzeldenkmälern gilt analog zu den Ensembles zusätzlich der Substanzschutz. So sind aufwendige Ertüchtigungen eines Dachtragwerks zur Installation einer Anlage nicht im Sinne des Denkmalschutzes.

Die immer effizienter werdende Zelltechnologie sowie die steigenden Produktionsraten der Zellen begünstigen den kostengünstigen Erwerb von Solarprodukten. So hat sich der Wirkungsgrad seit 2002 von durchschnittlich 13% auf 23% fast verdoppelt und der Preis pro kWp ist nunmehr ein Fünftel im Vergleich

zum Jahr 2006 (Bundesministerium für Wirtschaft und Klimaschutz BMWK 2021; Lackner et al. 2024). Produktinnovationen in Art, Form und Farbe ermöglichen heutzutage wirtschaftliche und gestalterisch anspruchsvolle Lösungen.

Photovoltaik-Indachanlagen sind im Falle einer Dachsanierung preislich konkurrenzfähig zu einer herkömmlichen Aufdachanlage und bringen weitere Vorteile mit sich. Die geringere Auflast und geringere Wind-Soglasten vermeiden Ertüchtigungen im Dachstuhl und die witterungsgeschützte Verlegung der Installationen trägt zu einer längeren Lebensdauer der elektrischen Bauteile bei. Mindererträge durch eine geringere Hinterlüftung können bei kleinteiligen Anlagen durch eine höhere Flächenausnutzung kompensiert werden.

Farbliche Anpassungen können durch die Verwendung von farbigen Rückgläsern, die Bedruckung mit wetterbeständigem keramischem Siebdruck oder die Verwendung von Farbfolien erfolgen und ermöglichen damit eine farbliche Annäherung an beispielsweise naturrote Ziegel oder patinierte Kupferdächer.Die Produktpalette bietet neben farblich angepassten Aufdachmodulen auch kleinteilige Indachlösungen, wie Solarziegel in verschiedenen Formen und Farben, spezielle Lösungen für Schiefer und Blechdächer, sowie PV-Folien, welche sich flexibel an bestehende Dachformen anpassen können. So können für die meisten Denkmäler individuell verträgliche Lösungen zur Integration von Photovoltaikanlagen gefunden werden.

Innovationen hinsichtlich Materialität und Oberflächen wie beispielsweise die Verwendung von satinierten Gläsern, welche die Reflexion der Deckgläser reduziert, versprechen weitere Verbesserungen hinsichtlich einer denkmalverträglichen Integration in das Erscheinungsbild der Denkmäler.

3.2 Erscheinungsbilder und Ensembles – Orte öffentlicher Aushandlung

Neben der baulichen Substanz zählt das Erscheinungsbild von Denkmälern zu den zentralen Schutzgütern der Denkmalpflege und ist als solches auch in allen deutschen Denkmalschutzgesetzen verankert (Eidloth et al. 2019).Besonders facettenreich ist dieses Erscheinungsbild in den Ensembles historischer Stadt- und Ortskerne überliefert, die nicht allein durch die Erhaltungsbestrebungen der Denkmalpflege, sondern vor allem den Gestaltungsansprüchen einer seit mehr als 100 Jahre andauernden kommunalen Planungskultur geprägt werden. Städte, Märkte und Dörfer, die ihre Kernbereiche im Sinne der Daseinsvorsorge attraktiv und lebendig halten wollen, haben dafür schon seit dem Ende des 19. Jahrhundert Regularien und Leitbilder in Form von Bebauungsplänen über Gestaltungssatzungen bis hin zu Werbeanlagensatzungen erlassen (Sandmeier 2023). Dem Erscheinungsbild eines Ortes scheint daher nicht nur im denkmalpflegerischen, sondern auch in gesellschaftlichen Wertbildungsprozessen eine besondere Rolle zuzukommen. Idealerweise soll es den Bewohnerinnen oder Besuchern durch Beständigkeit und Wiederholung von Strukturen Orientierung geben und zugleich offen sein für Innovation, Erneuerung und individuelle Zuschreibungen (Meier 2010, 2013). Aufgrund ihrer Komplexität und Geschichte bilden insbesondere denkmalschützte Orts- und Stadtkerne intuitive Bedeutungs- und Erfahrungsräume, die den Betrachtern leicht zugänglich erscheinen. Um diese Vielschichtigkeit und Aneignungsfähigkeit zu erhalten, setzen viele Kommunen darauf in der Entwicklung ihrer Ortskerne eine Brücke zwischen Zukunft und Vergangenheit zu schlagen und beispielsweise die Anpassung der Gesellschaft an gegenwärtige Bedürfnisse im baulichen oder strukturellem Bestand umzusetzen. Dabei investieren sie in der Regel viel Zeit und Geld in partizipative Aushandlungs- und Planungsprozesse, profitieren aber langfristig von diesen Bemühungen und den darin gesammelten Erfahrungen.

3.3 Solarrahmenpläne (in Bayern)

Der Solarrahmenplan will als sektorale, informelle Planung der Denkmalpflege Kommunen und ihren Bürgerinnen und Bürgern Hilfestellung in Mitten eines solchen Transformationsprozess geben. Ziel ist es, die spezifischen Werte und Potenziale des historischen Ortes zu erkennen und auf dieser Grundlage Handlungsräume für die energetische Erneuerung zu eröffnen. Die Grundzüge dafür wurden in einem ersten umgesetzten Solarrahmenplan für die kleine Stadt Lichtenberg in Oberfranken festgesetzt: Die Zonierung des Ensembles in eine Kernzone als die „Gute Stube“ des historischen Ortes– dazu zählen beispielsweise der Stadtplatz oder die Marktstraße, der Schlossplatz oder der Promenadenpark – und eine Nebenzone mit untergeordneten Straßen oder (halb-)privaten Bereichen, die als dienende Räume gesehen werden (Sandmeier und Fischer 2023). Neben dem Erscheinungsbild der Kernzone prägen vor allem die Fernsichten von besonders prominenten Aussichtspunkten ein historisches Ortsbild, das bedingt die Festlegung einer

entsprechenden weiteren Zone. Zusätzlich gibt es eine Verständigung auf sogenannte Stadtbausteine, das heißt Gebäude, die für den Ort aus kulturellen, gesellschaftlichen und geschichtlichen Gründen von maßgeblicher Bedeutung sind, das können beispielsweise das Schloss, die Pfarrkirche oder das Rathaus sein. Meist handelt es sich um Einzeldenkmäler oder ikonischen Bauwerke, so dass Solaranlagen hier gänzlich vermieden werden sollen beziehungsweise einer intensiven, auf den Einzelfall zugeschnittenen Planung bedürfen.

Inzwischen konnten für mehr als 20 Kleinstädte und Märkte, zunehmend auch für größere und komplexere Altstadtensembles nach dem Vorbild von Lichtenberg Solarrahmenpläne erarbeitet werden. Dabei wird die genaue Ausformulierung immer wieder neu dem Baubestand, der besonderen städtebaulichen Struktur und den verwaltungstechnischen Vorstellungen der Kommune angepasst. In Haßfurt, einer Kleinstadt in Unterfranken wurde die Nebenzone beispielsweise weiter ausdifferenziert, um der unterschiedlichen Wertigkeit und Bedeutung für das Stadtbild gerecht zu werden (Stadt Haßfurt 2023).In Bad Windsheim in Mittelfranken führten die Bearbeiter für die Gebäude im Bereich des ehemaligen Stadtgrabens als „Vorzone“ des Ensembles eine eigene Kategorie ein (Stadt Bad Windsheim et al. 2025).

In die Betrachtungen werden dabei in der Regel nur jene Dachflächen einbezogen, die aus dem öffentlichen Raum einsehbar sind, um damit den neuen gesetzlichen Regelungen Rechnung zu tragen. Die stadträumliche Analyse für den Solarrahmenplan in Weißenburg stellte in dieser Hinsicht eine besondere Herausforderung dar, da nahezu jede Dachfläche von einer der umliegenden Straßen und Plätze zu sehen ist. So wurden innerhalb der einzelnen ausdifferenzierten Zonen besondere Sichtachsen und Blickbeziehungen definiert, die sich aus der Morphologie der Stadt ableiten ließen (Stadt Weißenburg in Bayern et al. 2024).

Der Solarrahmenplan Bayreuth basiert ebenfalls auf der Zonierung des Ensembles in der beschriebenen Form, wird aber zusätzlich verschnitten mit einer Entscheidungsmatrix, in der Kriterien wie eine exponierte Lage oder die Angrenzung an eine Platzsituation abgefragt werden (Stadt Bayreuth und RHA Reicher Haase Assoziierte 2024).

Die Erstellung eines Solarrahmenplanes für das ausgedehnte Ensemble der Altstadt Würzburg wiederum startete zunächst mit einer topographischen Analyse. Anhand des 3D-Gebäudemodells wurden automatisiert Dachflächen ermittelt, die aus dem jeweiligen Straßenraum nicht, bzw. nur geringfügig einsehbar sind. Überlagert wurde diese Erhebung mit einer Fernsichtstudie vom Würzburger Burgberg, dem prägnantesten Aussichtspunkt auf das Stadtensemble. Erst in einem nächsten Schritt wurde die räumliche Sichtanalyse mit denkmalpflegerischen Werten verschnitten (Büro G.A.S. planen bauen forschen 2024).

Die dicht bebauten Mittel- und Großstädte stehen vor der Herausforderung, über eine Solaranlagensatzung hinaus vielfältige weitere Interessen und teilweise widerstreitende Belange der städtebaulichen Planung ausgewogen in die Betrachtung einzubeziehen. In Bayern bietet sich dafür die Bearbeitung in einem Kommunalen Denkmalkonzept (Bayerisches Landesamt für Denkmalpflege 2017) an, dass Kommunen, Fachplaner und Behörden in einen gemeinsamen Aushandlungsprozess bringt und in dem die Bedürfnisse der Bürgerinnen und Bürger besondere Beachtung finden. Ein erstes Modellprojekt dieser Art konnte für die Stadt Wasserburg zur Vereinbarkeit von Denkmalschutz und regenerativer Energie im Altstadtensemble bereits seit 2021 umgesetzt werden. Hier wurde die stadträumliche Analyse parzellenscharf vertieft, um für einzelne Gebäude- und Dachtypolgien angepasste Energieplanungen der Strom- und Wärmeversorgung anzubieten. In Modellprojekten wurde die Machbarkeit der Fallstudien demonstriert, innovative Produkte ausprobiert und Erfahrungen für die praktische Umsetzung gesammelt, um dieses Wissen auf weitere Solarplanungen in der Altstadt übertragen zu können (Solfrank 2024).

Unverzichtbarer Bestandteil eines jeden Solarrahmenplanes ist die Formulierung von abgestuften Gestaltungsleitlinien für die einzelnen Zonen. Ausgehend von der Bewertung der Ortsräume und –bauten, mitunter auch unter Einbeziehung der jeweiligen Dach- und Haustypologien, wird eine Aussage zu Lage, Maß, Materialität und Farbigkeit von Solarenergieanlagen getroffen. Im Zusammenspiel mit der kartografischen Fassung steht den Kommunen damit ein Planungswerkzeug zur Verfügung, das Transparenz gegenüber den Bürgern schafft.

3.4 DigitaleZwillinge

3D-Stadtmodelle stellen seit Jahrzehnten ein zentrales Werkzeug für die visuell ansprechende Vermittlung von Planungsinhalten dar – sei es analog oder seit den 1990er Jahren zunehmend digital. Bereits frühe

Projekte wie das Stadtmodell Graz (Luser & Lorber, 1997) oder das 3D-Stadtmodell von Bamberg (Zeile et al. 2005)verdeutlichten das Potenzial der Wissensvermittlung als auch der Planung im dreidimensionalen, digitalen Kontext. Die Entwicklung von CityGML und der darin enthaltenen Level-of-Detail (LOD) Spezifikation als universelles Austauschformat für 3D-Stadtmodelle (Kolbe und Gröger 2004; Brüggemann und von Both 2015; Benner et al. 2016) beschleunigten und standardisierten diese Entwicklung: Durch CityGML wurde es möglich, eine standardisierte Modellierung urbaner Strukturen und ihre Anwendbarkeit für verschiedenste Szenarien, etwa Energiebedarfsanalysen (Benner et al., 2016) durchzuführen. Offene Werkzeuge wie der KIT-ModelViewer für IFC als auch CityGML (KIT – IAI 2024) erleichtern mittlerweile die Arbeit und den Austausch der Dateien.

Parallel dazu etablierte sich das Konzept des digitalen Zwillings, das aus der Produktentwicklung stammt (Grieves 2014).Es beschreibt die virtuelle Replikation physischer Objekte und ermöglicht eine ganzheitliche Modellierung. Diese Idee wurde später in die Stadtplanung übertragen (Batty 2018). Digitale Zwillinge finden insbesondere Anwendung in großmaßstäblichen Modellen und Simulationen, wie etwa beim Projekt Herrenberg in Deutschland. Dieses nutzte immersive virtuelle Umgebungen zur Analyse urbaner Herausforderungen und zur Einbindung von Verkehrssimulationsmodellen (Dembski et al. 2019, 2020).

4 PROJEKT LANDSBERG AM LECH

Nachfolgend werden die durchgeführten Arbeitsschritte von der Datensichtung, die Ideen für eine Methodenentwicklung, Vorschläge für einen Solar-Rahmenplan sowie die Anwendung der gewonnenen Erkenntnisse auf Beispielgebäude näher beschrieben.

4.1 Datenverfügbarkeit

Im Rahmen des mFUND-Forschungsprojekts „TwinCity3D“ entwickelt die Stadt Landsberg am Lech zusammen mit 3D RealityMaps GmbH aus München aktuell eine Grundlage für einen digitalen Zwilling.Auf der Basis von Befliegungen des Stadtgebietes mit einem Multisensorkamerasystem (bestehend aus insgesamt fünf RGB-, einer Multispektral-, sowie einer Thermalkamera) werden verschiedene Luftbildprodukte zur späteren Analyse erzeugt. Das Multisensorsystem befindet sich dabei an dem elektrisch betriebenen Ultraleichtflugzeug „Elektra One Solar“ der Landsberger Firma Elektra Solar GmbH. Die realisierbare Flughöhe von 300m über Grund ermöglicht eine hohe Auflösung und sichert in der Folge einen hohen Informationsgehalt für die Anwendungsbereiche aus Klimaschutz, Mobilität und Stadtentwicklung. Das nach fotogrammetrischem Prinzip erstellte 3D-Meshmodell des Stadtgebietes bildet das Kernelement der prototypischen „TwinCity3D“-Plattform (Abb.1 rechts), welche zukünftig weiter ausgebaut werden soll. Aufgrund des niedrigen Abstraktionsgrades und der intuitiv angelegten Bedienoberfläche kann das Stadtgebiet – auch ohne Vorkenntnisse – nach kurzer Einarbeitungszeit virtuell erkundet werden (Broschart et al. 2024).

Zudem verfügt die Stadt Landsberg am Lech bereits über einen digitalen Zwilling des Straßenraum. Im Jahr 2023 wurde zuletzt eine Straßenbefahrung durch die in Baden (CH) ansässige Firma iNovitas AG durchgeführt. Dabei wurden die Straßen und Wege ebenfalls mit einem Multisensorsystem befahren. Dieses setzt sich aus drei stereoskopisch gerichteten RGB-Kameraeinheiten, einer hemispherischen „Ladybug“-RGB-Kamera, sowie einem ergänzenden LIDAR zusammen.

Diese „veredelten“ Geodaten werden ergänzt um die, von Seiten des Bayerischen Landesamtes für Digitalisierung, Breitband und Vermessung (LDBV) bereitgestellten Geobasis- und Geofachdaten im Rahmen der OpenData-Strategie.

Für die Anfertigung des Solar-Rahmenplanes konnte auf folgende Datensätze zurückgegriffen werden:

- 3D-Gebäudemodelle (LoD2) im CityGML-Format mit ALKIS®-konformen Standarddachformen und beschreibenden Attributen (Abb. 1 links)
- Digitales Geländemodell 1m (DGM1) als Punktwolke im ASCII-Format
- OSM-Datensatz der Stadt Landsberg am Lech
- Fotogrammetrisch identifizierte Dachformen als geschlossene Polygonzüge inklusive Neigungswinkel und Orientierung im SHP-Format. Die Daten wurden im Rahmen des TwinCity-Projektes erstellt.

- Zugriff auf den WebClient von TwinCity3D zur visuellen Sichtbarkeitsanalyse
- Zugriff auf den infra3D-Client zur Anfertigung von Straßenquerschnitten und Arbeiten mit Vorort-Bildmaterial sowie Zugriff auf die LIDAR-Punktwolke im LAS-Format.
- Ensemble-Daten / Baudenkmal-Daten des Bayerischen Denkmal-Atlasses im SHP-Format
- Aus Denkmalschutz-Gründen wichtige Stadtbausteine in SHP-Format

Abb. 1: Ausschnitt aus dem TwinCity3D-Client mit dem CityGML-LOD2-Modell auf der linken und des kongruenten texturierten Mesh-Modell aus den Befliegungsdaten auf der rechten Seite (RealityMaps)

4.2 Methodik

Im Rahmen eines Solarrahmenplans werden Untersuchungen durchgeführt, anhand derer beurteilt werden kann, wie eine PV-Anlage auf einem Gebäudedach zulässig ist und welche technischen und gestalterischen Kriterien aus denkmalpflegerischer Sicht einzuhalten sind.Die Sichtbarkeit aus öffentlichen Bereichen werden digital analysiert und validiert (Abb 2).

Für die Erstellung des Solarrahmenplans zur Klassifikation von Gebäudedächern für Photovoltaikanlagen werden folgende Arbeitsschritte definiert:

1) Grundlagenprüfung, bei der relevante Rahmenbedingungen aufgenommen werden. Dies sind im Einzelnen die Analyse von allgemeinen,rechtlichen Festsetzungen und Schutzstatus des Denkmals, die Bewertung der Dachneigung und -ausrichtung sowie die Prüfung der Sichtbarkeit – einer Identifizierbarkeit von Dachfarbe und -form im Radius von 800 m und 400 m – für eine potenziell stärker zu integrierende Form der PV-Module.

Dauraufhin werden in 2) die Gebäude für den Solarrahmenplan kategorisiert. Ausschlaggebende Attribute sind aus dem Bereich des Denkmalsschutzes ob ein Ensemble- oder Einzeldenkmalschutz vorliegt. Zusätzlich zu einer Solarpotenzialprüfung und der o.g. Sichtbarkeitsprüfung werden die Dachflächen, teilweise sogar Teildachflächen in vier Kategorien eingeordnet (von „höchste Anforderungen“ – Kategorie 0 bis „geringe Anforderungen“ Kategorie 3.3)Die PV-Modulkonfiguration schlägt dann Modulgrößen, Farben und Oberfläche für eine optimale Flächennutzung und visuelle Integration vor. 4) Der abschließende Gestaltungsvorschlagintegriert als eine Art „Fliesenspiegel Solar“ den Vorschlag als Textur auf die Dachflächen im digitalen Zwilling.

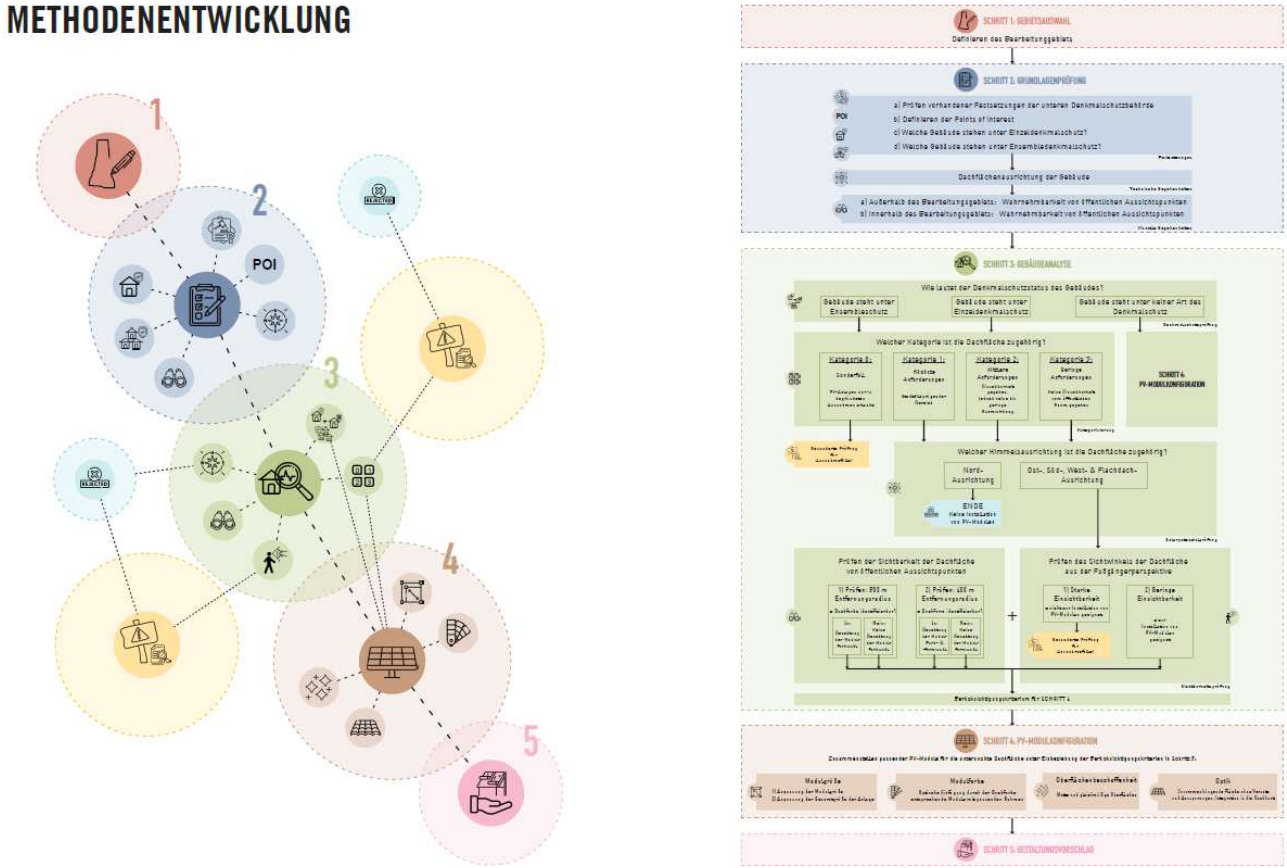

Abb.2: Methodisches Ablaufschema der einzelnen Untersuchungsschritte (Bürkle & Bauder 2025)

4.2.1 Grundlagenprüfung mit Sichtbarkeitsanalyse und Dachformen – Alles was Licht berührt

Ein besonderer Punkt von Gestaltungsplanung ist nicht nur im Denkmalschutz die Überprüfung von Sichtbarkeiten. Methoden wie „Line of Sight“ in 3D-Stadtmodellen (Kolbe und Donaubauer 2021) oder Isovist-Technologien (Lonergan und Hedley 2016)stehen hier als neue Arten der Berechnung von Sichtbarkeiten im dreidimensionalen Kontext. Ein einfacher Weg der ersten Klassifikation von Sichtbarkeiten ist eine Radius-Berechnung um einen bestimmten, historisch wichtigen Beobachtungspunkt in Form eines Puffers. Diese Berechnung funktioniert allerdings nur bei wenigen wichtigen Punkten, ist das Ensemble / das Denkmal stark einsehbar, stößt diese generelle Berechung an seine Grenzen bzw. muss auf Gebäudeebene nochmals über die o.g. Viewer überprüft werden.

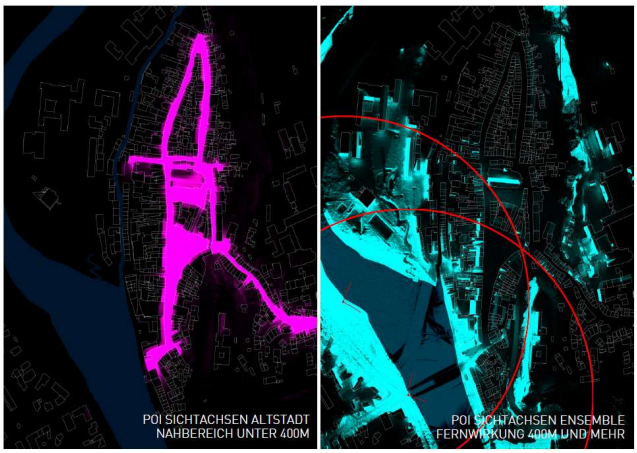

Abb. 3: Berechnung der sichtbaren Bereiche mithilfe von 2D-Radien um einen bestimmten Beobachtungspunkt (links) und mithilfe von Lichtberechnungen in den rechten drei Bildern inklusive der Sichtbarkeitslassifikation in Nah-, Fern- und Nah-und-Fernbereich (Bürkle & Bauder 2025, Herm&Benkeser 2025)

Ein in der Studie vielversprechender Ansatz ist die Sichtbarkeitsberechnung mithilfe von Flächenlichtern. Durch das Anheben des Flächenpolygons des öffentlichen Straßenraums auf 180cm über Bodenlevel und

Setzen einer über die Gesamtfläche ausstrahlenden Lichtquelle werden an jeder Stelle des Polygons die Einsehmöglichkeiten eines Beobachter simuliert. Alle Dachflächen, die direktes Licht von dieser Lichtquelle aus aufnehmen, sind einsehbar. Im Umkehrschluss sind die Schattenbereiche Potenzialbereiche für PV-Anlagen, in denen aufgrund der fehlenden Einsehbarkeit KEINE besonderen Gestaltungsmaßnahmen formuliert werden müssen.

4.2.2 Kategorisierung der Gebäude als Grundlage des Solarrahmenplans

Aus den Aspekten der stadthistorischen Bedeutung, dem Schutzanspruch des Denkmals und der Einsehbarkeit findet im nächsten Schritt eine Kategorisierung statt. Dabei wurden vier Kategorien gebildet, die sich nach der strenge der Anforderungen von „Kategorie 0 – Höchste Anforderungen“, über „Kategorie 1 – Hohe Anforderungen“ und „Kategorie 2 – Mittlere Anforderungen“ bis zur „Kategorie 4 – Geringe Anforderungen“ erstrecken. Die höchsten gestalterischen Anforderungen zur Nutzung von Solarenergie werden bei den Dachflächen derjenigen Gebäude formuliert, die aufgrund ihrer stadthistorischen Bedeutung und als Einzeldenkmal besonders sensibel zu behandeln sind. Für diejenigen Gebäude, die aufgrund ihrer Präsenz eine wichtige Bausteinwirkung innerhalb des denkmalgeschützten Ensembles haben, werden hohe Anforderungen formuliert werden müssen. Für Gebäude, die selbst keine oder nur eine geringe Raumwirkung aufweisen, im Hinblick auf die Dachlandschaft des Ensembles jedoch leicht einsehbar sind, werden später mittlere Anforderungen formuliert. Dachflächen von Gebäuden, die keine Einsehbarkeit aus dem öffentlichen Raum aufweisen, können mit geringen gestalterischen Anforderungen um eine solarenergetische Nutzung erweitert werden.Abb. 4zeigt die exemplarische Kategorisierung eines zu beurteilenden Gebietes in der Altstadt Landsberg am Lech, das anhand des o.g. Ablaufschemas / Datenworkflows beurteilt und kategorisiert wurde.

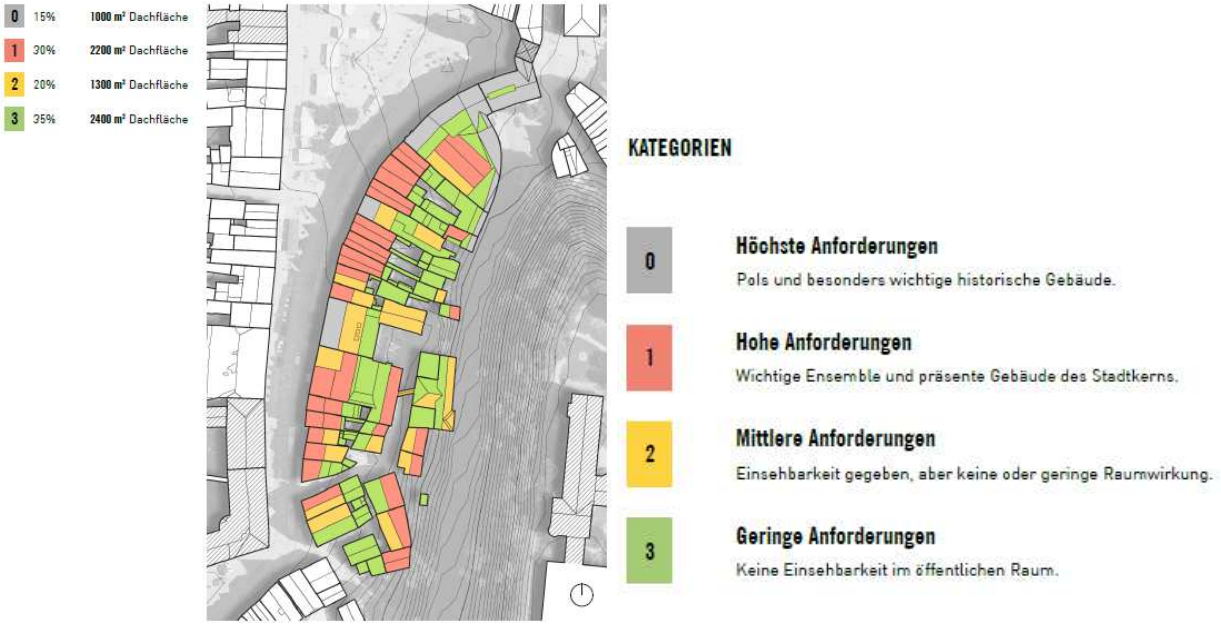

Abb.4: Solarrahmenplan des Gebietes östlich des Hauptplatzes in Landsberg am Lech inklusive der Kategorieeinteilung sowie Dachflächenbilanzierung (Heim & Mink 2025)

4.2.3 Geopositionierte Bearbeitung am Objekt – auf dem Dach

Mithilfe der in den vorigen Arbeitsschritten erstellten Datensätze kann nun relativ einfach ein hausbasierter Steckbrief erstellt werden, der wie in einer Art Steckbrief sämtliche für die Installation von PV-Modulen benötigten Informationen enthält. Neben der formalen Einteilung in den Kategorietypus sind dies Informationen zur potenziell installierbaren PV-Fläche nach Modultypus inklusive eines Muster-Vorschlages, eine Sichtbarkeitsüberprüfung des installierten Moduls sowie eine grobe Ertragsrechnung aus den, in der GIS-Analyse ermittelten, räumlichen Werten.

Im Rahmen der Studie wurden für verschiedene Kategorien auch Belegungspläne für die jeweiligen Module in der zugeordneten Kategorie erstellt, die ähnlich eines Fliesenspiegels den räumlichen Eindruck vermitteln. Dieser Belegungsplan wird wiederum als Textur ausgegeben und kann später, im Idealfall georeferenziert als optionale Dachinformation in das komunale GI-System zurück gespiegelt werden – CityGML liefert in der

LOD3-Beschreibung hierfür eine Möglichkeit des Speicherns. Diese Textur kann auch für eine Fotomontage in der Ansicht des infra3D-Clients oder TwinCity3D zur schnellen visuellen Prüfung überlagert werden. Ein Beispiel für diese Möglichkeiten ist in Abbildung zu sehen.

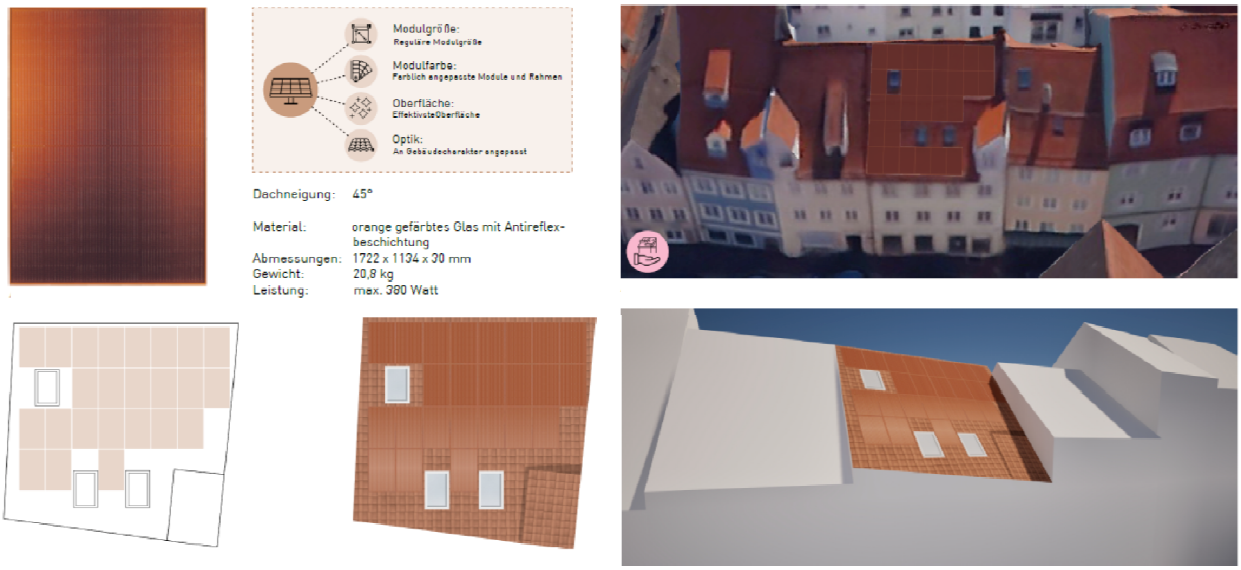

Abb.5: Informationen zum PV-Modul, der Belegungsplan als Rohzeichnung und mit Textur, sowie die Fotomontage in TwinCity3D und der gerenderten Ausgabe im LOD2-Stadtmodell der Stadt Landsberg (Bauder & Bürkle 2025)

5 FAZIT

Innerhalb der Forschungsstudie konnten die für die Aufstelllung eines Solarrahmenplans geforderten Aspekte in Kombination mit den vorhandenen Geodatenbeständen und unter Zuhilfenahme von Werkezeugen des digitalen Zwillings nicht nur erfolgreich bearbeitet werden, sondern die methodischen Ansätze für die Erstellung eine Solarrahmenplanes gehen über die bisher erfolgreich umgesetzten Projekte wie in Wasserburg, Würzburg oder Bayreuth einen Schritt weiter. Die konsequente Einbeziehung der dreidimensionalen Morphologie und der Gestalt der Dachflächen im Einzelfall bei einer gleichzeitigen Möglichkeit der Automatisierung einzelner Klassifikationsschritte könnte in Zukunft die Aufstellung von Solarrahmenplänen erleichtern, beschleunigen, teilweise automatisierten und bauteilorientierter (dachflächenorientierter) verständlicher gestalten. Die getesteten Methoden helfen, örtliche Begebenheiten ohne zeitaufwändige Ortsbegehungen im Vorfeld zu analysieren, ersetzen jedoch im Einzelfall nicht die zielgerichtete Expertise von Experten am Objekt – denn, wie bei allen digitalen Methoden: Das Online geht nicht ohne das Offline.

6 AUSBLICK

In den nächsten Schritten sind Verschneidungen von (theoretischem) Solarpotenzial und den Möglichkeiten nach denkmalpflegerischer Beurteilung vorstellbar. Desweiteren ist vorgesehen, die exemplarisch angefertigten Steckbriefbewertungen einzelner Gebäude auf die verbleibenden Altstadtgebäude auszuweiten. Der resultierende Solarrahmenplan als Ganzes soll schließlich in den TwinCity3D-Viewer integriert werden, so dass Bauinteressenten sich vorab darüber informieren können, was auf den eigenen (Teil-)Dachflächen unter Berücksichtigung denkmalschutzfachlicher Aspekte zur Nutzung von Solarenergie möglich ist.

Durch die weitere, konsequente Einbeziehung von CityGML bzw. sogenannte „City Information Modelling (CIM)“-Ansätze, die Eigenschaften von GIS und BIM/IFC komprimiert verbinden, sollten auch fehlende Dimensionen wie Energiebedarfe, Aussagen über Fassaden und weitere Parameter (eine DSGVO-Konformität vorausgesetzt) über ein Schnittstelle wie z.B. OpenFOAM in den digitalen Zwilling überführt werden können.

1 ABSTRACT

The paper presents the discussion regarding up-to-date development in such subject domains as “digital twins”, artificial assistant and etc. The two main topic will be presented in this paper: philosophical background and representation of a person as a digital automate. Philosophical background presents some conclusions from the our previous papers, published in REAL CORP proceedings.

Representation of a person as a digital automate aims to investigate how to present main philosophical existences form the modern computer science point of view. We have used our experience in computer science in such fields as systems of ontology, inference machine, scenario approach, object oriented approach. As an example, we should say that some abstractions in OOA are very similar to key abstractions in classical philosophy.

Keywords: Individual Track, Individual Profile, Digital Human, Digital World, Individual and Collective Unconscious

2 INTRODUCTION

In our previous works, published in the CORP proceedings, we have tried to consider the views of classical philosophers on such eternal problems as the relationship between consciousness and existence, the essence of human thinking, space and time, nature (the external world) and human, the ability to perceive the surrounding world and oneself.

And now we have set ourselves the task of transforming philosophical concepts and categories into the language of computer science. The goal of this transformation is to try to represent certain aspects of a person in the computer world. In this regard, existing ideas of “digital twins” concern only superficial, external factors, such as passport data, biography, medical characteristics, physical data. Such data do not characterize a person as a phenomenon. This is a social and physical portrait, which very approximately relates to the very essence of “human”.

Of course, it would be foolish to ignore these characteristics of a person, but focusing only on them is even more utopian in the direction of a digital twin. The theoretical developments that we present here serve as a theoretical and technological basis for building a real intelligent assistant for each person. An intelligent human assistant (Human Artificial Assistant (HA²)) should really help a person navigate our complex world, including with the advent of powerful computers and networks, some of which are even called artificial intelligence (AI), although before that there is a qualitative leap to overcome. So far, this is an imitation of AI, and not AI itself. BUT, in our opinion, the main task of HA² for a person is a tool for self-knowledge. We hope that HA² itself will be discussed in our next article.

3 PHILOSOPHICAL BACKGROUND

Based on the works of such philosophers as Spinoza, Descartes, Kant, Hegel, Fromm, Jung and others, which we have reviewed in our previous publications at CORP, we will consider the dynamics of the interaction of such entities as the conscious, individual and collective unconscious. Fig. 1 presents the hypothesis of individual’s development.

Point “O” is the beginning of the creation of human as a representative of a new civilization on planet Earth. Before this, “was” something else. The concept of “was” is not entirely appropriate, since perhaps there is something in parallel, but we have nothing else as an understanding, except for “was”. Point “X” is the point of “original sin” – let us call it that. At this point, presumably, the synthesis of spirit and matter is realized, and the spirit begins to know itself and matter.

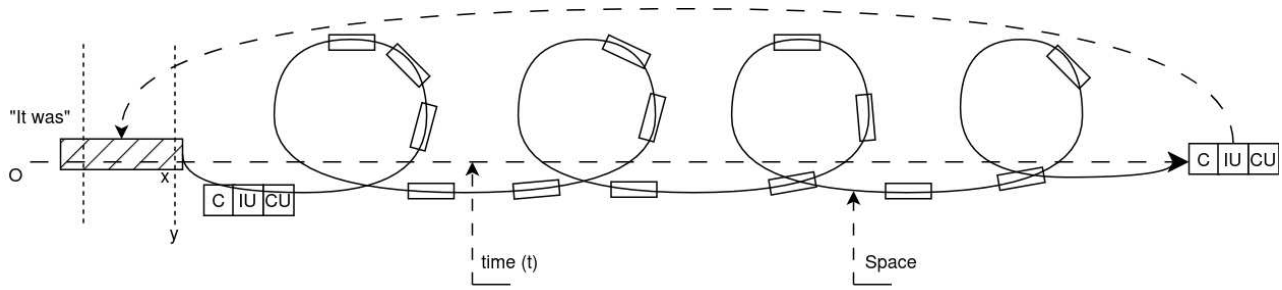

Fig. 1: Hypothesis of Individual Evolution – conscious (C), /// – individual unconscious (IU), xxx – collective unconscious (CU).

In this case, consciousness begins to divide into at least three parts: conscious, individual unconscious and collective unconscious, this is what was “installed” in the interval 0 – t. At point X, time t and space S appear. Apparently, the evolution of the individual, presented in Fig. 1, is common to all living beings. The interval X-Y is “childhood”.

It has two meanings – it is the beginning of modern civilization, and the period of childhood at birth. The birth of a person is also an imitation of the "original sin", a rupture of primary bonds. During this time, a person begins to adapt to the world he has entered. During this period, all three elements: conscious, IU and CU are closely connected. Therefore, a child after birth is of a significantly higher order than an adult, who is already very limited and has strong gaps between C, IU and CU. Apparently, the task of an individual is to make three entities united: C, IU and CU.

It is quite possible that it is impossible to do this in one period of life. The idea of reincarnation, for example, in the culture of Buddhism, has a similar meaning. The existing and diverging gap of the second kind (mathematical analysis) sharply limits the cognitive activity of the individual. But it is objectively conditioned. The fact is that the appearance of these “gaps”, the concepts of “space”, “time” is conditioned by our physical capabilities. Man is greatly limited, apparently due to energy capabilities. Even in the current state, the human brain spends more than 25% of all human energy. Any increase in brain function leads to an increase in energy costs. Man will need a completely different physical body and energy supply system, which, in the current conditions of planet Earth, is quite possibly already impossible. Here, according to the expression of Marxists, being clearly defines the limits of consciousness, our capabilities. To increase intellectual (cognitive) capabilities and progress in general, duality is encountered almost everywhere in our world. Man is also “divided” into two halves: man (M) and woman (W). In this sense, if we look again at Fig. 1, it shows a spiral of one half. Two spirals will have the form shown in Fig. 2.

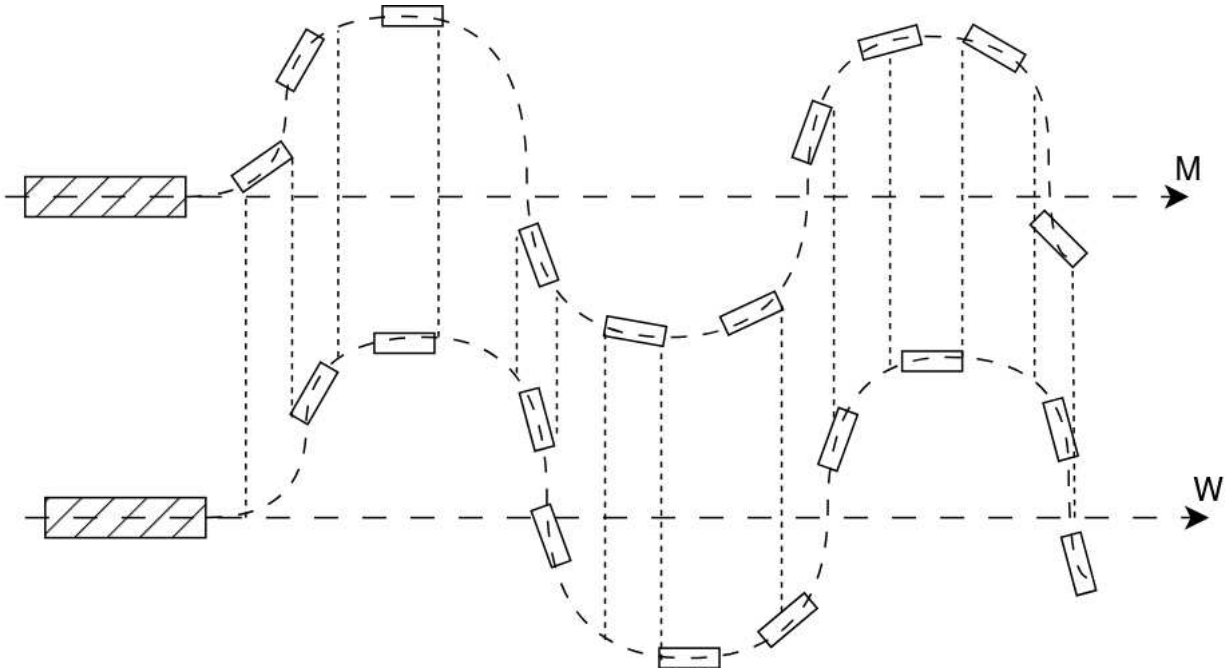

Fig. 2: Two spirals of evolution, probably for man (M) and woman (W).

The axes M and F shown in Fig. 2 look like curved lines, although this may not be the case at all, but the essence of the explanations does not change. In addition to the reproductive instinct and libido described by Z. Freud, the attraction between M and F may also be based on an unconscious desire to eliminate the second-order breaks between C, IU and CU. If we imagine that the spirals M and F coincide in phase, but the second-order breaks do not coincide, then we obtain an integral projection that is practically continuous, or with minimal breaks, when the second-order break turns into a first-order break, and ideally they tend to solid spiral rings, see Fig. 3. Note. Fig. 2 shows the idea itself, but not the appearance and essence of this hypothesis.

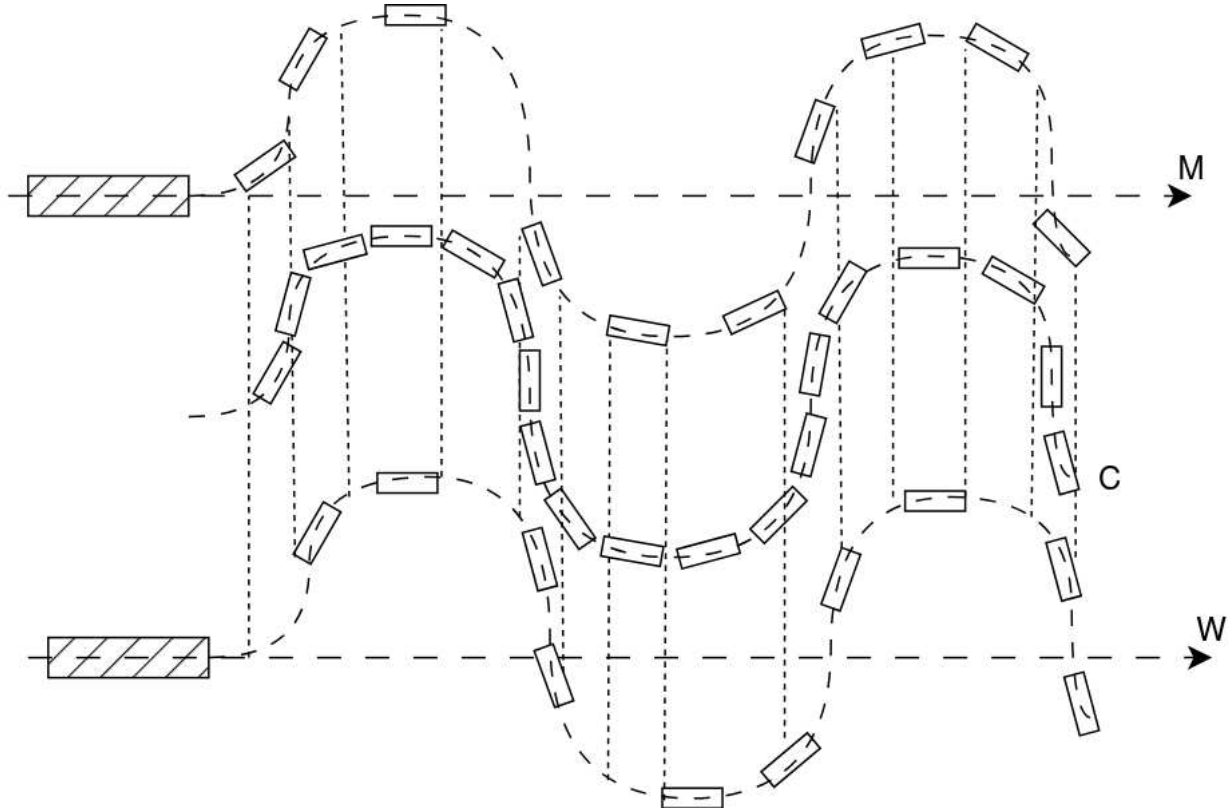

Fig. 3: Projection of two spirals for man (M) and woman (W).

The integral projection shown in Fig. 3 has unreal power and energy. When synchronizing spirals, such a concept as Anima in Hume's terminology arises. Let's make a few comments on the idea shown in Fig. 3.

(1) For synchronization, it is necessary to apply efforts, preferably from both sides.

(2) The feeling of synchronization is frightening with its power and energy and its beginning can be repulsive, especially for a modern person.

(3) The period of existence of synchronization depends on many factors. It can last for months, or even a lifetime.

(4) The fact of synchronization remains for life, regardless of the duration and result.

(5) The state of synchronization gives birth to brilliant scientific ideas, works of art, and motivates a person to a feat.

Another option is possible, an option for human development compared to the one shown in Fig. 1.

Fig. 4 shows a variant of a “diverging” spiral. In this case, not only does the second-order rupture increase, but there is also no tendency toward convergence. In this case, we can say that a person has lived his life in vain for himself. It is quite possible that he has become a negative example for others and has also fulfilled his assigned mission. It is quite possible that such a spiral can also be synchronized with another, which will entail sad consequences for the other spiral.

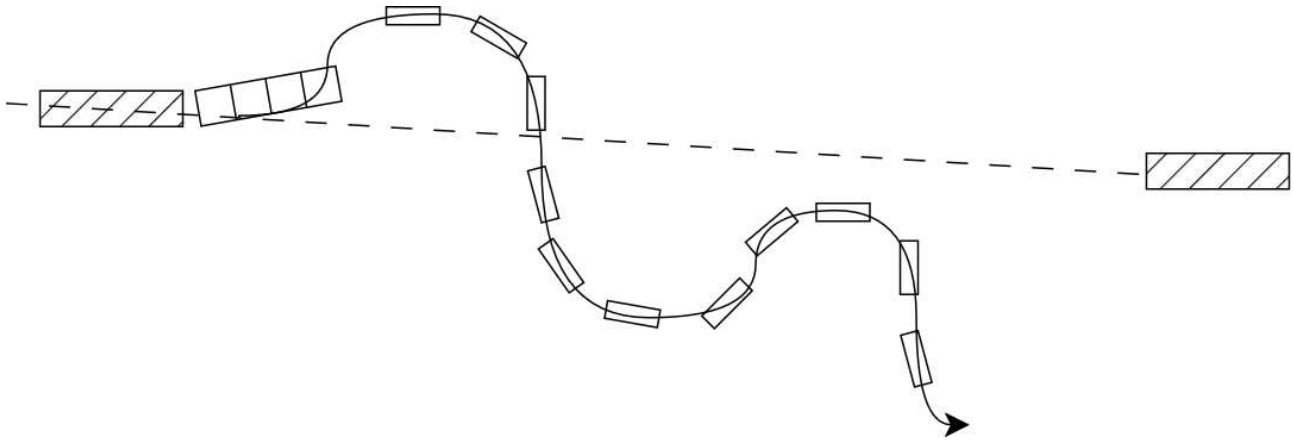

Fig. 4: Divergent spiral.

Notes. 1). It is necessary to separately study the question of when an ideology or religion takes hold of the consciousness of large masses of people? What happens in this case, what mechanisms are involved? What does it affect, what part of the soul? 2). Why does the fetus go through many forms of life on Earth during fetal development? Probably, this is due to the adjustment of a new life to the conditions of planet Earth, "training" and the formation of data, information, knowledge and understanding for existence in specific conditions occurs. This is evidence of the fact that planet Earth is not the only possible place for the existence of intelligent beings (the fusion of the spiritual and the material in one entity). A rational being must have multiple cycles of rebirth.

4 HUMAN REPRESENTATION AS A DIGITAL AUTOMATE

Human representation as a digital automate is the first step to connect computers directly to the essence of this topic, i.e. Human research. For such a representation, we will use the object-oriented approach – a direction in the field of development of large and complex computer systems that arose in the mid-60s of the last century. This is more than a programming paradigm, it is a programming philosophy based on real software development tools. Mechanical use of OOA languages leads to failures and disappointment, OOA itself is criticized. In our opinion, this is due to shortcomings in computer education and a lack of understanding of the basic foundations of this methodology (OOA).

Vulgar use of OOA leads to anarchy in classes, overloading computers, code redundancy and the impossibility of maintaining anarchic and tangled code. This was a lyrical digression, and now, in accordance with OOA, we will define the domain architecture of a human. In accordance with philosophical views, three level architecture of human: body (physical existence), soul and spirit can be selected. Let's try to make several analogies of a “philosopher's man” and a “computer man” at a primary, very simplified level. Let's assume that a person's physical body is the computer's “hardware”. We can connect power to the hardware, it will indicate that it is working, but will not be able to perform any functions (provided that the software is not pre-installed in memory, or is not implemented in hardware). In order for the hardware to come to life, an operating system is required, which organizes the work of all elements of the hardware and can load application software, i.e. what can be loaded. Thus, in our primitive analogy, the operating system is a kind of analogue of the human soul, which animates the physical body, makes it capable of existence and ready for learning, for a certain mission or actions. Application software is actually the implementation of the mission, or purpose of the computer. In our greatly simplified interpretation, it is the spirit of man. Thus, we have defined the main components for representing a person as a digital machine in a computer. A computer representation is the implementation of a virtual model of a person with various goals. We are primarily interested in the possibility of self-knowledge and the search for like-minded people. Possibility of self investigation.

Possibility of self investigation.

1. Individual conscious. That which we are relatively clearly aware of and can imagine in various forms.

2. Individual unconscious. That which we are not clearly aware of and can only imagine indirectly, through various mechanisms, possibly with the help of psychologists and psychotherapists.

3. Collective unconscious. That which we are not aware of and cannot individually imagine. A collective approach, a system of research and scientific knowledge are required.

Let us consider a set of modern computer technologies, the use of which can help in the implementation of a digital twin and a tool for helping a person.

5 SOFTWARE TOOLS

To present a set of tools from the software field, let us consider a person as a certain entity interacting with the outside world at the level of physical sensors and abstract thinking (consciousness).

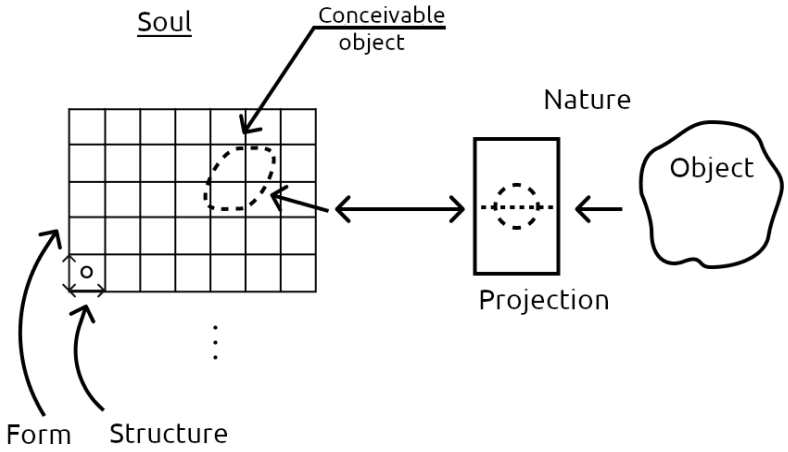

Fig. 5: "Mechanics" of nature and human interaction by K.G. Jung.

Let us also keep in mind that some elements of consciousness are pre-installed in us (I. Kant, K.G. Jung), so we perceive the reality around us through a system of filters. The first filter is the physical ability to react to external fields (limitations on wave ranges for vision and hearing, for example). Therefore, we will imagine the ability to have data about the outside world as capabilities (limitations) when working with a certain framework. At the same time, the choice of frameworks is very limited and determined by the power of our computer, perhaps this is the brain, unless it is an interface, and everything else is part of the virtual space. Thus, the main channels of communication with the outside world that are familiar to us are vision (the main flow of information), hearing, tactile capabilities, vibrations, etc. Information that comes through our senses is data that requires preliminary processing, which our brain does unnoticed by a person. Then the data acquires the meaning of information that is already obtained as a result of training and individual experience of the individual.

Tools such as data analysis packages, including big data, work with data. At this level, a computer today works better than a person. Information is indirect data or meta-data. For example, some information on a GIS map (streets, buildings, institutions, etc.). Modern computer technologies cope well with this level, but data models must first be developed, or clustering packages or pattern detection packages must be applied in data arrays. The use of neural networks and the SVD method allows us to detect information that is not obvious and not directly accessible to humans. The concept of "knowledge" arises only in the process of huge experience and/or training. This concept is no longer trivial for modern computer technologies. It can be implemented through some patterns or scenarios that have received approval, or have positive multiple experience of scenario behavior. It can be derived from logical inference. At the current time, first-order predicate algebra is a good approach in this regard. Logical inference can also be. automated using machines, such as the Rete logical inference machine (LIM). This LIM is widely used in various logical languages and programming environments. We use this technology to develop a scripting system, and have developed a visual script editor that greatly simplifies the use of logical languages. The situation with such a phenomenon as "understanding" is quite complicated.

As E. Fromm noted, modern humanity strives to know, but does not want to understand. This is the fundamental difference between these two concepts (knowledge and understanding). If the concept of "knowledge" can be implemented through a certain repository of scenarios implementing a certain business analytics, i.e. directly using existing tools, then with "understanding" everything is more complicated. After all, understanding is the establishment of cause-and-effect relationships of events. The answer to the question

of why exactly this happens and not something else. This property allows a person to make a decision in situations for which there are no patterns. In fact, only through understanding can new knowledge be generated. Experience is a weak assistant here. Thus, you can endlessly watch the sun rise and set. But without the appropriate theoretical knowledge, an ordinary person on Earth cannot imagine that the Earth revolves around the Sun, and not vice versa. In order to somehow get closer to the implementation of "understanding", we proposed an approach based on the theory of situational management – the analysis of tactical situations. Although the concept of "analysis of tactical situations" is widely used in military affairs, it was apparently first introduced by Gabriel Jacobson, a student of A. Pospelov.

Let's list the existing technologies that can be used to form a digital twin of oneself.

1. Implementation of interfaces: – Interfaces: human←-→environment, human←-→devices. Can be done using web devices (camera, microphone, etc.) and saved on a computer. We implement it using the appropriate protocols that are connected to the ontology system so that the input data stream is meaningful and ordered, and also open for analysis by humans and other applications. Tool – Java code or script.

2. Ontology system – ontology (individual, individual unconscious, collective unconscious, environment, scenarios). Individual conscious can be presented in the form of ontologies using visual ontology editors according to previously formed recommendations. Ontology can be formed by surveying and/or analyzing human actions on a computer. Tool – Java code and Drools logical programming language.

3. Business analytics. It is implemented on the basis of an ontology in the form of a scenario system. Tool – Protege ontology editor, or our own editor.

4. Body properties. It is implemented on the basis of an ontology in the form of a system of properties obtained as a result of instrumental measurements.

5. Soul properties. It is difficult to obtain such an ontology explicitly. It is necessary to develop special methods and analyzers with the ability to manually or automatically edit the editorial version.

6. Spirit properties. This is the most complex substance and determines a person's purpose in this life, his global goals. We do not have any ideas for implementing this phenomenon at the current time.

6 CONCLUSION

In this article we tried to form a certain system of correspondences between classical philosophy and computer science. This is the first step to form the idea of creating an artificial human assistant and a tool for studying oneself. The article showed that many categories of philosophy coincide with concepts in computer science, especially in the OOA methodology. However, the issue of creating an artificial human assistant – HA² has a number of difficulties, namely:

- to help a person, HA² must know who it is helping, i.e. know a lot about the person. Thus, the computer must store a real digital twin of a specific individual, and not formal characteristics;
- HA² must have access to all incoming and outgoing information from a person. This is very difficult and quite dangerous, given attempts to hack personal information, or erase it, or distort it;
- the entire ontology about a person will occupy quite a large physical space, so it must be stored in the cloud, well protected and reliable;
- for the full implementation of HA², interaction with other similar entities is necessary, sometimes in real time. Hence, a mechanism of mutual trust must be implemented, excluding unwanted or even malicious individuals, and sometimes banal scammers, from getting into a certain social group. This task can be implemented using technologies similar to Blockchain.

Despite the obvious difficulties, the creation of applications like HA2 is already on the way. In the near future, we expect the first such applications to appear, possibly based on social networks, or standalone applications.

In our next article, we plan to describe the technology of creating HA2 and its application to real people.

1 ABSTRACT

This paper explores how Citizen Observatories can foster participatory, data-driven governance by actively engaging local communities in co-creating urban knowledge and contributing to evidence-based decision-making processes. Within the EU-funded Innovation Action GREENGAGE (HORIZON 2020), five innovative Citizen Observatories have been established as dynamic ecosystems where technology, citizen science, and policy intersect. These ecosystems empower local communities through interactive socio-technical methodologies and tools, enabling them to monitor environmental conditions, share insights, and collaboratively develop solutions to pressing urban issues. Hence, the creation of Citizen Observatories requires a strong focus on two dimensions: social (socio-economic and political context) and technical (digital tools and platforms). By bringing together citizens, scientists, policymakers, and other stakeholders, GREENGAGE harnesses collective knowledge and expertise to co-create sustainable solutions. In GREENGAGE, Citizen Observatories are located in diverse geographical and social contexts: Bristol (UK), North Brabant (NL), Copenhagen (DK), Turano Valley (IT) and Gerace (IT). This paper highlights initial implementations carried out in these Observatories where local communities, further supported by the consortium members, were provided with skills for collecting valuable, community-sourced data from their neighborhoods using the provided tools. Citizens are involved as Citizen Observers throughout the onboarding, training, and implementation phases, contributing to environmental monitoring and urban planning. The data that is currently being gathered will help directly address local urban challenges that are identified as the most critical by these communities, helping to resolve issues that resonate with local needs and concerns. Furthermore, the paper also illustrates how such initiatives have the potential to not only contribute to healthier, more sustainable urban environments but also foster a culture of participatory governance, where citizens are co-creators of the cities they inhabit.

2 INTRODUCTION

2.1 Background

As cities increasingly confront challenges posed by climate change and urbanisation – ranging from extreme heat events to increasing demands on infrastructure and resources – there is a growing need for governance models that are both inclusive and data-driven (Asadzadeh et al. 2023). This demand is becoming a key priority in the international arena, highlighting a global recognition of the necessity for more collaborative and inclusive strategies of policy-making (Rocha Menocal et al. 2019; Hölscher et al. 2019; Avoyan 2023). Central to this need are socio-ecological challenges such as extreme weather events, social inequality, climate injustice, biodiversity loss, ecosystem degradation, and the growing mistrust among communities in

their local authorities' ability to address these issues effectively. Given the gravity of these challenges, the European Commission has made an ambitious effort to tackle climate change and drive a transition toward more sustainable development. This commitment is reflected in the EU Green Deal (Broto 2021), a comprehensive policy framework aimed at embedding sustainability and climate action across all EU policies and programs. The Green Deal presents cities with a unique opportunity to drive systemic economic and social transformation.

However, a significant obstacle to reshaping urban governance effectively is the persistent disconnect with local communities, including their concerns, needs, and perspectives. This gap is exacerbated by the absence of robust participatory approaches. As a result, the marginalisation of such grassroots perspectives is expected to exacerbate inequalities and existing disparities in access to opportunities and knowledge. At the same time, it is becoming increasingly clear that traditional top-down urban governance models are often ill-equipped to address the complexity and interconnected nature of these challenges (Baud et al. 2021). These models rely heavily on centralised decision-making by higher authorities, which can overlook the nuanced realities and diverse needs of local communities. Hence, the conventional urban governance approaches are being challenged by an imperative for innovative solutions that transcend institutional silos. Furthermore, there is a significant gap in comprehensive in-situ data (i.e., site-specific, real-time data gathered directly at the location where the phenomena occur) that can effectively capture the intricate and interconnected dynamics of urban environments. This absence of high-quality in-situ data severely limits the ability of decision-makers to identify and address emerging context-specific challenges (Tonne et al. 2020). As a result, responses often lack the timeliness, precision, and relevance needed to tackle complex urban issues in an informed and proactive manner. To address this, cities are increasingly turning to innovative solutions that prioritise public engagement through equitable participation and open dialogue. Prominent among these practices is citizen science, which empowers non-professional volunteers from the general public to contribute and co-produce new and complementary knowledge that benefits both science and society (Haklay et al. 2021). Despite its potential, citizen science has faced criticism for its fragmented landscape, often consisting of isolated activities focused on specific issues (O'Grady et al. 2021). Examples include initiatives centered on air quality monitoring (Mahajan et al. 2022), bird monitoring (Ding et al. 2022), butterfly counts (Butler et al. 2024), biodiversity conservation (Peter et al. 2021), and water quality assessment (Yevenes et al. 2022). This fragmentation highlights the need for more integrated and cohesive approaches that maximise the collective impact of citizen science efforts.

In response, a complementary concept, known as the Citizen Observatory (CO), has emerged. This concept builds upon the foundations of conventional citizen science while addressing its fundamental limitations and expanding its scope (Lie et al. 2017, O'Grady et al. 2021). Citizen Observatories (COs) function as comprehensive ecosystems of collaborative observation and action, tackling urban planning challenges linked to climate change and community disengagement through diverse and holistic perspectives. Unlike traditional citizen science initiatives, which often focus on singular issues, Citizen Observatories adopt an integrated approach that fosters a multifaceted understanding of complex problems (Rathnayake et al. 2020, O'Grady et al. 2021). This approach brings together the collective knowledge and expertise of citizens, scientists, policymakers, and other stakeholders to co-create solutions. Additionally, while citizen science primarily focuses on collecting objective, scientific data, COs go beyond that by integrating subjective information such as personal perceptions and experiences, which are crucial for understanding how people's attitudes and behaviours evolve. By incorporating diverse perspectives and methodologies, COs enable a more nuanced, participatory, and citizen-centric approach to problem-solving. This, in turn, facilitates deeper reflection and more agile, context-sensitive responses to emerging societal and environmental challenges.

2.2 Overview

The transformative potential of COs is currently being leveraged within the pan-European Innovation Action GREENGAGE, funded by the Horizon Europe program (GREENGAGE 2025). As part of this initiative, five innovative COs in diverse geographical and social contexts have been established as dynamic ecosystems where technology, citizen science, and policy intersect: Bristol (UK), North Brabant (the Netherlands), Copenhagen (Denmark), Turano Valley (Italy), and Gerace (Italy). The five pilots serve as living laboratories of innovation, showing how citizen engagement, technological advancement, and governance transformation can intersect to reshape civic participation and policymaking. To achieve this, a range of initiatives is being

implemented within these COs, supported by the GREENGAGE consortium. By providing expertise, resources, and guidance, the consortium ensures that local communities are equipped with tailored socio-technical methodologies and tools to observe, monitor, and actively engage with their neighborhoods. In this collaborative process, community members take on the role of Citizen Observers, actively participating in environmental monitoring, mobility pattern analysis, and the evaluation of public space usage in tourism. These thematic areas are selected based on the priorities identified by the communities themselves, ensuring that the initiatives address issues most relevant to their specific needs and concerns.

3 METHODOLOGY

3.1 Innovation pilots in GREENGAGE

GREENGAGE innovation pilots span diverse geographical and social contexts, with activities specifically designed to address local environmental and sustainability challenges, further aligned with the broader Green Deal priorities (see Figure 1). In Bristol, a densely populated city in southwest England, the CO operates at a neighbourhood level, engaging local communities in reimagining their neighbourhoods as people-centred, liveable spaces of clean air, quality green spaces, and a strong sense of community. In North Brabant, a predominantly rural and peri-urban province in the south of the Netherlands, the CO functions at the regional level, fostering community participation in the transition to a sustainable and smart mobility while enhancing climate resilience. Copenhagen, the capital of Denmark known for its waterfront developments and green urban planning, hosts its CO at the district level, mobilising citizens to contribute to the city's climate targets through air quality monitoring and climate adaptation initiatives. In the Turano Valley, a sparsely populated rural region in central Italy close to Rome, the CO operates at the municipal level, empowering communities to support climate resilience, regenerative practices, and the preservation of its rich cultural heritage. Similarly, Gerace, a historic hilltop town in southern Italy, hosts its CO at the municipal level, involving local communities in climate adaptation efforts and sustainable heritage conservation.

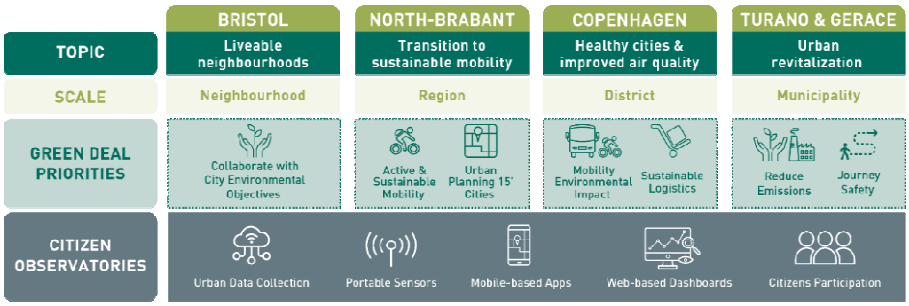

Fig. 1: Overview of the GREENGAGE pilots, highlighting their specific topic areas, scales of impact, Green Deal priorities, and core components of Citizen Observatories.

3.2 Foundational aspects of Citizen Observatories

The process of establishing Citizen Observatories in five pilot areas involves both social and technical dimensions. From a social perspective, it requires a deep understanding of the local socio-economic and political context, such as identifying key decision-makers, assessing community dynamics, and evaluating the unique challenges and opportunities within the area. From a technical perspective, it entails designing and implementing a robust technological framework, including digital tools and platforms, to facilitate data collection, analysis (including data validation), and collaboration effectively. The social dimension and its corresponding socio-political context are thoroughly mapped through a combination of surveys and interviews with key project partners leading each pilot area (i.e., pilot owners), offering a comprehensive overview of the local context with valuable insights into the social fabric, political structures, and community perspectives. The technical dimension was conceptualised through a series of collaborative discussions within the consortium to determine the appropriate tools and their intended applications, as well as the necessary levels of training and support.

However, both aspects are inherently dynamic and continuously evolving, shaped by the ever-changing real-world conditions, shifts in local power structures, and the evolving expectations and needs of communities. Therefore, to navigate the fluid nature of these challenges, our approach emphasizes flexibility through

adaptable strategies and continuous reassessment to ensure the COs remain relevant, responsive, and effective in tackling the priorities of the communities they serve. Hence, we have established a series of structured bi-weekly intra-consortia meetings, known as Pilot Support Teams (PST), to regularly reassess the local conditions, actively incorporate stakeholder feedback, and adjust our collective strategies accordingly. The PSTs consist of dedicated consortium members representing both technical domains (i.e., technology providers) and non-technical domains (i.e., participatory and social sciences). Together, they provide ongoing support to the pilot owners, who act as community representatives, ensuring a collaborative and holistic approach to addressing the needs of the communities involved. These meetings serve as a channel for ongoing collaboration and monitoring, enabling assessment of shifts in local power dynamics, as well as evolving community concerns and goals. This approach ensures agility, and through the iterative process, a continuous adaptation of the pilots to meet the changing needs and challenges.

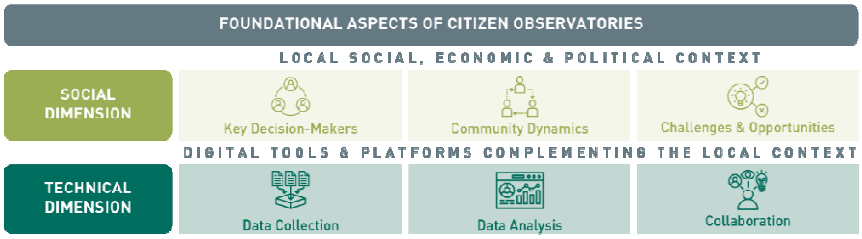

Fig. 2: Foundational aspects of Citizen Observatories: social and technical dimensions.

The PST sessions also provided the foundation for in-depth discussions on technical aspects. They facilitated the identification of the most suitable digital platforms, data collection methods, and socio-technical tools that would be most effective in meeting the goals of each CO. Specifically, participants in the COs have access to a diverse suite of technological assets designed to support the entire data-to-policy lifecycle. Curated for interoperability and scalability, these assets form the GREEN Engine – a comprehensive toolbox comprising three categories: (1) GREENGAGE tools, developed by the project consortium enabling data collection, visualisation, and analysis, also effective collaboration and engagement; (2) pilot-specific tools, tailored to the unique needs of individual pilots; and (3) open-source tools adopted by GREENGAGE, which enhance functionality and adaptability. Within proprietary GREENGAGE suite of tools, the starting point is the Collaborative Environment (Collaborative Environment 2025), a foundational tool for COs that facilitates the setup and management of co-production processes within a CO. Following, a range of mobile-based applications enables real-time mapping and image analysis (MindEarth app 2025), mobility patterns capture and modes of travel detection (MODE Software Library 2025), and qualitative spatial data collection on, e.g., local air quality or safety levels (GREENGAGE app 2025). Additionally, wearable environmental data capture devices (AtmoTube 2025), combined with visualisation dashboards and data analytics platforms, equip participants with powerful capabilities to visualise, analyse, and interpret environmental information effectively (Superset 2025). Altogether, these three categories of tools serve to facilitate community and process management as well as data crowdsourcing, empowering participants to contribute effectively to environmental monitoring and policy development.

3.3 Preparing for participatory data collection & analysis

In a participatory setting, individuals are not passive recipients of information; rather, they are recognized as active contributors, with their perspectives, knowledge, and skills integral to the process (Vaughn and Jacquez 2020). This collaborative principle is central to the GREENGAGE framework, which leverages co-creation and crowdsourcing to develop innovative data-driven solutions to urgent environmental challenges. At its core, the GREENGAGE project ensures that local communities are actively engaged from the very beginning, fostering a sense of shared responsibility and ownership in addressing these critical issues.

This process is realized through several steps that aim to co-deliver a thematic co-exploration (GREENGAGE Documentation 2025). Essentially, a thematic co-exploration is a collaborative process in which diverse stakeholders – including citizens, scientists, policymakers, and other relevant actors – jointly investigate, analyse, and develop insights on a specific theme or issue. This process unfolds in four key stages: (1) preparing, which involves identifying the theme, onboarding the core team, and providing necessary training; (2) designing, where experiments are specified, tools are selected, refined, and tested; (3) experimenting, which includes onboarding and training observers, followed by data collection and analysis;

and (4) sharing, where findings are communicated through storytelling and advocacy to drive awareness and action. All these aspects are addressed in the PST meetings, ensuring a structured and collaborative approach to planning, execution, and knowledge sharing throughout the process.

Once the theme of co-exploration is identified based on community concerns, the process moves forward with onboarding and training. Onboarding focused on identifying who should be involved, when and how they can best contribute to the co-creation process within COs. It defined the roles of key actors in collaborative efforts and assesses their technological and scientific capabilities. Essentially, it ensured a clear understanding of the communities to engage, the best timing and methods for their involvement, and their specific needs. Building on these insights, particularly technological and scientific needs, the next step focused on training. To support this, a range of training resources is developed as a part of the GREENGAGE Academy, including video tutorials on project-specific digital tools from the GREEN Engine toolbox, as well as guidance on the scientific methods, data standards, collection, processing, handling, and analysis. These were delivered through interactive online workshops, referred to as "Train the Trainers" training series. Initially, the training targeted the core team of Citizen Observers (i.e., selected members of the consortium), equipping them with the knowledge needed to oversee and support external participants (i.e., key actors from the onboarding phase), ensuring effective knowledge dissemination and capacity building beyond the consortium. The external training was conducted through community-oriented workshops held on-site in pilots, designed to foster hands-on learning and active engagement with key actors. These workshops were tailored to the specific needs of participants, ensuring accessibility and relevance while also incorporating their feedback on the proposed materials. This iterative approach allowed for continuous refinement, ensuring that emerging needs and perspectives were effectively addressed.

3.4 Advancing participatory governance models

To advance participatory governance models, the GREENGAGE project employs a robust approach grounded in transparency and inclusivity while fostering meaningful collaboration between local communities, policymakers, and experts. A crucial element of this approach is maintaining an open and continuous dialogue with these stakeholder groups, ensuring their voices are not only heard but actively integrated into decision-making processes. Efforts have been made to govern the co-creation process through the Collaborative Environment, supported by the thematic co-exploration process model. This model provides a structured framework that guides communities through the various phases, steps, and assets from the GREENGAGE Knowledge Base, ensuring they can effectively navigate and utilise the resources available at each stage of the process. However, not all aspects of this model have been fully embraced or implemented across GREENGAGE pilot contexts. This is primarily due to the varying local conditions, needs, and capacities of different communities, which can influence how certain tools or steps are adopted and integrated. To further facilitate a meaningful engagement, the GREENGAGE project is actively engaging in several structured activities, including public talks at international conferences, community forums, academic symposiums, and environmental summits. These events serve as a platform to connect with diverse audiences, share insights on participatory governance, and discuss innovative solutions to environmental challenges on both local and global scales. By bridging all these perspectives, we aim to create more effective and resilient governance structures.

In addition, we are organising a series of participatory workshops and are actively preparing for an upcoming datathon in Turano pilot in Italy. The aim of these activities is to create interactive spaces for co-creation, knowledge exchange, and data-driven decision-making. Specifically, participatory workshops empower both communities directly involved in the project and those beyond its scope to share firsthand experiences and insights. For instance, a series of workshops held with local communities from each pilot site are providing a valuable context on community dynamics, helping identify local priorities and better understand typical decision-making processes. Additionally, participatory workshops aimed at external audiences are engaging with students, academics, and other stakeholders to gather fresh perspectives on GREENGAGE activities. By incorporating external viewpoints, these workshops are continuously enriching the project's impact and ensuring its relevance across diverse contexts. Our upcoming datathons aim to engage citizens, researchers, technologists, and local stakeholders in collaboratively analysing real-world data and generating innovative, evidence-based approaches to environmental and urban challenges. The citizens who previously participated

in data collection will be invited to participate in the datahon, which should further deepen engagement and enrich the analysis.

4 RESULTS

4.1 Situational context and dynamics of pilot areas

We begin our discussion by reporting on the distinct situational context and dynamics of innovative pilots involved in the GREENGAGE project, as highlighted by our survey results, which collectively shaped the specific needs and priorities of each pilot area and influenced the design and implementation of COs.

Bristol, UK: The Bristol Pilot focuses on the East Bristol Liveable Neighbourhood (EBLN) initiative, which aims to enhance the quality of life in East Bristol through a smart urban governance approach. This approach involves co-discovery and co-development phases to understand the needs of the community, identify desired changes, and uncover barriers to creating a more liveable neighbourhood. During these phases, Bristol City Council (the GREENGAGE pilot owner) used a design toolkit to gather community aspirations through events and an online platform (Commonplace 2025). These phases served as precursors to a trial scheme design and delivery, where some of the community's aspirations will be tested. The EBLN project went through the Traffic Regulation Order (TRO) process. Bristol City Council held official consultations on proposed measures like bus gates and modal filters, which need TROs to make legal changes to the roads. Based on these consultations, the city council approved the trial scheme. At the time of writing this article, the trial scheme is being delivered. In addition to traditional methods, the GREENGAGE project plays a crucial role in monitoring the trial scheme. Continuous monitoring during the trial scheme will help assess the impact of changes on mobility, air quality, and equality. This monitoring will provide a basis for consultation with the community and implementing permanent changes in the EBLN.

North Brabant, NL: The North Brabant pilot focuses on exploring COs as a sustainable means of citizen participation. Following the Omgevingswet (Environmental Law) (Ministerie van Koninksrijkrelaties, 2024), public authorities (amongst others) have a duty to include citizen participation in projects. However, how this change in procedure should be sustainably integrated into the governance process is still debated. The pilot experiments with using a CO to structure citizen participation for the benefit of public authorities, civic organisations, and citizens alike. Following Pappers et al. (2022), the focus is on exploring COs as a valid method of policy participation by initiating a discussion rather than large-scale data collection. To test the validity of COs, a strong foundation was necessary. Therefore, the CO was built to complement existing governance processes with citizen data or input, rather than replacing or merely supplementing already existing practices. By consulting the citizen cyclist collective of the Fietsersbond (Fietsersbond 2025), cycle path maintenance was identified as a key topic for citizen engagement (in this case cyclists), ensuring intrinsic motivation. Currently, cycle path maintenance governance is a two-way but disconnected process. Public authorities assess and maintain paths through periodic expert judgment, while citizens can report maintenance needs through online mapping portals, often unsure of the correct authority to report to. Alternatively, citizens can collaborate with civic advisory organisations like the Fietsersbond, which collect subjective experiences to public authorities. The pilot aims to see how this two-directional process could complement each other to make the cycle path maintenance more inclusive and effective, enhancing the attractiveness of cycling overall.

Copenhagen, DK: Copenhagen pilot focuses on discovering new solutions and alternatives to fossil-based behaviours, particularly within the current transport systems, towards creating a climate-positive neighbourhood. At the core of the initiative is the definition of a new local traffic plan, introduced by the City Hall with a strong emphasis on citizen participation and a vision for a new approach to urban mobility. The plan has sparked political controversy, as the residents resist the City Hall’s plan of creating a new island in the Copenhagen area without fully considering the impact of heavy traffic in the district – given the added pressure from ongoing urbanisation. To address this, the pilot aims to develop a truly citizen-driven traffic plan for its Amager Vest district. Given the contentious nature of the project, the CO seeks to build a reliable and widely accepted dataset that can serve as a shared foundation for decision-making among all stakeholders. A key principle of the pilot is that data collection, when integrated with community engagement, can drive sustainable change. To achieve this, the project has focused on developing a citizen-led data collection methodology, ensuring the final dataset is credible and trusted by all involved parties.

Beyond data quality, the initiative also prioritises inclusivity, ensuring diverse representation in the data and identifying the key parameters that matter to both citizens and stakeholders.

Turano Valley & Gerace, IT: Turano Valley and Gerace, though located in different regions of Italy, share historical significance and face similar issues. Both regions struggle with hydrogeological instability, inadequate road infrastructure, and insufficient public transport. Additionally, poor broadband connectivity hampers economic development and exacerbates depopulation and aging population challenges, straining social services. The villages in these areas are part of the National Programme for Resilience and Recovery (NPRR 2024) and the 'Borghi più Belli d'Italia' consortium, which aims to preserve their significance by regenerating and revitalising heritage villages. The goal is to balance historic preservation with modern needs to attract investments, stimulate economic growth, and support local communities through cultural initiatives, despite demographic challenges. The CO in these areas aims to analyse socio-economic dynamics, focusing on mobility, environment and tourism. Improving infrastructure, connectivity, and urban revitalisation are essential to attract investment, enhance liveability, and support economic growth. The CO aims to achieve this through direct data collection from citizens, engaging with both political and social realities, and community datathons. A big focus of the Observatory is to educate residents on understanding and analysing the risks of degradation to natural and built heritage, assessing the current conditions, such as pollution and mobility, and raising awareness about interventions needed to protect the villages. Timely action can set a precedent for the wider region and serve as a model for other municipalities with similar characteristics. Therefore, the Observatory emphasises citizen science and a participatory approach in environmental monitoring. The goal is to involve citizens in monitoring their environment, advocating for inclusive and participatory decision-making processes that improve community sustainability and resilience.

4.2 Individual readiness of pilot areas

The maturity levels of each pilot significantly influence the activities and approaches employed throughout the project. More mature pilots, like those located in Bristol and North Brabant, build upon already established frameworks that provide a solid foundation for citizen engagement and the implementation of more tangible activities. In Bristol, this foundation is rooted in the Liveable Neighbourhood concept, which embraces a co-design approach that actively seeks community feedback to reimagine local streetscapes. The North Brabant pilot integrates COs into a larger public participation scheme that explores the contribution of cycle path users in ensuring a maintenance pattern more attuned to daily and recreational use, to remove deterrents for taking the bicycle. These strong foundations allow for a more seamless integration of planned GREENGAGE initiatives and a smoother real-world implementation process. In contrast, pilots in Copenhagen and Italy, still in earlier stages of execution, focus more on experimentation and future-oriented transformations. Without established frameworks to build upon, these pilots rely on testing new concepts, fostering cross-sector collaboration, and actively involving citizens in shaping the direction of the initiatives. This exploratory nature allows for innovative solutions but may also present challenges in securing long-term stability and integration.

4.3 First steps towards functioning Citizen Observatories

Building on the structured approach of continuous reflection established in the GREENGAGE methodology, our pilot implementations demonstrate varying degrees of progress in engaging local communities and integrating COs. As previously noted, some pilots remain in the experimental phase and have yet to implement concrete actions.

Bristol, UK: Through its methodology and tools, GREENGAGE reached out to seldom-heard voices, such as school children and youth groups, to identify their aspirations. It aligned these aspirations with the previously collected needs during the co-discovery and co-development phases, particularly through participatory workshops, and identified key gaps. The process began with awareness workshops focusing on sustainable travel and the environment, gathering around 35 participants, followed by a second round of workshops (15 participants per workshop and a wrap-up session with 24 attendees) to discuss possible solutions and highlight key issues. As a result, issues such as anti-social behaviour, poor lighting, narrow kerbs for pedestrians, safety concerns, lack of CCTV (Closed-Circuit Television, a video surveillance system), and public transport accessibility were highlighted. Although most of the issues are not directly relevant to the transport focus of the EBLN project, they can indirectly influence the implementation of the scheme. For

instance, anti-social behaviour, inadequate CCTV, and safety concerns while walking in poorly lit areas or on narrow kerbs were key barriers identified by the target (children and youth) groups. These issues were directed to relevant departments of Bristol City Council for action. Travel diaries were collected over a specific period, and a soft approach (without technology) was used to identify key points of interest and roads needing urgent attention. This data will be used to design experiments within the GREEN Engine, particularly using the GREENGAGE app and MindEarth app, in the upcoming phase. Both apps require setting up experimental tasks, such as Points of Interests (PoIs), research questions, and tasks for recording images between predefined geographical points (routes), to collect qualitative and quantitative observation data. The specifics on how these tools will be applied in the Bristol context are outlined as follows:

(1) Monitoring the environment and automatically identifying safety/threat levels: This use case helps the Bristol pilot owner gain insights into safety concerns and mobility conditions, enabling informed policy decisions on transportation and public safety in liveable neighbourhoods. MindEarth app will be used to gather images on specific roads at different times of a day to perform image analysis and predefined features such as road crossings, cars parked over kerbs, poor lighting, littering, accessibility such as level surfaces for people with disabilities etc will be detected from the collected images using AI. This will be complemented with the qualitative data collected through GREENGAGE app that will provide PoIs on a 2D map and residents will be able to identify spots of concerns and provide textual response to specific questions.

(2) Analysing and visualising the impact on the quality of journeys due to road closures: This use case provides valuable data on how road closures affect travel experiences, helping to optimize traffic management and improve journey quality. The GREENGAGE app with MODE integration is able to detect which routes people take to reach to specific PoIs (e.g., shops, schools, and other local amenities) and what mode of journey (walking, cycling, vehicle) is used. This data will be complemented with qualitative data of rating the overall journey experience by the participants.

Overall, the GREENGAGE methodology ensured that seldom-heard voices are included in the decision-making process, leading to more inclusive and representative outcomes. This bottom-up information collection contributes to top-down decision-making. The data collected and analysed through GREENGAGE tools will provide a robust basis for making informed policy decisions, thereby improving the effectiveness of interventions.

North Brabant, NL: A five-step process was set up, to streamline the expectation management of all parties, and explore the needs and contribution of each partner. Following the suggestions from Keseru et al. (2019), the CO would make use of the existing pilot-specific technology and collaboration infrastructures provided by the Fietsersbond. These technologies have the benefit of familiarity in interface and language to the volunteers of the Fietsersbond, while being comparable to the GREEN Engine technology. The process is carried out in the following steps:

(1) Voice of the Volunteers: Members from the Fietsersbond were onboarded (9 participants) and asked what they understand by ‘Maintenance’ and what they specifically look for in cycle path maintenance.

(2) Voice of the Road Authority: Public authorities explained their approach to bike path maintenance and considered where the volunteer additions from step 1 could potentially be of use. Volunteer representatives (30 participants) were present in this step to immediately attune the data complementation. The complement was found in a subjective assessment of bike paths qualified good, medium, and bad, according to the road authority. The contrast on seven scored characteristics provides added information for the maintenance departments and elaborates on the observations through subjective descriptions.

(3) Voice of the Bike Path: Volunteers go out and gather the data.

(4) Voice of the Data: A scientific partner analyses the data on maintenance, environmental, and traffic safety level, and visualises the results in a data platform.

(5) Voice of All: The visualisations are presented, and the road authority and volunteers discuss contrasts and similarities. A systematic continuation is discussed as well.

Copenhagen, DK: The pilot aims to establish a reliable and consistent data foundation as grounds for informed decision-making and democratic participation in the new Local Traffic Plan. To achieve this, the pilot builds on past and ongoing neighbourhood initiatives, prioritising areas where local contributions can have the most impact, but also integrating diverse data sources to provide a comprehensive picture of how

the neighbourhood's current layout affects its use. Ultimately, the goal is to use data as a tool for engagement, encouraging broader participation and cross-sector collaboration to develop innovative solutions. This approach considers three strategic steps:

(1) Baseline Assessment: Engaging citizens to document existing living and environmental conditions, ensuring data is both trustworthy and verifiable. The first implementation engaged around 40 participants in air quality measurement activities.

(2) Shared Dialogue: Creating a feedback loop where stakeholders recognize findings, leading to actionable steps for monitoring and improvement.

(3) Implementation Planning: Securing funding and political support to achieve long-term outcomes.

Two main use cases have been developed:

- Analysis of Public Space Usage: Examining how people interact with urban areas, how factors like traffic, trees, and urban design influence usage patterns, and identifying areas that should be protected from traffic.
- Participatory Traffic and Environmental Monitoring: Tracking traffic volumes, composition, and their impact on air and noise pollution to inform the Local Traffic Plan.

Turano & Gerace, IT: The Italian pilots adopted a similar approach to Copenhagen, focusing on collecting air quality data using portable sensors. This demonstrates that despite differing local contexts, the CO model can be effectively implemented in a comparable manner. It highlights the framework's adaptability, enabling diverse communities to engage in participatory data collection, analysis, and decision-making while addressing their unique environmental and social challenges. By following a structured yet flexible methodology, the Italian pilots demonstrate that COs can be scaled and replicated across various settings, fostering inclusive and data-driven policy development. The participatory workshops engaged between 19 and 39 participants varying across these sessions based on availability and relevance of the topics discussed.

4.4 Insights from first Citizen Observatory implementations

Bristol, UK: In the context of the Bristol pilot use cases, the GREENGAGE project has demonstrated its potential to contribute to creating safer and more livable neighborhoods by addressing safety concerns and environmental issues. Despite these benefits, the project faces several challenges. Key difficulties include collecting and integrating accurate data from a wide variety of sources and ensuring it is representative for informing policy decisions. Onboarding and maintaining sustained engagement, particularly from seldom-heard voices, requires ongoing effort and innovative strategies. Targeting existing communities of interest and collaborating with local schools has been crucial for expanding the participant base and increasing readiness to collaborate. The resulting benefits extended beyond the project itself, supporting Bristol schools in rewarding young people for engaging in sustainable practices. The scale of issues in the EBLN is widespread, requiring significant resources and coordination across multiple departments and stakeholders, which extends beyond the GREENGAGE project's scope and may affect its perceived effectiveness. Clear communication is essential to help stakeholders understand that GREENGAGE serves as a method for collecting observations on specific topics. While the evidence-based information gathered can influence policy, decision-making power ultimately lies with the pilot owner.

North Brabant, NL: The North Brabant Citizen Observatory demonstrated that, within a government mandated participation strategy and an existing data-rich environment, citizen observers can provide a valuable addition to maintenance of data, planning, and processes. The addition of more contextualised data provides a detailed layer to the objective maintenance inventory, offering insights into when safety and environmental departments (and their respective budgets) need to be involved in maintenance activities. This enriches decision-making and ensures that the relevant departments are informed and can allocate resources more effectively. Despite the promising complementary insights from closer collaboration with citizens, engaging new members presented several challenges. Firstly, intrinsic motivation for bike maintenance was predominantly found among avid cyclists, resulting in a less representative sample of respondents. Secondly, a more relaxed participatory setting proved more effective in fostering engagement, whereas overly complex and technical content hindered participation. This also limited the reach and data quality of the citizens observers. For future engagement, a specified approach for more specific target audiences is required.

Copenhagen, DK: Unlike municipal or authority-led pilots, the Copenhagen pilot is managed by a community organization that mediates in a politically sensitive environment. This highlights the importance of high-quality, citizen-led data in fostering democratic debates among diverse stakeholders. A key challenge identified is developing methodologies for citizen engagement that integrate new technologies while operating within resource constraints to ensure effectiveness and long-term sustainability. Additionally, the Copenhagen use case has shown the difficulty of aligning data collection timelines with municipal processes, often delayed by the procurement of external advisors and differing approaches – particularly due to municipal departments' limited interest in adopting a "new paradigm". Despite these challenges, the pilot has revealed greater-than-expected public interest in political participation. Many residents are eager to engage in discussions about the city's future but prefer accessible and time-efficient ways to contribute without becoming deeply involved in formal politics.

Turano & Gerace, IT: Italian pilots faced more challenges than other cases, due to the target community's demographics, which are predominantly older with limited digital and data literacy. Thus, a key challenge was building capacity within the community to effectively use the provided tools and to interpret the data collected through the CO activities. This pilot demonstrated that reliance on expert support throughout all stages of the process is absolutely essential to ensure meaningful participation and data utilisation. Also, constant interaction and communication with local communities to identify and align activities with the most pressing concerns and motivations proved to be essential for engagement consistency and deeper commitment. This sustained interaction equally affected the readiness to participate and fostered a stronger responsibility among participants, as the issues addressed are directly relevant to their everyday lives.

4.5 Reflections on participant profiles and participatory readiness

While each pilot area implemented tailored engagement strategies, a cross-cutting analysis reveals important differences in profiles, motivations, and readiness of participants across contexts. In more mature pilots such as North Brabant and Bristol, citizens were already involved in community or civic initiatives (e.g., Fietsersbond, school programs), which facilitated recruitment and sustained participation. These groups had higher digital and organizational readiness and required minimal support to use GREENGAGE tools. In contrast, Italian pilots faced challenges due to older and less digitally literate participants, requiring hands-on facilitation and social incentives. This highlights the need for inclusive governance models that consider participants diversity in demographics, digital skills, and prior civic involvement. Motivations also varied widely: from climate and mobility concerns (Copenhagen), to improving daily commuting experiences (North Brabant), to heritage preservation (Italy). These intrinsic motivations played a key role in participants' motivation and interest retention. However, ensuring that participants understood how their input would influence decisions remained a shared challenge across pilots. Ultimately, participatory governance in COs depends not only on tools and methodologies, but on the alignment between participant capabilities, expectations, and the governance structures in place. Future GREENGAGE phases will explore more systematic ways to match engagement strategies with local conditions and to create clearer pathways from participation to impact.

5 LESSONS LEARNED & FUTURE DIRECTIONS

As noted at the outset, GREENGAGE project adopts a reflexive approach that is used to derive recommendations for public authorities as well as the general public, highlighting crucial aspects of designing and managing COs, including methodological frameworks, digital tools, data use and validation, piloting, governance, evaluation, and impact assessment. These recommendations can be summarised across several critical dimensions, derived from the insights gathered across individual pilots:

- Methodological Framework: The situational scoping framework requires a context-sensitive, inclusive, and iterative approach that empowers local authorities to collaboratively develop customised solutions that address specific community needs. Central to this process is effective communication, which ensures that all stakeholders are engaged and informed, fostering a clear and collaborative development of customised solutions.
- Governance & Policy: Innovation in governance must be grounded in the unique challenges of each neighbourhood, district, city, or region where COs are situated. While existing models provide some

guidance, it is essential for local partners to actively engage in experimentation and collective learning, tailoring solutions to the unique context and dynamics of their specific environment.

- Public/Stakeholder Engagement: Understanding stakeholder motivations is crucial for the success of COs. COs must offer adaptable engagement pathways that go beyond mere data collection, fostering deeper involvement. Continuous dialogue is key to ensuring that stakeholder expectations are aligned, especially when navigating the complexities and limitations of policy frameworks.
- Pilot Readiness & Data Governance: Iterative co-design strengthens usability and builds trust, while scalable technologies enhance adaptability across diverse contexts. Transparent data workflows and interoperability are essential for ensuring accessibility and encouraging broad engagement. A well-structured data management plan ensures clarity in managing the entire data lifecycle, ensuring consistency and transparency throughout the process. Given the challenge of diverse levels of digital and data literacy at the pilot areas, the approach needs to be adapted to the local capabilities and needs.
- Training & Capacity Building: Engaging training methods, such as storytelling and visual aids, empower non-technical audiences by making complex concepts more accessible. Online platforms like the GREENGAGE Academy support continuous learning, while feedback mechanisms help refine and improve training effectiveness. Given the challenge of building capacity to interpret data collected by Citizen Observatories, collaboration with the scientific community can play a crucial role in enhancing understanding and providing expert support for data analysis and interpretation.
- Piloting & Experimentation: Iterative piloting helps refining tools and methodologies while effectively managing participant expectations, having solutions evolve based on real-world feedback. The use cases should be closely aligned with socio-political needs, integrating diverse dimensions such as cultural, economic, and environmental, to achieve impactful results.
- Evaluation & Impact Assessment: Defining measurable KPIs, such as evaluating the usability of provided solutions (digital tools) and assessing their impact, particularly in terms of innovation in governance, remains a challenge. This process requires a combination of quantitative and qualitative approaches. Simplifying assessment methods enhances evaluation clarity, focusing on practical applicability and ensuring that outcomes are both actionable and meaningful.

6 CONCLUSION

This paper introduces the GREENGAGE framework as a concrete example of how participatory approaches within Citizen Observatories can foster evidence-based decision-making. By utilising collaborative tools and methodologies, the GREENGAGE framework enables communities to actively engage with and address local urban/rural challenges, ensuring that solutions are not only relevant but also tailored to the specific needs and priorities of each context. While there are similarities across pilots, it is important to acknowledge that each observatory has a unique governance structure and diverse needs. Citizens' engagement can be workshop-based, targeting specific groups such as school children, minority communities, and employees, or sensor-based data collection, such as mobile air quality sensors. These co-creation and co-design processes help refine the technology, improve its accessibility, and enhance participant adoption. Our approach not only highlights the potential of citizen-driven initiatives to create more sustainable and responsive urban environments, but also draws attention to the challenges and limitations that can arise in their implementation, offering valuable insights for future initiatives. Ultimately, the GREENGAGE project is laying the groundwork for full-scale deployment of the Citizen Observatories.

7 ACKNOWLEDGEMENT

This research is carried out under the GREENGAGE project, funded by Horizon Europe reserach and innovation program (grant agreement n° 101086530). This work is co-funded by UK Research and Innovation (UKRI) under UK government's Horizon Europe funding guarantee project reference numbers: 10063933, 10062587, 10064231. The project is also co-funded by Switzerland's State Secretariat for Education, Research and Innovation (SERI) under the funding ID Contract No. 22.00496 REF-131-52014. The VRVis GmbH is funded by BMIMI, BMWET, Tyrol, Vorarlberg and Vienna Business Agency in the scope of COMET – Competence Centers for Excellent Technologies (911654) which is managed by FFG.

1 ABSTRACT

Minibus taxis are a prominent mode in the transport sector and serve as a backbone of public transport in South Africa. They are a transport of choice and more convenient, and they are the most easily accessible even if not preferred. They provide affordable and flexible mobility for South African commuters. However, the sector faces challenges such as safety concerns, inefficiencies, and a lack of formalized systems. The study aim to explore how technological innovations can enhance the efficiency, safety, and sustainability of minibus taxis and the spatial route network serviced by minibus taxi system in Soweto. It examines the impact of digital payment systems, GPS tracking, ride-hailing apps, and smart fleet management on improving service delivery and commuter experience.Through a qualitative case study approach, the research evaluates existing technological interventions and their effectiveness in modernizing the minibus taxi industry. Findings indicate that while digital innovations have the potential to streamline operations, barriers such as resistance to change, infrastructure limitations, and regulatory challenges hinder widespread adoption, and the minibus taxi system service many neighbourhood in Soweto.The study concludes by noting that there is a limitation of technological innovations deployed in the current operations of the minibus taxis in Soweto and there is a possibility of implementing technological innovations in transforming informal transport networks. Further, the study recommends to integrate smart solutions into Soweto's minibus taxi sector to improve urban mobility in vaious aspects for this mode and the system as a whole.

Keywords: Minibus taxis, technological innovation, urban mobility, digital transformation, Soweto, public transport.

2 INTRODUCTION

Travelling takes places everyday, everywhere globally. In developing countries, public transport is the most used transportation for travelling, and in South Africa minibus taxis is the most used mode of public transport. Many South Africans depends on this mode of transport due to its (i) flexibility and availability; it is available in many locations and its network can connect commuters from origin to destination, (ii) pricing; the pricing for a trip is mostly affordable for many South African as it caters for low income communities (iii) operation schedule; it is available from as earliest as 4am in morning to 11pm or 00:00am, however, this varies by location (iv) luggage accommodation; this mode is not very large to accommodate a large quantity of luggage, but taxi drivers try to fit all commuters luggage inside a taxi and if there are many commuters with too much luggage, commuters are strategically included in different taxis with other commuters with small quantity of luggage. This mode of transport is used by 80% of public transport users for daily commuting in South Africa (Kriel and Burger, 2023). Traditionally, minibus taxis operations use a manual method for scheduling, pricing and other methods that are found in transportation services to ensure easy services to passengers for commuting. The taxi industry has been falling behing with regards to deployment of technological innovations in their operations. However, recently there are new technological developments that are found in minibus taxi operations which include smart card payment through speed points inside a taxi and availability of wifi to commuters to connect to the internet, and in some areas there has been development of smart applications that allow commuters to request a ride. Therefore, the study aim to explore how technological innovations can enhance the efficiency, safety, and sustainability of minibus taxis and the spatial route network serviced by minibus taxi system in Soweto.

3 LITERATURE REVIEW

The use of biblometric mapping of literature has been adopted for this study. This is to identify suitable literature for this study and identify most of the common themes researched by various scholars on related to minibus taxis, technology and South Africa.

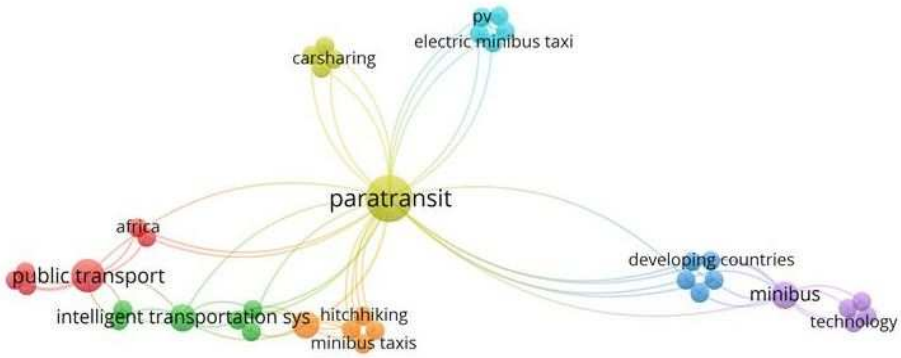

Figure 1: Keyword co-occurrence network visualisation 1

The above figure 1 indicates a biblometric mapping of literature about authors keywords. These keywords indicate the most used keywords related to the study. There are 37 items (keywords), 7 clusters (grouped keywords), 103 network links, and the 104 total link strength. Accordingly, the authors keywords formed 7 clusters that are indicated by different colours. Each cluster has subfields that most authors work focuses on. In cluster 1, there are six keywords indicated by red node which include Africa, infrastructure, mini-bus taxis, motor-bikes taxis, public transport and work. The cluster indicates that in African countries there are discussions of having improved public transport infrastructure specifically to minibus taxis and motorised taxis as mostly this is a daily used public transport to various areas of interest including work. Cluster 2 there are also six keywords represented by a green node which include intelligent transport systems, safe systems, service perfomance, service quality, transport safety and trotro. The cluster indicates the need of deploying intelligent transport systems to enhance service quality, service perfomance, and transport safety for trotro (term used for minibus taxi or shared public transport in Ghana).

In cluster 3 there are five keywords represented by a navy blue node which includes bussiness model, developing countries, maaslite, mobility as a service, and sub-saharan africa . In cluster 4 represented by a yellow node, there are also five keywords such as carsharing, jitneys, micromobility, paratransit, and station cars. These keywords are all related to improvement of shared public transportation and the importance of having micromobility supporting easy connectivity to paratransit. In cluster 5 represented by a purple node, there are five keywords such as digitalization, informal transport, minibus, South Africa, and technology. This cluster is related to the study indicating the importance of leveraging innovative technologies in informal transport and minibus taxis in South Africa. In cluster 6 represented by a light blue node, there are five keywords such as electric minibus taxi, pv, solar, storage, and wind. The cluster indicates that there are various studies taking place regarding green public transport through the introduction of electric minibus taxis. In cluster 7 represented by a orange node, there are five keywords such as contentious mobility, hitchhiking, maas, minibus taxis, and rural tranportation. Further, below figures 2 is the second keyword co-occurrence network visualisation.

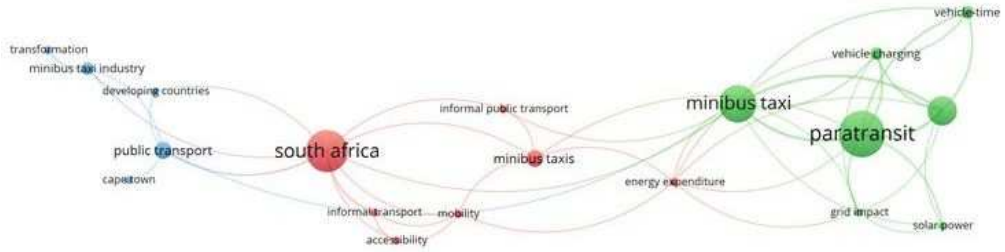

Figure 2: Keyword co-occurrence network visualisation 2

Figure 2 indicates a co-occurrence network visualisation 2 about authors keywords. The first biblometric mapping was based on the following keywords: Miibus taxis and technology and the second biblometric mapping keywords selected are minibus taxis and South Africa. These keywords indicate the most used keywords related to the study. There are 19 items (keywords), 3 clusters, 47 network links, and the 79 total link strength. The authors keywords formed 3 clusters that are indicated by 3 colour nodes. As in figure 1, each cluster has subfields that most authors work focuses on.

The first cluster represented by a red node, include accessibility, energy expendixure, informal public transport, minibus taxis, mobility, and South Africa. This cluster indicates that there are various works that are done on accessibility of informal public transport, specifically, minibus taxis in South Africa. The second cluster represented by a green node, include electric vehicle, grid impact, minibus taxi, paratransit, solar power, vehicle charging, vehicle time. The second cluster highlights that various works looks at the possibility of introducing electric minibus taxis that could be charged using various power sources such as solar power. The third cluster represented by a blue node, include Cape Town, developing countries, minibus taxi industry, public transport, and transformation. Cluster 3 highlights that in developing countries looking at various cities such as Cape Town there is a need to transform taxi industry to provide quality operation services to commuters. Accordingy, below is a table representing top 10 keywords of the biblometric map.

No	Keywords	Links	Occurences	Total link strengths
1.	Paratransit	8	17	54
2.	Minibus taxis	10	11	32
3.	Electric vehicle	7	7	22
4.	Maas	9	3	16
5.	Vehicle charging	6	3	12
6.	South Africa	9	10	11
7.	Public transport	8	3	11
8.	Vehicle-time	4	3	10
9.	Intelligent transport systems	8	2	8
10.	Developing countries	6	1	6

Table 1: Top 10 keywords

The above table 1 indicates the top 10 authors keywords that are mostly used by authors.This highlights most of the work that has been conducted related to the study. Accordingly, the table provides a further explanation of figure 1 and figure 2. Links indicate the connection between various keywords in the biblometric mapping of literatures, and the occurences shows how much a keyword has appeared in the networks. Furthermore, the total link strengths indicates which keywords are most connected to other keywords indicating that most author's works focuses on such keywords. According to the above table 1, paratransit is the most used keyword used in publications linking with more many keywords, followed by minibus taxis, and all the other keywords provided. The table indicates that there are various studies done in paratransit and minibus taxis, however, there are even fewer works on technological innovation in public transport as the table indicates most publications are on electric vehicle and fewer on intelligent transport system. This indicate that there are more studies that need to be conducted on minibus taxis and technological innovations in South Africa.

3.1 Minibus taxis in South Africa

Minibus taxis are one of the dominant modes of urban public transport in the republic. They do not operate according to timetables, a taxi departs from the starting point (taxi rank) when it is full and not according to a schedule, and most vehicles used are 16-seater minibuses. Further, in all cases that taxis start from the starting point (taxi rank), it picks up passengers on the main routes in any streets unlike bus or train as there are demarcated stops. Routing is structured (by the taxi associations to which all operators belong), and operators are assigned to a particular route or group of routes.

According to South African National Taxi Council (SANTACO) statistics (Competition Commission 2018) it has a collective national fleet of more than 250,000 minibuses with 123,000 owners. The government's official statistics put the number of minibus taxis at 130,996 (Grice and Oldjohn 2018). These are almost certainly an underestimate of the total numbers, with many taxis still unregistered. The deregulation of the industry in the 1980s had unleashed uncontrolled growth of the industry and provided fertile ground for conflicts ("turf wars") over route and ranking facilities. During the same period the industry boomed into a giant sector and became unmanageable in the absence of any form of regulatory framework. After a long and intensive government consultative process with taxi operators, the South African National Taxi Council

(SANTACO) was established in 2001 as an umbrella body governing the industry and act as the principal representative body for taxi owners. It was formed from 34 taxi federal organisations and three national bodies. It brought a significant amount of unity to the industry, but didn't completely end the conflicts (Labour Impact Assessment, 2018). Further, the government also attempted to modernise and regulate the industry through a programme of "taxi recapitalisation", whereby smaller vehicles would be phased out, and new larger and safer minibuses would be introduced with an electronic fare system. If properly registered and members of a recognised taxi association, owners were given the option of getting cash compensation for scrapping their old vehicle, or a deposit for a new vehicle.

In many cities, especially developing countries regular public transportation systems do not meet all the demands of the marketplace. The reasons for this shortfall often vary. It can result from an insufficient response to constantly changing travel and settlement patterns, poor attendance to service places (speeds, levels of service, job changes etc.), or purely from a lack of total capacity (Golub 2003). Cervero (1991) states that regular public transportation services normally employ full size vehicles, many times are poorly connected and coordinated and these vehicles cannot always serve residential areas with narrow entryways, poor roads and at times difficult terrain. In many of these cases informal modes of transportation they, illegally enter the market to fill the gaps that are left open by the regular public transit system.

According to (Statistics South Africa report on measuring household expenditure on public transport, 2015) 51,1% of public transport users use taxis and followed by busses at 18,1% and then trains 7,6%. It can be argued that in bus and train services were the first to be formally introduced to the public as a means of public transport. Amid the criticisms of the taxi industry, it remains the most popular mode of transport. The two possible reasons of which (1) being that it is a transport of choice and more convenient or (2) it is the most easily accessible even if not preferred. Noting that both bus and train services are the formal modes of transport and cheaper. The two cheaper transport modes are not the most popular and to add that the taxi customer service has been under criticism for many years (SA 2015). Further, to improve minibus services, few studies have indicated the importance of technology deoployment which could provide (i) Reliability of the service, (ii) variability in cost and (iii) responsiveness. Further, it has been noted that technologies could assist to (a) book, (b) report driver misbehavior, (c) make safe e-payments and (d) track the location of minibus taxis, as most likely to improve their minibus taxi service quality (Dzisi el al., 2021).

4 APPROACH AND METHODOLOGY

The use of biblometric mapping of literature was used in the study. The use of biblometric mapping of literature is to assist in identifying common research areas related to minibus taxis, and this assist to find the literature gab. The study used two methods to download publications which (i) included the keywords: minibus taxis and technology, and (ii) keywords were: minibus taxis and South Africa. Below is table 2 indicating types of publications used.

No.	Types of publications	Number of Documents	Citations
	Keywords: Minibus taxis and Technology		
1.	Journal articles and reviews	13	162
2.	Book chapters	4	4
3.	Conference papers	6	13
	Keywords: Minibus taxis and South Africa		
1.	Journal articles and reviews	38	371
2.	Book chapters	4	3
3.	Conference papers	9	16

Table 2: publication types adopted.

To perform biblometric analysis on VOSviewer, scopus was used to identify journal articles, and 25 articles were identified. During the refining process of selecting journal articles, 1 article was in french and 24 articles remaining were in the selected language which is English. Accordingly 24 abstracts were analysed and only one was retracted due to being not relevant to the study. Therefore 23 publications that were used for the biblometric analysis that featured keywords that include minibus taxis and technology. Accordingly, the second biblometric analysis publications were also downloaded from scopus. Keywords that were used were minibus taxi and South Africa only, this was done to see most of the works done in minibus taxis and south africa and to relations of themes. 87 documents were identified, and publications used are from 1995-2025. All 87 publication are published in English. 36 Publications were retracted due to being not related to

the study, unknwown authors identified and some are international studies. Only 51 publications were used for the final analysis.

Accordingly, semi structured interviews were conducted with 40 commuters, 10 minibus taxi drivers, and 5 queue marshalls. The questions conducted with minibus taxi drivers and queue marshalls were based on daily operations, technology integration, training and support, and community impacts. Consequently, the questions conducted with commuters were based on usage and preference, technology experience, safety concerns, and quality of service. Further, spatial approach was used to create a map that indicate spatial route network of minibus taxis and minibus taxi ranks. The data to create the map was received from the City of Johannesburg department of transport.

5 RESULTS AND ANALYSIS

Soweto is a township that is found in the City of Johannesburg in South Africa. It is a township that is dominated by black community followed by a coloured comunity. It is a home to a population of around 1271627 residents, with 37 different neighbourhoods. The below map indicates where Soweto is located in the Republic of South Africa, which is demarcated with blue in the locality showing the City of Johannesburg below in figure 3.

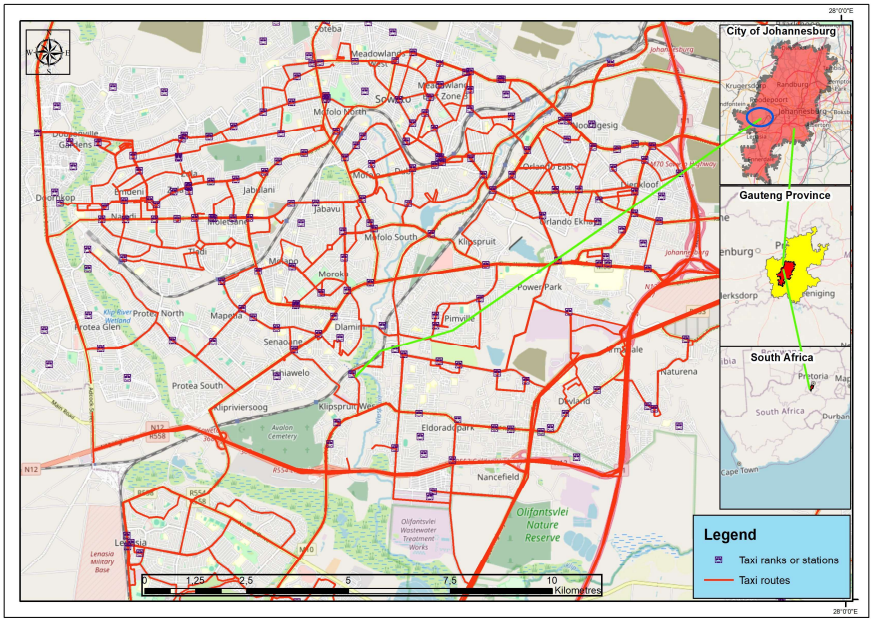

Figure 3: Soweto Taxi routes and ranks map

Soweto is serviced by various modes of public transport systems which include metrorail train system, bus rapid transit system (BRT, known as Rea Vaya system), metrobus, eyakho putco bus and more other public transport services. The above figure 4 indicates the minibus taxi spatial route network and taxi ranks in Soweto. This mode of transport is one of the modes offering a service that covers a large extent of geographical area in Soweto. As can be seen on the above map, the minibus taxi system services many routes which are indicated in red, and these routes are main routes. The minibus taxis penetrate inside the neighbourhood to collect commuters from various locations to provide a convenience service. Each neighbourhood has provision of minibus taxi ranks/ stations which some are informal, and some are formal but all of them are recognised by the commuters. Minibus taxis are one of the modes that provide reliability in servicing all Soweto locations and routes. These areas are serviced from early hours of the morning from approximately 4am till late which is around 11pm. Taxi ranks, or station are strategically located in all neighbourhoods to ensure easy access to commuters, in big neighbourhoods there is more than one taxi rank found to ensure that different sections of the neighbourhood are serviced by minibus taxis. Furthermore, there is a form of integration between minibus taxis, as commuters from certain locations can make switch inbetween from one taxi to another taxi to complete a journey which this however requires a different taxi fare, and commuters are dropped in suitable locations and stations for intended minibus taxi. Consequently, on various instance minibus taxi while in a journey communicate with each other to switch various commuters to suit the locations of where commuters are going without any extra payment.

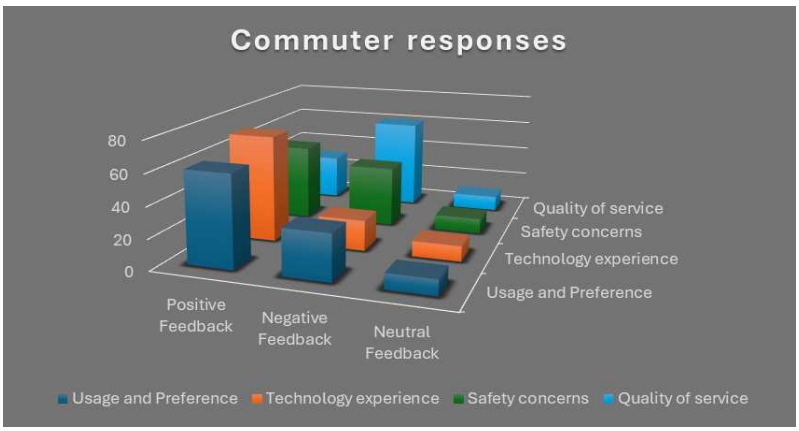

Figure 4: Commuter responses

The above figure 4 indicates the semi interviews conducted with minibus taxi users. 60% of the responses were positive about the usage and preferences. The commuters have indicated that the minibus services provides convinient services for them to reach intended destination around Soweto and beyond, the movement of minibus taxis are flexible as commuters can reach locations of interest easily as the minibus taxi system offers flexibility, hence, they prefer to use this mode of transport. 30% of commuters indicated that, due to limitation of other modes of public transport in their locations they use minibus taxis. On various occassions, minibus taxis travel slow due to trying to collect more commuters along the journey, and sometimes for a commuter to reach a desired destination they need to connect to other minibus taxis which is costly, especially when travelling from Soweto to other location. 10% of commuters indicated that minibus taxi usage is used based on that it the available mode in their are locations and it is cheap as well. On some instances, the journey is smooth but on some occasions it is not which this provides mixed feelings when using minibus taxis.

Most of the commuters have indicated that minibus taxis are not technological savvy. It is difficult to retrieve information about the mode of transport and for a commuter to be able to know travel times through online platforms. Accordingly, the commuters indicated that if a commuter does not have hardcash for a taxi fare, there is no electronic payment alternative that could be used which makes it hard on some occasion to use a minibus taxi when a commuter does not have hardcash. 70% of commuters indicated that it is important for minibus operations to introduce technological operations in the system for payment purposes as on some occassions they do not have hardcash. Accordingly, there is a need for online plartforms that can provide informartion of minibus taxis to know the availability of minibus taxis in certain specific times to know the intended taxi that they can use, also in the evening there is a need to know the times of the availibitity of the minibus taxis so that commuters can take an alternative mode of public transport than being found vulnerable at the minibus taxi routes that collect commuters and minibus taxi ranks. Consequently, commuters have indicated a need to have a online platform were they can share comments or remarks about the operations of the system and improvements that they need as most of the commuters shared frustrations that they are not sure were to share any grievances and when shared they do not reach the right people. 20% of the commuters shared that they are not used to technological operations which might make the use of minibus taxis complicated for them, and the traditional method of using minibus taxis compliment they are way of making trips. It was further indicated that if they need information they can receive it straight from the minibus taxi ranks as usual. Accordingly, some commuters feel like they can be inconvinienced if commuters will have to pay using smartcards as some commuters do not own any bankcards and if specific smartcards can be introduced to be used for minibus taxis only, to such an extent this can cause delays as they will have to load money in they cards first before they can use a taxi and what would happen if the systems to load money in the smartcards are offline as this they have experienced with the current modes of public transport that are operated electronically. Furthermore, 10 % of the commuters are neutral to the introduction of technological innovations within the minibus systems as mostly indicated that it could bring positive change in various aspects of the system operations but at the sametime there could be negative impacts due to technoligical errors that might occur during the process of using some of the services and then ending up inconviniencing commuters leading to missing of rides and ending up not being able to use the mode of transport intended.

Many commuters have shared they views on safety issues when using minibus taxis. 50% of the commuters indicated that using minibus taxi is safe as minibus taxi drivers are respected by people who commit crime, as criminal activities are not committed inside minibus taxis, and in taxi ranks. Accordingly, when they use minibus taxi's from origin to destination they arrive safe. However, 40% of commuters shared opposite views as it has been indicated that reaching some of the taxi ranks could be complicated as they have to pass through dangerous locations to get a taxi, and in some areas where they wait for taxi's on various routes is dangerous and minibus taxis take long to reach such areas making them vulnerable especially early mornings and later in the evening. Further, 10% of commuters indicated that taxi's are a safe mode of public transport but are unsafe on some instances as on some occassions dangerous commuters board in taxis and then rob commuters belongings when a taxi has left the rank. Accordingly, when commuters are dropped off in various locations of interested they become target of crime wereby they get robbed, and also there are some taxi drivers who are wreckless when they are driving leading to car accidents. Consequently, taxi drivers become involved in taxi wars wereby shoutout takes place in a random day leading to commuter injuries and death.

In addition, commuters have indicated different views in the quality operations of minibus taxis. 30% of the commuters have indicated that taxis provide a good service as they ensure that commuters are transported efficiently from origin to destination and they try to deliver fast service to commuters and there is provision of assistance by queue marshalls and taxi drivers when commuters need certain information related to the transport services and directions to a certain area. 60% of the commuters indicated that on various occassions the treatment that they receive from taxi drivers is unpleasant as taxi drivers do not communicate in a well mannered way and on other instances are threatened by the drivers. Accordingly, it has been indicated that the journey sometimes could be unsettling due to wreckless driving and a very slow movement of minibus taxis, and also the fights that emerge from know were due to fighting over commuters is unsettling and commuters on some instances are threatened. 10 % of the commuters have indicated that the quality of service provided differ, on some occasions its better and on some occassions is bad. The movement of minibus taxis is faster and on some instances the movement of the minibus taxis is slow. Accordingly, sometimes the taxi drivers understand a certain situation and sometimes they do not want to understand which this bring mixed feelings about the entire service quality of minibus taxis. Below are the responses received from minibus taxi drivers.

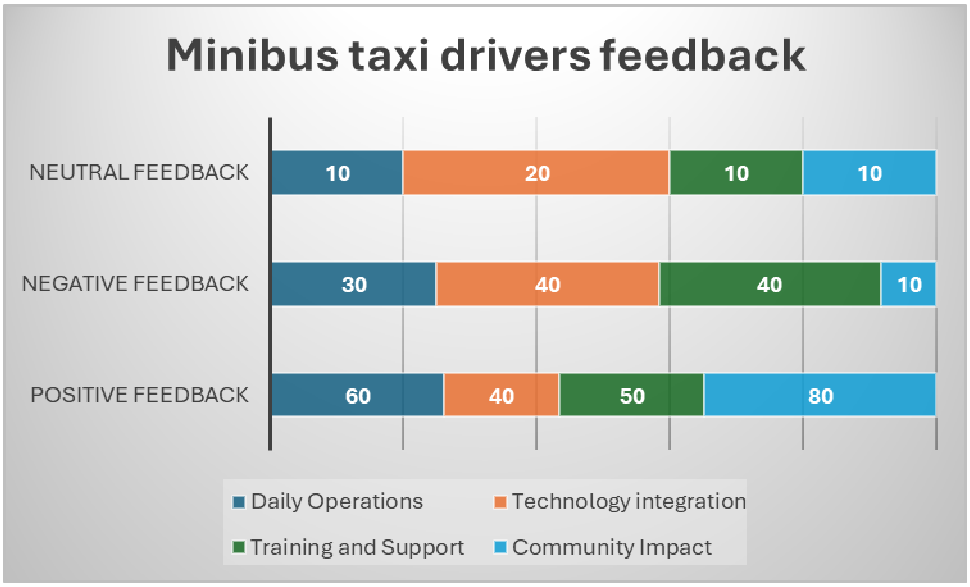

Figure 5: Minibus taxi drivers responses

The above figure 5 indicates the responses received from the semi interviews conducted with the minibus taxi drivers and some queue marshalls. 60% of minibus taxi drivers and queue marshalls have indicated that the daily operations run smooth as they ensure that they deliver fast services for commuters without any delays. 30% of minibus taxi drivers and queue marshalls have indicated that on some instances there are various challenges from the operations due to some taxi drivers not wanting to follow rules of operations making it hard for easy operations. Accordingly, some commuters make the customer service difficult due to

wanting to control locations of where commuters should be delivered and some infromation is always provided to commuters such as when paying taxi fare they should not bring a higher amount of hardcash as on some occassions they do not have loose counts of hardcash to provide change for commuters. 10% of minibus taxi drivers and queue marshalls indicated that the daily operations are better, however, on some instances its tough to provide efficient services as they have minibus taxi breakdowns during the operations but this does not happen all the time and on some instances they are challenged by traffic congestions.

Accordingly, minibus taxi drivers have indicated various views regarding technology integration in the minibus taxi system. 40% of minibus taxi drivers and queue marshalls have indicated that technological innovations can improve the minibus system operations in various aspect such as the payment method as this can make the transaction easy and so that the taxi owners can be able to review all the payments. Accordingly, there is an indication that commuters can be able to view locations that are serviced by certain minibus taxi lines online, as sometimes commuters want to make a fuss by making minibus drivers to drop them in areas that they do not service. There could be fair taxi collection of commuters in the taxi ranks and minibus taxi whereabouts could be identified, and arrival times to the taxi ranks for collection. 40% of drivers have indicated that the usage of technology will bring close monitoring to the services and these could lead to unneccessary penalties, and could make them not perform in a comfortable manner to deliver efficient services. Accordingly, it has been indicated that technological services have never been used in the area, and introducing such will require serious infrastructure meaning that they will have to spend more money and this will affect various parties in the mibus taxi system. 20% of minibus taxi drivers have indicated that technological innovation can assist improve the services, however, most of them are not good with technological operations which this will also lead them to attend training, as they are there to work (drive taxis), and also if they don't understand trainng what would happen.

Consequently, 50% of minibus taxi drivers are keen to training and support to improve quality of services by the minibus taxi system. 40% of minibus taxis drivers are hesitant about receiving training as it has been indicated that they are already producing a good service. 10% of minibus taxis support the notion of training but indicated that the challenge will be time to attend such trainings and these training will not pay them. Further, most of the taxi drivers have indicated that minibus taxis have a high impact to the community as they provide efficient services and they are cost effective, and they ensure that they deliver the commuters wherever they want. In addition, it is indicated that wherever minibus taxis are found there is less criminal activities as they ensure that they protect the community as this is humanity (ubuntu) and also the people are their customers.

6 DISCUSSIONS

There are different kinds of associations from different locations that regulate the taxi industries. Each location is serviced by the taxi association from that area to a specific destination. Taxi's registered from a certain location are not allowed to service another area they are not registered to and also with routes serviced, a taxi should remain servicing that particular route is registered for. Passengers on certain specific routes are not allowed to be transported by taxi drivers not registered to service that specific route (Mbatha and Gumbo 2022). Minibus taxis in Soweto are functional and efficient to a certain extent under traditional operations without the usage of technological innovations. There is no available platform for timetable schedule for commuters to plan trips. Commuters walk to the nearest taxi rank to take available minibus taxi, and to board in a taxi is based on the first come first serve basis where commuters have to queue. There are queue marshalls found in all taxi ranks to keep order on the commuters perspective that no passenger cut in a queue or moves forward, and as well as each minibus taxi comes in at a suitable time scheduled. There is a system used to ensure that there is fairness in the operations of minibus taxis. A queue marshall control which taxi can pickup commuters at which time and the information is recorded in a book manually.

Travelling from Soweto using minibus taxis to the CBD were there are larger taxi ranks and commuters connect to reach desired destination or to areas affording various activities of interest to commuters during the morning, usually, during the peak hours the movement of minibus taxis is efficient and fast whereby one taxi comes after the next to ensure that commuters are transported in a fast manner and during this period in some instances there arent much delays due to a quick movement of taxis. However, minor delay could be caused by long queues.

In this system developed in the taxi industry, commuters are aware that in the morning, the peak hour ends at 8:30am from 7:00am depending by location especially in small taxi ranks that are found in Soweto neighbourhoods. From after 8:30am, a taxi is not completely filled with passengers and it need an average of 7 passengers to live the rank so that other minibus taxis can also collect commuters. After 8:30am upto 11:30am commuters are required to take taxi's from the taxi ranks, and a taxi needs to have certain number of passengers to leave the taxi rank, and this leads to delays. Consequently, from this period to 12:00pm the mini (small) taxi ranks do not operate and commuters catch aminibus taxi along the routes that taxi's routes service. In the evenings, there is also a quick movement of minibus taxis transporting commuters from taxi ranks. However, the system time after time gets overwhelmed as much as there are many fleets but commuters are even more. Minibus taxis run out in the rank and then commuters have to wait longer in the queues.

Accordingly, in Soweto, Baragwanath taxi rank is a large taxi rank where commuters from different neighbourhoods across Soweto commuters use to connect to various locations away from Soweto. Which these areas could be to the CBD, other surburban locations and other provinces or states. There is smooth transition from local minibus taxis to minibus taxis making long distance trips.

Technological innovations provide enhancement in various disciplines. In the minibus taxi industry, if deployed, there could be aspects in the operations that can improve the system as a whole and provide quality services. With regards to payment services, this can allow easy transaction for commuters and minibus taxi operators. Commuters do not have to worry with carrying hardcash and as on some occasion there are issues of taxi drivers not having loose counts change for commuters, also commuters do not have to count the entire money and ensure that everyone has paid were certain conflicts emerge, and also this provide an alternative if a commuter does not have hardcash and having to worry about finding a nearest atm to withdraw hardcash for a taxifare. Consequently, minibus taxi operators could be assisted to keep track of earning, and which this makes it easier to ensure that all commuters have paid the appropriate taxi fare. Accordingly, commuters can be able to find relevant information about network of minibus taxis and could assist them to know which intended taxi maybe taken. Technological innovations such as global positiong system, can make a positive impacts in the operations as it could allow minibus taxi drivers to be aware of various challenges such as traffic congestion to take alternative routes. Further, this could also provide safety and security as real-time tracking can provide emegerncy response if a minibus taxi is under attack, and wreckless driving could be monitored which this could prevent unneccessary vehicle accidents. In addition, there could be reduction of taxi breakdown as minibus taxi operators could be notified by such technologies that the minibus needs a certain service.

7 CONCLUSION

In Soweto, there is a huge service of minibus taxi system which plays a vital role in providing functional and efficient public transport services which are used by a majority of the households, and minibus taxi services are found in all the neighbourhoods in Soweto. However, from the study it has been noted that the minibus taxi system still uses the traditional way of providing services without the usage of technology. The study has indicated that deployment of technological innovations in minibus taxis could improve the quality of services, and safety and security of the commuters. Therefore, the study reccomends minibus taxi application or online platforms that can provide various technolohical services making the entire usage of minibus taxi systems pleasant. With the introduction of such platforms, commuters can be able to share grievance, comments and remarks to reach in the right people, there could be an alternative method of payment that can create fast transactions, commuters could be able to know which suitable minibus taxi to use as there is provision of real-time tracking which this can provide safety for commuters. According minibus taxi drivers could be able to share communication to switch commuters effeciently to ensure that all commuters are transported to desired destinations. With efficient, functional, safe, reliable, competent, quality operation of services by minibus taxi services, minibus taxis could attract motorist and this could reduce various road negative impacts on the roads.

1 ABSTRACT

Fragmented sectoral policies hinder spatial planning from driving sustainable development and diminish the impact of EU-funded investments, posing a significant challenge for urban development in Europe (ESPON, 2018). The IN-PLAN project addresses this problem by empowering local and regional authorities to integrate climate adaptation, energy and mobility policies and spatial planning. The developed IN-PLAN Practice provides a structured framework, milestones and strategies for action and stakeholder engagement to support integrated planning. Pilot projects in Croatia, Ireland, Italy, Sweden and Romania demonstrate the adaptability and feasibility of implementation of the practice. This paper presents the findings throughout the project and highlights the lessons learnt from these pilot projects to stimulate a wider uptake of integrated planning approaches across Europe. It also reflects the provision of support structures and documents for integrated planning.

Keywords: Governance, Sustainability, Integrated Planning, IN-PLAN, Integrated Energy, Climate, and Spatial Planning

2 INTRODUCTION

Since 2021, the European Climate Law has established a legally binding target of net zero greenhouse gas emissions by 2050 (EU Regulation 2020/0036/COD from 30/06/2021) in alignment with the UN Paris Agreement of 2015. For the period from 2021 to 2030, EU Member States developed integrated National Energy and Climate Plans (NECPs) outlining their strategies for achieving the necessary greenhouse gas emissions reduction to meet the EU's climate neutrality objective.

In recent years, many local and regional authorities have set ambitious climate neutrality targets and are actively transforming energy and mobility systems to achieve them (Net Zero Cities, 2025). Despite operating under different overarching frameworks, these authorities play a crucial role in translating national and European climate targets into practical actions. They have control over spatial development within their jurisdictions and often hold the legal mandate to develop and enforce spatial development plans. These plans outline future settlement and economic development while imposing restrictions on land use. Given the close link between spatial structures, energy demand and supply, large and small-scale climate adaptation measures and mobility patterns, spatial planning is an enabler for municipalities to take meaningful action on climate change and advance toward net-zero targets.

2.1 Integrated planning as a holistic approach

Accelerating the transition to climate-neutral and climate-friendly cities requires not only the implementation of diverse sector-specific measures but also the adoption of a holistic approach. Given the constraints on time and financial resources, this approach should seek to harness synergies and proactively identify potential conflicts to develop effective solutions. Integrated energy, climate, mobility and spatial planning is pivotal to achieving climate neutrality while simultaneously preserving or enhancing the quality of life in municipalities. The concept of integrated planning can be illustrated through three key dimensions:

- Vertical integration involves cooperation across different levels of governance, from local to national and international bodies. This coordination ensures that policies and plans are harmonised to minimise redundancies and to create coherent development strategies.

- Horizontal integration focuses on cross-departmental collaboration within municipalities. Therefore, challenges are tackled holistically rather than in silos, integrating climate adaptation, sustainable mobility and renewable energy issues into spatial planning.
- Territorial integration entails regional partnerships among municipalities. Joint efforts enable them to tackle common issues, optimise resources, and implement strategies that extend beyond individual borders, resulting in a more coordinated and effective regional development.

2.2 Theory of integrated planning and its state of implementation

Considerations concerning energy production and consumption in urban environments first emerged during the 1920s energy crisis. De Pascali and Bargaini (2018) trace the evolution of spatial and energy planning integration, noting that the link between urban characteristics and energy systems has been studied since the 1970s. In 1974, "The Cost of Sprawl" examined the relationship between settlement density and energy consumption (Real Estate Research Corporation, 1974), whereas Knowles et al. (1974) highlighted the connection between urban environmental conditions and quality of life. The two-way relationship between energy and urban planning, stressing the need for a systemic approach that considers urban structure, mobility, and distribution of urban activities was defined by Owens et al. (1986).

Despite the concept of integrated spatial planning existing in various forms since the 1960s, a clear gap remains between theory and practical implementation at the municipal and regional levels in the EU. While some EU countries have been able to develop integrated planning processes, aligning sectoral policies under shared goals and creating joint policies spanning different sectors, others have a rather coordinated practice, which reflects clear efforts to align policies and enable mutual adjustment across sectors. Only a few Member States entirely neglect the integration of sectoral policies in spatial planning and therefore miss tangible relationships between sectors or acknowledgment of other sectoral policies (Nadin et al., 2020). Independent of their level of integrated planning, most of the European regions and municipalities continue to face the challenges of integrating different policy disciplines.

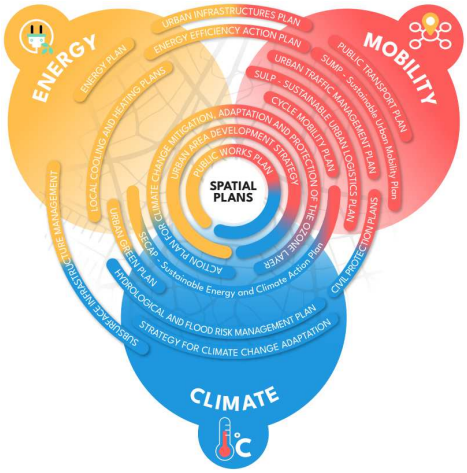

Fig. 1: Diagram mapping the intersections and overlaps between sectoral plans. https://fedarene.org/wp-content/uploads/2024/10/IN-PLAN_SPATIAL-PLANS.pdf

Several reasons can be identified to explain the discrepancy between the theory and the level of integration as well as the difficulties arising from a stable integration. With the Covenant of Mayors initiative in 2015, more than 8,000 municipalities signed up for the development of SECAPs – Sustainable Energy and Climate Action Plans (United Nations, 2024). Despite the enormous success of the initiative, it seems that SECAPs still miss the opportunity to translate energy, climate and environmental policies into ordinary spatial planning instruments because of sectoral-based responsibilities of urban strategies, as e.g., SECAPs and SUMPs (Sustainable Urban Mobility Plans) lie within different municipal and regional departments. Furthermore, local and regional governments often lack the authority to establish and enforce binding energy and climate strategies, plans and policies, as their competencies in developing and implementing such measures are typically limited, frequently restricted to voluntary schemes such as the SECAP. This lack of institutionalization also hampers the monitoring of measure implementation and the integration of plans into municipal and regional budgets. As a result, local and regional governments rarely have the necessary

financial resources to plan and implement energy and climate measures and therefore end up acting reactively.

2.3 A methodological approach to roll out integrated planning

The LIFE project IN-PLAN running from 2022 until 2026, addresses various planning systems across Europe with a diverse set of project partners entailing the Institute for European Energy and Climate Policy, UIV Urban Innovation Vienna GmbH, Technological University of the Shannon, Area di Ricerca Scientifica e Tecnologica di Trieste Area Science Park (IT), and FEDARENE as well as regional climate and energy agencies from Tipperary (IR), Alba (RO), North-West Croatia and West-Sweden. To help local and regional governments integrate climate and energy considerations into spatial planning, it offers general guidelines adaptable to different legal and planning contexts instead of a one-size-fits-all approach. Therefore, the project developed a long-lasting support structure with the IN-PLAN Practice and a two-step Capacity-Building Programme to empower regional agencies and local authorities to implement and monitor integrated strategies aligned with budget commitments to foster sustainable development.

3 THE IN-PLAN PRACTICE

A central product of the project is the IN-PLAN Practice (Höftberger et al., 2024), a comprehensive guidebook for integrating climate adaptation, mobility, and energy planning into spatial planning processes. The Practice is designed to support local and regional governments in developing, implementing, and monitoring ambitious integrated spatial plans with climate neutrality targets. It provides municipalities, regions, and other public authorities with a structured framework for identifying high-impact areas for climate action, a clear outline for an integrated planning process, and practical tools to use alongside exemplary case studies from across Europe. By fostering institutionalised collaboration among departments and various stakeholders, the IN-PLAN Practice promotes civic engagement and participatory governance.

To identify specific barriers faced by municipalities in integrating climate, energy, and mobility planning, a Europe-wide survey and a series of consultations with municipalities were conducted. The insights gained informed the design of a series of workshops aimed at identifying key characteristics of spatial planning systems and the challenges of integrated planning in different national and regional contexts. A comprehensive capacity gap assessment summarizes the findings (Forstinger et al., 2023). Based on this, the IN-PLAN Practice was designed as an advisory tool, also synthesising best practices identified in a stocktake of effective planning approaches (Holodkov et al. 2023). The document was further refined through an iterative feedback process with local project partners, incorporating lessons learned from their engagement with municipalities. This participatory approach ensures that the IN-PLAN Practice is not just a theoretical framework, but a practical, hands-on guide tailored to the real needs of local and regional planners.

3.1 Leveraging Synergies: Focus Topics for Climate Action

According to the Torremolinos Charter (CEMAT, 1983), spatial planning gives geographical expression to the economic, social, cultural, and ecological policies of society. While this definition dates back several decades, it already acknowledges the multifaceted factors of spatial development. Today, however, we emphasise that spatial planning is also a powerful instrument for actively shaping how land is used, energy is distributed, and mobility systems are implemented. It offers essential tools to drive progress in key policy areas that must be integrated to maximise its impact: energy, mobility and climate adaptation. Addressing these interlinked areas holistically enables municipalities to create sustainable, adaptable environments.

Spatial planning is key to aligning energy demand with renewable energy supply. Cities and industrial areas have high energy needs, while renewable sources – such as solar, wind, geothermal, and waste heat – vary in availability and space requirements. Effective planning helps municipalities identify optimal sites for energy production while minimising land-use conflicts. Built-up areas, such as rooftops and infrastructure zones, should be prioritised for solar PV to maximise output without encroaching on natural spaces. Additionally, strategic heating and cooling planning ensures that district heating, geothermal systems, and energy infrastructure match settlement patterns of municipalities and regions. By embedding energy considerations into spatial planning, municipalities can enhance energy efficiency and drive decarbonisation while ensuring a secure and cost-effective energy supply.

Spatial planning is vital for climate adaptation, helping cities and regions manage extreme weather and biodiversity loss. Integrating nature-based solutions – like green corridors, permeable surfaces, and urban forests – can reduce heat islands and boost resilience. Flood-prone areas benefit from sustainable drainage and retention zones, while coastal and mountainous regions need protective zoning, shoreline management, and slope stabilisation to prevent erosion and landslides. Climate-resilient public spaces with vegetation, shade, and water features enhance liveability during heatwaves. Biodiversity conservation through habitat protection and ecological corridors supports ecosystems adapting to change. Regulatory frameworks should require climate-responsive building design, such as passive cooling, green roofs, and rainwater management. Embedding these strategies into spatial planning enables municipalities to build resilience, protecting public health, infrastructure, and ecosystems from the long-term impacts of climate change.

Finally, spatial planning sets the basis for sustainable mobility by designing compact, multimodal urban environments that prioritise walking, cycling, and public transport. By applying the Avoid–Shift–Improve approach, municipalities can reduce travel demand through mixed-use neighbourhoods, shift mobility towards low-carbon modes, and enhance vehicle efficiency. Streets should be restructured to support active transport, with shaded pedestrian paths, dedicated bike lanes, and well-integrated public transit. Parking reform, including reduced on-street parking and repurposing spaces for urban greenery and mobility hubs, discourages car dependency. Additionally, traffic calming measures such as pedestrian zones and shared spaces improve safety and liveability. Mobility hubs offering public transport, bike-sharing, and carpooling enhance accessibility while zero-emission zones and EV charging infrastructure support the transition to CO_2-neutral propulsion technologies. Integrating sustainable mobility into spatial planning helps municipalities reduce congestion, lower emissions, and foster vibrant, friendly urban spaces.

With spatial planning as a major lever for advancement in these three climate-relevant fields, many synergies can be exploited when these fields are approached together.

3.2 Breaking Silos: How to Design and Implement an Integrated Spatial Plan

Integrated planning maximises synergies by addressing spatial interventions holistically:

(1) The process starts by establishing a planning framework, securing political support, and defining clear roles. A cross-sector team and steering committee enable collaboration across departments and governance levels, while a stakeholder engagement plan ensures broad, inclusive participation.

(2) The baseline assessment reviews existing policies, legal frameworks, and best practices to align sectoral strategies with spatial planning. Comprehensive data collection and analysis on energy, mobility, and climate risks informs decision-making, identifying conflicts and synergies.

(3) A common vision and goals provide strategic direction. Stakeholders align on priorities such as climate neutrality, sustainable land use, and resilient infrastructure, with measurable objectives ensuring a structured implementation.

(4) The planning phase translates this vision into actionable measures. Scenario planning assesses long-term impacts, and stakeholder feedback refines interventions. Ensuring regulatory coherence strengthens the spatial plan as a tool for implementation.

Fig. 2: Five phases of an integrated planning process according to the IN-PLAN Practice.

(5) Monitoring and evaluation of key performance indicators like emissions reduction, energy efficiency, and mobility improvements ensures adaptability. GIS mapping and digital tools support ongoing assessment,

while stakeholder feedback loops drive continuous improvement, keeping the plan responsive to evolving climate and sustainability targets.

3.3 Practical Tools and Good Practices for Implementation

The IN-PLAN Practice supports spatial, energy, and mobility planners with hands-on tools and international best practices. Each chapter includes structured approaches, decision-making frameworks, technical guidelines and practical tools as well as good practices to address complex planning challenges. Below are some key tools, while a comprehensive overview is available in the IN-PLAN Practice. The U4SSC Guideline (Rodriguez et al., 2021) highlights digital tools that support sustainable urban planning like the Digital Transformation Toolkit (International Telecommunication Union, 2022) which facilitates data-driven governance.

The IN-PLAN Checklist provides a structured overview of key considerations in energy, climate adaptation, and mobility planning. It ensures that planners systematically address all relevant aspects within their projects.

The guide for developing a Heating and Cooling (H/C) plan (Gnehm et al., 2022) offers a detailed methodology for creating an H/C plan. It covers infrastructure assessment, heat demand and potential mapping, feasibility analysis of heat supply, economic considerations, data quality, and the integration of H/C with the power grid amid increasing electrification.

Climate-ADAPT is a platform designed to support Europe's adaptation to climate change. It provides accessible data and insights on expected climate impacts, vulnerability assessments, adaptation strategies, case studies, and planning tools. Information is categorized by EU policy sectors, countries, and cities (European Environment Agency, 2024).

Two cities serve as examples of innovative tools supporting integrated planning:

- Zurich's climate information maps (Kanton Zürich, 2024) offer detailed data on air temperatures, cold air currents, and bioclimatic conditions during summer days and nights. These maps identify heat islands, compensation areas, and ventilation routes, helping planners mitigate urban heat.
- Paris' Climate Resilience Strategies integrate climate adaptation into public spaces through initiatives such as the Paris Resilience Strategy and the Bioclimatic PLU. These strategies enhance urban mobility and summer recreation while strengthening climate resilience (City of Paris, 2017).

4 GOOD PRACTICE: APPLICATION OF INTEGRATED PLANNING IN MUNICIPALITIES

Many municipalities already have different energy and climate action plans, strategies, and policy frameworks, yet struggle to translate them into enforceable measures within spatial planning often slowing down the energy transition, preventing key measures from being effectively implemented. The IN-PLAN project helps bridge this gap by providing municipalities with a structured methodology to embed sustainability into legally binding spatial plans. By leveraging existing energy and climate documents, cities can align their planning processes with long-term decarbonisation and resilience goals.

The following section presents two case studies in Karlovac (HR) and Narni (IT) where local partners have supported municipalities in strengthening spatial plans as tools for driving the energy transition. Their experiences demonstrate how technical expertise, stakeholder collaboration, and regulatory adaptation can turn climate commitments into actionable urban development policies.

4.1 Case study I: City of Karlovac

Through the IN-PLAN project, Karlovac became the first city of the IN-PLAN project to embed its SECAP measures into its General Urban Plan (GUP), ensuring enforceable, long-term sustainability commitments. This case outlines the initial urban and energy challenges faced by Karlovac, the opportunities leveraged for transformation, and the concrete planning and regulatory modifications made to align spatial development with energy transition goals. A detailed examination of the integrated planning process highlights how the City of Karlovac is effectively bridging the gap between strategic ambition and practical implementation.

4.1.1 Initial Situation of the Municipality

Karlovac, a mid-sized city in central Croatia, with approximately 50,000 residents, is uniquely positioned at the intersection of lowland and mountainous regions. Its strategic location in the narrowest part of Croatia, approximately 50 km from Slovenia and Bosnia and Herzegovina gives it significant transport and economic importance. The city is well connected to key regional hubs, lying less than 50 km from Zagreb, 90 km from the major port of Rijeka, and within 400 km of Ljubljana, Sarajevo, Budapest, and Vienna. Karlovac is also known as the "City on Four Rivers", referring to the Kupa, Korana, Mrežnica, and Dobra rivers, which shape both its landscape and environmental challenges, including frequent flooding risks.

Despite its historical and economic strengths, Karlovac, like many European cities, faced challenges in integrating sustainability measures into its urban development framework. The city's energy infrastructure was historically centred around gas, creating obstacles for decarbonisation. District heating systems existed but were underutilized, while renewable energy adoption remained limited. Urban planning was guided by multiple strategic documents, yet they often operated in isolation, leading to inefficiencies in energy distribution, mobility planning, and sustainability initiatives.

While Karlovac had adopted a SECAP to outline its long-term climate and energy goals, the lack of an implementation mechanism meant that these strategies were not effectively translated into action. At the same time, spatial planning policies governed zoning and construction permits but did not systematically incorporate climate resilience and energy efficiency measures. This disconnection between strategy and execution highlighted the need for a more integrated, enforceable planning framework – one that would align Karlovac's urban development with its energy transition and climate adaptation commitments.

4.1.2 Challenges as an Opportunity for Change

The decision to integrate energy planning into the spatial framework stemmed from a recognition that urban development and sustainability efforts must be interlinked. The North-West Croatia Regional Energy and Climate Agency (REGEA) and the City of Karlovac identified several structural challenges that, if properly addressed, could be transformed into opportunities for innovation and long-term resilience.

The primary challenge was the lack of enforcement mechanisms for the city's SECAP. While the document detailed decarbonisation pathways, its recommendations held no legal power, meaning proposed measures were dependent on political will and voluntary implementation. In contrast, the city's spatial plan had binding authority, making it a logical vehicle for embedding sustainability into urban governance.

Another issue was the inefficiency of Karlovac's energy infrastructure. The city had both a gas network and a district heating system, but they operated in competition. Gas infrastructure expansion conflicted with district heating development, preventing the efficient use of existing energy resources. Without regulatory intervention, the city's energy transition would remain stalled by entrenched infrastructure dynamics.

From a governance perspective, Karlovac faced the fragmentation of strategic documents, where urban mobility, energy planning, zoning, and climate adaptation were treated as separate spheres rather than components of a unified vision. This led to inefficiencies such as disjoint transport policies, weak incentives for energy-efficient construction, and no guidance on the integration of renewables for new construction. The city leadership recognised that integrating SECAP measures into the GUP could create a legally binding framework for sustainability, ensuring that energy transition and climate resilience became structural components of urban development rather than optional initiatives.

4.1.3 Influence of the IN-PLAN Project in the Change Process

Karlovac's participation in the IN-PLAN project played a critical role in supporting its energy transition and defining context-specific sustainability measures. Through collaboration with IN-PLAN experts, Karlovac received technical guidance and a structured methodology for integrating energy and climate policies into spatial planning.

A key outcome was the development of a systematic approach for future spatial planning iterations, ensuring that new energy and climate measures could be continuously integrated into the GUP. The IN-PLAN Practice methodology provided Karlovac with a clear framework for assessing sustainability policies, refining them over time, and aligning them with European energy transition goals.

The IN-PLAN team also advised Karlovac on which energy and climate measures could be expanded beyond individual pilot projects and incorporated into city-wide spatial planning regulations. Through further consultations with REGEA and key stakeholders, recommendations were developed for ensuring coordination between municipal departments, infrastructure providers, and urban developers. This collaborative process strengthened Karlovac's ability to institutionalise integrated planning, aligning urban development with long-term decarbonisation and resilience strategies.

4.1.4 Description of the Integrated Planning Process

Driven by the City of Karlovac's ambition for a greener spatial plan, the integration of SECAP measures into the General Urban Plan was carried out through a structured, step-by-step approach, combining technical analysis, stakeholder engagement, and policy development. In partnership with the City of Karlovac, REGEA conducted a comprehensive assessment of existing urban planning and energy strategies to identify gaps and opportunities for embedding SECAP provisions into spatial planning regulations.

To enable data-driven decision-making, Karlovac conducted a detailed energy and climate analysis, mapping heating demand, hot water consumption, and renewable energy potential across the city. The results guided the identification of priority zones for district heating expansion, areas for phasing out gas, and optimal locations for renewable energy integration. By embedding these insights into spatial plans, the city developed zoning regulations that aligned land-use policies with its energy transition goals.

The Lušćić district was chosen as a pilot project to test the integration of energy and climate measures into spatial planning. The resulting plan introduced progressive sustainability measures, including the exclusion of gas infrastructure, mandatory use of district heating or renewable energy, and the implementation of higher energy efficiency standards for new buildings. Additionally, green infrastructure and sustainable mobility solutions were incorporated. After a public consultation process, the Lušćić spatial plan was officially adopted, confirming the feasibility of integrating decarbonisation measures into urban planning.

Building on this success, Karlovac expanded its efforts, receiving expert guidance and technical support to further incorporate energy and climate policies into the GUP. With the assistance of the IN-PLAN team, Karlovac adopted legally binding measures for all new urban developments, including:

- Prohibition of gas infrastructure in new residential and commercial buildings.
- Mandatory use of 100% renewable energy or district heating for heating and domestic hot water.
- Implementation of strict energy efficiency standards to reduce overall energy demand.

By embedding these sustainability measures into the GUP, Karlovac became the first city within the IN-PLAN project to successfully integrate energy and climate planning into its spatial development framework, setting a scalable example for other municipalities.

4.2 Case study II: Municipality of Narni

The municipality of Narni, is located in the province of Terni in central Italy. It spans an area of 198 km2 and has a population of approximately 18,000 inhabitants. The most populous area is Narni Scalo, followed by the old city centre situated on a hill above the Nera River. Narni, with its pre-Roman origins, has preserved its medieval old town, rich in historical, artistic, and cultural sites.

4.2.1 Initial Situation of the Municipality

The General Urban Plan (GUP) of Narni, developed over 20 years ago, remains valuable for its focus on high-quality outdoor spaces. However, it is now outdated and lacks the capacity to support climate-resilient urban development in the face of increasingly frequent extreme weather events.

Despite its small size, Narni has faced administrative fragmentation, leading to a lack of cooperation between departments. This fragmentation had historically hindered the municipality's ability to implement cohesive and comprehensive urban planning strategies.

Municipal staff also struggle with limited access to the knowledge and data needed for effective climate adaptation and spatial planning. The absence of up-to-date, reliable data further challenges the development of informed, data-driven plans. To address this, IN-PLAN is supporting the municipality in institutionalising integrated planning and embedding a data-driven approach from the earliest stages of drafting the new GUP.

4.2.2 Occasion or Challenge of the Municipality

The involvement as a lighthouse municipality in IN-PLAN coupled with the National Resilience and Recovery Plan (NRRP) funded projects – whose implementation requires an effective, multidisciplinary management team in order to meet the tight deadlines – and the initiation of a new GUP presented Narni with an opportunity for change. The municipality began the process of updating its GUP in 2024, starting the revision of the cartography through photogrammetric and topographic surveys, an essential step for enhancing the knowledge framework as a basis for the integrated planning process.

It quickly became evident that enhancing the quality of geospatial data – both in geometry and content – is essential to optimizing land management and urban planning processes. This initiative aims to create a Land Cover vector database that meets the latest EU and AgID (Agency for Digital Italy) standards, promoting the interoperability of urban plans and facilitating territorial exchanges (SNPA, 2024). The funding and support from National Recovery and Resilience Plan (NRRP) projects have provided the necessary resources to address long-standing issues and modernise the municipality's planning processes, aligning them with current standards and sustainability goals.

4.2.3 Modifications and Developments in Favour of Integrated Planning

To foster integrated planning, Narni implemented internal governance reforms, establishing interdepartmental working groups with clear goals, deadlines, and responsibilities. These groups were tasked with ensuring that various departments collaborated effectively, breaking down the silos that had previously impeded progress (Alessandrelli et al., 2024).

The process of integrating energy and climate considerations into spatial planning took shape with the roll out of the IN-PLAN project at the end of 2022 and could benefit from capacity-building activities, peer learning, and jointly developed guidelines for a data management plan.

4.2.4 Description of the Integrated Planning Process

The integrated planning process in Narni involved several key steps:

(1) Committing to the UN-Agenda 2030 standards as a reference framework for the update of the GUP.

(2) Creation of an interdepartmental working group: as the team encountered cross-sectoral complex issues, such as adhering to the Do No Significant Harm (DNSH) principle to implement also NRRP funded projects, the IN-PLAN Practice provided a practical common framework for facilitating knowledge transfer and collaboration among colleagues belonging to different departments.

(3) Developing distinct sets of strategic objectives in three key areas: land consumption, sustainable mobility, and air quality improvement. For each area, the municipality established metrics to ensure effective monitoring and integration of measures. For each strategic objective, Narni identified additional action plans already in place (e.g., for air quality improvement, the Air Quality Agreement for air pollution mitigation in the Terni Valley). This approach enhanced awareness for the regulatory context and ensured strong vertical, horizontal and territorial synergies between strategies and stakeholders.

(4) Adopting a data-driven approach for the definition of the knowledge framework and the spatial planning process to acquire more detailed and comprehensive data layers, enhancing the municipality's ability to analyse and plan for various environmental, climatic and urban factors and ensuring consistency and accuracy in the data used for planning.

(5) Signing an agreement with national, regional and local stakeholders for data-driven spatial and urban planning (AgID, Umbria Region, and Bastia Umbra municipality).

(6) Working on land cover data according to a 4-step methodology:

(a) Analysis of the EAGLE[1] matrices used for creating the Land Cover national Chart

(b) Definition of a "Land Cover" data model

[1] EAGLE is a concept aiming at providing a tool to address the ambiguity between different nomenclatures or their comparability. It is based on description and characterization of land units through Land Cover (LC), Land Use (LU) and Characteristics and Parameters (CH) rather than their classification (ARNOLD et al., 2018)

(c) A detailed mapping plan was created to relate the objects contained in the Geographic Database to the instances expected in the new "Land Cover" data model.

(d) Application of the mapping procedure: this procedure was verified first on an urban test area of the municipality of Narni and later on the whole territory of the municipality.

The process is aiming to create an integrated map database with land cover and national information sheets, ensuring interoperability. The first results show the advantage of a data quality increase without significant additional costs, but, on the other hand, the weakness consists in the input data update frequency, which is not yearly or regular but depends on the specific needs and resources of the single local public administrations. The updated knowledge framework, based on aerial images and detailed layers (built environment, infrastructures, hydrography, orography), supports more informed and effective spatial planning.

4.2.5 Influence of the Change Process through the IN-PLAN Project

The IN-PLAN project played a key role in Narni's transition to integrated planning by advocating for the formation of interdepartmental working groups. The development of a shared vision in the beginning of the process and the participation of all relevant stakeholders supported streamlining the process.

Due to the initiative of developing a data-driven approach and a data management plan with consulting expertise from the IN-PLAN team, the municipality also focused on adopting new methods and technologies, such as advanced GIS systems and data analytics, to enhance the accuracy and efficiency of their planning processes. An intersectional knowledge framework based on geospatial data is now being developed by means of an innovative methodology for Land Cover content derivation through a multi-level-governance collaboration. This framework is facilitating the integration of various cartographic themes. The approach emphasises the importance of high-quality geospatial data for optimising territorial governance and planning processes.

A focus was put on urban resilience and ensuring that planning processes remain adaptable to future challenges, particularly those related to climate change. Therefore, the updated knowledge framework also incorporates information on climate-related risks.

The focus on digitization and technological innovation positions the municipality as a front runner in utilizing new data sources and methods for integrated and resilient urban planning. Narni's experience serves as an example for other small and medium-sized municipalities, demonstrating the benefits of an integrated and holistic approach to sustainable urban planning, capable of providing comprehensive solutions to complex challenges. Narni will continue the development of its new GUP with a strong focus on urban resilience baes on the updated and more detailed cartography as a solid foundation.

5 INNOVATIVE LEARNING APPROACHES FOR INTEGRATED PLANNING

Besides the direct support of cities and municipalities through the regional partners of the IN-PLAN project, another important pillar to enhance an integrated planning practice was capacity building amongst professionals from the planning and energy sector. The two activities of course benefited from each other with local practitioners from lighthouse and pilot cities participating in the trainings and successful pilot projects serving as best practices being presented within the capacity building programme.

Capacity building describes a range of activities aimed at strengthening the abilities, knowledge, and resources of individuals, organisations, and communities. It involves equipping key actors with necessary skills, knowledge, and resources to achieve goals and improve effectiveness. In the long-term, building capacity among policy makers – crucial decision makers in advancing integrated spatial planning – can support the sustainable development of appropriate policy measures. Effective capacity building requires an approach that involves identifying needs, setting clear goals and objectives, providing appropriate training and resources, and monitoring progress and impact. To be truly comprehensive, capacity building also requires the involvement of engaged stakeholders, including community members, civil society organisations, government bodies and statutory agencies, to ensure that efforts are tailored to the specific needs and contexts of the communities they serve.

Capacity building in the IN-PLAN context, of course, focused on integrated spatial planning. As this type of planning lends a holistic approach to land use planning and seeks to organise and integrate the various

aspects of spatial development, including social, economic, and environmental considerations, the capacity building was delivered as a multi-disciplinary approach that aims to address complex spatial problems and challenges, such as urban sprawl, environmental degradation, and social inequality.

As training is subject to time constraints, it is important that each session was utilised as effectively as possible. Based on these considerations, the Activity, Discussion, Input, Deepening and Synthesis (ADIDS) method was identified as being most adequate as adults learn most effectively when they are presented with information in a series of stages and using a variety of different formats and methods, such as relevant and thought-provoking case study presentation, group activities and breakout sessions, slide and audio-visual presentations, as well as hands-on practice, discussion and reflection. In particular, peer-to-peer exchanges created an integral part of the training experience, as it recognises the variety of experiences and range of expertise, whilst allowing participants to share their own perspectives and real life, lived experiences on the associated topics. ADIDS refers to the five main activities of a session including:

- Activity and Discussion – focusing on interaction, such as a poll or case study reading, followed by discussion. In the IN-PLAN training, participants first engaged in interactive introductions, which enabled them to share basic information like geographic background and areas of interest
- Input – Interactive expert lecture or presentation thus building capacity to act as multipliers of the IN-PLAN practice.
- Deepening and Synthesis – Hands-on activity to apply the input by completing a template analysis, policy framework, or guideline in small groups. Group work reinforced trust and mutual recognition building networks for sustainable local and regional application of the IN-PLAN practice.

Participants had to frame, understand and develop the skills and knowledge they were gaining within the IN-PLAN capacity building programme and apply them in real time. As the trainings were held online, it was vital that they were formatted around activities and interactive sessions while building on assignments and thus constructing strong knowledge bases and adding value to the work already carried out by participants. The methodology employed ensured that pertinent questions could be posed to carefully curated break out groups of likeminded peers. Over the course of three weeks, participants worked towards a final assignment using structured templates. Each group was asked to provide a real-world local example or case study regarding the integration of climate targets in urban planning within a local municipality. Using online break out rooms, online tools (e.g., mural workspace, expert capacity building facilitators, guest speaker involvement, peer-to-peer-learning and practical applications of new knowledge) participants built a solid, considered response to the posed query in collaboration with peers. These discussions allowed participants to hear outside perspectives and take away new ideas and concepts.

The two step capacity building measures as part of the IN-PLAN project, have to date (March 2025), resulted in more than 45 multidisciplinary participants from diverse European regions, having successfully completed the programme.

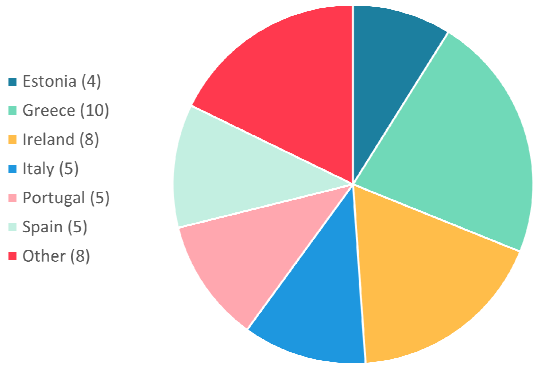

Fig. 3: Participation in the capacity building programme by country of origin.

5.1 Layout of the educational format

The four training modules included valuable and specific learning outcomes and are devised as follows:

5.1.1 Module 1 Spatial Planning an Introduction

The First Module aims to introduce participants to Spatial Planning and Integrated Planning. While participants may have a perception of what spatial planning is, this module addresses the topic from a novel perspective. Even seasoned spatial planners benefited from the conceptual overview.

5.1.2 Module 2 IN-PLAN Practice

The finalised IN-PLAN practice has been developed within the IN-PLAN project. This methodology was used to develop a presentation specifically tailored to the participants of each capacity building programme. This module consists of how to use the IN-PLAN practice and specifically highlight the most relevant areas and case studies to the participants of the capacity building.

5.1.3 Module 3 Case Study examples

Understanding what Integrated Planning looks like in practice is key to developing the capacity of participants and over the 4 sessions run to date, diverse European cities such as Karlovac, Galway, Vienna and Tipperary have been profiled by guest speakers.

5.1.4 Module 4 Module 4: Leadership and Communication

The final module aims to take the understanding of what needs to be done to examine different strategies and how this will be communicated through leadership. This module is a lively mix of activities and interactions primarily led by the main training facilitator.

5.2 Reflections on the IN-PLAN Training Experience

Evaluations have been conducted with all participants in the capacity building process resulting in generally positive feedback. The only criticism was related to the online delivery of the training programme as an in-person exchange would be more engaging. Participants appreciate the extra time to learn, reflect and consider spatial planning and energy and climate issues in a context of integration. The idea of fostering an "integrated planning mindset" amongst all stakeholders is gaining traction but some member states expressed this more than others. For example, participants from Croatia expressed greater optimism regarding the integration of different planning spheres within their regions, whereas in Ireland, further progress is needed before this approach becomes a well-established practice.

IN-PLAN regularly welcomes two types of stakeholders in its two-step capacity-building programme: local and regional authorities, and energy, climate, or development agencies. Step 1 aims at empowering energy, climate and/or development agencies from across Europe to become IN-PLAN Multipliers. Step 2 aims at passing on knowledge to local and regional authorities, which will be tutored either by the project partners or by the trained multipliers. Local and regional authorities as well as energy, climate, and development agencies will become increasingly important to spread the connected methodologies and tools of integrated planning as they are working together with spatial planners and technical energy and climate planners.

6 CONCLUSION

The IN-PLAN project demonstrates the value of a participatory approach to integrated spatial, energy, and climate planning. By fostering collaboration across different levels of governance and disciplines, the project has contributed to embedding integrated planning processes in municipalities such as Narni and Karlovac. However, further efforts are needed to achieve broader implementation. Improving the accessibility and applicability of the IN-PLAN Practice is a key step in this direction. Translating the IN-PLAN Practice into local languages and developing an interactive online version would significantly enhance its usability, facilitating its wider adoption.

Institutionalizing integrated planning remains a central challenge, as seen in Narni, where consolidating a transdisciplinary team proved to be essential. Addressing data gaps is also crucial – municipalities need reliable knowledge frameworks to make informed decisions, particularly in the context of climate change, where large amounts of data are being generated, yet many datasets and their applications are to present relatively unknown or untested but are gradually being explored and integrated into planning processes. A key challenge in this regard is that while data availability is increasing, institutional capacities for processing and utilizing this data remain limited.

Furthermore, municipalities often struggle to implement integrated planning due to limited resources and reliance on external consultants. This highlights the importance of equipping municipal staff with the necessary expertise in integrated planning to ensure they can provide the right guidance and oversight. Additionally, integrating learning formats such as the capacity building programme into professional education could further strengthen the efforts to build long-term institutional capacity. For example, incorporating integrated planning into academic curricula in the fields of energy, planning, and climate change could help prepare future consultants and civil servants more effectively.

Experiences from Karlovac underscore the need to equip spatial planners with knowledge about the energy sector and reinforce the value of localized training modules that reflect regional planning contexts and governance structures. This can be achieved by adapting the IN-PLAN Practice to align with regional planning systems and administrative structures in different European regional contexts, as well as by making insights from municipalities that have implemented the IN-PLAN Practice widely accessible.

To ensure the long-term sustainability of the IN-PLAN project and to enhance the integration of climate adaptation, energy and mobility policies and spatial planning, national and European coalitions will be established to support policy development and provide additional resources for capacity building. Strengthening these collaborative efforts will help secure the future of integrated planning and promote its widespread adoption across municipalities.

1 ABSTRACT

Im Rahmen des Transferprojektes „move.mORe“ wird ein nachhaltiges Asset-Management-System entwickelt, das zur Förderung der Mobilitätswende und zur Steigerung der Entwicklungspotenziale von Radverkehrsnetzen, insbesondere im ländlichen Raum, beitragen soll. Die konzeptionellen Aufgaben der Modellierung und Bewertung werden dargestellt. Durch eine multidimensionale Qualitätsbewertung auf Grundlage eines einheitlichen Datenmodells kann die Qualität von Radverkehrsnetzen strukturiert evaluiert und Handlungsbedarfe gezielt ermittelt werden.

Keywords: Datenmodell, Radwegenetzmodellierung, 4-D-Qualitätsbewertung, Asset Management, Radverkehrsinfrastruktur

2 EINLEITUNG

2.1 Hintergrund und Motivation

Das Fahrrad ist in Deutschland essenzieller Bestandteil der alltäglichen Mobilität. Es benötigt im Vergleich mit anderen Verkehrsmitteln eine geringe Flächeninanspruchnahme und besitzt unabhängige Betriebszeiten. Trotz der flexiblen Einsatzmöglichkeiten des Fahrrades ist die wesentliche Grundlage für die sichere und komfortable Nutzung eine befahrbare und funktionsgerechte Infrastruktur. Für eine Erhöhung des Radverkehrsaufkommens ist diese von wesentlicher Bedeutung (Popp et al., 2024). Verwaltungen, die Verantwortlichkeiten für Unterhaltung, Erhaltung, Instandhaltung, Bau und Betrieb auf Radverkehrsnetzen besitzen, müssen kompetent und organisiert sicherstellen, dass alle Anforderungen für eine qualitätsgerechte Infrastruktur erfüllt werden, sind jedoch gleichzeitig dazu verpflichtet mit ihrem zu betreuenden Anlagenbestand möglichst ressourcenschonend und sparsam zu wirtschaften. Hierfür müssen gezielt und strukturiert Maßnahmen über den gesamten Lebenszyklus priorisiert werden – eine Definition des Asset Managements. Vorhandene Problemstellen mit qualitativen Mängeln müssen in Abhängigkeit ihrer Ausprägung priorisiert und durch Maßnahmen optimiert werden. Ausreichende Fachkenntnisse zur effektiven und sachgerechten Entscheidungsfindung bilden die Grundlage der Umsetzung. Strategische, taktische und operative Aufgaben müssen hierfür definiert und in Prozessabläufen berücksichtigt sein. Ein einheitliches System, welches digital und objektbezogen den Bestand und Zustand der Infrastruktur übersichtlich und dynamisch widerspiegelt und infolge der notwendigen Anforderungen die Qualität bewertet, kann bei einer strukturierten Entscheidungsfindung helfen. Der nationale Radverkehrsplan beschreibt das Ziel vom Fahrradland Deutschland im Jahr 2030 und betont die Infrastruktur mit dem Leitziel von lückenlosen, sicheren, komfortablen und intuitiv nutzbaren Radverkehrsnetzen (BMDV, 2022). Um diese Ziele in der Praxis umzusetzen, müssen unzureichende Netzbereiche erkannt, identifiziert und verbessert werden. Für eine möglichst wirtschaftliche Nutzung von Ressourcen, sollten identifizierte Problemstellen in Hinblick auf deren Gesamtbedeutung priorisiert werden. Ein digitales Asset-Management-System auf Radverkehrsnetzen ist daher erstrebenswert, wofür bereits Ansätze zur Implementierung vorgestellt wurden (Stöckner, 2023). Die wesentlichen Teilbereiche der Modellierungsaufgabe und konzeptionellen Bewertung werden im Folgenden dargestellt.

2.2 Ziele

Ziele dieses Asset-Management-Systems sind die digitale Abbildung der Radverkehrsinfrastruktur sowie die Visualisierung einer Qualitätsbewertung. Dies bildet die Grundlage für Priorisierungen und Finanzprognosen späterer Maßnahmen. Der Qualitätserhalt der Infrastruktur soll dadurch effizient sichergestellt werden. Der

Bewertungsprozess soll anhand der ausgewählten Kriterien so aussagekräftig sein, dass ein repräsentatives Abbild geschaffen wird, ohne dabei zu viele Details zu berücksichtigen. Der Fokus liegt auf der Betrachtung von Radverkehrsnetzen für den Alltag.

3 THEORETISCHER HINTERGRUND

3.1 Asset Management

Im Infrastrukturwesen umfasst Asset Management die strukturierte Optimierung im Rahmen von Instandhaltung, Erneuerung und Verwaltung infrastruktureller Vermögenswerte über den gesamten Lebenszyklus eines Assets, welcher den Bau, Betrieb, Instandhaltung und Rückbau beinhaltet. Die Infrastruktur soll unter Berücksichtigung von anfallenden Kosten innerhalb der Lebensdauer, möglichst effizient betrieben werden, sodass der Lebenszyklus möglichst lange und der finanzielle Aufwand möglichst gering ist. Hierfür müssen zunächst die Assets, also der zu erfassende Anlagenbestand, definiert werden. Für den Radverkehr werden die Radverkehrsinfrastrukturelemente berücksichtigt. Um präventiv durch Wartung und Instandhaltung die Lebensdauer der Anlagenbestände zu maximieren, müssen deren gegenwärtige materiellen und technischen Zustände hinsichtlich Leistungs- und Betriebsfähigkeit klassifiziert werden. Die Zustandsermittlung erfolgt auf Basis von Indikatoren, um Kennwerte zur Leistungsfähigkeit bilden zu können. Der Zustand unterschiedlicher Infrastrukturelemente wird in Hinblick auf Ressourcenaufwand zur Wiederherstellung abgeglichen, sodass eine Priorisierungsreihung für die jeweiligen Elemente entsteht. Dies ermöglicht ein effizientes Risikomanagement, zur Reduktion von Kosten und Erhöhung der Langlebigkeit der Assets. Auf Grundlage dessen können spätere Finanzbedarfsberechnungen, welche im Rahmen von Maßnahmen zur Wiederherstellung und Verbesserung aufgewendet werden müssen, erstellt werden.

3.2 Radverkehrsnetze

In Deutschland wird unterschieden in Radverkehrsnetze für Tourismus, Freizeit und Alltag (FGSV, 2018). Diese können sich überschneiden, haben jedoch grundsätzlich variierende Anforderungen. Innerhalb eines Radverkehrsnetzes kann der Radverkehr unterschiedlich geführt werden. Welche Netzabschnitte dafür berücksichtigt werden, hängt in erster Linie vom Verkehrsaufkommen und der Netzbedeutung ab. Obwohl es standardisierte Vorgehensweisen für eine integrierte Netzgestaltung in Deutschland gibt (FGSV, 2009), finden sich auf Radverkehrsnetzen vielerorts noch Netzlücken. Zukünftig müssen diese Lücken im Radverkehr ermittelt und geschlossen werden. Zusätzlich muss der verfügbare Bestand des Radverkehrsnetzes bestimmte Qualitätskriterien erfüllen, um möglichst attraktiv für dessen Nutzung zu sein. Ein Radverkehrsnetz kann als hochwertig klassifiziert werden, wenn es eine hohe subjektive und objektive Verkehrssicherheit aufweist und komfortabel mit möglichst geringem Energiebedarf zu befahren ist. Außerdem sollten Verbindungen direkt sein und mit geringen räumlichen oder zeitlichen Umwegen einhergehen, wofür ein konnektives und zusammenhängendes Netz benötigt wird, welches relevante Orte miteinander verknüpft und gleichzeitig attraktiv in die Umgebung eingegliedert ist. (Ahmed et al., 2024; Arellana et al., 2020; FGSV, 2002, 2010; McCarthy et al., 2016; Weikl& Mayer, 2023). Konkrete Qualitätsbeschreibungen eines Radverkehrsnetzes ermöglichen einen gezielten Einsatz von Maßnahmen zur Erhaltung, Umbau, Ausbau sowie Neubau.

3.3 Qualität und Bewertung von Radverkehrsinfrastruktur

Zur Bewertung der Qualität auf Radverkehrsnetzen zeigt sich aus der Literatur eine Zieldefinition hinsichtlich der Kriterien Sicherheit, Komfort, Direktheit, Konnektivität und Attraktivität, wobei Sicherheit als wichtigstes Kriterium definiert wird. (Ahmed et al., 2024; Arellana et al., 2020; McCarthy et al., 2016; Weikl& Mayer, 2023). Eine Bewertung auf Basis dieser Kriterien ermöglicht die angepasste Kriterienkombination in Abhängigkeit des betrachteten Radverkehrsnetzes. Für die Analyse von Alltagsradverkehrsnetzen sollte dem Kriterium Direktheit eine größere Gewichtung zugeteilt werden als dem Kriterium Attraktivität, wohingegen für ein Freizeitradverkehrsnetz die Attraktivität höher gewichtet werden sollte (McCarthy et al., 2016). Laut (FGSV, 2018) ist der Einfluss der infrastrukturellen Umgebung für die Routenwahl des Radverkehrs deutlich höher als bei anderen Verkehrsmitteln. Eine Vielzahl von Indikatoren wirkt sich auf die Hochwertigkeit und Nutzbarkeit eines Radverkehrsnetzes aus. Hierzu zählen dieFührung des motorisierten Individualverkehrs (FGSV, 2021a; Liu et al., 2019; Rossetti et al., 2019; Watkins et al., 2020), parkende Kraftfahrzeuge (FGSV, 2021b, 2021a; Liu et al., 2019; Rossetti et al., 2019; Watkins et al.,

2020), Führungen des Fußverkehrs (Arellana et al., 2020; Barrero& Rodriguez-Valencia, 2022; FGSV, 2021b), Längsneigungen (Barrero& Rodriguez-Valencia, 2022; FGSV, 2021b), dieBreite der Radverkehrsführung (FGSV, 2021a; Pais et al., 2022; Song et al., 2021; Watkins et al., 2020), Hindernisse und Barrieren (FGSV, 2021b: Ros-McDonnell et al., 2020), das Verkehrsaufkommen des motorisierten Individualverkehrs (Arellana et al., 2020; FGSV, 2021a, 2021b; Song et al., 2021), die zulässige Höchstgeschwindigkeit für Kraftfahrzeuge (Arellana et al., 2020; Song et al., 2021), Beleuchtungen (Barrero& Rodriguez-Valencia, 2022; FGSV, 2018, 2021b; Grigore et al., 2018), Markierungen (Ahmed et al., 2024; Lowry et al., 2016; McCarthy et al., 2016), dieOberflächenqualität (Ahmed et al., 2024; Merkens et al., 2024; Pais et al., 2022; Silvestri et al., 2024), Vorfahrtsregelungen an Knotenpunkten (Arellana et al., 2020; Jensen, 2012), Wartezeiten und Zeitverluste (Ahmed et al., 2024; FGSV, 2018; Reggiani et al., 2022; Silvestri et al., 2024), die Überquerungsdistanz an Knotenpunkten (Jensen, 2012; Lowry et al., 2016), der Umwegefaktor (Arellana et al., 2020; Reggiani et al., 2022; Schmid-Querg et al., 2021; Weikl & Mayer, 2023), Abstellanlagen (Ahmed et al., 2024; Ros-McDonnell et al., 2020; Schmid-Querg et al., 2021), die ÖPNV-Anbindung (Pucher & Buehler, 2008; Silvestri et al., 2024) oder die Netzdichte (Ahmed et al., 2024; Gu et al., 2018; Vierø et al., 2024).

Analysen zu infrastrukturellen Einflüssen auf den Radverkehr sind international weit verbreitet (Ahmed et al., 2024). Mit dem BSIR (Bicycle Safety Index Rating) wurde bereits in den 80er Jahren die erste Bewertungsmethode für die Sicherheit von Radfahrenden entwickelt (Davis, 1987). Seither hat sich eine Vielzahl weiterer Bewertungsmethoden gebildet, wie beispielsweise dem BLOS (TRB, 2010), dem BCI (Liu et al., 2019), dem LTS (Mekuria et al., 2012) oder dem BI (Arellana et al., 2020).

Nach (Ahmed et al., 2024) ist der systematische Prozess zur Konzeption von Bewertungsmethoden in mehrere Bereiche aufgeteilt. Er beginnt mit einer Zieldefinition von Kriterien, für welche eine Zusammensetzung aus Indikatoren ermittelt wird. Für jeden Indikator muss eine klassifizierende Einstufung gebildet und in Abhängigkeit dessen Ausprägung bewertet werden. Anschließend müssen die Indikatoren untereinander in Abhängigkeit ihres Einflusses gewichtet werden (Ahmed et al., 2024). Der Gewichtungsprozess gestaltet sich hierbei komplexer als die Identifikation der Indikatoren, eine Gewichtung ist jedoch essenziell, da eine gleichgroße Berücksichtigung der Indikatoren nicht repräsentativ ist.

3.4 Analytischer Hierarchieprozess

Der Analytische Hierarchieprozess (AHP), entwickelt durch (Saaty&Kearns, 1985), ermöglicht die Gewichtung mehrerer Parameter, um auf Basis komplexer, multikriterieller Einflüsse, strukturiert und konsistent, Entscheidungen treffen zu können. Wesentlicher Bestandteil des AHP ist der paarweise Vergleich im Rahmen einer Präferenzenmatrix entsprechend der relativen Bedeutung der Kriterien untereinander. Im Rahmen der Bewertung von Radverkehrsnetzen wurde der AHP von (Karolemeas et al., 2022; Zuo& Wei, 2019) verwendet. Im Kontext der durchgeführten Methodik wird der AHP zur Gewichtungsermittlung eingesetzt, um die Relevanz der Parameter relativ zueinander zu bewerten.

3.5 DigitaleModelle

Die Zukunft des Planens, Bauens und Betreibens wird wesentlich durch den digitalen Wandel bestimmt (BMDV, 2015). Um von der Digitalisierung zu profitieren und damit die Anforderungen bei der netzweiten Qualitätsbewertung und bei einem effizienten Asset Management der Radverkehrsnetze erfüllen zu können, ist ein geeignetes digitales Modell erforderlich. Hierzu ist eine klare Standardisierung für die Datendefinition und -struktur von zentraler Bedeutung. Vor diesem Hintergrund stellt die Building Information Modelling (BIM) Methode ein gutes Beispiel dar. Die Quintessenz von BIM besteht unter anderem darin, eine konsistente und kompatible Datengrundlage zu schaffen, sodass gemeinsame, reibungslose Kommunikation und Arbeit möglich sind. Der Standard für die Datengrundlage ist als „Industry Foundation Classes" (IFC) bekannt und setzt sich aus der semantischen Beschreibung eines Bauteils und seiner geometrischen Repräsentation zusammen. Dabei ist die semantische Beschreibung als eine Entität dominierend und kann mit einer oder mehreren geometrischen Verkörperungen verbunden werden (Borrmann et al., 2021). Die BIM-Methode schafft große Vorteile durch realitätsnahe 3D-Modellierung für die Planung und den Neubau eines Bauwerks. Wird der Schwerpunkt von Neubau auf die Betriebs- und Erhaltungsphase verlagert, dann werden zusätzlichen externen dynamischen Echtzeitdaten aus dem Bestand in Ergänzung zu statischen Daten aus der Planungsphase benötigt, um ein immer mit der Realität synchronisiertes digitales Modell zu erhalten.

Somit wird die Arbeitsmethode „Digitaler Zwilling“ als Erweiterung von BIM genutzt, um eine optimierte Entscheidungsgrundlage für ein nachhaltiges Management im Lebenszyklus der Infrastruktur zu schaffen (Fazekas, 2024). Im Vergleich zu BIM und dem digitalen Zwilling konzentriert sich die GIS-Methode auf geodatenbezogene Analysen und Darstellungen eines Betrachtungsraums. Die detaillierten Geometrie- und Funktionsbeschreibungen besitzt teilweise nur eine sekundäre Bedeutung, sodass diese oft vereinfacht oder weggelassen werden können. Die Grundstruktur bei der Modellierung, also die Kombination von Geometriemodell und dem damit verbundenen standardisierten Datenmodell bleibt jedoch gleich. Ein typischer Standard für GIS ist beispielsweise das GML (Geography Markup Language) entwickelt vom OGC (Open GeospatialConsortium) (Jarosch, 2023).

Im Sinne von Asset Management eines Straßennetzes liegt der Schwerpunkt eines digitalen Modells auf einer großräumigen, netzweiten Zustandsanalyse zur optimalen Erhaltung der vorhandenen Infrastruktur. Zu diesem Zweck wurde die Anweisung Straßeninformationsbank (ASB) erarbeitet, sodass alle überörtlichen Straßen im Netz mit umfassend genauen Daten analysiert und bewertet werden können. Die Straßeninformationsbank (SIB) nach ASB setzt sich aus einem Ordnungssystem basiert aus Netzknoten und Stationierungssystem sowie einer damit verbundenen Datenbank zusammen. Das Ordnungssystem bildet die Grundlage für die Visualisierung der Daten und Auswerteergebnisse in GIS. Die damit verbundene Datenbank ist ein Datenmodell mit einer standardisierten Struktur, auf dem eine beliebige Anzahl von Daten angehängt werden können. Die Standardisierung für den Datenaustausch wird in dem OKSTRA festgehalten und fortgeschrieben. OKSTRA ist ein Katalog von Objekten des Straßen- und Verkehrswesens sowie den zugehörigen Sachdaten und Beziehungen (BMDV, 2024). Die SIB nach ASB ist somit eine Art „Semi-“ Digitaler Zwilling, sie übernimmt die Vorteile von BIM, GIS und digitalem Zwilling und passt die Konzipierungsstruktur nach konkreten Anwendungsfällen und Zielsetzungen für ein geeignetes Datenbanksystem an.

Für Radverkehrsnetze bestehen derzeit weder standardisierte Verfahren zur Zustandserfassung und -bewertung (ZEB), noch ein offizielles Netzmodell. Bestehende Modelle zur Radverkehrsinfrastruktur konzentrieren sich vor allem auf die Routingfähigkeit und grundlegenden Datendokumentationen. OSM (Open Street Map) ist eine communitybetriebene Datenplattform für Karten und beinhaltet auch Daten zur Infrastruktur. Es folgt einem einfachen Modell basierend aus Punkten (Nodes), Linien (Ways) und Relationen (Relations), wobei Punkte sowohl Knotenpunkte als auch zahlreiche andere Objekte wie Bäume, Gebäude und Lampen darstellen können. Die Geometrie von Linien kann durch Referenz von Punkten definiert werden. Zusätzliche Eigenschaften können durch sogenannte „Tags“ beliebig hinzugefügt werden. Da die Daten nicht aus offiziellen Quellen stammen, sind die Qualität und Vollständigkeit oft unzureichend. Es bietet jedoch eine Datengrundlage mit guter Aktualität und globaler Zugänglichkeit, die auf Überprüfung und Korrektur bei Datenmängeln nützlich sein können. In Baden-Württemberg wurden 2011 die Online-Anwendung des Radroutenplaner und 2020 die Datenplattform RadVIS (Radverkehrs-Infrastruktur-System) entwickelt. Der Radroutenplaner berücksichtigt unter anderem das Radnetz von Baden-Württemberg und ist in erster Linie für Nutzende gedacht, um Empfehlungen zu einfachen und bequemen Routen zu geben. RadVIS ist eine Datenbank zur Unterstützung der Städte und Kommunen bei der Konzeption und Dokumentation ihrer Radnetze. Im Rahmen der Digitalisierung der Radverkehrsinfrastruktur können beide Plattformen als großer Fortschritt verzeichnet werden. Angesichts der steigenden Anforderungen eines Managementsystems für die Fahrradinfrastruktur zeigen sich dennoch Schwächen. So wird beispielsweise in RadVIS nur ein vereinfachtes Modell für Knotenpunkte gepflegt, sodass nur die reine Information der Knotenpunktart berücksichtigt werden kann, was für eine repräsentative Bewertung der Knotenpunkte und folglich des gesamten Netzes ungünstig wirken kann. In (BALM, 2023) wurden die Rahmenangaben des nationalen Datenschemas der Radverkehrsdaten analog zum OKSTRA im Straßensystem vorgelegt. Damit ist eine Grundstruktur für ein einheitliches Datenmodell vom Radverkehrssystem errichtet. Das Datenschema ist jedoch derzeit auf kein Bewertungsverfahren ausgelegt, sodass die Vollständigkeit und Umsetzfähigkeit noch zu prüfen sind. Im Rahmen des vier-dimensionale Qualitätsbewertungsverfahren für Radverkehrssysteme nach (Stöckner, 2023) sind deutlich höhere Anforderungen zum digitalen Radnetzmodell zu erwarten, insbesondere bezüglich Netzstruktur und Datenmodell. Die bestehende Datenbank muss auf eine standardisierte Weise erweitert werden. Es ist davon auszugehen, dass ein geeignetes Informationssystem je nach gesonderten Anwendungsfällen und Ansprüchen für Radwegenetze analog zur SIB in naher Zukunft eine immer wichtigere Rolle spielen wird, wodurch eine Standardisierung

zweckmäßig ist. Im Kontext der Zielsetzung einer Qualitätsbewertung und Asset Management des vollständigen Radverkehrsnetzes liegt der Fokus nicht auf nuancenreichen 3D-Geometrie-Planungen und Visualisierungen von einzelnen Straßenelementen. Vielmehr spielen ihre geographischen Positionen und Qualitätsmerkmalen eine wichtige Rolle. Aus diesem Grund ist eine Kombination zwischen einem Geometriemodell auf Basis von GIS und einem Datenmodell im Sinne von BIM oder digitalem Zwilling zielführend. Dabei ist zu beachten, dass eine Standardisierung mit Berücksichtigung bestehender Datenmodelle bei der Modellierung anzustreben ist, um den künftigen Datenaustausch reibungslos zu gestalten.

4 METHODIK

4.1 Entwicklung des konzeptionellenBewertungsmodells

Das Bewertungsmodell soll bisherige Methoden durch die Kombination der Zielkriterien mit einer differenzierten Elementbetrachtung von Strecke und Knotenpunkt erweitern und so eine georeferenzierte Defizitanalyse bei gleichzeitig ganzheitlicher Qualitätsbetrachtung ermöglichen. Zunächst wird das Radverkehrsnetz in Elemente von Streckenabschnitten und Knotenpunkten eingeteilt, da aufgrund der individuellen Qualitätsmerkmale eine Bewertung getrennt für beide Elemente durchgeführt werden muss. Diese sind in beliebiger Form und Anzahl miteinander verknüpfbar, sodass durchgehende Verbindungen entstehen können, welche als Routen bezeichnet werden. In Abhängigkeit der zu bewertenden Eigenschaften, werden individuelle Streckenabschnitte, Knotenpunkte, Routen oder das gesamte Netz betrachtet. Nach (Taubitz et al., 2025) können unterschiedliche Zielgrößen für die Bewertungsbereiche gebildet werden. Hierbei bleibt die Attraktivität im Rahmen der Betrachtung von Alltagsradverkehrsnetzen unberücksichtigt, da diese stark von subjektiven Faktoren beeinflusst wird und eine vernachlässigbare Bedeutung im Alltagsradverkehr aufweist. Ein einzelner Streckenabschnitt ist gekennzeichnet durch Sicherheit und Komfort. Knotenpunkte können ebenfalls hinsichtlich Sicherheit und Komfort bewertet werden. Für Routen ergibt sich eine zusätzliche Bewertung der Direktheit und im gesamten Netz kann die Konnektivität analysiert werden. Das aufeinander aufbauende System ermöglicht je nach Anwendungsbereich, Einzelbewertungen und Gesamtbewertungen. Dies ist erforderlich, um Mängel innerhalb des Radverkehrsnetzes georeferenziert zu identifizieren, da eine gesamtheitliche Betrachtung auf Netzebene keine Georeferenzierung erlaubt. Im Rahmen der durchgeführten Methodik wird je ein Gesamtwert für die individuellen Bewertungsbereiche Strecke, Knotenpunkt, Route und Netz benötigt. Dies erfordert die Gewichtung und Erstellung von je einem analytischen Hierarchieprozess für alle Parameter je Bewertungsbereich.

4.2 Parameter und Daten

Die zu berücksichtigende Parameter sollten keine zeitlich zu hohen Änderungen aufweisen, da kurzweilige Qualitätseinschränkungen keine langfristigen Auswirkungen auf die Gesamtqualität das Radverkehrsnetz haben. Ziel des Bewertungssystem ist es, die grundlegenden und langfristigen Qualitätseinschränkungen zu identifizieren und quantifizieren und nicht geringfügige Aspekte in Form von Details in die Betrachtung einfließen zu lassen. Die Befahrbarkeit sollte auf hochwertigen Radverkehrsnetzen durch eine betriebliche Unterhaltung sichergestellt sein, ist jedoch aufgrund der nicht kompensatorischen Eigenschaften nicht in den folgenden Parametern berücksichtigt. Die betriebliche Unterhaltung umfasst die Abwicklung der betrieblichen Aufgaben hinsichtlich Winterdienst, Reinigung, Grünpflege, Wartung und Instandhaltung der Ausstattung sowie baulicher Unterhaltung. Diese Aufgaben unterliegen im Verlauf eines Jahres starken Schwankungen und müssen über die Zuständigkeiten der Baulastträger hinweg koordiniert werden. Dafür ist eine ausreichende Personal- und Maschinenkapazität notwendig. Diese Anforderungen resultieren in einer komplexen Umsetzungssituation, die jedoch an dieser Stelle nicht weiter ausgeführt wird. Nach (Taubitz et al., 2025) werden den Kriterien Sicherheit und Komfort an Streckenabschnitten und Knotenpunkten folgende Parameter zugeteilt:

Sicherheit Strecke: Baulicher Zustand, Breiten, Verkehrsaufkommen Kfz, zulässige Höchstgeschwindigkeit Kfz, Trennungen zum Kfz-Verkehr, Parken Kfz, Beleuchtungen, Markierungen

Komfort Strecke: Baulicher Zustand, Breiten, Längsneigung, Trennungen zum Fußverkehr, Hindernisse

Sicherheit Knotenpunkt: Baulicher Zustand, Breiten, Verkehrsaufkommen Kfz, zulässige Höchstgeschwindigkeit Kfz, Vorfahrtsregelung, Trennungen zum Kfz-Verkehr, Markierungen

Komfort Knotenpunkt: Baulicher Zustand, Breiten, Überquerungslängen, Wartezeiten, Trennungen zum Fußverkehr

Die Einzelbewertungen der Parameter werden in eine Skala von eins (sehr schlecht) bis fünf (sehr gut) übertragen. Der bauliche Zustand (BZ) bewertet die Oberflächenqualität auf Basis von Ebenheit, Substanzmerkmalen und Griffigkeit (Merkens et al., 2024). In Abhängigkeit der vorhandenen Ausprägungen von beispielsweise Rissen, Abplatzungen oder Wurzelhebungen wird ein Gesamtwert zur Oberflächenqualität auf Basis des vorhandenen Oberflächenmaterials im Rahmen einer Zustandserfassung und -bewertung gebildet. Für die Bewertung der Breiten (BR) wird die vorhandene Breite mit der vorgegebenen Mindestbreite (Bmin)und Regelbreite (Breg) aus dem Regelwerk abgeglichen (FGSV, 2010; Weikl & Mayer, 2023). Das Verkehrsaufkommen (VA) entspricht der durchschnittlich täglichen Verkehrsstärke (DTV) für den Kfz-Verkehr. Die zulässige Höchstgeschwindigkeit des Kfz-Verkehrs wird stufenhaft eingeteilt und geringere Geschwindigkeiten besser bewertet. Die Führungsform des Radverkehrs im Vergleich zum Kfz-Verkehr dient der Bewertung von Trennungen zum Kfz-Verkehr (TK). Zur Bewertung von Parken Kfz (PA) wird der Abstand zu parkenden Fahrzeugen von der Radverkehrsführung ermittelt (Weikl & Mayer, 2023). Die Bewertung der Beleuchtung (BE) umfasst das Vorhandensein und die Abwesenheit von Beleuchtungsanlagen. Die Bewertung der Markierungen (MA) erfolgt in Abhängigkeit von vorhandenen Bodenmarkierungen. Zur Bewertung der Längsneigung (LN) werden vorhandene Steigungen als auch die Länge der Steigungsstrecke benötigt. Die Bewertung erfolgt nach (Weikl & Mayer, 2023) in Form eines Steigungsindex, mit der Formel $S = H^2*L$ (S = Steigungsindex, H = Steigung, L = Streckenlänge). Die Bewertung von Trennungen zum Fußverkehr (TF) basiert auf der Führungsform des Radverkehrs und des Fußverkehrs. Hindernisse (HI) wie beispielsweise Poller, Pfosten, Umlaufgitter oder sonstige Einbauten werden zur Bewertung entsprechend der Anzahl pro 1.000 Meter bewertet. Die Bewertung erfolgt mit der Formel HI = 1000m/L*AH (L = Streckenlänge, AH = Anzahl der Hindernisse). Zur Bewertung der Vorfahrtsregelung (VR) wir die Art der Vorfahrtsregelung für den Radverkehr ermittelt und die Bewertung der Überquerungslängen (ÜL) berücksichtigt die Länge des zu überquerenden Knotenpunktes. Die Bewertung der Wartezeiten (WZ) erfolgt stufenhaft in Abhängigkeit der vorhandenen Wartezeiten am Knotenpunkt. In Tabelle 3 sind die möglichen Einteilungen zusammengefasst, welche in Abhängigkeit des erstrebten Qualitätsniveaus angepasst werden können.

Parameter	1	2	3	4	5
BZ [-]	5	4	3	2	1
BR [m]	$<0,7*B_{min}$	$0,7*B_{min}– B_{min}$	$>B_{min} – <B_{reg}$	B_{reg}	$>B_{reg}$
VA [Kfz/Tag]	≥5.000	≥2.500	≥2.000	≥1.000	<1.000
HG [km/h]	>70	70	50	30	<30
TK [-]	Mischverkehr	Radfahrstreifen; Schutzstreifen	Fahrradstraße	Straßen-begleitende Führung	Separate Führung
PA [m]	<0,75	<1,50	<2,00	<5,00	≥5,00
BE [-]	Nicht vorhanden				Vorhanden
MA [-]	Keine Markierung		Randstreifen		Flächenhafte Einfärbung
LN [m]	≥0,400	≥0,200	≥0,075	≥0,033	<0,033
TF [-]	Gehweg mit Radverkehr frei	Geh- und Radweg gemeinsam	Landwirtschaft-licher Weg; Waldweg	Geh- und Radweg getrennt	Separate Führung
HI [1/km]	≥4	3	2	1	0
VR [-]	Keine Regelung	Rechts-vor-links	Verkehrszeichen ohne Vorfahrt	Verkehrszeichen mit Vorfahrt	Lichtsignal-anlage
ÜL [m]	>20	≤20	≤15	≤10	≤5
WZ [s]	>20	≤20	≤15	≤10	≤5

Tabelle 1: Mögliche Bewertungen für Parameter von Strecke und Knotenpunkt, teils basierend auf (Weikl & Mayer, 2023)

Die Parameter, welche zur Bewertung der Kriterien Direktheit und Konnektivität verwendet werden, sind:

Direktheit Route: Umwegefaktor, Zeitverluste an Knotenpunkten

Konnektivität Netz: Abstellanlagen, ÖPNV-Anbindung, Netzdichte, Hauptradwegenetzanteil

Zur Bewertung des Umwegefaktors (UF) muss das Verhältnis aus Luftliniendistanz und Routenlänge zwischen Start- und Zielort mittels folgender Formel gebildet werden UF = LR/LD (LR = Routenlänge, LD = Luftliniendistanz). Die Zeitverluste an Knotenpunkten (ZK) werden pro Routenkilometer angegeben und mit der Formel ZK = ∑(WZ)/LR (WZ = Wartezeit je Knotenpunkt, LR = Routenlänge) berechnet. Die

Bewertung von Abstellanlagen erfordert die Ermittlung des Typs der Abstellanlage sowie deren Auslastung (Weikl & Mayer, 2023). Die Kombination der Bewertungen wird durchgeführt durch AA = (BS+AL)*0,5 (BS = Stellplatzbewertung, AL = Auslastung). Die ÖPNV-Anbindung (ÖA) wird durch Ermittlung der Luftliniendistanz zwischen Haltestelle und Radverkehrsnetz ermittelt. Die Netzdichte (ND) setzt sich zusammen aus der Länge des Radverkehrsnetzes und der Fläche des Radverkehrsnetzes mit der Formel ND = FN/LN (FN = Netzfläche, LN = Netzlänge). Zur Bewertung des Hauptradwegenetzanteils (HN) wird die Länge des Hauptradwegenetzes im Verhältnis zur Netzlänge berechnet mit HN = LH/LN (LH = Hauptradwegenetzlänge, LN = Netzlänge). Mögliche Einstufungen der Bewertungen basieren größtenteils auf (Weikl & Mayer, 2023) und sind in Tabelle 2 dargestellt.

Parameter	1	2	3	4	5
UF [-]	>1,5	>1,4	>1,3	>1,2	≤1,2
ZK [s/km]	>46	>36	>26	>16	≤16
BS [-]	Vorderradanschluss	Anlehnbügel	Sammelanlage	Fahrradbox	Fahrradparkhaus
AL [%]	≥90	<90	<80	<70	<60
ÖA [m]	>500	>400	>300	>200	≤200
ND [m]	>1000	>500	>400	>250	≤250
HN [%]	<40	≥40	≥50	≥60	≥70

Tabelle 2: Mögliche Bewertungen für Parameter von Route und Netz, größtenteils nach (Weikl & Mayer, 2023)

4.3 Gewichtungs- und Bewertungsverfahren

Damit eine georeferenzierte Gesamtwertanalyse ermöglicht wird, müssen für jeden Bewertungsbereich neue Kombinationen der Gesamtwertbildung erfolgen. Auf Basis der Analyse verschiedener wissenschaftlicher Quellen (Arellana et al., 2020; McCarthy et al., 2016; Weikl & Mayer, 2023) wurde eine mögliche Struktur für die Gewichtungsverteilung für Alltagsradverkehrsnetze abgeleitet.

Gesamtwert Strecke = 0,60 * Sicherheit Strecke+ 0,40 * Komfort Strecke

Gesamtwert Knotenpunkt = 0,60 * Sicherheit Knotenpunkt + 0,40 * Komfort Knotenpunkt

Gesamtwert Route = 0,48 * Sicherheit + 0,31 * Komfort + 0,21 * Direktheit

Gesamtwert Netz = 0,40 * Sicherheit + 0,29 * Komfort + 0,16 * Direktheit + 0,15 * Konnektivität

Da im Gesamtbewertungssystem jeder Parameter individuell angezeigt werden kann, kann spezifisch nach Schwachstellen gefiltert werden. Die Gesamtwertbildung dient der Priorisierung auf Netzebene. Die Gewichtungsermittlung der jeweiligen Parameter wurde durch analytische Hierarchieprozesse in Abhängigkeit der definierten Parameter durchgeführt. Die Gewichtungen innerhalb der analytischen Hierarchieprozesse basieren auf generischen Einschätzungen, welche durch Ergebnisse der Literaturanalyse gestützt werden, da keine numerischen Daten verfügbar waren.

Die Bewertung der Streckenabschnitte erfordert Gesamtwerte zu Sicherheit und Komfort. Für jeden dieser Kriterien wurde ein analytischer Hierarchieprozess durchgeführt, um Einzelgewichte der Parameter zu ermitteln. Die Ergebnisse sind in den folgenden Gleichungen dargestellt.

Sicherheit Strecke = 0,10*BZ + 0,09*BR + 0,19*VA + 0,13*HG + 0,39*TK + 0,02*PA + 0,03*BE + 0,05*MA

Komfort Strecke = 0,17*BZ + 0,38*BR +0,36*LN + 0,06*TF + 0,03*HI

Zur Ermittlung der Gewichte der Parameter für Knotenpunkte wurden ebenfalls zwei analytische Hierarchieprozesse entsprechend den definierten Parametern durchgeführt mit folgenden Ergebnissen.

Sicherheit Knotenpunkt = 0,04*BZ + 0,03*BR + 0,22*VA + 0,20*HG + 0,37*VR + 0,11*TK + 0,03*MA

Komfort Knotenpunkt = 0,10*BZ + 0,20*BR + 0,04*ÜL + 0,54*WZ + 0,08*TF*0,04*MA

Die Gewichtungsverteilungen zu den Kriterien Direktheit und Konnektivität sind nachstehend dargestellt. Für beide Kriterien wurde ein AHP durchgeführt.

Direktheit Route = 0,83*UF + 0,17*ZK

Konnektivität Netz = 0,57*AA + 0,05*ÖA + 0,25*ND + 0,13*HN

Um die vollständige Bewertung einer Route durchzuführen, werden zusätzlich zur Direktheit die Kriterien Sicherheit und Komfort benötigt. Diese setzen sich zusammen aus der relativen Sicherheit für Strecken unter

Berücksichtigung der jeweiligen Streckenlänge sowie der durchschnittlichen Sicherheit an Knotenpunkten entsprechend deren Anzahl. Die folgenden Gleichungen veranschaulichen dies.

Sicherheit Route = (∑ (Sicherheit Streckenabschnitt * Streckenlänge) / Routenlänge +

∑ (Sicherheit Knotenpunkt) / Anzahl Knotenpunkte) / 2

Komfort Route = (∑ (Komfort Streckenabschnitt * Streckenlänge) / Routenlänge +

∑ (Komfort Knotenpunkt) / Anzahl Knotenpunkte) / 2

Für die Gesamtbewertung des Netzes muss zusätzlich zum Kriterium Konnektivität eine Betrachtung von Sicherheit, Komfort und Direktheit unter Berücksichtigung aller Strecken, Knotenpunkte und Routen erfolgen. Sicherheitswert und Komfortwert werden aus Streckenabschnitten und Knotenpunkten gleich der Vorgehensweise der Routenkombination gebildet, mit der Erweiterung, dass alle Streckenabschnitte und alle Knotenpunkte berücksichtigt werden. Um eine Aussagekräftige Bewertung zur Direktheit eines Radverkehrsnetzes geben zu können, müssen alle relevanten Routen berücksichtigt werden, bevor der Durchschnittswert als Kriterium der Netzbewertung einfließt. Dies betrifft die Verbindung relevanter Start- und Zielpunkte in Form individueller POI (Points of Interest) innerhalb des Radverkehrsnetzes. Die Kombinationen der Kriterien sind in den folgenden Formeln veranschaulicht.

Sicherheit Netz = (∑ (Sicherheit Streckenabschnitt * Streckenlänge) / Netzlänge +

∑ (Sicherheit Knotenpunkt) / Anzahl Knotenpunkte) / 2

Komfort Netz = (∑ (Komfort Streckenabschnitt * Streckenlänge) / Netzlänge +

∑ (Komfort Knotenpunkt) / Anzahl Knotenpunkte) / 2

Direktheit Netz = ∑ (Direktheit Route * Routenlänge) / ∑ Routenlängen

Auf Basis der bisherigen Bewertungen können Einstufungen entsprechend der infrastrukturellen Qualität unabhängig vom Radverkehrsaufkommen getroffen werden. Sofern vorhandene Daten zum Radverkehrsaufkommen vorliegen, können diese mit den vorhandenen Qualitätswerten überlagert werden. Dies ermöglicht eine verkehrsabhängige Priorisierung, sodass die Qualität auf Netzbereichen mit viel Radverkehrsaufkommen eine höhere Bedeutung hat als die Qualität auf Netzbereichen mit wenig Radverkehrsaufkommen. Sofern keine Daten zum Radverkehrsaufkommen auf dem Radverkehrsnetz vorliegen, kann die Netzbedeutung in Abhängigkeit der räumlichen Relevanz des Netzabschnitts berücksichtigt werden.

4.4 Modellierungsrichtlinie

Um das Bewertungsmodell umzusetzen, wird ein digitales Netzmodell als Grundlage benötigt. Grundelemente dafür sollten die bestehenden Modellsysteme und Zustandserfassungsmethoden berücksichtigen. Infolge von unterschiedlichen Nutzungsansprüchen der Anwendungsfälle muss ein Kompromiss zwischen Übersichtlichkeit, Leistungsfähigkeit, Begreifbarkeit, Genauigkeit, Effizienz und Wirtschaftlichkeit gefunden werden. Dies bedeutet, dass das Modell möglichst einfach aber gleichzeitig ausreichend robust für folgende Anwendungsfälle sein muss:

- Darstellung der Topologie und Geometrie des Radverkehrsnetzes
- Georeferenzierung
- Dokumentation und Fortschreibung der umfangreichen Bestands- und Zustandsdaten der Infrastruktur
- Streckenbezogene, Knotenpunktbezogene, Routenbezogene sowie Netzbezogene Qualitätsbewertung und Defizitanalyse anhand der Bewertungsalgorithmen und Zustandsdaten
- Visualisierung der Bewertungsergebnisse
- Effiziente Datenübertragung und -zuweisung aus Quellen wie SIB und RadVIS

Demzufolge wird ein Objektmodell mit den Grundelementen in Tabelle 3 erarbeitet.

Die Trennung der Richtung für eine Strecke hängt ausschließlich davon ab, ob Radfahrende aus zwei Richtungen dieselbe Fahrspur teilen müssen oder ob eine zusätzliche Zustandserfassung für die Gegenrichtung durchgeführt werden muss. Die Unterscheidung von NK und LK besteht darin, die

Verkehrssituation ausreichen bewerten zu können. Typische LK finden sich dort, wo Radfahrende als häufigstes Verkehrsmittel vertreten sind. In solchen Fällen sind die zu verbindenden Strecken oft auch durch eine einzige Primärstrecke für beide Richtungen repräsentativ. An großen Knotenpunkten mit LSA ist es sowohl für die Bewertung des Knotenpunktes als auch für Routenbewertung relevant, die Fahrbeziehungen getrennt zu betrachten. Die Verbindungsstrecken sind entsprechend der vorhandenen Verkehrsführung anzulegen, indem zum Beispiel für indirektes Linksabbiegen eine zweistufige Verbindung modelliert wird und für direktes Linksabbiegen eine diagonale Verbindung anzulegen ist. Die Verbindungsstrecken sind neben ihrer topologischen Verbindungsfunktion wichtig für die Betrachtung der Sicherheit und Leistungsfähigkeit. Unabhängig von Start- und Endnetzknoten wird die Geometrie einer Strecke analog zur SIB bzw. OSM durch eine Punktliste definiert. Abb. 1 zeigt eine Beispielmodellierung.

Objektkategorie	Objekttyp	Kennzeichen	Bedeutung und Merkmale
Knotenpunkt	Netzknoten	NK	Große Knotenpunkte, Netzbedeutung; Achsenschnittpunkt
	Teilknoten	TK	Teil von einem großen Knotenpunkt; Streckenanschlusspunkt
	Lokalknoten	LK	Kleine Knotenpunkte, lokale Verbindung; Streckenanschlusspunkt
Streckenabschnitt	Primärstrecken	PS	Beschreibt eine ganze Strecke zwischen NK; Zur Datenübertragung, ZEB-Datenimport
	Sekundärstrecken	SS	Segmente von zugehöriger PS; Zur differenzierten Datenhaltung und Datenvisualisierung
	Verbindungsstrecken	VS	Verbindet TK; Zur separaten Betrachtung unterschiedlicher Fahrbeziehungen

Tabelle 3: Grundelemente als Kernkonzept für das Netzmodell

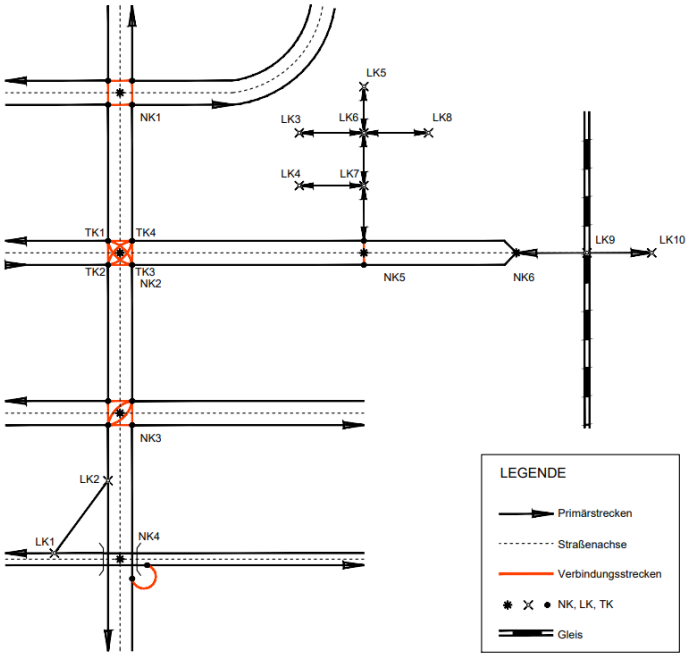

Abb. 1: Schematische Darstellung für das Modellierungsgrundprinzip

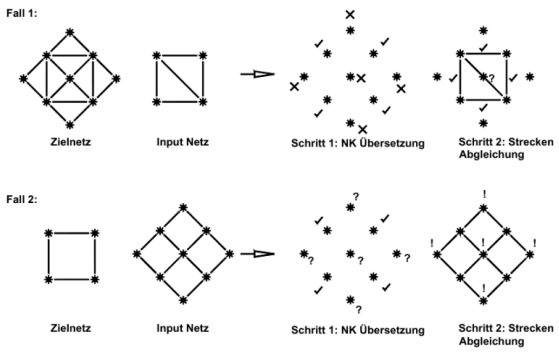
Aufbauend auf dem Modell können Routen sowie Netze zusätzlich definiert werden. In Abhängigkeit der Verkehrssituation kann die Netzstruktur vereinfacht dargestellt werden oder komplexe Fahrbeziehungen repräsentieren. Dabei wird besonders die Datenübertragung aus dem Netzknotensystem der SIB berücksichtigt. Zwischen Netzknoten und Teilknoten sowie Primärstrecken und Sekundärstrecken soll eine Referenzstelle hergestellt werden, sodass die Beziehung verdeutlicht und unterschiedliche Darstellungen ermöglicht werden können. Die Netzübertragung und Datenzuweisung kann über zwei Lösungsansätze erfolgen. Die erste Lösung umfasst die Datenzuweisung durch den Abgleich von klar definierten Routen aus zwei Systemen. Hierbei müssen Von- und Nach-Netzknoten sowie der gesamte Routenverlauf aus zwei Systemen klar definieren werden. Um beispielsweise die Ergebnisdaten der ZEB von NK1 nach NK6 aus der SIB auf das Zielmodell zu übertragen, wird zunächst die gleiche Route in zwei Systemen festgelegt, beispielsweise von NK1 über NK2 und NK5 nach NK6. Anschließend wird der Datenstrom aus dem Quellsystem exportiert, sortiert und auf das Zielmodell übertragen. Die Primärstrecken werden dabei entsprechend der Auflösung vom Quelldatenstrom in Sekundärstrecken segmentiert, welche den einzelnen

Datensatz pro Einheitstrecke mit einer räumlichen Auflösung von beispielsweise einem Meter auffangen. Ein Nachteil dieser Vorgehensweise ist, dass für die manuelle Definition ein Abgleich der Routen erforderlich ist.

Die zweite Lösung umfasst die Datenübertragung auf Basis automatischer Abgleichung der Koordinaten der Netzknoten aus zwei Systemen. Hierbei werden die Lokalknoten des Zielmodells wie Netzknoten behandelt, Teilknoten jedoch vernachlässigt. Sobald die Koordinaten der Netzknoten aus zwei Systemen innerhalb von bestimmten Abweichungstoleranzen übereinstimmen, werden sie als identische Netzknoten betrachtet, obwohl sich die Nummerierungen unterscheiden können. Dieser Schritt kann als NK-Übersetzung verstanden werden. Anschließend sollen im Zielnetz alle vorhandene Streckenobjekte basierend auf ausgefilterten NK aufgelistet werden und mit denen im Zielnetz verglichen werden. Wenn die Strecke in zwei Systemen besteht, wird diese Strecke als eine Route betrachtet und die Datenübertragung analog zur Vorgehensweise der ersten Lösung durchgeführt. Sofern eine Strecke der gleichen NK-Matrix im Inputnetz vorhanden, jedoch im Zielnetz nicht vorhanden ist, werden die Von- und Nach-NK von der Strecke verwendet, um die kürzeste Route im Zielnetz zu erzeugen. Sobald die Länge der erzeugten Route im Rahmen bestimmter Abweichungstoleranzen der Länge der Strecke im Inputnetz entspricht, werden die Route und die Strecke gleichgesetzt. Andernfalls kann diese Strecke entweder als neue Strecke ins Zielmodell aufgenommen oder abgelehnt werden. Falls der NK im Inputnetz nicht vorhanden ist, wird er für die Datenübertragung nicht berücksichtigt. Falls der NK im Inputnetz vorhanden, jedoch im Zielnetz nicht vorhanden ist, dann kann dieser entweder ins Zielnetz aufgenommen oder abgelehnt werden. Eine Aufnahme sorgt automatisch für die Vervollständigung des Netzes und Einbezug von Daten. Abb. 2 zeigt die schematische Darstellung des Übertragungskonzeptes.



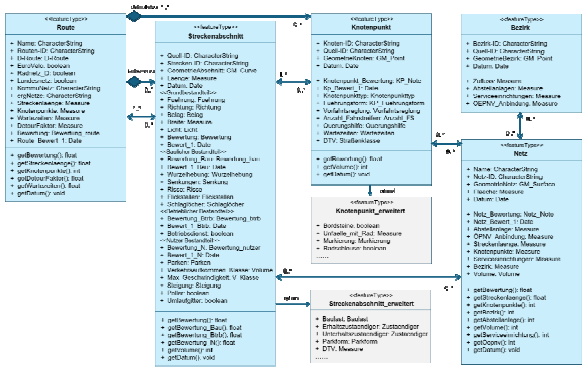


Abb. 2 (links): Schematische Darstellung für das Datenübertragungskonzept. Abb. 3 (rechts): UML für die Objektplanung des Modells.

Je nach Anforderung des Bewertungsmodells lassen sich Attribute zum jeweiligen Objekt ableiten und somit ein Objektkatalog verfassen. Dies stellt die Grundlage für die Implementierung des Datenmodells dar (Abb. 3).

Zur Unterstützung des Datenimport aus unterschiedlichen Quellen ist es zweckmäßig, ein Parameter-Wörterbuch zu erstellen, sodass die Barriere zwischen unterschiedlichen Semantiksystemen abgebaut werden können. Mit der Integration von Bewertungsalgorithmen des Bewertungsmodells lassen sich so auf netzweiter Analyse, Ergebnisse visualisieren.

5 DISKUSSION

Es wurde eine Methodik vorgestellt, um die Qualität auf Radverkehrsnetzen ganzheitlich zu bewerten und digital abzubilden. Um die Nutzung des Fahrrads als Verkehrsmittel besser zu ermöglichen, muss die Radverkehrsinfrastruktur nicht nur die baulichen und regulatorischen Anforderungen einhalten, sondern auch den Bedarfen und Bedürfnissen der Nutzenden entsprechen. Eine effektive Förderung des Radverkehrs setzt voraus, dass Qualitätsmängel nicht nur identifiziert, sondern auch behoben werden. Hierbei sind für bauliche Maßnahmen oder betriebliche Unterhaltungen die Baulastträger auf den verschiedenen Abschnitten verantwortlich. Das digitale Modell und die Bewertungsmethodik können zwar Defizite identifizieren, für die spätere Instandsetzungen, Umbauten, Ausbauten sowie Neubauten müssen jedoch konkrete Maßnahmen und Vereinbarungen erbracht werden. Um aussagekräftige Qualitätswerte zu erhalten, welche die Basis für eine langfristige, ganzheitliche Förderung des Radverkehrs sicherstellen, ist eine Vielzahl von Daten

notwendig. Diese müssen für die Bewertung auf dem gesamten Radverkehrsnetz vorliegen. Landesweite Radverkehrsnetze, wie beispielsweise das Radnetz Baden-Württemberg verfügen bereits über eine hohe Anzahl von Bestandsdaten. Kleinere Gebietskörperschaften verfügen jedoch häufig nur über geringere Datenbestände, was eine vollumfängliche Bewertung erschwert. Um dennoch Qualitätsbewertungen durchführen zu können, müssen zukünftig alternative Parameter und Minimalanforderungen zur Bewertung definiert werden. Die Ermittlung der Gewichtungen ist bisher nur qualitativ durchgeführt worden. Um genauere Ergebnisse liefern zu können, muss eine Sensitivitätsanalyse in realen Netzen durchgeführt werden. Hierbei können auch Parameter mit Einflüssen auf die Attraktivität berücksichtigt werden, um zukünftige Bewertungen für Radverkehrsnetze für den Tourismus und Freizeit durchführen zu können. Das beschriebene Modell ist auf Basis von der Modellierungsrichtlinie zu implementieren und mithilfe von Pilotprojekten auf Handhabung und Leistungsfähigkeit zu prüfen.

6 FAZIT

Das bisherige System ermöglicht die Abbildung und Bewertung von Radverkehrsnetzen zur Unterstützung der datengetriebenen Entscheidungsfindung zu Maßnahmen auf Radverkehrsnetzen. Die Erweiterung der Parameter ist durch die Berücksichtigung von beispielsweise Unfalldaten, Serviceeinrichtungen, wegweisender Beschilderung, Sichtfeldern oder Fahrtgeschwindigkeiten möglich, sofern der Gewichtungsprozess angepasst wird. Eine Ergänzung des Bewertungssystems kann durch die Implementation von Erreichbarkeiten erfolgen. Auch die Verteilung von Bevölkerungsdichten kann in einer Erreichbarkeitsanalyse berücksichtigt werden. So könnte beispielsweise eine Pufferzone um das bestehende Radverkehrsnetz gelegt werden und diese mit den Bevölkerungszahlen überlappt werden. Inwiefern sich die Qualität eines Radverkehrsnetzes auf das Verkehrsmittelwahlverhalten auswirkt, kann wichtige Erkenntnisse zur Förderung zukünftiger nachhaltiger Mobilität geben. Hierzu müsste untersucht werden, wie sich eine Veränderung der Qualität auf die Verkehrsmittelwahl auswirkt. Das bisherige System berücksichtigt ausschließlich Anlagen des Radverkehrs. Eine Erweiterung des Systems unter der Berücksichtigung des Fußverkehrs ermöglicht eine vollumfängliche Aussagekraft zu komplexen Verkehrssystemen.

1 ABSTRACT

Das Forschungsprojekt PART-COM zielt darauf ab, Bürgerinnen und Bürger aktiv in kommunale Transformations- und Innovationsvorhaben einzubinden, wofür durch nationale und internationale Expertinnen- und Experteninterviews neun Konfliktfelder und zehn Erfolgsfaktoren identifiziert wurden. Die Konfliktfelder wurden in einer Abwärtsspirale visualisiert, wobei sechs Hauptkonflikte (mangelhafte Repräsentativität, fehlender politischer Wille, mangelhafte Kommunikation, fehlende Transparenz, Wissensmangel und hohe Hürden) zu tieferliegenden Problemen wie Entfremdung, Scheinpartizipation und Gleichgültigkeit führen können. Die Erfolgsfaktoren, die teilweise durch eine Bürgerinnen- und Bürgerumfrage validiert wurden, betonen die Bedeutung vielfältiger Kommunikationsformate, einer starken Feedbackkultur, niederschwelliger Beteiligungsangebote sowie der Integration digitaler und analoger Kanäle für eine erfolgreiche Öffentlichkeitsbeteiligung.

Keywords: Partizipation, Erfolgsfaktoren, Konfliktfelder, Öffentlichkeitsbeteiligung, Beteiligungsprozesse

2 EINLEITUNG: BÜRGERINNEN UND BÜRGER ALS AKTIVE GESTALTENDE

Partizipation wird durch das Bundesministerium für wirtschaftliche Zusammenarbeit und Entwicklung als die aktive Mitgestaltung von Leben beeinflussenden Entscheidungen durch Bevölkerungsgruppen, Organisationen und Parteien definiert (BMZ 2023, o. S.).

Um diese Mitgestaltung zu sichern und damit Bürgerinnen und Bürger als aktive Gestalter in kommunale Transformations- und Innovationsvorhaben einzubinden spielt Öffentlichkeitsbeteiligung eine entscheidende Rolle. Im Infrastrukturbereich reicht diese von im BauGB gesetzlich festgeschriebener formeller Beteiligung (BauGB 2024) bis hin zu informellen Verfahren, die über gesetzliche Anforderungen hinausgehen (Quilling & Köckler 2018, S. 102). Die Intensität der ausgeführten Partizipation hat dabei Wright et al. (2010, S. 3) sehr anschaulich durch sein Stufenmodell dargestellt. Bei diesem Modell kann die Partizipation von der reinen Instrumentalisierung bis zur Selbstorganisation der Bürgerinnen und Bürger gehen.

Eine stärkere Partizipation führt in der Wirtschaft nachweislich zu höherer Produktakzeptanz, indem Konsumentinnen und Konsumenten in den Wertschöpfungsprozess eingebunden werden (Hofbauer 2013, S. 1; Merlo et al. 2014, S. 88). Diese Erkenntnisse lassen sich auch auf Infrastrukturprojekte übertragen: Die frühzeitige Einbindung der Bürgerinnen und Bürger ermöglicht es, deren Wissen und Erfahrungen zu nutzen und gleichzeitig die Akzeptanz gegenüber einem Vorhaben zu steigern (Quilling & Köckler 2018, S. 101).

Dass Partizipation aber nicht immer gelingt, zeigt sich besonders, wenn sich die Fronten zwischen Politik, Verwaltung und Bürgerinnen und Bürgern verhärten – wie zum Beispiel im Fall Stuttgart 21. Das Gefühl der Ausgrenzung führte dort zu massiven Protesten, die 2010 im „Schwarzen Donnerstag“ ihren Höhepunkt fanden (DLF 21). Stuttgart 21 wurde zu einem Wendepunkt, der ein Umdenken in der Öffentlichkeitsbeteiligung nach sich zog, mit der Folge, dass Verwaltungen und Politik Bürgerinnen und Bürger heute früher in Planungsprozesse einbinden wollen (DLF 21). Doch die Herausforderung bleibt, Beteiligung nicht nur anzubieten, sondern auch Bürgerinnen und Bürger zu erreichen und zu motivieren, an dieser teilzunehmen.

Welche Konfliktfelder dabei eine Rolle spielen und welche Impact- und Erfolgskriterien die Partizipation im Infrastrukturbereich von Städten und Gemeinden verbessern können, wurde durch die Befragung von Expertinnen und Experten aus verschiedenen Bereichen ermittelt.

3 FORSCHUNGSFRAGE UND METHODIK

Wie lassen sich Bürgerinnen und Bürger effektiver in Planungs- und Entscheidungsprozesse einbinden und welche Kriterien werden von Expertinnen und Experten dabei als wesentlich für den Erfolg und den Impact von Öffentlichkeitsbeteiligung angesehen?

Zur Bearbeitung dieser Fragestellung kommt eine zweistufige Methodik zum Einsatz. Im ersten Schritt werden Interviews mit Expertinnen und Experten aus den Bereichen Verwaltung, Planung, Wissenschaft, Wirtschaft und Nichtregierungsorganisationen (NGOs) durchgeführt (Brow et al 2023). Ziel dieser Gespräche ist es, ein fundiertes und umfassendes Verständnis der aus Expertinnen- und Expertensicht entscheidenden Kriterien für den Erfolg und die Wirkung von Beteiligungsverfahren zu gewinnen. Die Auswahl der Expertinnen und Experten erfolgt dabei anhand ihrer Fachkompetenz und Erfahrung in der praktischen Umsetzung oder wissenschaftlichen Untersuchung von Öffentlichkeitsbeteiligung.

Im zweiten Schritt werden die in den Expertinnen- und Experteninterviews ermittelten Kriterien durch eine Umfrage unter Bürgerinnen und Bürgern überprüft und validiert (Penka et al 2024). Ziel dieser Umfrage ist es, die Bedeutung der von den Expertinnen und Experten genannten Kriterien aus der Perspektive der Bevölkerung zu bewerten und gegebenenfalls weitere, aus Sicht der Bürgerinnen und Bürger relevante Kriterien zu identifizieren. Durch die Kombination von qualitativen Interviews und quantitativen Befragungen entsteht ein differenziertes Bild der Impact- und Erfolgskriterien. Dies ermöglicht die Ableitung fundierter Empfehlungen für die Praxis der Öffentlichkeitsbeteiligung. Die Methodik stellt sicher, dass die entwickelten Kriterien nicht nur theoretisch durch Expertinnen und Experten fundiert, sondern auch praxisnah und breit akzeptiert sind aus Bürgerinnen- und Bürgerperspektive.

3.1 Expertinnen- und Experteninterviews

3.1.1 Durchführung der Expertinnen- und Experteninterviews

Die Experteninterviews wurden mit 18 Fachpersonen und drei zusätzlichen Workshops mit Stadtverwaltungen durchgeführt (Brow et al. 2023). Die Auswahl der Expertinnen und Experten erfolgte gezielt auf Basis ihrer Fachkenntnisse und Erfahrungen in der praktischen Umsetzung oder wissenschaftlichen Analyse von Öffentlichkeitsbeteiligung. Dabei wurde ein flexibler Interviewleitfaden verwendet, der es ermöglichte, die Gespräche strukturiert zu führen, gleichzeitig aber auch individuell auf die spezifischen Perspektiven und Fachkenntnisse der Gesprächspartnerinnen und Gesprächspartner einzugehen. Diese auf Döringer 2020 und von Soest 2023 basierende Vorgehensweise ermöglichte das Erfassen von explizitem Wissen wie auch impliziten Perspektiven. Die Länge der Interviews variierte zwischen etwa 30 und 90 Minuten, abhängig von der terminlichen Verfügbarkeit sowie der Gesprächsfreude der Interviewten.

Um dabei ein möglichst breites Spektrum an Perspektiven abzudecken wurden Expertinnen und Experten aus unterschiedlichen Bereichen befragt:

- Wissenschaft: Fünf Interviews, darunter drei mit internationalen Expertinnenund Experten, lieferten Einblicke in aktuelle wissenschaftliche Diskurse und länderspezifische Unterschiede.
- Stadtverwaltungen: Zwei Interviews, eines davon international, beleuchteten praktische Herausforderungen und Erfolgsfaktoren aus Verwaltungssicht.
- Planungsbüros: Zwei Gespräche brachten praxisnahe Perspektiven zur Gestaltung von Beteiligungsverfahren ein.
- Agenturen und Mediationsbüros: Sechs Interviews fokussierten auf die Moderation und Vermittlung zwischen Stakeholdern.
- Nichtregierungsorganisationen (NGOs): Drei Gespräche boten Einblicke in die zivilgesellschaftliche Perspektive und deren Rolle als Sprachrohr für Bürgerinnen- und Bürgeranliegen.

Zusätzlich fanden drei halbtägige Workshops mit zwei Verwaltungen und einem Arbeitskreis statt, die durch ihre interaktive Natur eine kollektive Bearbeitung der Themen ermöglichten. Diese Kombination aus Interviews und Workshops erlaubt es, sowohl individuelle als auch gruppendynamische Erkenntnisse zu gewinnen.

3.1.2 Analyse der Expertinnen- und Experteninterviews

Die Analyse der Interviews wurde mithilfe des Tools Miro durchgeführt, das durch Mind Maps eine visuelle Strukturierung der Daten ermöglichte. Die zentralen Themenfelder für die Analyse wurden aus den Projektzielen sowie gängiger Literatur aus der Öffentlichkeitsbeteiligung abgeleitet. Diese sind: Folgen von Öffentlichkeitsbeteiligung, Nutzung von Sprache und Technischer Kommunikation, Input-Verwertung und Feedback, Digitale Beteiligungslösungen und -plattformen, Erreichen von Bürgerinnen und Bürgern, Beteiligungsscore, Unterschiede National und International sowie Häufigkeit und Zeitpunkt des Dialogs. Diese Kategorien dienten als Rahmen für die systematische Auswertung jedes Interviews. Dabei wurden relevante Aussagen extrahiert, thematisch gebündelt und quantitativ ausgewertet.

Die Ergebnisse wurden tabellarisch aufbereitet, wobei alle relevanten Aussagen kategorisiert wurden. Punkte, die mindestens zweimal genannt wurden, wurden in die weitere Analyse einbezogen. Insgesamt ergaben sich so über 60 Aspekte, die schließlich in neun Konfliktfelder sowie zehn thematisch gegliederte Impact- und Erfolgskriterien zusammengefasst wurden. Der Einsatz von Mind Maps erwies sich dabei als besonders hilfreich, um Beziehungen zwischen Themen visuell darzustellen und eine ganzheitliche Perspektive auf die umfangreichen Daten zu ermöglichen.

4 KONFLIKTFELDER DER ÖFFENTLICHKEITSBETEILIGUNG

Abbildung 1: Abwärtsspirale der Öffentlichkeitsbeteiligung (Sagnol et al 2024, Icons generiert mit OpenAI)

Basierend auf diesen Interviews konnten eine Reihe sich wechselseitig beeinflussende Konfliktfelder identifiziert werden, die, wenn unbeachtet, in einer gefährlichen Demokratieverdrossenheit gipfeln können. Diese Konfliktfelder wurden in einer Abwärtsspirale (Abbildung 1) zusammengefasst (Sagnol et al 2024).

Die oberste Ebene der Abwärtsspirale zeigt insgesamt sechs Konfliktfelder. Mangelhafte Repräsentativität der Bürgerinnen und Bürger, Fehlender Wille seitens Verwaltung/Politik, Mangelhafte Kommunikation, Fehlende Transparenz, Mangel an Wissen seitens Bürgerinnen und Bürger sowie Hohe Hürden. Je intensiver und je stärker diese sechs Konfliktfelder ausgeprägt sind, desto stärker sind auch die weiterführenden und tiefer sitzenden Konfliktfelder Gleichgültigkeit, Scheinpartizipation und Entfremdung. Diese tiefer sitzenden Konfliktfelder sind in der Auswirkung deutlich gravierender sowie in der Problembehandlung wesentlich schwieriger zu lösen und führen im schlimmsten Fall zu einem Systemversagen.

Im Folgenden werden die einzelnen Konfliktfelder erläutert sowie Lösungsansätze dafür beschrieben.

4.1 Mangelhafte Repräsentativität der Bürgerinnen und Bürger

Die Recherchen im Rahmen des Projektes haben ergeben, dass es in der aktuellen Öffentlichkeitsbeteiligung bei Infrastrukturprojekten, ohne entsprechend größeren Aufwands seitens der Verwaltung bzw. der Stadt oder Kommune, nicht möglich ist eine gemischte und repräsentative Gruppe an Menschen anzuhören.

Betrachtet man zuerst die Bevölkerungsgruppen, die an Öffentlichkeitsbeteiligungen im Rahmen der Infrastrukturplanung teilnehmen, trifft man auf zwei unterschiedliche, überrepräsentierte Gruppen:

(1) Es beteiligen sich hauptsächlich die „üblichen Verdächtigen“:

Der Tenor der Interviewten charakterisierten diese Teilnehmergruppe als männlich sowie meist im fortgeschrittenen Berufslebensalter oder darüber hinaus. Damit bestätigen die Interviews die Ergebnisse der Studie der Universität Hohenheim (Brettschneider, 2022).

(2) Es beteiligen sich hauptsächlich diejenigen, die dagegen sind:

„Wir gehen selten für etwas auf die Straße. Wir gehen eigentlich immer gegen etwas auf die Straße. [...] Dadurch entstehen in der Beteiligung immer Verzerrungseffekte“ – Matthias Burgbacher, PLAN:KOOPERATIV, 2023

Eine Beobachtung, die sowohl in Deutschland, als auch im internationalen Kontext gültig ist. Je unzureichender die Repräsentativität in Formaten der öffentlichen Beteiligung ist, desto größer die Gefahr, dass Entscheidungen auf der Basis individueller Interessen einer kleinen Gruppe getroffen werden, anstatt im Sinne des Gemeinwohls. Insbesondere die ältere Generation, deren direkte Betroffenheit an den Entwicklungen in 15 Jahren und darüber hinaus begrenzt ist, tragen maßgeblich an der Entscheidungsfindung bei. Gleichzeitig bleiben die Meinungen der jüngeren Generationen, die von solchen Zukunftsentscheidungen maßgeblich betroffen sind, oft gänzlich unausgesprochen. Es wäre aber verfehlt, die Ursache hierfür bei der älteren Generation zu suchen. Vielmehr sollte die Frage aufgeworfen werden: Warum bleiben viele Menschen stumm, und wie lässt sich dieser Umstand ändern? Besondere Aufmerksamkeit muss dabei auch den stillen Gruppen gewidmet werden, wie etwa Migrantinnen und Migranten, die sich von Sprachbarrieren betroffen fühlen, oder jenen, die der Überzeugung sind, dass ihre Teilnahme keinen Einfluss hat.

„Ich glaube Bürgerbeteiligung ist für viele Menschen einfach so ein total abstraktes Konzept“ – Jakob Krieger, Fridays for Future, 2023

Niedrigschwellige und dezentralisierte Formate	Beteiligungsprozesse an Orte anpassen, wo sich Menschen aufhalten (z. B. Märkte, öffentliche Plätze).
	Nutzung von Tools wie interaktiver Poster oder QR-Codes zur einfachen Beteiligung.
Barrieren gezielt abbauen	Sprachliche Hürden durch Sprach- und Gebärdendolmetscherinnen und Gebärdendolmetscher oder einfache Sprache überwinden.
	Zeitlich flexible Formate und spezifische Zugänge schaffen.
Aufklärung und Bildung fördern	Informieren, wie Bürgerinnen und Bürger Einfluss nehmen können.
	Frühzeitige Einbindung von Kindern und Jugendlichen in kurze aber auch langfristige Projekte, etwa durch interaktive Methoden.

Lösungsansätze für das Konfliktfeld „Mangelhafte Repräsentativität der Bürgerinnen und Bürger“

4.2 Fehlender Wille seitens Verwaltung/Politik

Ein Mangel an frühzeitiger Rückkopplung mit der Bevölkerung kann dazu führen, dass wertvolles lokales Wissen ungenutzt bleibt und geplante Lösungen an den Bedürfnissen der Bürgerinnen und Bürger vorbeigehen. Widerstand wird oft erst erkannt, wenn Entscheidungen bereits getroffen sind. Die Gründe, warum eine Stadt oder Kommune dennoch nur begrenzt in die Öffentlichkeitsbeteiligung investiert, sind vielfältig – sie können sich gegenseitig beeinflussen, aber auch unabhängig voneinander wirken.

Der erste Aspekt Machtabgabe basiert dabei auf den hierarchischen Strukturen, die in Deutschland weit vorherrschend sind. Merkmale einer solchen Struktur sind zum einen eine klare Rollenverteilung, zum anderen eine vertikale Kommunikation. Interpretiert wird dieses Verständnis gerne damit, dass gewählte Vertreter sich bereits durch das Gewählt-sein legitimiert sehen, zu entscheiden, ohne die Öffentlichkeit abermals zu fragen.

„Da gibt es [in Deutschland] unheimlich viel Angst und Bedenken, zu viel Macht abzugeben.“ – Jelena Gregorius, Go Vocal, 2023

Eine mangelnde Repräsentativität bei von der Verwaltung organisierten Öffentlichkeitsbeteiligungen führt auch unweigerlich zu dem Gefühl, dass Bürgerinnen und Bürger ein mangelndes Interesse an der Mitgestaltung ihrer Stadt oder Gemeinde an den Tag legen. Die Bruchsaler Verwaltung erklärte diesbezüglich, dass die geringen Rücklaufquoten von Beteiligungsangeboten dazu führten, dass eine effiziente Zusammenarbeit auf Augenhöhe nicht möglich ist (Stadt Bruchsal 2023).

(1) Mangelnde Ressourcenfreigabe für Öffentlichkeitsbeteiligung

Häufig wird der Prozess als weitaus unkomplizierter angesehen, als er in Wirklichkeit ist, was dazu führt, dass unzureichende Ressourcen bereitgestellt werden. Im Ergebnis fehlt es an den notwendigen Mitteln, um eine hochwertige Beteiligung zu ermöglichen.

„Und häufig ist alles was in die Richtung Marketing, Kommunikation, Öffentlichkeitsarbeit und Beteiligung geht so nach dem Motto: Das ist das Sahnehäubchen auf der Torte. Aber das ist es halt eben nicht. Eigentlich ist es Grundvoraussetzung für den Erfolg von Projekten und Maßnahmen, hier eine gute Arbeit zu machen“ – Kristina Oldenburg, KOKONSULT, 2023

(2) Fehlendes Bewusstsein über die Vorteile von Öffentlichkeitsbeteiligung

Die positiven Aspekte einer frühzeitigen und umfassenden Einbindung der Öffentlichkeit, wie die Verringerung von Konflikten, die Einsparung von Zeit und die Gewinnung wertvoller Erkenntnisse, werden nicht ausreichend erkannt.

Ziele und Grenzen definieren	Klare Kommunikation der Entscheidungsmöglichkeiten der Bürgerinnen und Bürger.
	Transparenz, um Vertrauen aufzubauen und Enttäuschungen zu vermeiden.
Ressourcen bereitstellen	Schulung von Verwaltung und Politik, um den Nutzen von Beteiligung zu verstehen.
	Sicherstellen, dass personelle und finanzielle Ressourcen für kontinuierliche Beteiligung vorhanden sind.
Hierarchie als Chance nutzen	Zentrale Vorgaben können standardisierte, effiziente und qualitativ hochwertige Beteiligungsprozesse sicherstellen.

Lösungsansätze für das Konfliktfeld „Fehlender Wille seitens Verwaltung/Politik“

4.3 Mangelhafte Kommunikation

Bevor eine Beteiligung beginnen kann, muss die Stadt oder Kommune zunächst ihre Bürgerinnen und Bürger umfassend informieren und erreichen. Dies stellt ein größeres Problem dar, als es auf den ersten Blick erscheinen mag. Viele Städte und Kommunen kämpfen mit veralteten Technologien und Prozessen, die den Anforderungen einer zunehmend digitalen Gesellschaft nicht gerecht werden. Neben der Auswahl geeigneter Medienkanäle ist es daher ebenso entscheidend, dass der Inhalt und die Zielsetzung der Kommunikation klar und zielgerichtet formuliert werden.

Je länger Menschengruppen nicht erreicht werden oder worden sind, desto höher wird der Aufwand, diese wieder in die Beteiligung einzubringen. Kommunen und Städte befinden sich insofern in einer Holschuld, die sich auch unter dem Aspekt der aufsuchenden Beteiligung zusammenfassen lässt. Hier geht es also darum, dezentral auf die Bürgerinnen und Bürger zuzugehen um ihnen die Möglichkeiten der Beteiligung vorzustellen.

„Ich finde die Zielgruppen nicht schwierig. Nur ich muss erst entscheiden, dass ich ganz gezielt den Aufwand betreiben möchte, diese Menschen zu erreichen.“ – Kristina Oldenburg, KOKONSULT, 2023

Multi-Channel und hybride Kommunikation	Kombination aus Online- und Offlineangeboten, in diverser Art, um unterschiedliche Zielgruppen anzusprechen.
	Nutzung von sozialen Medien, Plakaten, interaktiven Plattformen und spielerischen Ansätzen (z. B. Wettbewerbe oder Gamification).
Aufsuchende Beteiligung	Bürgerinnen und Bürger proaktiv aufsuchen, z.B. bei Stadtfesten, in Kitas oder auf Marktplätzen.
	Dezentrale Formate und die Nutzung neutraler Orte wie Hochschulen oder Bibliotheken fördern eine niederschwellige Teilnahme.
Emotionale und kreative Ansprache	Triggernde negative Aufrufe (z. B. provokative Plakate) regen Diskussionen an.
	Positive oder humorvolle Aufrufe (z. B. witzige Projekt-Namen, z.B. buxtewho.de) schaffen einen freundlichen Zugang.
Transparenz und Bildung	Klar kommunizieren, warum die Beteiligung wichtig ist, welche Einflussnahme es gibt und welche Auswirkungen sie hat.
	Bürgerinnen und Bürger durch verständliche Inhalte und humorvolle oder spielerische Formate aktivieren.

Lösungsansätze für das Konfliktfeld „Mangelhafte Kommunikation“

4.4 Fehlende Transparenz

Ein Mangel an Transparenz in Bezug auf Abläufe, Ergebnisse und Ziele von Beteiligungsprozessen kann schnell zu Missverständnissen und Frustration zwischen Verwaltung, Politik und Bürgerinnen und Bürger

führen. Die effiziente Meinungsbildung wird durch unzureichende Informationsvermittlung stark behindert oder sogar gänzlich verhindert. Besonders kritisch wird es, wenn fehlende Transparenz das Vertrauen der Bürgerinnen und Bürger in die städtische Verwaltung erschüttert. Dies geschieht, wenn der Eindruck entsteht, dass Informationen absichtlich zurückgehalten oder verschleiert werden.

Letztlich ist es ein Abwägungsprozess: Hat die Verwaltung mehr zu verlieren, wenn Informationen zurückgehalten werden oder dadurch, dass das Vertrauen der Bürgerinnen und Bürger verspielt wird? Die Antwort dürfte in aller Regel sein: Verprelle die Bürgerinnen und Bürger nicht.

„Vertrauen in den Prozess heißt, dass es ein glaubwürdiger, transparenter, ehrlicher Prozess ist, finde ich. Ein Beteiligungsprozess.“ – Jochen Plückelmann, CP/COMPARTNER, 2023

Regelmäßige und transparente Kommunikation	Kontinuierliche Updates zu Projekten, auch bei fehlenden Neuigkeiten, um Vertrauen zu wahren.
	Klar kommunizieren, warum bestimmte Maßnahmen Zeit brauchen oder Ideen nicht umgesetzt werden können.
Feedback und Verständlichkeit sicherstellen	Rückmeldungen zu Beiträgen von Bürgerinnen und Bürgern verständlich kommunizieren.
	Fachsprache vermeiden und komplexe Abläufe in einfacher Sprache, bzw. ziel- gruppenorientiert Sprache erklären.
Koordination und Struktur stärken	Einrichtung zentraler Koordinations- stellen für große Projekte, um Abstimmungen zwischen Ämtern zu verbessern.
	Moderationspersonen innerhalb der Verwaltung einsetzen und mit Entscheidungs- und Weisungsbefugnis ausstatten.
Erweiterung der Kommunikationskanäle	Nutzung etablierter zusammen mit neuen Kanälen wie Newsletter, digitale Plattformen oder Plakate.
	Reichweite und Sichtbarkeit von Informationen erhöhen, wie in „Mangelhafte Kommunikation“ empfohlen.

Lösungsansätze für das Konfliktfeld „Fehlende Transparenz“

4.5 Mangel an Wissen seitens Bürgerinnen und Bürgern

Zur Erläuterung dieses Konfliktfeldes muss zwischen drei grundsätzlichen Punkten unterschieden werden:

(1) Allgemeines ingenieurtechnisches Wissen

Bürgerinnen und Bürgersind zum Großteil weder ausgebildete Planerinnen und Planer, Ingenieurinnen und Ingenieure oder ähnliches. Einen technischen Text zu verstehen oder einen Plan zu erfassen mag den jeweiligen Mitarbeitenden aus der Verwaltung einfach fallen, weil sie jeden Tag damit konfrontiert sind. Für Bürgerinnen und Bürger kann das aber durchaus eine zu komplexe Aufgabe bedeuten.

(2) Spezifisches Wissen zu Projekten

Werden Informationen zu Projekten nicht oder unzureichend weitergeleitet, können sich Bürgerinnen und Bürger kein Bild von dem Thema machen. Das Zurückhalten von Informationen ist dementsprechend nicht nur als ein Problem für das Verhältnis zwischen Bürgerinnen und Bürger und Stadt bzw. Kommunen zu sehen. Können sich Bürgerinnen und Bürger nicht informieren, wird zum einen das Interesse, an einer Veranstaltung teilzunehmen, sinken.

Nutzung einfacher Sprache und Visualisierungen	Vermeidung von Fachsprache und „Beamtendeutsch“ zugunsten verständlicher und zielgruppengerechter Sprache.
	Visuelle Hilfsmittel wie realistische Visualisierungen, Vorher-Nachher-Vergleiche oder Virtual Reality erhöhen das Verständnis und wecken damit Betroffenheit.
Sprachbarrieren abbauen	Bereitstellung von Informationen in mehreren Sprachen, dazu zählt auch einfache Sprache oder Gebärdensprache.
	Einsatz von unterstützenden Tools, wie z. B. interaktiven Erklärungen oder Videos.
Bildung und Unterstützung anbieten	Aufbau von Wissenskapazitäten durch die Aufklärung über Beteiligungsprozesse und -rechte der Bürgerinnen und Bürger.
	Durchführung von sogenannten Ideenwerkstätten, in denen Bürgerinnen und Bürger bei der Formulierung ihrer Vorschläge aktiv unterstützt werden.
Realistische Erwartungshaltung schaffen	Projekte und deren Konsequenzen objektiv aber nachvollziehbar darstellen, um Missverständnisse und unrealistische Erwartungen zu vermeiden.
	Klare Abgrenzung und Kommunikation darüber, welche Aspekte Bürgerinnen und Bürger mitentscheiden können und welche in der Verantwortung der Fachleute liegen.

Lösungsansätze für das Konfliktfeld „Mangel an Wissen seitens Bürgerinnen und Bürgern“

(3) Wissen zu den Möglichkeiten der Partizipation und der Teilhabe

Schon die alleinige Tatsache, dass es bei Infrastrukturprojekten mindestens ein Recht auf Anhörung geben muss, ist keine allgemeingesellschaftlich bekannte Tatsache. Damit fehlt die Kenntnis innerhalb der Bevölkerung über das Recht sich einzubringen und aktiv Einfluss zu nehmen. Doch auch wenn das Recht bekannt ist, wird durch intransparente Kommunikation nicht immer klar, wo und wie das geschehen kann.

Solange aber Kommunikationsdefizite nicht behoben und Bürgerinnen und Bürger nicht umfassend über ihre Rechte und Mitwirkungsmöglichkeiten informiert werden, bleibt ihre Teilhabe stark eingeschränkt.

„Wenn man eine gute Öffentlichkeitsbeteiligung will, muss man auch ein bisschen politische Bildung betreiben, immer wieder Kapazitäten aufbauen und den Menschen das geben, was sie brauchen, um sich effektiv zu beteiligen." – Winnie Mitullah, University of Nairobi, 2023 (übersetzt aus dem Englischen)

4.6 Hohe Hürden

Unter den hier aufgeführten Hürden im Bereich der Partizipation sind Barrieren gemeint, die Menschen daran hindern, sich aktiv an Entscheidungs- oder Planungsprozessen zu beteiligen. Dabei handelt es sich nicht nur um physische oder sprachliche Barrieren und Hürden, sondern um alle Arten von Hürden, die einen Menschen im Allgemeinen aufgrund seiner Lebensweise oder seiner Alltagszwänge daran hindern könnten, an Partizpationsveranstaltungen teilzunehmen.

(1) Mangel an Information und Bildung

Aufbauend auf den vorherigen Abschnitten lässt sich der Mangel an (verständlicher) Information in der Öffentlichkeitsbeteiligung als Hürde betrachten.

„Information ist der erste Schritt hin zu einer co-kreativen Prozessgestaltung. Und wenn ich gut informiere, dann kann ich auch motivieren und aktivieren." Kristina Oldenburg, KOKONSULT, 2023

(2) Mangel an Zeit

„[...] dass wir ja die Beteiligungen in der Regel zu Zeiten durchführen sollten, die man auch den Beschäftigten der Stadt noch irgendwie zumuten kann, aber gleichzeitig auch, wo man das Potenzial sieht, dass die Bewohner, dass die Betroffenen eben auch können. Das sind dann meistens so spätnachmittag bis früher Abend. In der Theorie ist das so die Schnittmenge. In der Praxis ist es so, dass die Leute – die Beteiligten – vor Ort sind, die halt Zeit haben. Das sind nicht die jungen Berufstätigen, erst recht nicht die Familienväter und -mütter, sondern das sind die Rentner." – Jan Riel, Hochschule Karlsruhe, 2022

(3) Ungeeigneter Veranstaltungsort

Stellt der Ort der Veranstaltung für die Interessierten einen erhöhten Reiseaufwand dar, wird sich das negativ auf die Teilnehmerquoten auswirken. Das Stichwort Dezentralisation sollte auch hier nochmal zum Tragen kommen. Ebenfalls bedacht werden muss die multimodale Erreichbarkeit des Ortes.

(4) Mangel an digitaler Affinität

Als vierten Punkt ist die Hürde der Digitalität zu nennen. Nicht jede Person hat das passende Endgerät, das nötige Wissen oder auch die passende technische Ausstattung um an einer digitalen Beteiligungsveranstaltung teilzunehmen.

Überwindet man sowohl die Verständnishürde, wie auch die zeitlichen und örtlichen Beschränkungen, eröffnen sich also für deutlich mehr Bürgerinnen und Bürger die Möglichkeit, sich in der Beteiligung einzubringen.

Niedrigschwellige und verständliche Kommunikation	Bereitstellung klarer, einfacher Informationen über geeignete Kanäle.
	Kombination von Texten, Visualisierungen und digitalen Hilfsmitteln, um Verständnis zu fördern.
Zeitliche Flexibilität bieten	Veranstaltungen zu verschiedenen Tageszeiten und an unterschiedlichen Tagen wiederholen.
	Asynchrone Beteiligungsmöglichkeiten bereitstellen, wie Kommentierung, Online-Umfrage oder abrufbare Inhalte.
Dezentrale und barrierefreie Veranstaltungsorte	Veranstaltungen an leicht erreichbaren und barrierefreien Orten mit multimodaler Zugänglichkeit organisieren.
Digitale und hybride Formate fördern	Kombination aus analogen und digitalen Angeboten für unterschiedliche Zielgruppen.
	Nutzung von interaktiven Tools wie Poster, Umfragen oder VR-Simulationen zur niederschwelligen Teilnahme.
	Sicherstellen, dass digitale Formate benutzerfreundlich sind.
Partizipation durch Gamification	Spielerische Ansätze, wie einfache Planungs-Tools oder Wettbewerbe, motivieren zur Beteiligung.

Lösungsansätze für das Konfliktfeld „Hohe Hürden"

4.7 Scheinpartizipation, Gleichgültigkeit und Entfremdung

„Meiner Meinung nach ist schlechte Beteiligung schlimmer als gar keine Beteiligung, weil die Leute dann beim nächsten Mal einfach nicht mehr kommen." – Jelena Gregorius, Go Vocal, 2023

Werden Bürgerinnen und Bürger zwar formal beteiligt, aber nicht ernst genommen wird das schnell dazu führen, dass jene, die sich noch die Mühe machen, Stellungnahmen zu Projekten abzugeben, enttäuscht und frustriert werden. Besonders kritisch wird es, wenn die Stadt mehr als nur formale Beteiligung anbietet, die daraus gewonnenen Erkenntnisse jedoch dann einfach ignoriert.

„Das schreckt die Leute wirklich ab, denn sie denken: ‚Was hat es für einen Sinn, sich zu beteiligen und mitzumachen, wenn man mir nicht zuhört?'" – Winnie Mitullah, University of Nairobi, 2023 (übersetzt aus dem Englischen)

Gleichgültigkeit entsteht dort, wo nicht nur das Engagement der Bürgerinnen und Bürger, sondern auch ihr Interesse an den Geschehnissen ihrer lokalen Umgebung schwindet. Eine Stadtverwaltung wird das insbesondere daran spüren, dass sie den Eindruck bekommt, dass die Menschen kein Interesse mehr daran haben, ihre Lebenswelt aktiv mitzugestalten. Es geht dann längst nicht mehr nur um ein Erreichbarkeitsproblem – die Menschen sehen schlicht keinen Sinn mehr darin, über Projekte zu diskutieren.

Eine effiziente Zusammenarbeit, geschweige denn eine Partnerschaft auf Augenhöhe, wird hier unmöglich. Die Rücklaufquoten bei Beteiligungsangeboten sinken drastisch, und die Bürgerinnen und Bürger distanzieren sich zunehmend von der Arbeit und den Ideen der Stadtverwaltung.

Die Entfremdung beschreibt dann die Situation, in der sich Bürgerinnen und Bürger emotional von ihrer Stadt oder Kommune distanziert haben. Es ist ein Ergebnis mehrerer bereits stark ausgeprägter Konfliktfelder der Abwärtsspirale. Bürgerinnen und Bürger haben an dieser Stelle zunehmend das Gefühl, dass ihre Bedürfnisse in der Mitgestaltung des Lebensumfeldes keine Rolle mehr spielen.

„[...] wir arbeiten daran, dass ein Platz im Viertel San Lorenzo als Fußgängerzone umgestaltet werden soll. [...] Also werden wir dort etwas vorschlagen, und es ist nicht die Schwierigkeit das Vorschlagen dieser Sache selbst, aber es geht um die Bürger, die sich über etwas anderes beschweren. [...] So wie ‚Schau, wir können über alles reden, auch das was du möchtest, aber zuerst musst du diese vier, fünf wichtigen Probleme lösen, und dann werden wir darüber reden.' – Fabrizio Benvenuti, Roma Servizi per la Mobilità, 2023 (übersetzt aus dem Italienischen)

Informationsverbreitung und Sichtbarkeit erhöhen	Präsenz auf Social Media ausbauen, um Bürgerinnen und Bürger gezielt und zeitgemäß zu erreichen.
	Verbindung von Beteiligungsformaten mit Stadtfesten oder anderen lokalen Events in entspannter und neutraler At- mosphäre.
	Unterstützung durch Agenturen oder Forschungseinrichtungen einholen, um Expertise und Struktur aufzubauen.
	Emotionale und affektive Beteiligung durch kreative, spielerische (Gamification) oder visuelle Ansätze.
	Direkte Programme zur Einbindung isolierter oder unterrepräsentierter Gruppen entwickeln.
Echtes Mitspracherecht schaffen und Transparente Feedbackkultur etablieren	Beteiligung zu einem möglichst frühen Zeitpunkt, wenn Ziele und Rahmenbedingungen noch mitgestaltet werden können.
	Offene Kommunikation über die Verwertung von Vorschlägen und die Gründe für deren Annahme oder Ablehnung.
	Regelmäßige Berichte in einfacher Sprache auf mehreren Kanälen.
	Moderierte, professionelle Formate für respektvollen Austausch und Konsens- bildung auf Augenhöhe.
Lokale und kleine Projekte zur Wiederannäherung	Schaffung neuer Identifikationspunkte durch bspw. Nachbarschaftsgärten, kulturelle Veranstaltungen, lokale Märkte oder kleine Quartiersprojekte.
	Gestaltung von Grünflächen, Spielplätzen oder anderen öffentlichen Räumen mit Bürgerinnen- und Bürgerbeteiligung.
Echtes Mitspracherecht schaffen und Transparente Feedbackkultur etablieren	Identifikation von Problemen und Erstellung eines Maßnahmenkatalogs mit Priorisierung.
	Kombination kurz-, mittel- und lang- fristiger Maßnahmen, deren Wirksamkeit aufeinander abgestimmt ist.
	Kinder und Jugendliche gezielt ansprechen, um eine neue Generation aktiver Bürgerinnen und Bürger zu fördern.
	Systematisierte Beteiligungsprozesse einführen, die klare und vorhersehbare Abläufe für Beteiligungsprozesse darstellen, die sowohl für Verwaltung und Bürgerinnen und Bürger nachvollziehbar sind.

Lösungsansätze die Konfliktfelder „Scheinpartizipation, Gleichgültigkeit, Entfremdung"

Um eine Wiederannäherung zu ermöglichen muss umfassend gedacht werden. Einzelne technische Anpassungen reichen nicht mehr aus, Lösungsansätze sind deshalb in erster Linie aus den Lösungsansätzen der vorigen sechs unterschiedlichen Konfliktfeldern herauszusuchen.

Insgesamt ist eine Abkehr von rein hierarchischen Strukturen erforderlich, hin zu einer Konsens- und Diskussionskultur, in der alle Beteiligten gleichberechtigt miteinander agieren und eine echte Mitgestaltung

zu ermöglicht. Dafür gilt es, den Bürgerinnen und Bürgern mehr Möglichkeiten der Einbindung an die Hand zu geben, als das gesetzlich vorgeschriebene Minimum. Statt eines reinen Anhörungsrechts braucht es ein echtes Diskussionsrecht, das ihnen die Möglichkeit gibt, aktiv Einfluss zu nehmen.

„Mit diesen ‚Bausteinen-Maßnahmen' in einer neuen Leitlinie geht es ja darum, Sachen in die Routine zu bringen und auch nach einem bestimmten Schema durchlaufen zu lassen, die jetzt quasi immer individuell gelöst werden. Deswegen Systematisierung. Und das reduziert natürlich ganz stark auch Abläufe oder den Aufwand, den man in sie investieren muss" – Jan Lange, Büro für Mitwirkung und Engagement, Stadt Karlsruhe, 2022

5 IMPACT- UND ERFOLGSKRITERIEN

Aus den Experteninterviews wurden nicht nur zentrale Konfliktfelder sichtbar, sondern auch entscheidende Kriterien für eine nachhaltige und wirkungsvolle Öffentlichkeitsbeteiligung herausgearbeitet. Diese Kriterien spiegeln die wesentlichen Faktoren wider, die nach Einschätzung der Expertinnen und Experten maßgeblich zum Erfolg und Impact von Beteiligungsprozessen beitragen (Brow et al 2024).

(1) Aufsuchende Formate
Die zielgruppenorientierte und proaktive Ansprache ist ein elementares Kriterium für erfolgreiche Öffentlichkeitsbeteiligung und wirkt sich positiv auf die Teilnahmebereitschaft aus, während ausschließlich zielgruppenunspezifische oder allgemeine Ansprachen die Öffentlichkeitsbeteiligung hemmen.
(2) Feedback und Kommunikationskultur
Klare Kommunikation über die Möglichkeiten und Grenzen der Beteiligung werden als relevanter Teil erachtet, um Scheinpartizipation zu vermeiden. Mangelhafte Kommunikation über den aktuellen Projektfortschritt stellt ein großes Problem dar. Kontinuierliches Feedback wird als elementares Kriterium angesehen.
(3) Visualisierung
Pläne und technische Informationen sind für Laien häufig unverständlich und zu kompliziert. Gute und verständliche Visualisierungen erhöhen die Bereitschaft und den Grad der Teilnahmemöglichkeit.
(4) Niederschwellige Informations- und Beteiligungsangebote
Niederschwellige Informations- und Beteiligungsangebote sind notwendig um Aufmerksamkeit zu erregen und eine erste Form der Beteiligung zu generieren. Dabei impliziert Niederschwelligkeit, dass ein Angebot unmittelbar bei der Person ankommt und dieses schnell aufgefasst werden kann, wodurch eine sofortige Informationsaufnahme und/oder Beteiligung ermöglicht wird.
(5) Zeitpunkt der Beteiligung
Eine frühzeitige und umfassende Beteiligung aller relevanten Akteure ist essenziell, da eine verspätete Einbindung oft schwerwiegende negative Auswirkungen in verschiedenen Bereichen (z. B. Verzögerungen in Projekten, erhöhte Kosten, mangelnde Akzeptanz von Entscheidungen und ineffiziente Prozesse) nach sich zieht.
(6) Multi-Channel
Gute Öffentlichkeitsbeteiligung ist asynchron und vereint digitale und analoge Beteiligungsformate. Dabei ist eine gut aufgesetzte Plattform ebenso wichtig wie eine enge Social-Media-Begleitung und Vernetzung allgemein.
(7) Digitale Beteiligungslösungen und -plattformen
Digitale Beteiligungsplattformen sind ein elementarer Bestandteil des Multi-Channel-Ansatzes und eignen sich besonders gut dazu, die Kommunikations- und Feedbackkultur im Rahmen von Beteiligungsprozessen zu verbessern. Digitale Beteiligungsplattformen werden analoge Beteiligung nicht verdrängen, sondern ergänzen.
(8) Diskussionskultur
Die vorliegenden Erkenntnisse verdeutlichen, dass Deutschland von einer stark hierarchischen Struktur geprägt ist, die von einer Kultur des Dissenses anstelle des Konsenses geprägt ist. Dies äußert sich insbesondere in Frontalveranstaltungen als Ausdruck dieser Kultur. Als Lösungsansatz wird die Schaffung von Räumen betont, in denen Ideenaustausch auf Augenhöhe und in respektvollem Rahmen ermöglicht wird.
(9) Beteiligung der Jugend
In deutschen Schulen mangelt es an Informations- und Beteiligungsformaten zur demokratisch partizipativen Bildung junger Menschen. Darüber hinaus, haben junge Menschen aufgrund des mangelnden Wahlrechts keine Möglichkeiten, ihre Meinungen über Bürgerbegehren oder Petitionen einzubringen. Dies sind, unter anderem, Gründe dafür, dass sich die Jugend nicht ernst genommen fühlt.
(10) Übergreifende Dialoge
Das Fehlen von Transformationsdialogen führt dazu, dass gesellschaftliche Muster und Entwicklungen nicht erkannt werden. Dies wiederum resultiert darin, dass es keine bis wenige Möglichkeiten gibt, die Zukunft der Gemeinde oder Stadt gemeinsam strategisch weiterzuentwickeln.

Tabelle 1: Die zehn relevanten identifizierten Impact- und Erfolgskriterien gelungener Öffentlichkeitsbeteiligung auf Basis der Interviews ohne Reihenfolge.

5.1 Bürgerinnen- und Bürgerumfrage

5.1.1 Durchführung der Bürgerinnen- und Bürgerumfrage

Bei der Gestaltung der Umfrage wurde das Ziel verfolgt, eine möglichst hohe Teilnahmebereitschaft zu erreichen. Daher wurde die Befragung bewusst kompakt und fokussiert gestaltet. Die soziodemografische Abfrage wurde dafür auf ein Minimum beschränkt und lediglich nach Geschlecht und Altersgruppe gefragt. Auf weitere demografische Fragen, wie etwa zum Haushaltseinkommen, wurde verzichtet, obwohl diese für die Auswertung potenziell relevant gewesen wären. Dieses Befragungsdesignsollte die Teilnahmehürden senken und sicherstellen, dass sich die Befragten auf die inhaltlichen Fragen zur Öffentlichkeitsbeteiligung konzentrieren können.

Allerdings führte diese Herangehensweise dazu, dass nicht alle Kriterien der Öffentlichkeitsbeteiligung gleichermaßen detailliert überprüft werden konnten. Die Umfrage deckt jedoch alle Erfolgskriterien zumindest indirekt ab (siehe Tabelle 2). Zu den Kriterien Aufsuchende Formate, Feedback- und Kommunikationskultur, Niederschwellige Informations- und Beteiligungsangebote, Multi-Channel sowie Digitale Beteiligungslösungen und -plattformen konnten fundierte Aussagen getroffen werden.

Andere Kriterien, wie beispielsweise Visualisierung, erfordern eine tiefere Herangehensweise, die über den Rahmen einer Online-Befragung hinausgeht. Um die Verständlichkeit und Wirksamkeit von Visualisierungen zu bewerten, wären praktische Beispiele und detaillierte Feedbackprozesse notwendig gewesen. Ähnlich verhält es sich mit den Kriterien Beteiligung der Jugend, Diskussionskultur oder Übergreifende Dialoge. Diese Bereiche hängen stark von spezifischen Zielgruppen oder kulturellen Kontexten ab und lassen sich durch allgemeine Umfragen nur schwer erfassen. Für eine umfassendere Analyse dieser Aspekte wären qualitative Methoden wie Fokusgruppen oder vertiefende Interviews besser geeignet. Ein weiteres Beispiel ist der Zeitpunkt der Beteiligung. Dieser wurde zwar teilweise durch Fragen zur Informationsfrequenz und Projektkommunikation adressiert, hätte jedoch eine spezifischere Fragestellung erfordert, um detaillierter untersucht zu werden.

Die für diese Umfrage konzipierten Fragestellungen wurden mit vorgegebenen Antwortmöglichkeiten versehen. Diese basierten auf den Interviews bzw. den definierten Impact- und Erfolgskriterien (Penka et al 2024):

(a) In welcher Altersgruppe bist du?

(b) Welches Geschlecht hast du?

(1) Deine Stadt oder Kommune möchte deine Meinung einholen. Wie möchtest du darauf aufmerksam gemacht werden?

(2) Deine Stadt hat dich erreicht. Welche Möglichkeit würde dich jetzt ansprechen, um deine Meinung zu einem Projekt abzugeben?

(3) Feedback zu meinen Beiträgen oder Meinungsäußerungen im Rahmen einer Beteiligung zu bekommen ist mir wichtig.

(4) Ich wünsche mir eine gemeinsame Reflektionsveranstaltung mit Verwaltung und Projektträgern zum Abschluss eines Projekts.

(5) Das Projekt geht voran. Wie soll dich die Stadt weiter informiert halten?

(6) Und wie oft möchtest du über Projektfortschritte informiert werden?

(7) Öffentlichkeitsbeteiligung stärkt das Demokratieverständnis.

(8) Öffentlichkeitsbeteiligung ermöglicht die Entwicklung gemeinsamer Leitbilder.

(9) Ich habe das Gefühl, dass Öffentlichkeitsbeteiligung zu weniger Konflikten im spätereren Projektverlauf führt.

(10) Ich habe das Gefühl, Öffentlichkeitsbeteiligung bereichert die Qualität der Planung.

(11) Ich fühle mich aktuell durch Formate der Öffentlichkeitsbeteiligung erreicht.

(12) Ich finde, meine Meinung wird momentan durch Öffentlichkeitsbeteiligung vertreten.

(c) Möchtest du uns noch etwas anderes mitteilen?

Der Schwerpunkt lag darauf, die wichtigsten und die am besten messbaren Kriterien innerhalb der gegebenen Rahmenbedingungen zu validieren. Eine tiefergehende Untersuchung anderer Kriterien könnte im Rahmen ergänzender Studien oder spezifischer Erhebungsmethoden erfolgen. Tabelle 2 zeigt auf, welche der Fragestellungen welche Erfolgskriterien direkt (D) oder indirekt (ID) validieren.

Die Zielgruppe wurde nicht eingegrenzt, da grundsätzlich alle Bürgerinnen und Bürger angesprochen waren. Allerdings könnten bestimmte Zielgruppen durch das gewählte Umfragedesign schwerer erreichbar sein. Die Umfrage war online verfügbar und konnte in den Sprachen Deutsch, Deutsch – Leichte Sprache sowie Englisch ausgefüllt werden. Zur Verbreitung wurden verschiedene Online-Kanäle wie LinkedIn, WhatsApp und Instagram genutzt. Zusätzlich wurden 2.500 Flyer mit einem Hinweis auf die Online-Umfrage in Briefkästen unterschiedlicher Stadtteile im Stadtkreis Karlsruhe verteilt.

		Kriterium									
		1	2	3	4	5	6	7	8	9	10
Fragestellung	1	D			D		D				
	2	D			D			D			
	3		D								
	4		D								
	5		D				D	D			
	6		ID			ID					
	7								ID		ID
	8										ID
	9		ID			ID					
	10		ID			ID					
	11	ID			ID						
	12		ID								

Tabelle 2: Validierungsmatrix zwischen Fragestellung und zu validierendem Erfolgskriterium.

5.1.2 Ergebnis der Bürgerinnen- und Bürgerumfrage

Im Befragungszeitraum vom 14.08.2024 bis 26.09.2024 wurden insgesamt 213 vollständig abgeschlossene Fragebögen erfasst. Obwohl diese Zahl im Vergleich zur Gesamtbevölkerung Deutschlands gering erscheint, liefern die Ergebnisse dennoch wertvolle Einblicke. Die errechnete Fehlermarge beträgt etwa ±7,2 %, was auf eine gewisse Unsicherheit hindeutet. Aufgrund der begrenzten Stichprobe können die Resultate möglicherweise nicht vollständig repräsentativ für alle Bevölkerungsgruppen sein, sodass Verzerrungen in Bezug auf Altersstruktur, regionale Verteilung und soziale Schichten auftreten können. Für präzisere und umfassendere Analysen sollten zukünftige Untersuchungen mit größeren Stichproben durchgeführt werden.

5.1.3 Validierung der Kriterien

Das methodische Vorgehen zur Validierung der Impact- und Erfolgskriterien erfolgte durch die Kombination und den Abgleich von Expertinnen- und Expertenmeinungen und den Ergebnissen der Bürgerumfrage. Die Validierung beschränkt sich auf die Kriterien die mit den Ergebnissen der Umfrage fundiert durchgeführt werden können.

Die Ergebnisse der Bürgerinnen- und Bürgerumfrage sowie die Validierung der Expertinnen- und Expertenmeinungen verdeutlichen, dass eine erfolgreiche Öffentlichkeitsbeteiligung auf mehreren zentralen Säulen basiert: zielgerichtete und vielfältige Kommunikationsformate, eine ausgeprägte Feedbackkultur, niedrigschwellige und leicht zugängliche Beteiligungsangebote sowie die Verknüpfung digitaler und analoger Kanäle. Gleichzeitig wird deutlich, dass weitere wichtige Aspekte wie die Visualisierung von Informationen, die Einbindung junger Menschen, übergreifende Dialoge und die Qualität der Diskussionskultur stärker in zukünftige Beteiligungsprozesse integriert werden müssen, um eine umfassende und nachhaltige Öffentlichkeitsbeteiligung zu gewährleisten. Für diese Kriterien steht eine Validierung durch die Bürgerinnen und Bürger noch aus. Die gewonnenen Erkenntnisse sollten in künftige Planungen und Umsetzungen von Beteiligungsprozessen einfließen, um die Akzeptanz und Wirksamkeit von Projekten zu steigern und eine breite sowie engagierte Teilhabe der Bevölkerung zu fördern.

6 FAZIT UND AUSBLICK

Die Analyse der Erfolgsfaktoren und Herausforderungen der Öffentlichkeitsbeteiligung in kommunalen Transformationsprojekten zeigt deutlich, dass eine effektive Bürgerinnen- und Bürgerbeteiligung mehrdimensional zu betrachten ist. Trotz bestehender Defizite, wie etwa mangelnder Repräsentativität, fehlender Transparenz oder unzureichender Kommunikation rückt das Thema in der Praxis immer weiter in den Fokus. Ein zentrales Problem bleibt jedoch die geringe Beteiligung und Rückmeldequote, mit der viele Kommunen konfrontiert sind. Daher ist es entscheidend, neben der Schaffung zielorientierter Beteiligungsformate auch konsequent und strategisch daran zu arbeiten, die Bürgerinnen und Bürger zur Teilnahme zu motivieren. Besonders hervorzuheben ist in diesem Zusammenhang die Bedeutung aufsuchender Formate und die partizipative Bildung der jungen Generation. Eine frühzeitige Verankerung des Themas in der Gesellschaft ist für die Etablierung einer stärkeren Mitgestaltungskultur von entscheidender Bedeutung. Eine gemeinsame und multiperspektivische Erschließung des Themas ist von wesentlicher Bedeutung für dessen Erfolg. In diesem Zusammenhang kann Bildungs- und Forschungseinrichtungen eine Schlüsselrolle zukommen, indem sie zur Sichtbarkeit und Weiterentwicklung von Beteiligungsprozessen beitragen. Die Hochschule Karlsruhe geht diesbezüglich mit gutem Beispiel voran, indem sie das Thema Partizipation und Öffentlichkeitsbeteiligung durch Forschungsprojekte wie

PART-COM, die Entwicklung eines Öffentlichkeitsbeteiligungsscores und gemeinsamer Beteiligungsformate mit Studierenden und der Stadt Karlsruhe sowie Vorlesungsinhalten in den Hochschulalltag integriert.

Insgesamt zeigt sich, dass eine nachhaltige und wirkungsvolle Beteiligung der Öffentlichkeit eine strategische, ressourcengestützte und inklusionsorientierte Herangehensweise erfordert. Die gewonnenen Erkenntnisse liefern wertvolle Impulse für Kommunen und politische Akteure, um partizipative Prozesse langfristig zu verbessern und das demokratische Engagement der Bevölkerung zu fördern.

Erfordernis eines Flächenkompensationsmodells zur Erreichung des Flächensparziels "Netto-Null-Flächenverbrauch"

Christoph Binder

(M. Eng. Christoph Binder, Professur für Raumplanung und Mobilität an der Universität der Bundeswehr München, Werner-Heisenberg-Weg 39, 85579 Neubiberg, christoph.binder@unibw.de)

DOI: 10.48494/REALCORP2025.9053

1 ABSTRACT

Fläche ist eine Ressource, welche aufgrund ihrer Trägerfunktion für Funktionen des Naturhaushalts, der Erholung, der Klimaregulation, etc. schützenswert ist. Aufbauend auf der grundlegenden Bedeutung von Flächenveränderungen und deren Wirkungen auf den Naturhaushalt wird die Fläche als Ressource und Gegenstand vieler Nachhaltigkeitsstrategien beleuchtet. Dabei steht die anhaltend hohe, nicht nachhaltige Flächeninanspruchnahme für Siedlungs- und Verkehrsflächen im Vordergrund, welche mithilfe verschiedener Umweltziele begrenzt, bzw. in der Bilanz gestoppt werden soll. Bis zum Jahr 2030 ist in Deutschland das 30-X-Hektar-Ziel zu nennen und in Österreich wird ein Zielwert von netto 2,5 Hektar pro Tag anvisiert. Auf europäischer Ebene ist bis zum Jahr 2050 ein Netto-Null Flächenverbrauchsziel gesetzt, welches eine Flächenkreislaufwirtschaft bedeutet.

Da bisher einige Unsicherheiten die Umsetzung der Flächensparziele behindern, werden die nicht rechtlich bindenden Umweltziele näher betrachtet, um mögliche Ursachen für die schleppende Umsetzung auszumachen. Desweiteren werden inhaltliche Lücken aufgezeigt und Forderungen formuliert, welche eine bessere Handhabung der Umweltziele bewirken sollen. Es existieren bereits einige vielversprechende Modelle zur Reduzierung der Flächeninanspruchnahme, wovon zwei Beispiele kurz vorgestellt und deren Erfolgsaussichten zur Erreichung der Flächensparziele ausgelotet werden. Dabei wird deutlich, dass die genannten Umweltziele bis 2030 – bei entsprechender Implementierung – durchaus erreicht werden könnten. Das Netto-Null Flächenverbrauchsziel benötigt für seine Zielerreichung bis 2050 jedoch weitergehende Instrumente, um wirksam etabliert werden zu können.

Für eine stabile Flächenkreislaufwirtschaft bedarf es eines Flächenkompensationsmodells, welches Flächen vergleichbar, und dadurch substituierbar macht. Dabei wird Flächen eine individuelle, numerische Wertigkeit (Flächenwertigkeit) zugewiesen, welche sich aus Indikatoren und Parametern berechnet. Zudem wird die Struktur und Funktionsweise des Flächenkompensationsmodells dargestellt, welche an die naturschutzfachliche Eingriffsregelung im deutschen Recht angelehnt sind. Dieser Beitrag zeigt mit der Vorstellung des Flächenkompensationsmodells einen möglichen Weg zu einem Netto-Null-Flächenverbrauch auf, und weist im Fazit auf weitere erforderliche politische, rechtliche und planungspraktische Rahmenbedingungen für eine Flächenkreislaufwirtschaft hin.

Keywords: Flächenkreislaufwirtschaft, Netto-Null-Flächenverbrauch, Flächensparziele, Flächenverbrauch, Flächenkompensationsmodell

2 ÖKOLOGISCH-NACHHALTIGE FLÄCHENNUTZUNGSDYNAMIK

Flächenveränderungen sind grundsätzlich natürliche Vorgänge, denn es bedeutet in erster Linie, dass Flächen neugestaltet werden. Dabei ist ein Eingreifen des Menschen nicht zwingend erfolrderlich. Flüsse ändern bei starken Hochwässern ihren Lauf, Hangrutsche schaffen Ruderalstandorte, Biber (Castor fiber L. 1758) gestalten durch Aufstauen von Gewässern und der Fällung von Gehölzen Auen neu, etc. Diese natürlichen Prozesse gestalten Flächen neu, schaffen ökologische Nischen und bieten Lebensraum für spezialisierte Artengemeinschaften, indem sie die Strukturvielfalt in der Landschaft erhöhen. Auch seitdem der Mensch sesshaft wurde und Flächen gezielter für seine Bedürfnisse umnutzte, schuf er Orte mit verschiedenen Sukzessionsstufen und ökologischen Nischen, welche ohne menschlichen Einfluss gar nicht oder nur selten in Erscheinung treten. Strukturreiche Kulturlandschaften mit Elementen wie Hecken, Feldrainen und Wiesen sind dabei nur eines von vielen Beispielen.

Problematisch ist jedoch die steigende Effizienz und Dominanz der menschengemachten Flächenumnutzungen, welche vom Begriff des Flächenverbrauchs widergespiegelt werden. Flächen werden effizienter genutzt, das bedeutet eine Fläche wird für eine Nutzung optimiert und der Verlust anderer

Funktionen wird dabei in Kauf genommen. Die steigende Monofunktionalität der Flächen ist ökonomisch teilweise sinnvoll, da Flächen maximalen Ertrag bringen. Jedoch ist es die Multifunktionalität, welche Flächen aus ökologischer Sicht wertvoll macht. Als Beispiel können hier intensiv landwirtschaftliche genutzte Flächen wie Äcker angeführt werden. Solche Flächen werden auf die anzubauende Pflanzensorte optimiert und weitere Funktionen wie Lebensraum für wilde Tiere, Pilze und Pflanzen gehen weitgehend verloren. Versiegelte Flächen für Siedlungen und allgemeine Infrastrukturen stellen das Maximum an Monofunktionalität dar. Solche Flächen haben eine dominante Nutzung und weitere Funktionen im Sinne des Naturhaushalts fallen meist so gering aus, dass diese vernachlässigt werden können. Dem Naturhaushalt sind solche versiegelten Flächen faktisch vollständig entzogen worden, da ökologische Funktionen, wenn überhaupt, nur stark begrenzt ihre Wirkung entfalten können.

Insgesamt ist zu sagen, dass aus ökologischer Sichtweise Flächenumnutzungen nicht grundsätzlich einen negativen Einfluss auf unsere Umwelt haben. Die Art und die Intensität der Umnutzungen sind entscheidend. Wenn Flächen so gestaltet werden, dass sie multifunktional und/oder strukturell vielfältig sind, können Umnutzungen von Flächen sogar einen positiven ökologischen Effekt haben. Werden Flächen jedoch zu monofunktional gestaltet, wirkt sich dies negativ auf die Umwelt aus. Diese negativen Effekte auf die Umwelt und den Naturhaushalt gilt es kurzfristig zu minimieren, mittelfristig eine weitere Zunahme zu vermeiden, und langfristig wieder abzubauen. Dafür bedarf es einer Form von Kompensation, welche speziell auf die Fläche ausgerichtet ist. Mit dem Fokus auf der ökologischen Dimension der Nachhaltigkeit wird die Fläche aus der Perspektive ihrer drei Zieldimensionen (Quantität, Qualität und nachhaltige Entwicklung) jeweils separat beleuchtet und zielgerichtet der Handlungsbedarf herausgestellt.

3 SCHUTZ DER RESSOURCE FLÄCHE ALS NACHHALTIGKEITSZIEL

Der Begriff Flächenverbrauch steht für die Inanspruchnahme von Flächen für Siedlungs- und Verkehrszwecke (SuV). Dieser Indikator wird im Rahmen der Deutschen Nachhaltigkeitsstrategie (vgl. u.a. Die Bundesregierung 2021) erhoben und betrachtet dabei den täglichen Anstieg der bebauten Siedlungsfläche (Nutzungsarten: Wohnbaufläche, Industrie- und Gewerbefläche, öffentliche Einrichtungen, sowie Erholungsflächen und Friedhöfe) und die Verkehrsfläche (Nutzungsarten: Straßen- und Wegeverkehr, Bahn-, Flug- und Schiffsverkehr) in Hektar pro Tag [ha/d] (Destatis 2023). Die Flächenerhebung und deren Abgrenzung wird nach ALKIS (Amtliches Liegenschaftskataster) vorgenommen. Flächenumnutzungen, welche als Flächenverbrauch gewertet werden, sind allerdings nicht mit kompletten Versiegelungen von Flächen gleichzusetzen, da diese zwar gänzlich umgenutzt, aber meist nur teilweise versiegelt werden.

Flächenverbrauch als Begriff ist jedoch nicht korrekt, da Flächen nicht verbraucht, sondern nur umgenutzt werden können (vgl. z. B. LfU 2015, S. 84). Flächeninanspruchnahme, bzw. Flächenneuinanspruchnahme sind bessere Alternativen für den Begriff Flächenverbrauch. Da der Begriff Flächeninanspuchnahme besser etabliert ist als “Flächenneuinanspruchnahme” wird folgend dieser Begriff verwendet. Ebenfalls als fachlich eher unpassend wird der Begriff des Flächensparens gewertet. Obwohl damit der sparsame Umgang mit der Ressource Fläche gemeint ist, können Flächen nicht, im Gegensatz zu z.B. Geld, angespart werden. Treffender wäre die Verwendung des Begriffs Flächeninanspruchnahmen-Reduktion, da dieser unmissverständlich den Sachverhalt wiedergibt. Dennoch kann der Begriff des Flächensparens als Synonym weiterhin verwendet werden, da dieser relativ prägnant und bereits etabliert ist.

Fläche fungiert im ökologisch-nachhaltigen Sinn als Träger der Funktionen des Naturhauhalts. Oft erfüllt eine Fläche mehrere Funktionen und wird dadurch zunehmend schützenswerter. Der Schutz der Flächen dient also keinem Selbstzweck, sondern u.a. dem Schutz des Freiraums sowohl im Innen-, als auch im Außenbereich.

Für den Indikator Siedlungs- und Verkehrsfläche (siehe Deutsche Nachhaltigkeitsstrategie) wird eine Begrenzung der Flächeninanspruchnahme für SuV-Flächen bis zum Jahr 2030 auf unter 30 Hektar pro Tag angestrebt. Das deutsche Bundesministerium für Umwelt, Naturschutz, Bau und Reaktorsicherheit (BMUB) präzisiert den Zielwert 20-X Hektar pro Tag auf maximal 20 Hektar pro Tag (BMUB 2016, S. 82). Nach der aktuellen Statistik liegt der Anstieg der Siedlungs- und Verkehrsfläche in Deutschland bei 52 Hektar pro Tag (Stand 2022) und deutet somit auf eine Zielverfehlung hin (vgl. Figure 1). Eine erneute Zielverfehlung ist dringend zu vermeiden, da das vorherige Ziel, bis zum Jahr 2020 weniger als 30 Hektar pro Tag in Anspruch zu nehmen, bereits deutlich verfehlt wurde. Der Bedarf an einer baldigen und wirksamen Umsetzung des Flächensparens ist klar erkennbar.

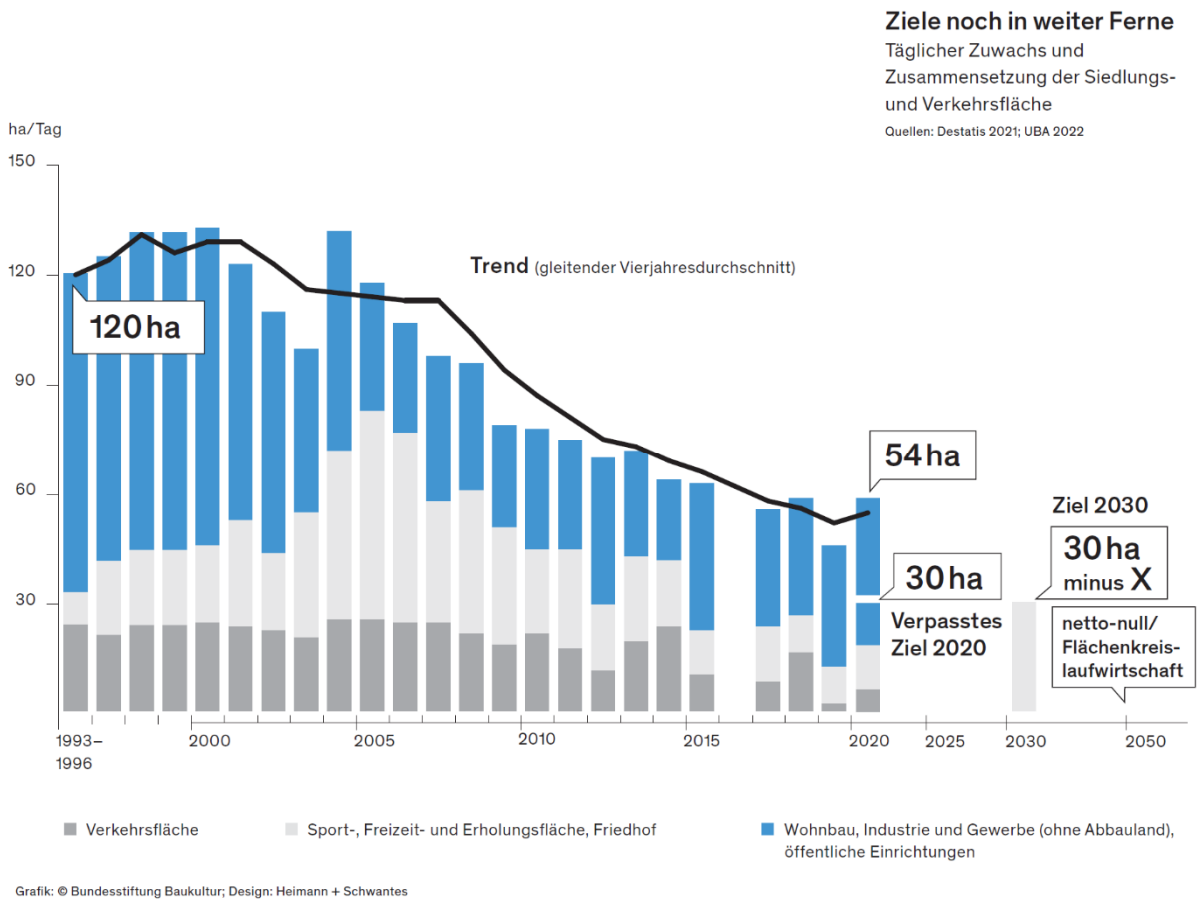

Fig. 1: Entwicklung der Flächeninanspruchnahme in Deutschland der letzten Jahrzehnte mit Abbildung der deutschen Flächensparziele (Bundesstiftung Baukultur, S. 39)

3.1 2,5-Hektar-Ziel in Österreich

In seinem Umweltkontrollbericht des Österreichischen Umweltbundesamtes (2022, S. 117 ff.) wird trotz der leicht sinkenden Flächenneuinanspruchnahme eine Verfehlung des im Regierungsprogramm festgehaltenen Ziels von 2,5 Hektar pro Tag bis 2030 erwartet. So lag der Wert der Flächeninanspruchnahmen im Jahr 2020 bei 11,5 ha/d, wobei im Umweltkontrollbericht vor allem die zuletzt gestiegenen Baulandumwidmungen und der Ausbau erneuerbarer Energien als wichtige Treiber erachtet werden. Obwohl die negativen Auswirkungen der anhaltend hohen Flächeninanspruchnahme, wie zunehmend gefährdete Versorgungssicherheit, der Biodiversität oder dem Klimaschutz, in Österreich bekannt sind, wird voraussichtlich nicht nur das nationale 2,5 Hektar-Ziel, sondern auch übergeordnete Flächensparziele europäischer Programme verfehlt. Zu nennen sind hier vor allem der Green Deal (Europäische Kommission 2019) und die EU-Bodenstrategie (Europäische Kommission 2021).

3.2 30-X-Hektar-Ziel in Deutschland

Die Absicht bis zum Jahr 2030 weniger als 30 Hektar, möglichst maximal 20 Hektar (BMUB 2016, S. 82) pro Tag für SuV-Flächen in Anspruch zu nehmen, stellt ein Umweltziel mit dem Namen 30-X-Hektar-Ziel dar. Dabei wird die Flächeninanspruchnahme für SuV-Flächen im Außenbereich auf rein quantitativer Ebene betrachtet und bewertet und ist in der Nachhaltigkeitsstrategie der deutschen Bundesregierung verankert (vgl. Die Bundesregierung 2021 und 2024). Obwohl dieses Umweltziel keine rechtliche Bindungswirkung hat, wird dem 30-X ha-Ziel eine hohe Bedeutung zugesprochen, da es neben nationalen auch internationale politische Interessen widerspiegelt. Die Nachhaltigkeitsstrategie orientiert sich an der Agenda 2030 der Vereinten Nationen (UN 2015), welche 17 SDGs (Sustainable Development Goals, deutsch: Ziele für nachhaltige Entwicklung) formuliert, und ist im Grundsatzbeschluss der Bundesregierung zur Deutschen Nachhaltigkeitsstrategie festgehalten (vgl. Die Bundesregierung 2022).

Bis zum Jahr 2030 sollen alle 17 Ziele erreicht werden. Dafür erscheint als Monitoring-Maßnahme im zweijährlichen Rhythmus der Indikatorenbericht, um die Fortschritte der einzelnen SDGs zu messen (vgl.

Destatis 2023). Im 11. Ziel „Nachhaltige Städte und Gemeinden“ wird der Bereich Flächeninanspruchnahme anhand der Indikatoren Anstieg der SuV-Fläche, Freiraumverlust und Siedlungsdichte betrachtet.

Das 30-X-Hektar-Ziel thematisiert die Flächeninanspruchnahme dabei rein auf der quantitativen Ebene, da es nur den täglichen Anstieg der Flächen berücksichtigt, welche dem SuV-Bereich zuzuordnen sind und im Außenbereich liegen. Grundlage für die Einschränkung auf SuV-Flächen im Außenbereich ist der Bezug auf den Indikator Anstieg der Siedlungs- und Verkehrsfläche. Im Rahmen dieses Indikators werden SuV-Flächen folgendermaßen definiert: „Siedlungs- und Verkehrsfläche ist nicht gleichzusetzen mit versiegelter Fläche. Zur Siedlungsfläche zählen die Nutzungsarten Wohnbaufläche, Industrie- und Gewerbefläche, öffentliche Einrichtungen sowie Erholungsfläche und Friedhöfe“ (Destatis 2023, S. 90). Dadurch wird der Innenbereich, inklusive noch vorhandener Freiflächen und dem Außenbereich im Innenbereich komplett zu den SuV-Flächen gezählt. Fände eine Nachverdichtung im Innenbereich statt, würde diese nicht als Flächeninanspruchnahme für SuV-Flächen zählen, da bereits vorhandene SuV-Fläche lediglich umgenutzt würde. Deswegen kann der Indikator nur Flächeninanspruchnahmen im Außenbereich betrachten.

Eine weitere Einschränkung bei der Betrachtung von Flächeninanspruchnahmen aus Sicht des 30-X-Hektar-Ziels ist die Ausnahmeregelung für Nutzungen des Rohstoffabbaus und der Energieerzeugung. Diese werden nicht für den Indikator Anstieg der SuV-Fläche gerechnet. Dies wird ebenfalls im Indikatorenbericht deutlich, in welchem es heißt: „Fläche ist eine begrenzte Ressource. Um ihre Nutzung konkurrieren beispielsweise Land- und Forstwirtschaft, Siedlung und Verkehr, Naturschutz, Rohstoffabbau und Energieerzeugung“ (Destatis 2023, S. 90).

Zusammengefasst ist das 30-X-Hektar-Ziel ein Umweltziel, welches nur einen Teil der tatsächlichen Flächeninanspruchnahmen betrachtet und damit kein realitätsgetreues Bild zeichnet. Flächeninanspruchnahmen werden zudem rein quantitativ und ausschließlich im Außenbereich erfasst. Um die tatsächliche Flächeninanspruchnahme besser widerspiegeln zu können, werden hier einige Erfordernisse formuliert, um das 30-X-Hektar-Ziel inhaltlich aufzuwerten:

(1) Der Fokus des Umweltziels sollte nicht ausschließlich auf dem Außenbereich liegen, sondern auch die Flächen des Innenbereichs miteinbeziehen. Die aktuelle Annahme, alle Flächen des Innenbereichs seien bereits durch SuV-Flächen in Anspruch genommen, ist zu grob und lässt wertvolle freie, unbebaute Flächen im Innenbereich außer Acht. Findet eine Nachverdichtung im Innenbereich statt, schont dies zweifelsohne den Außenbereich, nimmt aber trotzdem hochwertige, unbebaute Flächen in Anspruch. Diese Form der Flächeninanspruchnahme sollte mitberücksichtigt werden. Eine Unterscheidung des Innen- und Außenbereichs ist und bleibt sinnvoll und sollte nicht aufgehoben werden. Im Rahmen einer Variantenanalyse kann es in Bezug auf die Ressource Fläche wichtig sein, wo eine Fläche räumlich verortet ist.

(2) Statt Siedlungs- und Verkehrsflächen sollte der Indikator besser Siedlungs- und Infrastruktur-Flächen (SuI) betrachten und entsprechend umbenannt werden. Damit würden alle Flächeninanspruchnahmen, welche vom Menschen verursacht werden, untersucht und angemessen beleuchtet. Aus Sicht des aktuellen Indikators Anstieg der Siedlungs- und Verkehrsfläche würden dann auch die Nutzungen, welche in die Kategorie Rohstoffabbau (vgl. UBA 2024b) und Energieerzeugung fallen, mitdazugerechnet werden. Während Flächen für Energieerzeugung eindeutig zur Infrastruktur gezählt werden, ist das bei Flächen für Rohstoffabbau weniger offensichtlich. Sie gelten dennoch aus Sicht der Raumordnung als eine Freiraumnutzung und nehmen erheblich Flächen in Anspruch (vgl. UBA 2024b). Unbebaute Flächen der Land- und Forstwirtschaft sowie des Naturschutzes sollten weiterhin nicht zur Flächeninanspruchnahme von SuV-, bzw. SuI-Flächen zählen. Zu klären wäre auch der Umgang mit Wasserflächen, da auch solche Flächen erheblich von ihrem natürlichen Zustand und funktionalem Beitrag für den Naturhaushalt durch menschliches Eingreifen abweichen können.

(3) Neben der quantitativen Zieldimension, welche beim Indikator Siedlungs- und Verkehrsfläche ausschließlich betrachtet wird, sollte auch die Qualität der Flächen mitbetrachtet werden. Bei der Flächeninanspruchnahme wird bereits der Indikator Freiraumverlust miteinbezogen, welcher als ein erster Ansatz für die Betrachtung der Flächenqualität betrachtet werden kann. Inhaltlich geht es dabei um das Verhältnis von Freiraumflächen und der Einwohnerzahl. Unter Freiraumflächen werden Vegetationsflächen, Abbauflächen und Wasserflächen bezeichnet (vgl. Destatis 2023, S. 93). Freiflächen im Innenbereich werden trotz ihrer hochwertigen Qualitäten nicht in diesem Indikator betrachtet. Für die Qualität von Flächen sollte

unter anderem die (Multi-)Funktionalität der Flächen für den Naturhaushalt betrachtet und ein Bezug zur räumlichen Verortung hergestellt werden.

(4) Das letzte Erordernis für das 30-X-Hektar-Ziel besteht in dem Bedarf nach einem Flächenkompensationsmodell. Mit fortschreitender Zeit, der Verschärfung des Ziels von weniger als 30 Hektar auf besser maximal 20 Hektar pro Tag und dem ebenfalls zunehmenden Anteil der Siedlungs- und Verkehrsfläche, bzw. der Siedlungs- und Infrastrukturfläche an der Gesamtfläche, wird die Einhaltung der Flächenschutzziele zunehmend dringlicher. Mit der Einführung eines solchen Kompensationsmodells würde jeder Fläche eine substituierbare Wertigkeit zugewiesen, welche planerische Spielräume offenhält und eine Flexibilität bei der Einhaltung der Flächenschutzziele bewirkt.

3.3 Netto-Null Flächenverbrauchs-Ziel

Das Netto-Null-Flächenverbrauchs-Ziel beschreibt, wie der Name bildlich erklärt, eine Netto-Reduzierung des Flächenverbrauchs bis zum Jahr 2050. Dabei ist jedoch kein absoluter Stopp aller Flächeninanspruchnahmen für SuV-Zwecke gemeint, sondern vielmehr eine ausgeglichene Bilanz der Flächeninanspruchnahmen. Bedeutet, wenn eine bisher unbebaute Fläche in eine SuV-Fläche umgenutzt wird, muss eine andere Fläche aufgewertet werden, um den Flächenverbrauch zu kompensieren. Eine konkrete Definition, bzw. ein inhaltlich-scharfes und allgemein akzeptiertes Verständnis, was unter diesem Flächenschutzziel zu verstehen ist, fehlt bisher jedoch. Ebenso wie das 30-X-Hektar-Ziel ist dieses Ziel ein Umweltziel ohne rechtliche Bindung, aber mit Erwähnung in den Nachhaltigkeitsstrategien der deutschen Bundesregierung (vgl. 2021 und 2024), in welchen eine Flächenkreislaufwirtschaft angestrebt wird. Seinen Ursprung hat dieses Ziel auf europäischer Ebene, welches ein Teil einer Strategie ist, die Europäische Union nachhaltiger zu gestalten (vgl. z. B. Europäische Kommission 2011 und EEA 2021).

In ihrem Positionspapier 149 nähert sich die Akademie für Raumentwicklung in der Leibniz-Gemeinschaft (ARL) dem Thema Netto-Null Flächenverbrauch und lotet die Bedeutung einer Flächenkreislaufwirtschaft aus(vgl. ARL 2024). Die eben angesprochene nötige Kompensation wird durch folgendes Zitat gestützt: „Eine Flächenkreislaufwirtschaft mit netto-null Flächenverbrauch ist nur zu erreichen, wenn bei der Neuausweisung von Siedlungs- und Verkehrsflächen an einer Stelle an anderer Stelle im selben Umfang Siedlungs- und Verkehrsflächen an Natur und Landschaft zurückgegeben werden“ (ARL 2024, S. 10). Weiter wird gefordert, dass eine solche Rückgabe von Flächen an Natur und Landschaft mit einer Aufwertung der freiwerdenden Flächen einhergehen muss (ARL 2024, S. 10). Zu dieser Folgerung gelangen auch Eichhorn et al. (2024, S. 90) und weisen darauf hin, dass eine Renaturalisierung (bzw. Flächenaufwertung) ein Novum sowohl im akademischen Diskurs als auch in der planerischen Praxis darstellt.

Auch für das Netto-Null-Flächenverbrauchsziel werden einige Erfordernisse dargestellt, mit der Intention das Umweltziel zu schärfen und praktikabel zu gestalten:

(1) Wie bereits beim 30-X-Hektar-Ziel gefordert, soll bei einer Flächeninanspruchnahme für SuV-, bzw. SuI-Flächen sowohl die Flächen des Außenbereichs als auch die Flächen des Innenbereichs gleichermaßen betrachtet werden. Eine Aufhebung der Unterscheidung der beiden Bereiche allgemein wird auch hier als unnötig erachtet. Der Miteinbezug des Innenbereichs hat neben der realitätsnäheren Betrachtung auch den großen Vorteil, dass viele Flächen mit hohem Aufwertungspotenzial im Innenbereich liegen. Ein Beispiel sind hierfür Industriebrachen oder sonstige stillgelegte und damit untergenutzte Flächen im Innenbereich. Würde weiterhin nur der Außenbereich auch bei Einhaltung des Netto-Null-Ziels betrachtet, erschöpfen die Flächen zur Aufwertung rapide, welche dringend für weitere Flächenumnutzungsdynamiken erforderlich sind. Auch würden Aufwertungen, welche im Innenbereich stattfinden, folglich nicht positiv in der Flächenbilanz erscheinen und die Spielräume bei der Planung einschränken. Die planerische Flexibilität, welche der Miteinbezug des Innenbereichs bietet, wird maßgeblich zur erfolgreichen Implementierung des Umweltziels beitragen.

(2) Obwohl das 30-X-Hektar-Ziel und das Netto-Null-Flächenverbrauchsziel im weiten Sinn denselben Zweck haben, nämlich effektiven Flächenschutz zu gewährleisten, darf das Netto-Null-Ziel nicht als eine bloße Verschärfung des 30-X-Hektar-Ziels betrachtet werden. Während das 30- Hektar-Ziel lediglich einen reduzierten Anstieg der SuV-Flächen fordert, verlangt das Netto-Null-Ziel einen Netto-Stopp der Flächeninanspruchnahmen für SuV, bzw. SuI, welcher in der Flächenbilanz sichtbar werden soll. Zudem betrachtet das 30-X-Hektar-Ziel aktuell nur die quantitative Zieldimension der Flächeninanspruchnahme für

SuV-Flächen. Spätestens bei Etablierung einer Flächenkreislaufwirtschaft wird es zwingend notwendig, auch die Qualitäten der Flächen miteinzubeziehen, da Flächen gleicher Ausdehnung unterschiedliche Qualitäten aufweisen können.

(3) Fläche ist eine Ressource: nicht vermehrbar, in ihrer Ausdehnung begrenzt und steht unter hohem Nutzungsdruck, vor allem in Bezug auf Nutzungsansprüche (vgl. Hüppauf 2023, S. 389). Dieser Ressourcencharakter der Fläche sollte stärker hervorgehoben werden. Die aktuelle Planungspraxis und Rechtslage erweckten den Anschein, dass weiterhin SuV-Flächen unbegrenzt ansteigen könnten. Die negativen Folgen für Natur und Mensch sind zwar bereits bekannt, werden jedoch aktuell nicht relevant in den Entscheidungsprozess miteinbezogen. Ohne den Einbezug der belegten Folgen ist die Einführung einer vollumfänglichen Flächenkreislaufwirtschaft nicht nur schwer umsetzbar, es ist auch schwierig solch einem System Akzeptanz zu verschaffen. Das Netto-Null-Ziel und die damit zusammenhängende Flächenkreislaufwirtschaft sind spätestens zum Jahr 2050 anzustreben, um einen nötigen ökologisch-nachhaltigen Umgang mit der Ressource Fläche zu etablieren. Des Weiteren wäre die Einführung eines Verschlechterungsverbots und eines Verbesserungsgebots anzustreben, welches bereits aus der deutschen Wasserrahmenrichtlinie (WRRL) bekannt ist (vgl. z.B. §27 WHG), da diese Regelungen den Ressourcencharakter der Fläche stärker hervorheben.

4 BISHERIGE MODELLE ZUR REDUZIERUNG DER FLÄCHENINANSPRUCHNAHME

Es gibt bereits einige Ansätze, wie die Flächeninanspruchnahme für SuV-Flächen gesenkt werden können. Vielversprechend sind dabei planerische Ansätze, wie die Regionalplanung, über eine gesteuerte Innenentwicklung und der Abbau von Fehlanreizen. Es existiert bereits eine Vielzahl an vielversprechenden Ansätzen, welche aktuell aber noch keine, bzw. eine unzureichende Anwendung finden und somit auch nicht wirksam sein können (vgl. u.a. Blecken et al. 2024 und Adrian et al. 2018). An dieser Stelle sollen zwei ausgewählte Modelle vorgestellt werden, welche bereits intensiv wissenschaftlich untersucht worden sind: Die Flächenkontingentierung und dem darauf aufbauenden Flächenzertifikatehandel (vgl. Bizer et al. 2021) (Henger et al. 2019).

Bei der Flächenkontingentierung wird einer Planungsebene, bzw. einer Planungseinheit wie beispielsweise eine Kommune, eine fixe Anzahl an Flächenzertifikaten ausgestellt. Die Anzahl der Flächenzertifikate hängt dabei von der Fläche der Kommune und deren Einwohnerzahl ab. Solch ein Zertifikat, meist in der Einheit [m²] wiedergegeben, befähigt die verwaltende Behörde dazu Flächen, welche vorher noch nicht den SuV-Flächen zugerechnet wurden, in eine solche zu überführen. Damit wird die Flächeninanspruchnahme für SuV-Flächen also rein quantitativ gesteuert. Die Qualität der Flächen kann dadurch nicht differenziert werden. Das 30-X-Hektar-Ziel könnte mit diesem Instrument theoretisch einfach erreicht werden, indem von Seiten der Politik jeder Kommune nur eine begrenzte Anzahl von Flächenzertifikaten pro Jahr ausgestellt wird. In Bezug auf das Umweltziel Netto-Null-Flächenverbrauch müsste die Flächenkontingentierung aber ausgebaut und umstrukturiert werden. Würden bis zum Jahr 2050 den Kommunen in Summe keine Flächenkontingente ausgegeben, würde sich dieses Modell selbst abschaffen. Lediglich über die Rückführung von SuV-Flächen in naturnähere Flächennutzungen könnte noch ab 2050 weiter die SuV-Flächen-Struktur ausgebaut werden.

Auf der Flächenkontingentierung aufbauend stellt der Flächenzertifikatehandel ein Handelssystem mit Flächenzertifikaten dar. Dieser umweltökonomische Ansatz, welcher ebenfalls den Flächenschutz als Ziel hat, stellt ein überregionales Handelssystem dar, welches auf eine Kombination aus Mengenbegrenzung und Preisimpuls setzt. Flächenzertifikate können also unter den Kommunen gehandelt werden. Strukturschwache Regionen könnten Zertifikate, welche sie durch ihre Bevölkerungsentwicklung nicht benötigen, an Interessenten verkaufen. Dadurch können dann Kommunen mehr SuV-Flächen schaffen, als ihnen ursprünglich zugesprochen wurden. Strukturschwächere Regionen würden durch diesen Handel finanziell profitieren.

Durch die künstliche (politische) Verknappung der Flächenzertifikate soll eine Verhaltensanpassung der Marktakteure bezüglich des Umgangs mit der Ressource Fläche bewirkt werden. Sowohl mit der Flächenkontingentierung als auch mit dem Flächenzertifikatehandel würde die kommunale Planungshoheit erhalten bleiben, wenngleich auch Einschränkungen einen festen Rahmen vorgeben.

Bezüglich der Flächenschutzziele ließe sich auch mit dem Flächenzertifikatehandel das 30-X-Hektar-Ziel leicht erreichen. Von politischer Seite müssten lediglich die verfügbaren Zertifikate mengenmäßig angepasst werden. Das Netto-Null-Flächenverbrauchsziel wäre jedoch auch nur in Kombination mit einer Form eines Flächenkompensationsmodells nachhaltig zu erreichen. Dabei muss zwingend neben der Quantität der Flächen auch deren Qualität eine wichtige Rolle einnehmen. Das ist wichtig, um dem natürlichen Haushalt nicht weiter unreflektiert wertvolle Flächen zu entziehen. Hochwertige Flächen wiederherzustellen kann sehr lange dauern, je nachdem wie stark diese überprägt wurden. Sobald eine Flächenkreislaufwirtschaft mit in der Bilanz gleichbleibender Flächenwertigkeit etabliert wurde, ist es auch ökonomisch sinnvoller geringerwertige Flächen, welche beispielsweise schon baulich überprägt wurden, für Flächeninanspruchnahmen heranzuziehen. Würden hochwertige Flächen in Anspruch genommen, ist der Kompensationsbedarf erheblich höher und deswegen unattraktiver. Bei der Eingriffsregelung ist es auch gängige Praxis größere Flächen ökologisch aufzuwerten, da diese ihre volle Funktionalität erst in einigen Jahren, meist Jahrzehnten, entwickeln. Der Kompensationsbedarf muss auch hier bereits frühestmöglich gedeckt werden, was zu einem erhöhten Kompensationsaufwand führt.

5 VERGLEICHBARKEIT VON FLÄCHEN

Die Kompensation von Flächen beruht auf der Annahme, dass Flächen eine Wertigkeit besitzen, welche substituierbar ist. Jede Fläche hat demnach eine individuelle Flächenwertigkeit, die in Form eines numerischen Werts wiedergegeben wird und sich aus mehreren Indikatoren berechnet. Die Indikatoren werden dabei in die Zieldimension Quantität und Qualität unterteilt. Aufgrund ihrer Struktur, der Zusammensetzung aus mehreren Indikatoren, welche unterschiedliche Teilbewertungen über eine Fläche abgeben, kann die Flächenwertigkeit verändert werden. Je höher der Wert der Flächenwertigkeit ist, desto höherwertiger ist die Fläche.

Für die Berechnung der Flächenwertigkeit soll ein 5-stufiges Bewertungsmodell herangezogen werden. Die Flächenwertigkeit wird als numerischer Wert wiedergegeben. Je höher die der Wert ist, desto wertvoller ist die Fläche. Die Flächenwertigkeit kann dabei einen Maximalwert erreichen, welcher durch die Ausgestaltung und Gewichtung der Indikatoren definiert ist. Es ist sicherzustellen, dass die Flächenwertigkeit keine negativen Werte annimmt. Das bedeutet, dass eine Fläche im schlechtesten Fall eine Wertigkeit von Null Punkten innehaben kann. Die beiden beschriebenen Extremfälle werden höchst unwahrscheinlich eintreten, vor allem der Null-Fall, dennoch müssen beide beschrieben werden.

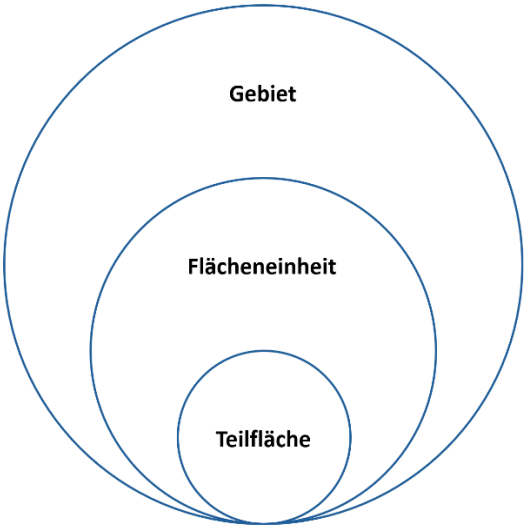

Fig. 2: Schema zur Veranschaulichung der Systematik bei Flächen, eigene Darstellung

Oftmals wird aber nicht nur eine Fläche in SuV-Flächen umgenutzt, sondern gleich mehrere. Sobald mehrere Flächen betroffen sind, bezeichnet man diese Anzahl an Flächen als Gebiet. Ein Gebiet besteht aus mindestens zwei bis beliebig vielen Flächen. Da jede Fläche eine eigene Flächenwertigkeit besitzt, können auch die verschiedenen Flächenwertigkeiten der Flächen eines Gebiets zu einem Wert addiert werden: Das Flächenkapital. Abgegrenzt werden die Flächen dabei nach ALKIS. Es kann jedoch vorkommen, dass eine Fläche sehr heterogen ausgestaltet ist. Dann kann es sinnvoll sein, diese Fläche, bzw. eine Flächeneinheit, in mehrere Teilflächen aufzuspalten. Für jede Teilfläche wird dann die entsprechende Teilflächenwertigkeit

ermittelt und im Anschluss mit den anderen Teilflächenwertigkeiten zur eigentlichen Flächenwertigkeit summiert. In Figure 2 ist das entsprechende Schema vereinfacht dargestellt.

Im Beispiel in Figure 3 ist ein Beispielhaftes Gebiet als Polygon dargestellt, welches aus mehreren Flächen(-einheiten), hier dargestellt als Dreiecke, besteht. Jede Flächeneinheit hat dabei eine individuelle Flächenwertigkeit, welche summiert das Flächenkapital des Gebiets darstellt. Im Fall von Figure 3 beträgt das Flächenkapital 437.

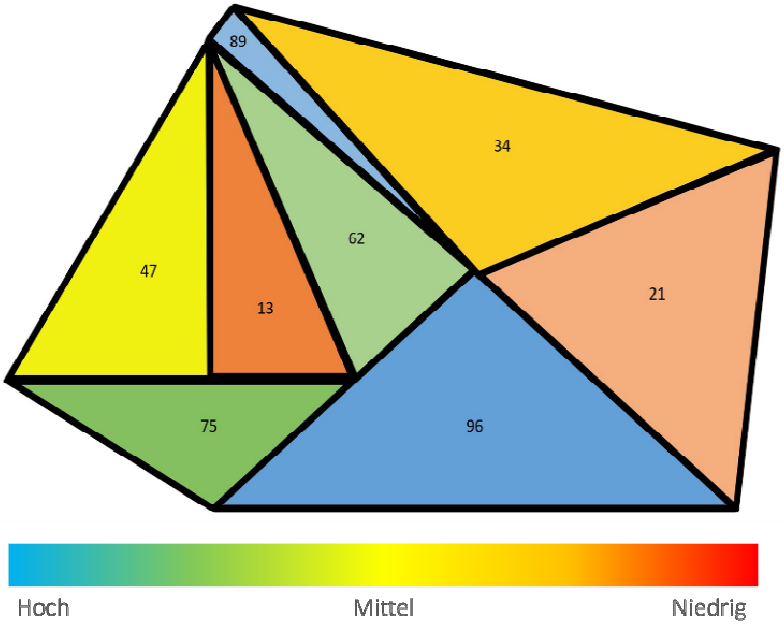

Fig. 3: Beispielhaftes Gebiet mit mehreren Flächeneinheiten, eigene Darstellung

Wenn nun für das in Figure 3 abgebildete Gebiet eine Änderung der Flächennutzung geplant ist, verändern sich die individuellen Flächenwertigkeiten der Flächeneinheiten, und dadurch auch das Flächenkapital des Gebiets. Ergibt sich eine Verringerung der Flächenkapitals, stellt dieser Wert X den Flächenkompensationsbedarf dar, wenn das Netto-Null Flächenverbrauchsziel eingehalten werden soll.

6 FLÄCHENKOMPENSATIONSMODELL ALS LÖSUNGSANSATZ ZUM ERREICHEN DER FLÄCHENSPARZIELE

Ziel des Flächenkompensationsmodells ist eine Flächenkreislaufwirtschaft. Das bedeutet, dass sich das Flächenkapital nicht mehr verringern darf. In Bezug auf Deutschland darf ab dem Jahr 2050 das gesamte Flächenkapital in der Bilanz nicht unter den Wert zum Stichtag 31.12.2049 fallen, bzw. muss eine Flächenkreislaufwirtschaft schon vorher etabliert worden sein. Der genaue Wert des Flächenkapitals am 31.12.2049 kann nur unter unverhältnismäßig hohem Aufwand ermittelt werden. Die Ermittlung des Flächenkapitals ist aber nicht notwendig, da jede Kommune, bzw. sonstige Planungsverwaltung, dazu verpflichtet ist, das eigene Flächenkapital in der Bilanz nicht zu verringern. Dadurch bleibt der voraussichtlich unbekannte Wert des gesamten Flächenkapitals gleich, bzw. verringert sich nicht, und es ist ein vollumfänglich funktionierender Flächenkreislauf gewährleistet.

Wie in den vorherigen Kapiteln angedeutet, gibt es bereits vielversprechende Ansätze, um das 30-X-Hektar-Ziel zu erreichen. Um jedoch eine Flächenkreislaufwirtschaft, das Resultat einer erfolgreichen Umsetzung des Netto-Null-Flächenverbrauch-Ziels, zu erreichen, genügen die bestehenden Ansätze nicht. Ein Flächenkompensationsmodell stellt einen möglichen Weg zur Zielerreichung dar. Folgend werden die wichtigsten Merkmale eines solchen Modells vorgestellt:

6.1 Struktur

Die Struktur des Flächenkompensationsmodells basiert auf dem der deutschen naturschutzrechtlichen Eingriffsregelung und bedarf einer noch final zu definierenden Datengrundlage: dem Flächenkonto. Auch das Flächenkonto lehnt sich in seiner Struktur am Ökokonto an, wobei das Flächenkonto die Flächenwertigkeiten enthält und inhaltlich klar vom Ökokonto abgegrenzt ist. Mit der Übernahme bereits in

der Planung angewandter Strukturen soll eine leichtere und schnellere Etablierung des Flächenkompensationsmodells erreicht werden.

Theoretisch kann ein solches Flächenkompensationsmodell auf allen planerischen Ebenen eingesetzt werden. Da der Fokus und auch die Datenlage aber von Ebene zu Ebene variiert, muss das Kompensationsmodell pro Ebene angepasst werden. Auf hohen Ebenen, wie beispielsweise des Bundesraumordnungsplans, kann mit dem Modell ein grober Flächenkompensationsaufwand ermittelt werden. Dies ist vor allem bei Variantenvergleichen wichtig, um hochwertige Flächen zu schützen. Auf niedrigeren Planungsebenen, wie zum Beispiel der Bauleitplanung, liegen oft detaillierte Daten vor und lassen eine flächenscharfe Ermittlung der Flächenwertigkeiten und des Flächenkapitals des Gebiets zu.

6.2 Funktionsweise

Ähnlich wie die Funktionsweise der naturschutzfachlichen Eingriffsregelung verlangt das Flächenkompensationsmodell die restlose Kompensation von Flächenwertigkeit im Sinne des Netto-Null Flächenverbrauchsziels, welche in den meisten Fällen durch den Ausbau der Siedlungs- und Infrastruktur verursacht wird. Wertet man ein Gebiet, oder auch nur eine Fläche, ab, so muss die Menge an Flächenwertigkeitspunkten möglichst räumlich nah durch Aufwertungen von Flächen komplett kompensiert werden. Dabei ist die räumliche Nähe wichtig, um die Funktionsfähigkeit des lokalen Naturhaushalts bestmöglich zu erhalten.

Außerdem soll die Bündelung von kleineren Kompensationsbedarfen möglich sein, um große Flächen, wie Industriebrachen etc., aufwerten zu können. Eine komplette oder nur teilweise Kompensation durch Ersatzzahlungen, wie sie in der Eingriffsregelung erlaubt sind, entsprechen nicht dem Gedanken der Kreislaufwirtschaft und sind deshalb strikt abzulehnen. Des Weiteren soll ein Mindestaufwertungsmaß bzw. eine Bagatellschwelle eingerichtet werden, welche sich an der gesamten Flächenwertigkeit orientiert und nicht nur an einzelnen Indikatoren. Damit soll der planerische Aufwand verhältnismäßig gestaltet und trotzdem die Einhaltung der Flächenschutzziele garantiert werden.

6.3 Indikatoren

In den vorherigen Kapiteln bereits erwähnt, wird die Wertigkeit einer Fläche aus verschiedenen Indikatoren ermittelt, welche in die Zieldimensionen Quantität und Qualität unterteilt werden. Zur Bewertung ist eine fünfstufige Skala der Flächenwertigkeit vorgesehen. Des Weiteren soll eine gesonderte Prüfung für die dritte Zieldimension der nachhaltigen Entwicklung erstellt werden, welche zwar nicht mit die Flächenwertigkeit beschreibt, aber eine Aussage trifft, wie sehr ein geplantes Vorhaben, Programm, etc. zur ökologisch-nachhaltigen Entwicklung der betroffenen Flächen beiträgt. Statt rechnerisch mit messbaren Indikatoren wird diese Prüfung verbal-argumentativ durchgeführt. Aufgrund der unterschiedlichen Gegebenheiten im Untersuchungsgebiet und der Vielfalt an möglichen Flächeninanspruchnahmen ist eine Bewertung über Indikatoren nur schwer darstellbar.

6.3.1 Quantitative Zieldimension

Im Rahmen der Quantitativen Zieldimension sollen Indikatoren wertgebend sein, welche zum Beispiel die räumliche Ausdehnung, die Beschaffenheit und die Häufigkeit der betroffenen Flächen im Untersuchungsgebiet ermitteln.

Ein möglicher Indikator, welcher anteilig die quantitative Zieldimension in der Flächenwertigkeit angemessen repräsentieren könnte, ist die Freiraumversorgung. Hierbei ist die verfügbare Freifläche pro Einwohner wertgebend. Je mehr Einwohner auf einen Quadratmeter Freiraum angewiesen sind, desto höher wird die Fläche aus Sicht dieses Indikators gewertet. Ebenfalls den Freiraum betreffend ist der Indikator Freiraum-Zerschneidung. Alternativ könnte hierfür auch die Zersiedlung herangezogen werden. Dabei wird die Ausdehnung unzerschnittener Freiräume untersucht. Eine Fläche ist dabei höherwertiger wenn der unzerschnittene Freiraum, in dem sie sich befindet, groß ist. Je größer der Freiraum, desto höherwertiger die Fläche für diesen Indikator.

6.3.2 Qualitative Zieldimension

Im Fall der qualitativen Zieldimension werden die Flächennutzungsfunktionen in Form von Indikatoren wiedergegeben und damit bewertet. Ein möglicher Sammelindikator, welcher viele Aspekte beinhaltet, ist

der Biotopwert nach BKompV (D). Dabei werden hochwertige Lebensräume bewertet, welche hohe Ansprüche an ihren Standort stellen. So sind solche Standorte meist nur wenig mit Schadstoffen belastet, die Bodenerosion ist nur in natürlichem Ausmaß ausgeprägt und der Erhalt der heimischen biologischen Vielfalt ist auch berücksichtigt. Es ist auch anzunehmen, dass solche Standorte aufgrund ihres geringen menschlichen Einflusses auch standorttypische, naturnahe Filter- und Reinigungsfunktionen erhalten haben und ein standortgemäßes Leitungs-/ Puffer-/ Speicher- und Rückhaltemedium sind.

Zudem wird auch die Multifunktionalität der Flächen als wertgebend angesehen, da aufgrund des steigenden Nutzungsdrucks Flächen umso wertvoller werden, je mehr Funktionen diese erfüllen. Mit dem Indikator Klimawirkung der Fläche wird die Aufnahme, Speicherung oder Emission von klimawirksamen Gasen (in CO_2-Äquivalenten gemessen) beleuchtet.

6.3.3 Gesonderte Bewertung der Zieldimension nachhaltige Entwicklung

Nicht wertgebend für die Flächenwertigkeit, aber dennoch wichtig, um den Beitrag zu einer ökologisch-nachhaltigen Entwicklung von Plänen, Programmen, Vorhaben, etc. zu erfassen, werden folgende Aspekte fokussiert: Effizienz, Konsistenz und Suffizienz. Mit diesen drei Schwerpunkten können zum Beispiel festgestellt werden wie sehr eine geplante Nutzung das Potenzial der Fläche ausschöpft und wie sehr die Fläche überprägt wird, was die Regenerationsdauer der Fläche beeinflusst. Die Erfassung des Beitrags einer ökologisch-nachhaltigen Entwicklung ergänzt die Flächenwertigkeit inhaltlich und trägt zu einer vollumfänglichen Flächenkreislaufwirtschaft bei.

7 FAZIT

Der Schutz der Ressource Fläche ist essenziell für einen funktionsfähigen Naturhaushalt und seiner nachhaltigen Nutzung. Dabei wird der Flächenschutz zunehmend dringlich, da die Flächen für SuV, bzw. SuI, stetig zunehmen. Dies liegt an einem mangelnden Bekenntnis zum Flächenschutz sowohl in Gesellschaft, Wirtschaft und damit auch der Politik. In allen drei Bereichen ist ein Umdenken erforderlich, um die Flächenschutzziele wie das 30-X-Hektar-Ziel als auch das Netto-Null-Flächenverbrauchsziel einhalten zu können. Zudem müssen bereits existierende Flächenschutzziele verbindlich im Gesetz verankert werden. Der bisherige Ansatz über die Freiwilligkeit ist fehlgeschlagen und es bedarf nun verbindlicher und stringenter Vorgaben für den Umgang mit der Ressource Fläche.

Das Flächenkompensationsmodell, welches in seinen Grundzügen vorgestellt wurde, ist ein möglicher Weg, um die Flächenschutzziele zu erreichen und trotzdem weiterhin genug planerische Flexibilität für weitere Flächenumnutzungsdynamiken zuzulassen. Ein weiterer Vorteil ist die Kombinationsmöglichkeit mit anderen Instrumenten, wie dem Flächenzertifikatehandel, was weitere Spielräume ermöglicht. Bei flächendeckender Anwendung des Flächenkompensationsmodells ist der Erhalt der Flächenwertigkeit garantiert und damit auch eine Flächenkreislaufwirtschaft etabliert.

1 ABSTRACT

Der weltweite Verlust von natürlichen Böden durch Überbauung zu Siedlungs- und Verkehrszwecken ist nach wie vor hoch. Damit gehen auch immer mehr Flächen für die Landwirtschaft verloren. Derartige Böden werden aufgrund der wachsenden Weltbevölkerung und dem erforderlichen Wandel zu einer ökologischen Landwirtschaft dringend gebraucht. Darauf verweist auch der Wissenschaftliche Beirat der Bundesregierung Globale Umweltveränderungen in seinem Hauptgutachten“ Landwende im Anthropozän“ (WBGU, 2021)

Die Verhinderung eines weiteren Verlustes an Biodiversität, die Gewährleistung der Ernährungssicherheit und die Produktion gesunder Lebensmittel, die Verhinderung weiterer Zersiedelung und Landschaftszerschneidung sowie die Regionalisierung von Kreisläufen, dies alles sind Ziele der ökologischen Transformation. Lösen lässt sich das Problem des Flächenverbrauchs nur durch eine konsequente Kreislaufwirtschaft von Siedlungs- und Verkehrsflächen, d. h. keine neue Inanspruchnahme von Freiraumflächen ohne adäquaten Flächenausgleich. Eine vollständige Kreislaufwirtschaft bis 2050 zu erreichen, hat sich die EU und auch Deutschland zum Ziel gesetzt (Fina et al., 2023; BUMB 2016).

In Indikator der Sustainable Development Goals (SDGs) und in der Deutschen Nachhaltigkeitsstrategie (DNS), erstmals formuliert im Jahre 2002, ist der Flächenindikator „Anstieg der Siedlungs- und Verkehrsfläche“ (11.1.a) kurz auch Flächen(neu)inanspruchnahme oder Flächenverbrauch genannt (Bundesregierung 2002). Dieser Indikator erfordert eine verlässliche, genügend genaue und aktuelle Bestimmung. Nur so können Erfolge und Misserfolge einer Flächensparpolitik raumscharf bewertet werden. Den dahinterliegenden Herausforderungen und Lösungsansätzen widmet sich dieser Beitrag. Er enthält u. a. Ergebnisse eines erst kürzlich abgeschlossenen Forschungsprojekts „Konsistenz und Aussagefähigkeit von Flächendaten – Untersuchungen zur Zeitreihenfähigkeit der amtlichen Flächenstatistik“ des Umweltbundesamtes (UBA, 3719 751020).

Einleitend wird die Methodik der Flächennutzungserhebung in Deutschland beschrieben. Dabei wird auf die Datengrundlagen der Flächenstatistik – das Amtliche Liegenschaftskatasterinformationssystem (ALKIS, AdV 2023) – eingegangen. Dieses hat Schwächen bzgl. der deutschlandweiten Homogenität und Aktualität der Daten. Zudem sind die darauf basierenden Indikatorzeitreihen durch methodische Veränderungen der Erhebung des Attributs „Tatsächlichen Nutzung“ (TN) im Liegenschaftskataster beeinträchtigt. Besonders sensibel darauf reagiert der Flächenverbrauchswert, da er der einzige Differenzindikator der Flächenstatistik ist.

Die Erhebung des Flächenverbrauchs wird darum auch auf geotopographischer Datengrundlage vorgestellt und die Werte verglichen. Denn das Basis Landschaftsmodell des Amtlichen Topographisch-Kartographischen Informationssystem (ATKIS Basis-DLM, AdV 2021) ist deutschlandweit homogener und aktueller und liefert verlässlichere TN-Attribute und Indikatorwerte.

Eine gegenwärtig besondere Herausforderung bei der Erstellung von Flächennutzungsstatistiken sind die Erfassung und Bilanzierung von Flächen für erneuerbare Energiegewinnung (EE-Flächen). Denn Freiflächen-Photovoltaikanlagen (FF-PVA)benötigen riesige Flächen. Da diese derzeit in der TN-Erhebung als Siedlungsflächen bewertet werden, beeinflussen sie den Indikatorwert Flächenverbrauch. Wie sich die Gesamtfläche von FF-PVA in den letzten Jahren entwickelt hat und wie sich die Entwicklung fortsetzen wird, ist Teil dieses Beitrags.

Zudem wird ein Vorschlag unterbreitet, wie die Erhebung des Flächenverbrauchsindikators durch den Rückgriff auf originäre Informationen zur geplanten Überbauung und der Bodenversiegelung aus den Bauerhebungsbögen verbessert werden könnte und die Ergebnisse einer Abschätzung des zukünftigen Flächenverbrauchs durch automatisierte GIS-basierte Auswertung von Bebauungsplänen vorgestellt.

Keywords: Flächennutzungsstatistik, Flächenverbrauch, Erneuerbare-Energie-Flächen, ATKIS, IÖR-Monitor

2 HINTERGRUND

Die Überbauung von natürlichen Böden und die Inanspruchnahme von Freiraum für Siedlungs- und Verkehrszwecke ist weltweit fortschreitend und ein erhebliches Problem einer nachhaltigen Entwicklung. Darum hat die UN in den Sustainable Development Goals (SDGs) u. a. das Ziel formuliert, Städte und Siedlungen nachhaltiger zu entwickeln. Der Flächenverbrauch wird in Europa gemessen auf Grundlage des CORINE Land Cover (CLC).[1] CLC-Daten sind europaweit verfügbar seit 1990. Aller sechs Jahre wird die Landnutzung differenziert nach 44 Landnutzungsklassen im Maßstab 1:100.000 auf Basis von Satellitenbilddaten erhoben. Abb. 1 zeigt den Flächenverbrauch zwischen 2000-2018 für die europäischen Länder in Vergleich. Weitere Analysen findet man hier. Allerdings wird durch die begrenzte Auflösung der CLC-Daten (25 ha Mindestgröße einer Erfassungseinheit), die eine Erfassung kleiner neuer Siedlungsflächen oder Verkehrstrassen unmöglich macht, der Flächenverbrauch stark unterschätzt. Während die fernerkundliche CLC-Erhebung die Flächenbedeckung erhebt, erfassen nationale Systeme wie die deutsche Flächenstatistik die Flächennutzung. Dadurch ist die Zuordnung überbauter Flächen nicht gut vergleichbar. In Deutschland wird der Flächenverbrauch durch die CLC-Daten um fast 80 % unterschätzt.

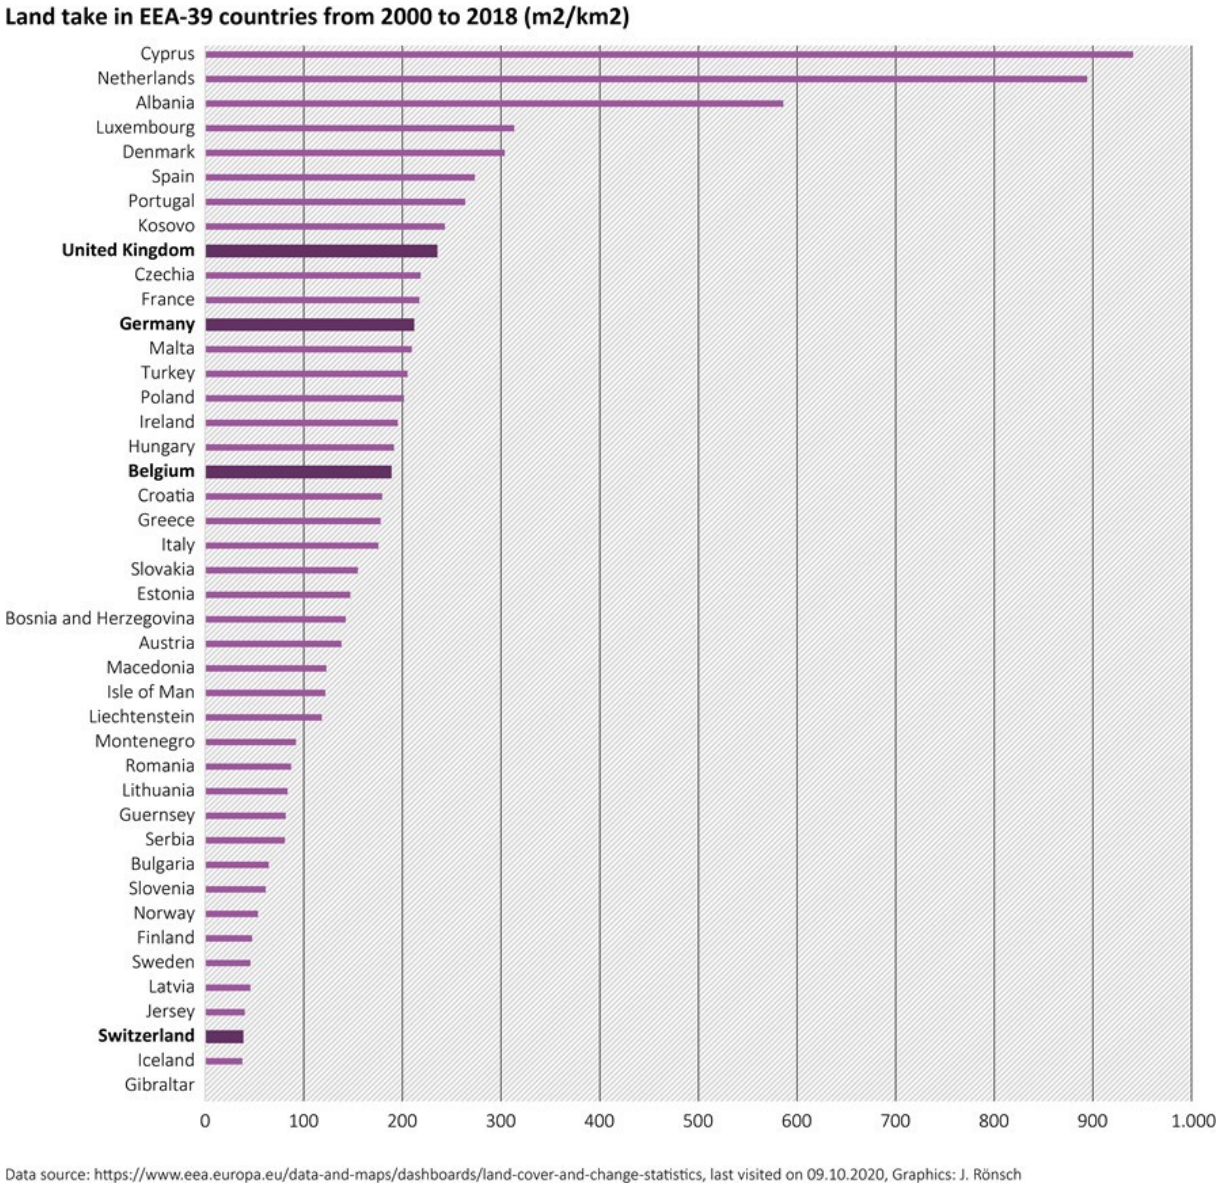

Abb. 1: Flächeninanspruchnahme europäischer Länder zwischen 2000 und 2018, https://www.eea.europa.eu/en/analysis/indicators/net-land-take-in-cities

[1] https://land.copernicus.eu/en/products/corine-land-cover

In Österreich wird die Flächeninanspruchnahme und die Bodenversiegelung landesweit von der Österreichischen Raumordnungskonferenz (ÖROK) publiziert.[2] Das Datenmodell wurde mit dem Bund, den Ländern, Städten und Gemeinden abgestimmt. Als Ergebnisse liegen robuste Daten zur Flächeninanspruchnahme für Siedlungs- und Verkehrszwecke, Freizeit- und Erholungs-, Ver- und Entsorgungszwecke sowie der Versiegelung für das Referenzjahr 2022 („Baseline“) vor. Gesamterhebungen werden in einem dreijährigen Zyklus durchgeführt. Belastbare Zahlen zu Entwicklungstendenzen werden erstmals Ende 2025 vorliegen.

3 FLÄCHENSPARPOLITIK IN DEUTSCHLAND

Die Reduzierung des täglichen Anstiegs der Siedlungs- und Verkehrsfläche kurz Flächenneuinanspruchnahme oder auch Flächenverbrauch auf max. 30 ha pro Tag (30-Hektar-Ziel) bis 2020 fand im Jahr 2002 als Flächenindikator Eingang in die Nationale Nachhaltigkeitsstrategie der Bundesregierung. In der seit 2016 aktualisierten Fassung der Deutschen Nachhaltigkeitsstrategie (DNS) lautet das Ziel nunmehr unter 30 ha pro Tag bis zum Jahr 2030 (Bundesregierung 2017). Bis 2050 soll nach dem Klimaschutzprogramm der Bundesregierung (BUMB 2016) der Übergang zu einer Flächenkreislaufwirtschaft realisiert werden, so dass netto keine neuen Flächen mehr für Siedlungs- und Verkehrszwecke mehr in Anspruch genommen werden müssen (Netto-Null-Ziel).

Auch wenn der Flächenverbrauch in Deutschland sukzessiv in den letzten 20 Jahren abgenommen hat, wird derzeit mit ca. 55 ha/Tag das Ziel weit verfehlt. Das hast viele Gründe. So soll die Baukonjunktur nicht eingeschränkt werden und es besteht eine erhebliche Nachfrage nach mehr Wohnraum und neuen Gewerbeflächen. Bauen im Bestand, Innen- vor Außenentwicklung können diese Nachfrage nur zum Teil decken. Auch wurde das bundesweite Flächensparziel nie regionalisiert, d. h. untersetzt auf Ebene der Bundesländer, Regionen und Kreise. Inzwischen haben sich aber 12 von 16 Bundesländern Flächensparziele gesetzt. Auch ein vom Umweltbundesamt in drei Forschungsprojekten ausgetesteter handelbarer Flächenzertifikatehandel wurde nie installiert. Dieser hätte durch die Festlegung von Kontingenten, die über die Jahre immer weniger werden, die Flächensparziele genau erreicht.

Ambitionierte Flächensparpolitiken findet man in Deutschland auf unterschiedlichen Ebenen: Beispielhaft hingewiesen sei z. B. auf die NRW-Flächenampel (Siedentop et al. 2024),im Landesentwicklung plan von Baden-Württemberg wird eine Flächenkreislaufwirtschaft bis 2035 angestrebt[3] und auf kommunaler Ebene sei das Bodenschutzkonzept Stuttgart (BOKS[4]) hervorgehoben.

4 MESSUNG DES FLÄCHENVERBRAUCHS

4.1 Amtliche Flächenerhebung

Die Landnutzung beschreibt die sozioökonomische Nutzung des Bodens z. B. für Wohn- oder Erholungszwecke oder Land- bzw. Forstwirtschaft, während die Landbedeckung das physische Material an der Erdoberfläche wie Gras, Bäume, Gestein, Wasser oder versiegelte Siedlungs- und Verkehrsflächen beschreibt. Dabei sind die Begriffe Land-, Boden- und Flächennutzung bedeutungsgleich. Das gilt auch für die Begriffe Land-, Boden- und Flächenbedeckung.

Die Flächenstatistik ist Teil der Agrarstatistik. Nur eine kurze Zeit war sie auf Bundesebene Teil der Umweltökonomischen Gesamtrechnungen der Länder (UGRdL). Grundlage der Berechnung des Indikators „Anstieg der Siedlungs- und Verkehrsfläche“ und der Erstellung der entsprechenden Indikatorzeitreihen sind die jährlich erscheinenden statistischen Berichte zur Flächenerhebung nach Art der tatsächlichen Nutzung von Bund und Ländern. Die Fachserie 3 Reihe 5.1[5] mit den Angaben der Bodenfläche nach Art der tatsächlichen Nutzung erschien 2021 zum letzten Mal. Die Angaben werden seitdem nur noch in der Datenbank GENESIS-Online[6] veröffentlicht.

[6] https://www-genesis.destatis.de/genesis/online?sequenz=statistikTabellen&selectionname=33111#abreadcrumb

Die Statistischen Berichte zur Flächenerhebung weisen in den Bundesländern eine unterschiedliche räumliche und sachliche Informationstiefe auf. Mehrheitlich erfolgt eine räumliche Ausweisung der Flächennutzung bis auf Gemeindeebene. In einigen Bundesländern werden die Werte jedoch nur bis auf Kreisebene kostenfrei veröffentlicht.

Die inhaltliche Auswertung variiert zwischen der alleinigen Angabe der SuV-Fläche oder der zusätzlichen Angabe der Veränderung der SuV-Fläche gegenüber Vorjahr. Eine direkte Ausweisung des Anstiegs der Siedlungs- und Verkehrsfläche in Hektar pro Tag erfolgt in der Regel nicht (Ausnahmen Bayern und Hessen). Auch weist das Statistische Bundesamt diesen Indikatorwert in seinen Berichten zur amtlichen Flächenerhebung nicht aus. Dieses erfolgt nach Plausibilisierungen mit halbjähriger Verzögerung im Internet. Auch einige Bundesländer weisen die Flächenneuinanspruchnahme nur separat im Internet aus und nicht in ihren statistischen Berichten.

Die Ausgabe des Indikatorwertes „Anstieg der Siedlungs- und Verkehrsfläche“ auf Ebene der Bundesländer in Hektar pro Tag erfolgt zudem auf dem gemeinsamen Statistikportal der Statistischen Ämter des Bundes und der Länder.[7] Eine weitere Informationsquelle stellt die Regionaldatenbank Deutschland[8] dar, welche die Daten bis zur kommunalen Ebene bereitstellt.

Weiterhin werden vom Statistischen Bundesamt die Jahreswerte[9] sowie der gleitende vierjährige Mittelwert seit 2000 jährlich im Rahmen der Umweltökonomischen Gesamtrechnung veröffentlicht. Durch die Ausweisung des gleitenden Mittelwertes werden die Indikatorvarianzen einzelner Jahre geglättet, was allerdings die Aktualität des Indikatorwertes beeinträchtigt.

4.2 Indikator Flächenneuinanspruchnahme

Dieser sogenannte Flächenindikator der Deutschen Nachhaltigkeitsstrategie beschreibt die Umwandlung von Freiraumfläche (meist Vegetationsfläche) in Siedlungs- und Verkehrsfläche (SuV). Dabei werden Flächennutzungsänderungen aus der Freiraumfläche hin zur SuV-Fläche als Differenz der kumulierten Werte der TN zweier aufeinanderfolgender Jahre ermittelt. Um migrationsbedingte Schwankungen zu minimieren, wird ein gleitender vierjähriger Mittelwert berechnet, der den amtlichen Wert des Flächenindikators (Anstieg der Siedlungs- und Verkehrsfläche (Flächenneuinanspruchnahme bzw. Flächenverbrauch) darstellt. Dieser wird zur Bewertung der Flächenentwicklung im Vergleich mit den Flächensparzielen der Bundesregierung herangezogen. So soll der Anstieg der SuV-Fläche bis 2030 auf unter 30 Hektar pro Tag und bis 2050 durch den Übergang zu einer Flächenkreislaufwirtschaft soweit gesenkt werden, dass netto keine neuen Flächen mehr in Anspruch genommen werden (Netto-Null-Ziel, Die Bundesregierung 2017, BMUB 2016). 2022 beträgt der vierjährige Mittelwert (2019-2022) der Flächenneuinanspruchnahme 52 ha/Tag[10], nachdem er 2021 (2018-2021) noch 55 ha/Tag betrug. Die Entwicklung des Indikators zeigt Abbildung 2. Die migrationsbedingten Einflüsse auf den Indikatorwert werden differenziert für die Bundesländer im Methodenbericht zur Flächenerhebung dargestellt (Statistisches Bundesamt, 2019a). Unter migrationsbedingten Einflüssen sind alle Effekte zu verstehen, die durch geänderte Modellierungsvorschriften der TN-Erhebung im Kataster die Flächenstatistik unabhängig von realen Änderungen der Flächennutzung beeinflussen.

Einige Bundesländer haben eigene Flächensparziele festgelegt.[11] Einen Vorschlag für eine Berechnung legte das UBA 2009 vor und schlägt auch für den maximalen Flächenverbrauch Zwischenziele für 2010 und 2015 vor.[12] Das Ziel und die Zwischenziele wurden jeweils deutlich verfehlt.

[12] https://www.umweltbundesamt.de/daten/flaeche-boden-land-oekosysteme/flaeche/siedlungs-verkehrsflaeche#politische-ziele

Für das Monitoring der Flächenentwicklung und der Flächensparziele ist eine verlässliche Datengrundlage mit kontinuierlich fortgeführten Zeitreihen erforderlich. Die SuV-Fläche als Basisgröße zur Berechnung der Flächenneuinanspruchnahme wird dabei durch das Statistische Bundesamt folgendermaßen definiert:

„Die Siedlungs- und Verkehrsfläche setzt sich zusammen aus den Nutzungsarten Gebäude- und Freifläche, Betriebsfläche (ohne Abbauland), Verkehrsfläche, Erholungsfläche und Friedhof. Diese Zuordnung macht deutlich, dass die SuV-Fläche nicht mit versiegelter Fläche gleichgesetzt werden darf, da die SuV-Fläche auch unbebaute und nicht versiegelte Flächen enthält. Schätzungen ergeben einen Versiegelungsgrad der Siedlungs- und Verkehrsfläche zwischen 43 % und 50 %." (Statistisches Bundesamt ohne Jahreszahl).

Abbauland wird nicht zur Siedlungs- und Verkehrsfläche gezählt, da es sich durch die spätere Rekultivierung um eine temporäre Nutzung handelt. Diese riesigen und sich dynamisch entwickelnden Flächen würden die Zeitreihe des Flächenverbrauchs stark beeinflussen.

Auch Flächen für erneuerbare Energien (Photovoltaik-Freiflächenanlagen) sowie Kranstellflächen und Zuwegungen zu Windkraftanlagen werden der SuV-Fläche zugeordnet.

Das Statistische Bundesamt (StaBA) wurde beauftragt, die Daten für den Indikator zu liefern, um eine nachvollziehbare Erfolgskontrolle dieser politischen Zielsetzungen auf der Zeitachse zu ermöglichen. Dieser – auch als Flächenstatistik bezeichnete Datensatz – ist ein vom StaBA eigens zusammengestellter Datensatzauszug aus der Agrarstatistik, der die „Bodenfläche nach Art der tatsächlichen Nutzung" – auch Statistische Berichte genannt – beschreibt. Die Flächenstatistik ist eine Sekundärstatistik. Das heißt, das StaBA aggregiert die Datenlieferungen der 16 Statistischen Landesbehörden. Diese erhalten ihrerseits die Daten von den Behörden der Landesvermessung (Katasterämter). Statistische „Unplausibilitäten" werden vom StaBA bearbeitet. Etwaige Unplausibilitäten ergeben sich als Folge von Umstellungen im Katasterwesen sowie immer wieder vorgenommenen Umschlüsselungen einzelner Flächennutzungen durch die Länder. Zur Interpretation der Daten – insbesondere im Hinblick auf Vergleiche mit den Daten aus den Vorjahren – musste das Statistische Bundesamt deshalb die Datensätze in den jährlichen Flächenstatistiken zunehmend durch Fußnoten erläutern und erklären.

Die Zeitreihenfähigkeit der Flächenstatistik wurde zum Diskussionsgegenstand. Verstärkt wurde die o. a. Entwicklung durch die sukzessive Einführung des Amtlichen Liegenschaftskataster-Informationssystem ALKIS. Dreh- und Angelpunkt dieser Umstellung ist ein von der Arbeitsgemeinschaft der Vermessungsverwaltungen der Länder der Bundesrepublik Deutschland (AdV) für ALKIS leicht verändertes Nutzungsartenverzeichnis. Daraus ergaben sich weitere „Umschlüsselungserfordernisse", so dass eine konsistente Darstellung der Flächenstatistik auf der Zeitachse kaum noch möglich war.

Zuverlässige, zeitstabile und valide Daten der Flächennutzung sind jedoch nötig, um die Entwicklung der Siedlungs- und Verkehrsflächenzunahme (Flächenverbrauch) auf der Zeitachse zuverlässig abzubilden und eine Erfolgskontrolle des Flächenindikators im Rahmen der Umsetzung der Deutschen Nachhaltigkeitsstrategie zu ermöglichen.

4.3 Messung der Flächenneuinanspruchnahme im IÖR-Monitor

Der IÖR-Monitor stellt Daten und Informationen zur Flächennutzungsstruktur und deren Entwicklung sowie zur Landschaftsqualität für die Bundesrepublik Deutschland zurück bis zum Jahr 2000 bereit. Er ist Teil des IÖR-Forschungsdatenzentrums (IÖR-FDZ) des Leibniz-Instituts für ökologische Raumentwicklung (IÖR).

Der IÖR-Monitor bietet quantitative indikatorbasierte Beschreibungen durch Analyse amtlicher Geobasis- und Geofachdaten (ATKIS, LoD2, GA, Schutzgebiete, Bodenversiegelung) in Kombination mit amtlicher Statistik und Fernerkundung (Copernicus). Jährlich erfolgt eine Auswertung aller TN-Objekte des ATKIS Basis-DLM nach einem Flächenschema. Stand und Veränderung der Flächennutzung wird durch eine GIS-basierte Berechnung von derzeit 90 Indikatorwerten für alle administrativen Gebietseinheiten (Länder, Kreise, Gemeindeverbände, Gemeinden), Raumordnungsregionen, Stadtteile und Rasterzellen bis 100 m Rasterweite für das terrestrische Staatsgebiet der Bundesrepublik bereitgestellt. Darüber hinaus erfolgt eine Berechnung statistischer Merkmale und eine Visualisierung der Indikatoren werte durch Karten, Tabellen, Entwicklungsdiagramme und Statistiken für administrative Gebietseinheiten und als hochaufgelöste Raster. Ein Kartenviewer[13] ermöglicht die interaktive Darstellung von Entwicklungsdiagrammen, den Export von

[13] https://www.ioer-monitor.de/

Karten, Tabellen und Diagrammen sowie die Bereitstellung der Daten in Form von Geodiensten (WMS, WCS, WFS) zur Einbindung in eigene GIS-Umgebungen. Grundlage, Methodik und Anwendungsbeispiele des IÖR-Monitors wurden u.a. hier beschrieben (Meinel et al. 2023). Die Berechnung der Flächenneuinanspruchnahme berücksichtigt auch Verschiebungen von TN-Objekten im Zuge von geometrischen Genauigkeitsverbesserungen sowie thematische Neuzuordnung von TN-Objekten im Zuge von Migrationsprozessen (Schorcht et a. 2016).

Der Flächenverbrauchsindikator wird berechnet in der amtlichen Flächenerhebung, die auf dem Liegenschaftskataster beruht. Eine alternative Berechnung des Indikators erfolgt im IÖR-Monitor auf Grundlage geotopographischer Daten des ATKIS Basis-DLM. Die tägliche Flächenneuinanspruchnahme im Vergleich zeigt Abb. 2. Zur SuV-Fläche zählen dabei Flächen für Wohnbau, Industrie und Gewerbe (ohne Abbauland), Flächen für öffentliche Einrichtungen, für Sport, Freizeit und Erholung (inkl. Friedhofsflächen) sowie Verkehrsflächen.

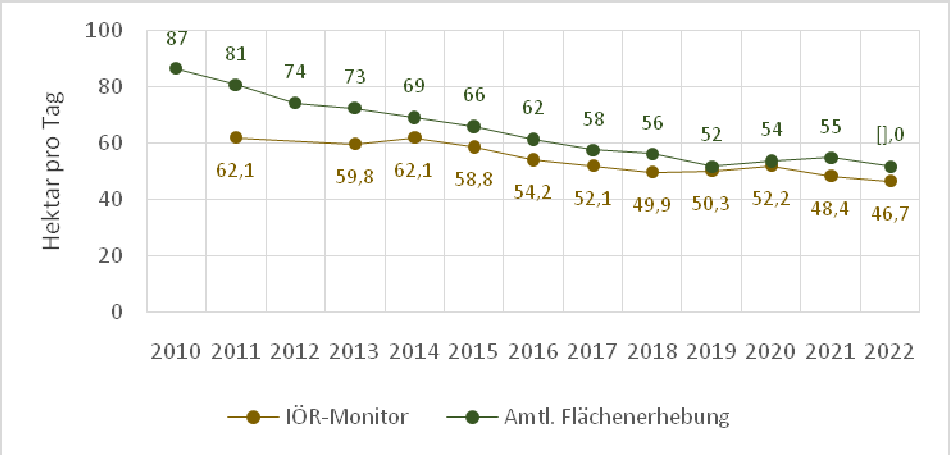

Abb. 2: Flächenneuinanspruchnahme in ha/Tag nach amtlicher Flächenerhebung im Vergleich zum IÖR-Monitor (vierjähriger bzw. fünfjähriger Mittelwert)

4.4 Flächenverbrauchsmessung auf Grundlage der Bauerfassungsbögen

Die amtliche Flächenstatistik gibt die Flächenneuinanspruchnahme nur mit großem Zeitverzug wieder. Das macht eine zeitnahe Nachjustierung der Flächenhaushaltspolitik unmöglich. Grund dafür sind die verzögerte Erfassung einer Flächenneuinanspruchnahme im Liegenschaftskataster nach der Einmessung eines Gebäudeneubaus, einer Gebäudeerweiterung oder eines Gebäudeabrisses.

Andererseits liegen mit den Erhebungsbögen der Bautätigkeitsstatistik[14] hochaktuelle Informationen zum gegenwärtigen Gebäudeneubaugeschehen vor, die wertvolle Aussagen zur aktuellen bzw. geplanten Flächeninanspruchnahme ermöglichen würden.

Die Bautätigkeitsstatistik erfasst die genehmigten, fertiggestellten und abgegangenen Gebäude. Die zugrundeliegenden Erhebungsdaten bieten viele interessante Auswertemöglichkeiten. Die Datenqualität der Bautätigkeitsstatistik ist vergleichsweise hoch durch die Vollerhebung, die gesetzlich geregelte Auskunftspflicht, die tiefe regionale Gliederung, die Verfügbarkeit längerer Zeitreihen und den umfangreichen Merkmalskatalog. Obwohl die Erhebungsdaten der Bautätigkeitsstatistik die aussagekräftigste Primärinformation für die bauliche Entwicklung in Bezug auf die geplante oder neu bebaute Fläche ist, werden diese derzeit nicht für die Bestimmung des Flächenverbrauchs genutzt. Sie dient ausschließlich zur Fortschreibung des Bestandes an Wohngebäuden und Wohnungen und zur Feststellung des Umfangs und der Struktur der Hochbautätigkeit. In den Erhebungsbögen der Bautätigkeitsstatistik sind die Lage, Nutzungsart, der Gebäudeart, der Haustyp, der Rauminhalt, die Geschosszahl, Fläche, Wohnungs- und Raumanzahl erfasst.

Grundlage der Bautätigkeitsstatistik ist das „Gesetz über die Statistik der Bautätigkeit im Hochbau und die Fortschreibung des Wohnungsbestandes (Hochbaustatistikgesetz)“(HBauStatG 1998), Informationsgrundlage der Erhebungsbogen, der vom Träger eines genehmigungs- oder anzeigepflichtigen Bauvorhabens – das sind weitestgehend alle Gebäude – zwingend auszufüllen ist. Die Angaben dieser

[14] https://www.statistik-bw.de/baut/servlet/LaenderServlet

Erhebungsbögen werden in den Statistischen Landesämtern aggregiert und die Baugenehmigungen nach § 5 monatlich, die Baufertigstellungen jährlich veröffentlicht.

Zur Beantragung einer Baugenehmigung muss ein Statistikbogen ausgefüllt werden, sodass alle Baugenehmigungen erfasst werden. Für all diese Baugenehmigungen muss bei Fertigstellung der Baumaßnahme auch eine Meldung zur Statistik der Baufertigstellungen erfolgen. Bei der Statistik der Baufertigstellungen handelt es sich also um eine Totalerhebung und keine Stichprobe. Darum wird die Genauigkeit der Bautätigkeitsstatistik im Qualitätsbericht zur Statistik als hoch eingeschätzt (Destatis 2016a).

Wie könnten nun die Informationen der Erhebungsbögen der Bautätigkeitsstatistik für die Ermittlung der Flächenneuinanspruchnahme einen Beitrag leisten und welche Vorteile hätte dieses Vorgehen? Die Erhebungsbögen beinhalten – bezogen auf die Bestimmung der Flächenneuinanspruchnahme – fast alle wichtigen Informationen zum aktuellen Baugeschehen, sowohl im Neubau als auch Umbau und Gebäudeabriss. Das sind insbesondere die adressgenaue Lage der aktuellen Flächenneuinanspruchnahme, die Nutzungsart (Wohnen oder Gewerbe) und die Nettogrundfläche des Baukörpers. Derzeit ist die Adresse des Baugrundstücks aber leider ein Hilfsmerkmal nach § 4 HBauStatG und darf darum nach § 9 Abs. 2 nur auf Nachfrage der kommunalen Verwaltung an deren abgeschottete Statistikstellen weitergegeben werden. Diese Umstände verhindern derzeit eine Nutzung der Basisinformationen der Bautätigkeitsstatistik für eine deutschlandweite Auswertung der aktuellen Flächenneuinanspruchnahme.

Durch Auswertungen der Lage neuer Baugrundstücke aus den Erhebungsbögen der Bautätigkeitsstatistik könnten aktuelle, lagegenaue, vollständige und verlässliche Angaben zur laufenden Flächeninanspruchnahme in Deutschland gewonnen werden. Der Auswerteaufwand dazu wäre relativ gering und der Nutzen hoch. Die Datennutzung erfordert eine Novelle des Hochbaustatistikgesetzes, die die Auswertung der Lage des Baugrundstücks erlauben würde. Durch Verschneidung der Adresspunkte der neuen Gebäude mit dem Liegenschaftskataster könnte die Grundstücksgröße der Neubebauung erfasst werden. Dann könnten aktuelle und qualitativ hochwertige, flächenbezogene Informationen zur Bautätigkeit in Deutschland gewonnen werden, beispielsweise gemeindescharfe Indikatorwerte zur Flächenneuinanspruchnahme, differenziert nach Nutzungsarten einschließlich des Verhältnisses von Innen- zu Außenentwicklung.

5 FLÄCHENINANSPRUCHNAHME VON FREIFLÄCHEN-PHOTOVOLTAIKANLAGEN

5.1 Derzeitige Erfassung von FF-PVA

Flächen für erneuerbare Energien wie Windkraft- (WKA) und Photovoltaik-Freiflächenanlagen (PV-FFA) prägen zunehmend das Landschaftsbild. Sie haben aufgrund ihrer großen Zahl und ihrem Flächenanspruch einen erheblichen Einfluss auf die Flächennutzung. Dabei werden PV-FFA sowohl in ALKIS als auch in ATKIS als Bauwerk separat von der Tatsächlichen Nutzung mit der Funktion Solarzelle erfasst (Lipfert 2023). Nach einer Statistik von Kurstedt 2023 liegen die 4.713 PV-FFA mit einer Fläche von 18.438 ha (Stand: I/2023, Quelle: ATKIS Basis-DLM) zu über 98 % auf Industrie- und Gewerbeflächen. (Wenige Anlagen liegen auf Unland- oder Verkehrsflächen, Flächen gemischter Nutzung oder Flächen besonderer funktionaler Prägung, Landwirtschafts- oder Wasserflächen oder auf Tagebauflächen). Durch die Kennzeichnung der Tatsächlichen Nutzung unterhalb der Bauwerke als Industrie- und Gewerbeflächen gehören sie zum Nutzungsartenbereich Siedlung und gehen in die Flächenneuinanspruchnahme ein.

Nicht relevant für die Berechnung der Flächenneuinanspruchnahme sind PV-FFA oder WKA, die im bestehenden Siedlungsraum errichtet wurden wie auf Halden, Straßen- oder Flugverkehrsflächen. Auch wenn diese Anlagen keine Freiraumfläche beanspruchen, wäre deren Erfassung für statistische Auswertungen von Bedeutung.

Schon im Jahre 2018 wurde durch PV-Freiflächenanlagen eine Fläche von 25.500 ha eingenommen. Die Flächenentwicklung der Anlagen bis 2022 wird bei Walz. et al. 2022 beschrieben. Die Flächenneuinanspruchnahme durch FF-PVA in den letzten 10 Jahren beträgt rechnerisch ca. 10 ha/Tag (Kurstedt 2023, Walz et al. 2022). Mit den gesetzten Ausbauzielen der Bundesregierung wird bei Böhm 2023 abgeschätzt, dass sich die Gesamtfläche auf 150.000 ha bis 2030 erhöhen wird. Um den landwirtschaftlichen Flächenverlust zu begrenzen, sollte man zunehmend zu einer multifunktionalen Flächennutzung durch aufgeständerte Freiflächen-PV-Anlagen (Agri-PV) oder schwimmender Photovoltaik

(FPV) auf Wasserflächen übergehen. Auch darum sollte eine Erfassung derartiger multifunktionaler Flächennutzung im Flächenmonitoring zum Standard werden.

5.2 Berücksichtigung von FF-PVA-Flächen in der Flächenstatistik

Genau genommen stellen diese Anlagen nur eine temporäre Nutzung dar, denn deren Betriebszeit beträgt ca. 20 Jahre. Zudem handelt es sich oft um eine multifunktionale Flächennutzung, denn unter diesen Anlagen erfolgt häufig z. B. eine Beweidung, also eine landwirtschaftliche Nutzung. Der Verlust an Landwirtschaftsfläche kann in Zukunft durch aufgeständerte Anlagen (Agri-PV) gemindert werden. In Umsetzung der Ausbauziele für Solarenergie rechnet Böhm 2023 mit ca. 150.000 ha neuer PV-FFA allein auf Agrarflächen. Das zeigt, wie wichtig eine separate Erfassung dieser überlagerten Nutzung wäre. Darum sollten diese Anlagen auch nicht wie derzeit in die Berechnung des SuV-Anstiegs einfließen. Es empfiehlt sich eine separate Ausweisung der Flächenneuinanspruchnahme durch erneuerbare Energien in einem eigenen Indikator. Denn die Vermischung von erwünschten Entwicklungen (Ausbau Freiflächen-Photovoltaik) und unerwünschten (Flächenverbrauch) im Indikator Flächenneuinanspruchnahme wird als problematisch angesehen und konterkariert das Netto-Null-Ziel des Flächenverbrauchs.

6 ABSCHÄTZUNG DES ZU ERWARTENDEN FLÄCHENVERBRAUCHS

Will man vorausschauender in der Flächensparpolitik agieren und wirkliche Steuerungsoptionen gewinnen, sollte man die geplanten Flächenneuinanspruchnahmen in den Blick nehmen. Das erfolgte früher schon einmal durch die „Statistik der Bodenfläche nach Art der geplanten Nutzung“ zwischen 1996 und 2004. Diese Statistik basierte auf der Auswertung der Flächennutzungspläne der Kommunen durch Summierung der geplanten Nutzungen der Kommunen. Für den Vergleich der Planungen mit dem aktuellen Stand der Bodennutzung musste die Planzeichenverordnung mit dem AdV-Nutzungsartenverzeichnis in Einklang gebracht werden. Zudem war die Erhebung hochaufwendig und wurde im Zuge der Verwaltungsliberalisierung ab 2004 eingestellt.

Eine Erhebung der geplanten Flächenneuinanspruchnahme wäre heute sehr viel einfacher und genauer zu realisieren als vor 20 Jahren. Denn der Zugriff auf Bebauungspläne (B-Plan) ist heute in der Regel digital möglich geworden. B-Pläne werden bereits in 11 Bundesländern (Stand 2024) in Form von landesweiten Datenpaketen der rechtskräftigen B-Pläne digital und Open Data angeboten. Durch Verschneidung der geplanten Siedlungs- und Verkehrsflächen mit den Freiraumflächen einer aktuellen Flächennutzungskarte könnte die geplante Flächenneuinanspruchnahme berechnet werden, um die tägliche Flächenneuinanspruchnahme abzuschätzen. Für die Umsetzung der Pläne würde man nach Expertenmeinung einen Zeitraum von 8-10 Jahren ansetzen. Damit kann man den zukünftigen Flächenverbrauch abschätzen und kommt auf eine tägliche Flächenneuinanspruchnahme von 80 ha/Tag (Bronold 2024), was das Ziel von unter 30 ha/Tag weit überschreitet.

Die Ergänzung bisher noch fehlender digital und frei verfügbarer B-Pläne wird durch INSPIRE[15] befördert. Dort wird die Bereitstellung von Daten zur geplanten Flächennutzung zwingend vorgeschrieben. Zudem würde die Bereitstellung aller neuen Pläne im XPlan-Datenaustauschformat, wie diese in Deutschland seit 2023 vorgeschrieben ist, die GIS-technische Auswertung noch wesentlich erleichtern. Auch die mit der geplanten Flächenneuinanspruchnahme einhergehende Bodenversiegelung wäre analysierbar, denn diese ist Bestandteil in XPlan.

Die Ergebnisse, sind diese anfänglich auch noch nicht flächendeckend für Deutschland verfügbar, würden über den Stand neuer geplanter Siedlungs- und Verkehrsflächen und damit die zu erwartende Flächenneuinanspruchnahme informieren. Es liegt in der Natur der Sache, dass die Ergebnisse unsicher bleiben, denn nicht jeder Plan wird auch umgesetzt. Durch eine jährliche Wiederholung könnte ein Monitoring der geplanten Nutzung aufgebaut und eine entsprechende Statistik abgeleitet werden. Auch wenn es nach Expertenmeinung noch ca. drei Jahre dauern wird, bis alle Bundesländer die Pläne downloadbar und GIS-analytisch bereitstellen, könnten die Vorbereitungsarbeiten dazu schon beginnen. Damit würden erstmals empirische Datengrundlagen für Entscheidungs- und Genehmigungsprozesse bereitstehen, die eine evidenzbasierte Steuerung der Flächenneuinanspruchnahme ermöglichen.

[15] https://www.geoportal.de/INSPIRE/3

7 EMPFEHLUNGEN UND AUSBLICK

Zusammenfassend werden an die Akteure der Erhebung der Flächennutzung folgende Empfehlungen ausgesprochen.

Empfehlungen an die AdV, Vermessungsverwaltungen und Katasterbehörden:

- Einheitlichere Erfassung der Tatsächlichen Nutzung in allen Katasterämtern Deutschlands. Dafür müssen diese unmissverständlicher beschrieben werden durch Sammlungen mit TN-Erfassungsbeispielen mit unterlegtem Luftbild, erläuternden Handbüchern und Schulungen der TN-Erfasser.
- Schnellere Aktualisierung der Tatsächlichen Nutzung in ALKIS auf Grundlage potenzieller Änderungsflächen abgeleitet aus dem neuen Produkt Landbedeckung (LB).
- Bundesländer mit derzeit noch anlassbezogener Aktualisierung sollten so bald wie möglich eine zyklische Aktualisierung einführen.
- Photovoltaik-Freiflächenanlagen (in ALKIS und ATKIS als Solaranlagen bezeichnet) sollten im Kataster vollständig und einheitlich erfasst werden.
- Erstellung und jährliche Aktualisierung eines ALKIS-Produktblattes mit Informationen zur Datenaktualität. Diese fehlt derzeit noch im Kataster, ist aber zur Bewertung der Zeitreihen der Flächenstatistik erforderlich.
- Die Kennzeichnung der Ursache für jedes geänderte TN-Objekt, ob technisch bedingt oder real im Attribut „ErgebnisDerUeberpruefung“ (EDU) ist im Referenzmodell GeoInfoDok 7.1 angelegt. Nur wenn man diese auch konsequent ausfüllt, kann man perspektivisch zu genaueren Indikatorwerten für den Anstieg der Siedlungs- und Verkehrsfläche kommen.
- Einheitlichere und schnellere Umsetzung der AdV-Beschlüsse durch die Vermessungsverwaltungen und Katasterämter der Länder.
- Leichtere Auffindbarkeit von Dokumenten im AdV-Online-Auftritt (Übersichtlichkeit, Struktur, Vermeidung kryptischer Links).
- Katasterdaten sollten generell archiviert werden. Nur so sind spätere Rekonstruktionen und Behebungen von Unstimmigkeiten in den Zeitreihen von Bund und Ländern möglich.

Empfehlungen an die Statistischen Ämter des Bundes und der Länder:

- Systematische Auswertung des Attributs EDU, um unreale TN-Änderungen aus dem Flächenverbrauchsindikator zu eliminieren.
- Schnellere und nutzerfreundlichere Ergebnisveröffentlichungen z. B. in einem Dashboard vergleichbar mit dem „Kommunalen Flächenrechner“ des UBA[16] (Gutsche und Grimski 2021).
- Ergänzende statistische Auswertungen u. a. zur Flächeninanspruchnahme durch Freiflächen-Photovoltaikanlagen, neue Abbau- und Tagebauflächen und deren Nachnutzung, Flurneuordnungen usw.
- Auswertungen der primären Erhebungsbögen der Baugenehmigungen, welche Grundlage für die Erstellung der Bautätigkeitsstatistik sind. Diese enthalten die verorteten und fachlich präzisen aber bisher fehlenden Primärinformation des Flächenverbrauchs.
- Nutzung der geotopographischen ATKIS-Daten statt des Katasters für die Erstellung der Flächenstatistik.
- Wiedereinführung einer Statistik zur geplanten Flächennutzung.

Bezüglich der Homogenität gibt es in ALKIS noch zahlreiche Länderspezifika, welche die Vergleichbarkeit zwischen den Bundesländern einschränken. Einen besonders starken Einfluss auf die Flächenneuinanspruchnahme haben schon heute die Flächen für erneuerbare Energien (PV-FFA und WKA). Diese Anlagen, in der Regel im Freiraum errichtet, bewirken schon jetzt einen SuV-Zuwachs von ca. 10 ha/Tag (Walz et al. 2022). Deshalb ist eine einheitliche, flächendeckende und aktuelle Erfassung dieser

[16] https://gis.uba.de/maps/resources/apps/flaechenrechner/index.html?lang=de

Anlagen sicherzustellen und die derzeit bestehenden bundeslandspezifischen Erfassungsunterschiede zu beseitigen.

Die Einbeziehung der Primärdaten der Erhebungsbögen der Bautätigkeitsstatistik als Referenzdaten neuer Gebäude würde die Qualität der Flächenerhebung und deren Zeitreihen wesentlich verbessern (Meinel, 2017). Sie würde eine direkte objektscharfe Auswertung aller Flächenneuinanspruchnahmen ermöglichen. Leider aber wird dieses derzeit noch durch das Hochbaustatistikgesetz (HBauStatG) verhindert. Eine Einzelauswertung der primären Bauerfassungsbögen könnte neben einer verlässlicheren Bestimmung des Flächenverbrauchs auch ein wichtiger Baustein eines Gebäudemonitorings werden, das dringend gebraucht wird.

Anzustreben wäre zudem die Erstellung eines Referenzdatensatzes der Flächennutzung einschließlich dessen zyklischer Aktualisierung für eine kleine Teilfläche in Deutschland. So könnte die Güte von Flächennutzungserhebungsverfahren bestimmt werden. Mit Hilfe derartiger Referenzflächen könnte zudem ein Training neuer KI-basierter Bildklassifikatoren erfolgen.

Ein genügend genaues und belastbares Flächennutzungsmonitoring ist und bleibt eine große Herausforderung (Meinel 2023). Aber eine sichere Bewertung der Entwicklung der Flächenneuinanspruchnahme ist erst auf Grundlage langer robuster Zeitreihen möglich. Sowohl das Liegenschaftskataster ALKIS als auch das geotopographische Landschaftsmodell ATKIS sind nicht ursächlich für ein Flächennutzungsmonitoring und daraus abgeleitete Flächenstatistik konzipiert. So zeigen beide Datenmodelle Schwächen, wenn auch einige Gründe für die Nutzung geotopographischer Daten im Flächenmonitoring sprechen.

Sowohl ALKIS auch als ATKIS werden sich mit der Umsetzung der GeoInfoDok 7.1 (AdV 2023) verändern. Auch in Zukunft sind immer wieder Modelländerungen zu erwarten, da beide Modelle auch andere Aufgaben haben als die Flächenerhebung. Bei zukünftigen Modelländerungen ist stärker als bisher darauf zu achten, welche Auswirkungen diese auf die Zeitreihen des Anstiegs der SuV-Fläche haben. Denn die schleichende und vergleichsweise geringe Dynamik der Flächennutzungsänderungen erfordert ein sehr behutsames Vorgehen bei jeglichen Erhebungsveränderungen.

Die Hinzunahme der geotopographischen ATKIS-Daten für die amtliche Flächenerhebung hat im Jahr 2024 mit der Erstellung des Produkts Landnutzung begonnen. Nach der Zusammenführung der Nutzungsartenkataloge sollte darüber nachgedacht werden, ATKIS-Daten noch stärker als Grundlage der Flächenstatistik zu nutzen, denn diese sind homogener (nur 14 ATKIS im Vergleich zu 300 ALKIS-Erfassungsstellen mit bestehenden Erfassungsunterschieden), in dynamischen Veränderungsgebieten aktueller (keine verzögerte Erfassung von großflächigen Flächenveränderungen bedingt durch die Vermessung, die erst nach Abschluss der Baumaßnahme oder der Renaturierung von Bergbaugebieten erfolgt), differenzieren die Landnutzung stärker und ermöglichen die Erfassung multifunktionaler Flächennutzungen (z. B. Freiflächen-Photovoltaik), die immer mehr an Bedeutung gewinnen. Das Problem der nur linienhaften Erfassung von Straßen in ATKIS könnte durch Pufferung mit dem Attribut Straßenbreite zu Flächen behoben werden bzw. die bestehenden Straßenflächen aus ALKIS entnommen und verschnitten werden.

1 ABSTRACT

aspern Die Seestadt Wiens ist eines der größten Stadtentwicklungsprojekte Europas. Die Überlegungen zur Entwicklung des multifunktionalen Stadtteils auf dem Rollfeld des ehemaligen Flughafens Aspern im 22. Wiener Gemeindebezirk starteten bereits vor Jahrzehnten. Heute ist mehr als ein Drittel der rund 240 Hektar großen Seestadt realisiert, in den 2030er-Jahren soll sie komplett fertig gebaut werden. Am Ende werden über 11.500 Wohneinheiten und mehr als 20.000 Arbeits- und Ausbildungsplätze geschaffen sein. Für die nächsten Etappen stellt sich aspern Seestadt selbst auf den Prüfstand: die Entwicklung eines umfassenden Zielsystems ermöglicht, das bis dato Erreichte einer Zwischenbilanz zu unterziehen und die Performance der Seestadt von nun an laufend zu monitoren.

Die Evaluierung wurde entlang von zwei Säulen – Empirie und Benchmarking – durchgeführt. Der empirische Teil umfasst den Blick auf die Seestadt von außen, also wie sie wahrgenommen wird. Das Benchmarking zeigt auf, wo die Seestadt gemessen an ihren Ansprüchen und Zielen steht. Kern der Empirie war ein „Deep Dive“, bei dem über 100 Expertinnen und Experten zu ihren Einschätzungen sowie zu den Herausforderungen und Potentialen der Seestadt befragt wurden. Ergänzt wurde dies durch eine Fortführung des in den 2000er Jahren gestarteten „Markencontrollings“, einer standardisierten Befragung zum Image der Seestadt. Das Benchmarking ermöglichte eine Objektivierbarkeit der Qualitäten der Seestadt. Das zu diesem Zweck entwickelte Zielsystem umfasst neun strategische Leitziele, die über eine Reihe an Subzielen konkretisiert werden. Diesen werden Key Performance Indikatoren (KPIs) zugeordnet, welche den Stand der Zielerreichung messbar machen.

Mit EVA wurde eine fundierte Basis geschaffen, um die Performance der Seestadt im Hinblick auf eigene Projektziele wie auch übergeordnete Ziele der Stadt Wien objektiv messbar zu machen. Das Reporting soll den Fachdiskurs bezüglich nachhaltiger und zukunftsorientierter Stadtentwicklung mit einer breiten Zielgruppe, wie Developern, Investorinnen, Investoren, der Wirtschaftswelt, der österreichische und internationale Fachcommunity und nicht zuletzt auch interessierten Laien, unterstützen.

Keywords: Stadtentwicklung, Zielekatalog, Evaluierung, aspern Seestadt, Key-Performance-Indikatoren KPI

2 EIN BLICK ZURÜCK – STRATEGIE UND PLANUNGSPRINZIPIEN VON ASPERN SEESTADT

In den 1920er-Jahren war das Flugfeld Aspern einer der modernsten Flughäfen Europas. Heute, rund 100 Jahre später, ist an derselben Stelle aspern Seestadt entstanden, eines der modernsten Stadtentwicklungsprojekte Europas. Der Baustart erfolgte 2010, doch die Planungen begannen bereits in den 1990er-Jahren. Nach dem Fall des Eisernen Vorhangs wuchs der Bedarf an Wohnraum und wirtschaftlicher Infrastruktur in Wien. Zunächst scheiterte die Entwicklung jedoch an der fehlenden Verkehrsanbindung. Erst durch den „Masterplan Verkehr 2003“, der den Ausbau von U-Bahn, Bahn und Straßeninfrastruktur vorsah, wurden die Voraussetzungen für die heutige Seestadt geschaffen. 2007 wurde der Masterplan für die Entwicklung des neuen Stadtteils vom Wiener Gemeinderat einstimmig beschlossen.

Die Seestadt liegt strategisch günstig im Nordosten Wiens zwischen den „Twin Cities“ Wien und Bratislava, mitten in der wirtschaftlich und demografisch dynamischen Region Centrope. Dank der Nähe zu Bahnhöfen, Flughäfen und Stadtzentren beider Hauptstädte bietet die Seestadt enormes Potenzial. Konzipiert wurde sie als multifunktionaler Stadtteil vom schwedischen Architekturbüro Tovatt Architects & Planners. Die Kernidee: ein Mix aus Wohnbau, Gewerbe, sozialen Einrichtungen, Arbeitsstätten, Industrie und Forschungseinrichtungen. Im Zentrum des Stadtteils liegt mit dem asperner See ein künstlicher

Grundwassersee, der als Herzstück und Namensgeber dient. Dieser Erholungsraum symbolisiert ein neues Planungsprinzip: öffentlicher Raum zuerst, Gebäude danach. Rund die Hälfte der Fläche sollen später als öffentlicher Raum zugänglich sein. Die Leitlinien für sämtliche Freiraumplanungen basieren auf der „Partitur des öffentlichen Raums“ des dänischen Büros Gehl Architects.

Der Masterplan der Seestadt wurde mehrfach überarbeitet und setzt klare Leitlinien: Der öffentliche Raum soll eine hohe Aufenthaltsqualität bieten, flexibel nutzbar und ansprechend gestaltet sein. Ein vielfältiges Angebot soll unterschiedliche Lebens- und Arbeitsformen ermöglichen, während lebendige Erdgeschoßzonen und nutzungsoffene Gebäude für nachhaltige Quartiere sorgen. Zudem wird auf Klimaschutz, Ressourcenschonung und energieeffizientes Bauen Wert gelegt. Ziel ist es, mehr Energie vor Ort zu produzieren, als verbraucht wird. Auch die Mobilität ist ausbalanciert: umweltfreundliche Verkehrsmittel werden gefördert, während der Autoverkehr reduziert wird.

Die Seestadt sollte seit jeher als regionales Zentrum der Donaustadt fungieren. Heute liegt sie als Zentrum an der Entwicklungsachse U2. Diese befindet sich in stetem Wachstum, nicht nur was die Bevölkerung betrifft. Auch die Wirtschaft hat den Standort entdeckt und schafft laufend neue Arbeits- und Ausbildungsplätze, die nördlich der Donau dringend gebraucht werden. Federführend bei der Entwicklung der Seestadt ist die eigens zu diesem Zweck gegründete Entwicklungsgesellschaft Wien 3420 aspern Development AG, ein Public-Private Partnership, das Städtebau, Infrastruktur, Investorinnen und Investoren koordiniert.

3 STADTENTWICKLUNG MESSBAR MACHEN

Für die Entwicklung von aspern Seestadt wurde von Beginn an ein umfangreiches Zielsystem mit begleitenden Instrumenten für das Qualitätsmanagement entwickelt. Dazu gehören unter anderem der Masterplan, die Ziele und Prinzipien einer qualitätsvollen Stadtteilentwicklung, die Smart City Leitlinien für die Seestadt sowie baufeldbezogene Qualitätsvorgaben. Darüber hinaus orientiert sich das Projekt an den Strategien der Stadt Wien, insbesondere an der Smart City Strategie, dem Stadtentwicklungsplan STEP 2025 und den zugehörigen Fachkonzepten, die als Rahmen für die städtebauliche Entwicklung dienen. In den letzten Jahren wurde diese Grundlage durch die IBA_Wien (Internationale Bauausstellung) ergänzt, die für ausgewählte Quartiere und Projekte spezifische Qualitäten sicherstellt.

Das so entstandene Zielsystem zeichnet sich durch eine große inhaltliche Breite aus, was dem Anspruch der Seestadt gerecht wird, auf nahezu allen Ebenen der innovativen, nachhaltigen und zukunftsorientierten Stadtentwicklung als Vorzeigeprojekt zu gelten. Die Mehrdimensionalität und Detailtiefe der Zielsetzungen bringt jedoch auch Herausforderungen mit sich. Einerseits besteht die Gefahr, im Laufe des langjährigen Entwicklungsprozesses die „großen Linien“ und übergeordneten Leitideen aus den Augen zu verlieren. Andererseits wird es zunehmend schwieriger, nach außen klar zu kommunizieren, was die Seestadt im Kern ausmacht und worin ihre Hauptmerkmale liegen.

Vor diesem Hintergrund initiierte die Wien 3420 eine umfassende Strategie-Evaluierung zur Seestadt. Ziel war es, eine kritische Zwischenbilanz zu ziehen und daraus strategische Leitlinien für die kommenden Entwicklungsphasen abzuleiten. Im Rahmen der Evaluierung (EVA) im Jahr 2022 wurde der aktuelle Stand analysiert. Aufbauend darauf entstand 2023/2024 ein neues Zielsystem, das mit dem klaren Commitment verbunden ist, die erreichten Fortschritte zukünftig kontinuierlich zu überwachen und zu dokumentieren. Dieses Monitoring soll sicherstellen, dass die Seestadt weiterhin als Modellprojekt für innovative und nachhaltige Stadtentwicklung gilt und ihre langfristigen Visionen bewahrt.

3.1 Strategie-Evaluierung: Prozess und Methodik

Die Strategie-Evaluierung für aspern Seestadt wurde auf zwei zentrale Säulen gestützt: Empirie und Benchmarking.

Die Säule Empirie umfasste einen „Deep Dive“, bei dem die Entwicklungsansätze und Qualitäten der Seestadt durch Expertinnen-, Experten- und Stakeholder-Gruppen analysiert wurden. Über 100 Expertinnen und Experten wurden in Fokusgruppengespräche und 30 Einzelinterviews eingebunden. Das Ergebnis ist ein umfassender Überblick über aktuelle Stärken, Potenziale und Herausforderungen der Seestadt aus Expertensicht.

Das Benchmarking hingegen diente dazu, die Performance von aspern Seestadt objektiver zu bewerten. Ein zentraler Output war die Entwicklung von Key Performance Indicators (KPI). Diese ermöglichen die

Ausrichtung und Bewertung der Projektentwicklung und sollen künftig unter dem Motto „Daran sollt ihr uns messen“ transparent gemacht werden. Die KPIs erfüllen mehrere wichtige Funktionen:

- Strategische Prioritätensetzung: Durch die Auswahl weniger, aber zentraler Indikatoren wird der Fokus auf die wichtigsten Erfolgsfaktoren gelegt.
- Grundlage für Steuerung: Die regelmäßige Erhebung der KPIs macht Entwicklungen sichtbar und schafft eine evidenzbasierte Entscheidungsgrundlage.
- Werkzeug für Kooperation: KPIs fördern Transparenz und Verbindlichkeit für eine abgestimmte Umsetzung zwischen den verschiedenen Akteurinnen und Akteuren, die an der Seestadt-Entwicklung beteiligt sind.
- Kommunikationsinstrument: Sie ermöglichen eine klare Kommunikation priorisierter Ziele und Fortschritte im öffentlichen Diskurs.

KPIs allein ersetzen jedoch keine Strategie, sondern müssen in ein übergeordnetes Zielsystem eingebettet sein. Dieses Zielsystem wurde im Rahmen der Evaluierung auf Basis der Erkenntnisse aus dem „Deep Dive“ angepasst, um neue Herausforderungen und Ambitionen zu berücksichtigen. Auch internationale Vergleichsprojekte wurden analysiert, um das KPI-Set zu bereichern und eine globale Vergleichbarkeit zu ermöglichen.

Als Ausgangspunkt der Zwischenbilanz wurden über 25 Strategiepapiere und Dokumente analysiert. Dabei wurden acht zentrale Handlungsfelder definiert, die in den „Deep Dive“-Prozess eingeflossen sind. Zur Vorbereitung wurden auch Daten aus dem sogenannten Markencontrolling genutzt, darunter ein Besiedelungsmonitoring, das die Wohnzufriedenheit in der Seestadt wissenschaftlich untersucht. Diese Untersuchung wurde bereits 2015, 2019 und zuletzt 2022 durchgeführt. Ergänzt wurde dies durch Umfragen zur Wahrnehmung der Seestadt bei Bewohnerinnen, Bewohnern und Betrieben innerhalb und außerhalb des Stadtteils sowie durch eine Medienresonanzanalyse und Erhebungen zur wirtschaftlichen Entwicklung.

Insgesamt waren 116 Personen in den „Deep Dive“ involviert. Neben 30 Einzelinterviews fanden elf Fokusgruppengespräche statt. Zu jedem der acht Handlungsfelder wurden Qualitäten, Potenziale und Herausforderungen der Seestadt herausgearbeitet.

Abschließend wurde das neue Zielsystem in einem intensiven Diskussionsprozess mit dem Team der Wien 3420, dem aspern Beirat und externen Expertinnen und Experten abgestimmt. Dieses Zielsystem bildet die Grundlage, um aspern Seestadt auch künftig als innovativen und zukunftsorientierten Stadtteil zu entwickeln.

3.2 Internationale Vorbilder

Bei der Entwicklung des KPI-Systems von aspern Seestadt dienten auch ausgewählte internationale Stadtentwicklungsgebiete, die sich einem ähnlich ambitionierten Weg der Erfolgsmessung von urbaner Quartiersentwicklung verschrieben haben, als Inspiration, darunter London (Olympic Legacy), Paris (Clichy-Batignolles), Kopenhagen (Nordhavn), Stockholm (Royal Seaport) und Freiburg (Dietenbach). Diese Referenzgebiete befinden sich in unterschiedlichen Entwicklungsphasen, von der Planung bis hin zur fast vollständigen Fertigstellung. Erkenntnisse aus der Analyse:

- Einbettung in Zielsysteme: In allen untersuchten Projekten sind die KPIs Teil eines umfassenden Zielsystems. Übergeordnete Ziele werden oft durch Subziele und konkrete Indikatoren präzisiert.
- Unterschiedliche Komplexität: Die Zahl der KPIs variiert stark: Kopenhagen arbeitet mit 12 KPIs, während London knapp 50 und Stockholm über 50 Indikatoren einsetzt.
- Referenz auf gesamtstädtische KPIs: London verknüpft das KPI-System mit dem übergeordneten „London Plan“, der für Stadtteile ein individuelles Monitoring vorsieht.
- Steuerung und Kommunikation: KPIs dienen sowohl der internen Steuerung als auch der Außenkommunikation. Kopenhagen und Stockholm konzentrieren sich in ihrer Kommunikation auf positive Ergebnisse, um Fortschritte hervorzuheben.
- Monitoring-Rhythmus: In den untersuchten Projekten werden jährlich umfassende Monitoring-Berichte erstellt. Dies ermöglicht ein rasches Reagieren auf Fehlentwicklungen und die Verstärkung positiver Trends.

Die internationale Analyse belegte, dass ein gut durchdachtes KPI-System nicht nur der Steuerung dient, sondern auch ein wirkungsvolles Werkzeug für die Kommunikation der Erfolge und Ambitionen eines Stadtentwicklungsprojekts ist.

4 EVA-ZIELEKATALOG NEU – STRATEGISCHE ZIELE, SUBZIELE UND KPIS

Innerhalb der Handlungsfelder wurden neun strategische Leitziele erarbeitet und jeweils in einer Reihe von „Subzielen“ konkretisiert. Den Subzielen sind wiederum Key Performance Indicators (KPIs) zugeordnet, die den Stand der Zielerreichung mess- beziehungsweise beurteilbar machen.

Für die kommenden Umsetzungsetappen ist ein periodisches Monitoring des Entwicklungsfortschritts der Seestadt entlang der definierten Ziele und KPI vorgesehen. Um eine größtmögliche Vergleichbarkeit der Monitoring-Ergebnisse im Zeitverlauf sicherzustellen und Unschärfen durch subjektive Interpretationen gering zu halten, definiert ein Monitoring-Handbuch für jeden KPI die exakte Erhebungsmethodik, einen angestrebten Zielwert und Entwicklungspfad dorthin.

Strategisches Ziel 1	**Der öffentliche Raum ist hochwertig, klimaresilient und interagiert mit privaten Räumen.**
Subziel	Der öffentliche Raum in aspern Seestadt ist inklusiv und qualitätsvoll gestaltet; die Menschen halten sich gerne im öffentlichen Raum auf. KPI Subjektive Wahrnehmung der Qualität des öffentlichen Raums
Subziel	Die Gestaltung des öffentlichen Raums reduziert Hitzeinseln. KPI Versiegelungsgrad im öffentlichen Gut KPI Beschattung auf allen relevanten Wegerelationen im öffentlichen Raum KPI Überschirmungsgrad durch ausgewachsene Bäume im öffentlichen Gut
Strategisches Ziel 2	**aspern Seestadt bietet allen Personen, die hier leben und arbeiten, eine hohe Lebensqualität und die Möglichkeit, das Alltagsleben gut und komfortabel zu gestalten.**
Subziel	Die Bewohnerinnen und Bewohner leben gerne in der Seestadt. KPI Wohnzufriedenheit KPI Qualität des Zusammenlebens KPI Wahrgenommene Sicherheit
Subziel	aspern Seestadt bietet ein angenehmes Arbeitsumfeld für alle Formen der Arbeit. KPI Gesamteindruck der hier Beschäftigten von der Seestadt
Subziel	Die Seestadt bietet ein gesundheitsförderndes Umfeld. KPI Spiel-, Bewegungs- und Sportplätze, die allen Bewohnerinnen, Bewohnern, Besucherinnen und Besuchern zur Verfügung stehen KPI Niedergelassene Ärztinnen, Ärzte und gesundheitsnahe Dienstleister KPI Möglichkeiten für Urban Gardening
Subziel	Der Wohnraum in aspern Seestadt ist vielfältig und leistbar. KPI Anteil leistbarer Wohnbau an der gesamten Wohnnutzfläche KPI Realisierte Sonderwohnformen KPI Vielfalt von Wohntypen
Strategisches Ziel 3	**aspern Seestadt zeigt als Klimamusterstadtteil vor, wie die Wiener Klimaziele erreicht werden können, schafft die Voraussetzungen für einen nachhaltigen Lebensstil und geht sorgsam mit den Ressourcen um.**
Subziel	Ein schonender Umgang mit der Ressource Boden zeichnet aspern Seestadt aus. KPI Flächeninanspruchnahme pro Einwohnerin oder Einwohner
Subziel	Alle Quartiere und Gebäude in der Seestadt sind in der Lage, die Wiener Smart City Klimaziele und die Vorgaben der EU-Taxonomie hinsichtlich Klimaschutz zu erfüllen. Der aspern klimafit-Standard schafft die Voraussetzungen im Neubau, der Bestand wird laufend nachgerüstet und ertüchtigt. KPI Tatsächlicher Endenergieverbrauch der Gebäude KPI Jährliche Stromproduktion aus Photovoltaik am Gebäude KPI Energieaufbringung für Gebäudeheizung und -kühlung aus erneuerbaren Quellen KPI Graues CO2 bzw. graue Energie in Gebäuden (für zukünftige Bauvorhaben/in progress:

	Zielwerte und Erhebungsmethodiken in Abstimmung mit öffentlicher Verwaltung, Forschung und Bauträgern)
Subziel	aspern Seestadt steht für Rückbau- und Recyclingfreundlichkeit von Gebäuden und von Materialien im öffentlichen Raum. KPI Umnutzbarkeit bzw. Rückbau- und Recyclingfreundlichkeit von Gebäuden und Materialien KPI Anteil von Recycling- (bzw. Re-use-) Material im Neubau (für zukünftige Bauvorhaben/in progress: Zielwerte und Erhebungsmethodiken in Abstimmung mit öffentlicher Verwaltung, Forschung und Bauträgern)
Strategisches Ziel 4	**aspern Seestadt ist Vorbild für die Klimawandelanpassung und den Erhalt der Biodiversität.**
Subziel	In aspern Seestadt gelingt die Verbindung zwischen Urbanität und Natur. KPI Grünflächenanteil von aspern Seestadt (Straßen, Plätze, Parks, bebaute Baufelder und Grüngürtel) KPI Grün- und Freiflächenfaktor von Baufeldern
Subziel	Die Seestadt weist eine hohe ökologische Resilienz gegenüber den Auswirkungen des Klimawandels auf. KPI Anteil der Flächen, die ermöglichen, dass Regenwasser vor Ort versickert oder zur Bewässerung gesammelt werden kann KPI Artenvielfalt im öffentlich zugänglichen Raum
Subziel	Durch vorausschauende Planung sind in der Seestadt alle Menschen vor übermäßigen Hitzebelastungen geschützt. KPI Gebäude mit außenliegendem Sonnenschutz KPI Überschirmungsgrad durch ausgewachsene Bäume im öffentlichen Gut KPI Beschattung auf allen relevanten Wegerelationen im öffentlichen Raum KPI Erreichbarkeit von hochqualitativen Grünflächen im öffentlichen Raum KPI Versiegelungsgrad im öffentlichen Gut
Strategisches Ziel 5	**aspern Seestadt ist lebendig, urban und zeichnet sich durch hohe architektonische Qualität und Vielfalt im Stadtbild aus.**
Subziel	Eine professionelle Wettbewerbs- und Baukultur sichert ein qualitätsvolles Stadtbild. KPI Anteil von Bauplätzen, die bei Verkauf über städtebauliche Leitbilder, ein standortbezogenes Quartiersprofil und/oder einen vertraglich überbundenen Qualitätenkatalog verfügen KPI Anteil an Bauplätzen, deren Qualität durch Wettbewerbe (o.Ä.) gesichert ist auf Basis von Leitbildern, Quartiersprofilen, Qualitätenkatalogen KPI Anteil der Projekte, die bis in die Umsetzung vom aspern Beirat auf Zielerreichung überprüft werden
Subziel	Nutzungsmischung und Nutzungsoffenheit sind Grundprinzipien der Seestadtstruktur. KPI Anteil der Nicht-Wohnnutzungen auf Baufeldern mit Wohnen KPI Realisierte Sonderwohnformen
Strategisches Ziel 6	**aspern Seestadt ist ein Businessstandort, der inspiriert und für Fortschritt, Innovation und Pioniergeist steht.**
Subziel	aspern Seestadt bietet Unternehmen in deren unterschiedlichen Entwicklungsphasen ein dynamisches Umfeld. KPI Bis zum Ende der Bauzeit werden ca. 20 000 Arbeits- und Ausbildungsplätze geschaffen KPI Anzahl Betriebsansiedlungen national und international
Subziel	Die Seestadt ist attraktiver Standort für Life Science und Industrie 4.0. KPI Anzahl branchenspezifischer Betriebsansiedlungen
Strategisches Ziel 7	**aspern Seestadt garantiert eine CO2-arme, stadtverträgliche, komfortable und sichere Mobilität.**
Subziel	aspern Seestadt und das Umfeld sind gut im Umweltbund vernetzt. KPI Modal Split der Bewohnerinnen und Bewohner KPI Motorisierungsgrad der Bewohnerinnen und Bewohner KPI Differenzierte Sharing-Angebote pro Bewohnerin oder Bewohner

	KPI Anzahl Fahrrad-Abstellplätze KPI Erreichbarkeit der Seestadt aus dem Umfeld und vice versa mit dem Rad bzw. dem ÖV
Subziel	Der Arbeits- und Wirtschaftsverkehr in der Seestadt ist bis 2030 weitgehend CO2-frei. KPI Anteil der neuen „Seestadt-Betriebe“ mit über 20 Mitarbeiterinnen^und Mitarbeitern, die ein betriebliches Mobilitätsmanagement umsetzen KPI Anteil der neuen Unternehmen in der Seestadt, die Maßnahmen für CO2-freie Logistik-Verkehre umsetzen KPI Abdeckung mit White Label Paketboxen
Subziel	Wege können in der Seestadt sicher zurückgelegt werden. KPI Verunglückte im Straßenverkehr KPI Barrierefreiheit im öffentlichen Raum
Subziel	Die Organisation des ruhenden Kfz-Verkehrs wird im Sinne der Mobilität im Umweltverbund optimiert. KPI Anzahl der dauerhaften Stellplätze im öffentlichen Raum KPI Anzahl von innovativen Pilotprojekten für autoreduziertes Wohnen
Strategisches Ziel 8	**aspern Seestadt ist ein nutzungsgemischter Stadtteil, der mit dem städtischen und regionalen Umfeld vernetzt ist und weit über seine Grenzen hinaus wirkt.**

5 FAZIT UND AUSBLICK

Der Rahmen ist gesetzt, der erste Schritt getan. Ein initialies Pilotreporting ausgewählter KPIs liegt vor und bildet die Grundlage für das künftige langristig laufende Monitoring.

Das Monitoring ist als „Work in Progress“ zu sehen – nicht alle KPIs konnten von Beginn an erhoben werden, da einige erst in späteren Entwicklungsphasen relevant werden. Wie das Stadtentwicklungsprojekt selbst ist auch die Strategie-Evaluierung ambitioniert. Mit EVA stellt sich die Seestadt bewusst auf den Prüfstand und ermöglicht einen „Blick in die Werkstatt“.

Das Pilotmonitoring zeigt: Die Seestadt entwickelt sich in vielen Bereichen gut, teils sogar sehr gut. Aber es ist klar: es gibt Verbesserungspotenzial., insbesondere in der Außenwahrnehmung. Während Seestädterinnen

und Seestädter ihre Lebensqualität schätzen, ist das Image bei Außenstehenden weniger positiv. Auch Wirtschaftstreibende vor Ort sehen die Entwicklung grundsätzlich positiv, wenn auch mit kritischem Blick.

Die Erfahrungen zeigen, dass rein quantitative Analysen nicht ausreichen. Ergebnisse müssen kontextualisiert und qualitativ interpretiert werden. Denn es ist wichtig zu reflektieren, warum Ziele erreicht bzw. nicht erreicht wurden oder Ergebnisse im Hinblick auf das Erreichen des Anspruches, der in den Sub-Zielen formuliert wurde, abzuwägen.

Transparenz ist essenziell für Glaubwürdigkeit und Akzeptanz. Eine offene Kommunikation der Ergebnisse stärkt die Seestadt als Vorbild und Innovationsmotor. Neben dem laufenden Monitoring sollte in größeren Zeitabständen auch eine strategische Reflexion, Etwa in Form eines komprimierten „Deep Dives“ zur Anpassung und Weiterentwicklung der Ziele erfolgen.

1 ABSTRACT

This paper investigates the effectiveness of spatial development policies in addressing spatial inequalities in the City of Johannesburg (CoJ), a city marked by historical exclusion and segregation. Despite efforts through Integrated Development Plans (IDPs) and Spatial Development Frameworks (SDFs) to promote spatial justice and integration, significant disparities still persist, particularly for marginalised communities who continue to face barriers to essential resources such as housing, transport, and public services. By analysing the evolution and implementation of these policies, the research revealed that while they aimed to rectify historical injustices, their impact remains uneven. The study contextualised spatial justice within broader social and economic transformations, examining how urban policies interact with power dynamics and resource distribution to affect the residents' daily lives. The findings underscored ongoing challenges related to urban inclusion and exclusion, highlighting the disconnect between policy objectives and real-world outcomes. The paper advocates for transformative approaches that prioritise participatory governance and equitable resource distribution as critical components of sustainable urban planning. Ultimately, this research enhances the understanding of spatial justice complexities and contributes to discussions on fostering more integrated and just urban environments in cities facing similar spatial challenges.

Keywords: spatial development, spatial justice, integrated development planning, urban governance, Johannesburg

2 INTRODUCTION

The CoJ remains a manifestation of old apartheid geographical planning, where race, class, and spatial locations were isolated one from the opportunity to have access to housing, transport, and economic opportunities. Johannesburg, or Joburg as it is commonly known, was established in 1886, following the discovery of gold. Not only did it develop rapidly from a small mining town to a thriving city, but also made significant contributions to the national markets (Beavon, 2004; O'Meara, 1996; Roodt, 2012).While the CoJ is characterised as one of the most economically affluent neighborhoods in Africa, there also exist areas of abject poverty in informal settlements and townships, as well asinformal settlements such as Diepsloot which are located close to the wealthy neighborhood of Steyn City (Huchzermeyer, 2004). These areas face persistent struggles due to decades of intentional socio-spatial division that has its roots in colonial/apartheid spatial planning, as well as the post-1994 inefficiencies in urban governance (Mabin, 1990; Parnell and Pieterse, 2010; Turok, 2016).

This colonial/apartheid racial planning legacy has resulted in the creation of Johannesburg and other South African cities as arguably the world's most spatially divided cities, where social, economic, and environmental inequalities continue to define the urban landscape (Bremner, 2000; Nleya, 2017; Turok and Visser, 2018).While policies that are aimed to remedy these inequalities such as the IDPs, theSDFs, and the Integrated Urban Development Framework aim to address these gross disparities, many residents of Johannesburg still experience exclusion and economic marginalisation (CoJ, 2021).It ultimately justified the promotion of spatial justice through higher levels of infrastructure, affordable housing, urban regeneration, and the reintegration of informal settlements (Harrison and Todes, 2017; Parnell, 2019; Sutherland, 2020). Beyond access to services, spatial justice advocates for equitable access to resources and a voice in the economy and community (Soja, 2010).However, the apartheid-era segregation is still apparent in many of our communities that are still without reliable public transport, opportunities work work, and access to education. This exacerbates rather than ameliorating socio-economic inequalities (Mabin, 2020).

This study undertook a qualitative research approach, which is appropriate for understanding complex social problems such as spatial justice and urban planning (Creswell, 2013). This approach enables an exploration of policy formation, policy implementation, and policy perceptions, particularly about the complexities of an urban environment such as that of the CoJ.This research specifically used content analysis as the method of analysis to be applied to key spatial policy documents. In this capacity, it will help reveal how spatial justice, alongside urban integration, is conceived and accounted for within the CoJ's strategic intent and projects outlined in these documents.This method will contribute to understanding the trajectory and prominence of commitments towards spatial inequalities and consolidating cities through the analysis of the rhetoric, priorities, and strategic direction enshrined in these documents.

3 STUDY AREA

The CoJis a metropolitan municipality, and one of the three metros located in the Gauteng province. It is also the largest metropolitan municipality in South Africa (Johannesburg City Profile, 2020). With the fastest-growing urban area on the continent with over 5.6 million people (Statistics South Africa, 2022), it is South Africa's most populated city.The city boasts exceptional infrastructure such as world-class telecommunications, transport, water, and electricity, in addition to world-class healthcare and education.The city has a diverse range of ethnic groups, which are broadly reflective of the national demographic, including those identified as African, White, Coloured, and Indian/Asian. The majority of the people, about 80% of the city's residents, have African roots. The rest of the population blends well with the existing cultural fabric of the city(CoJ, 2021).

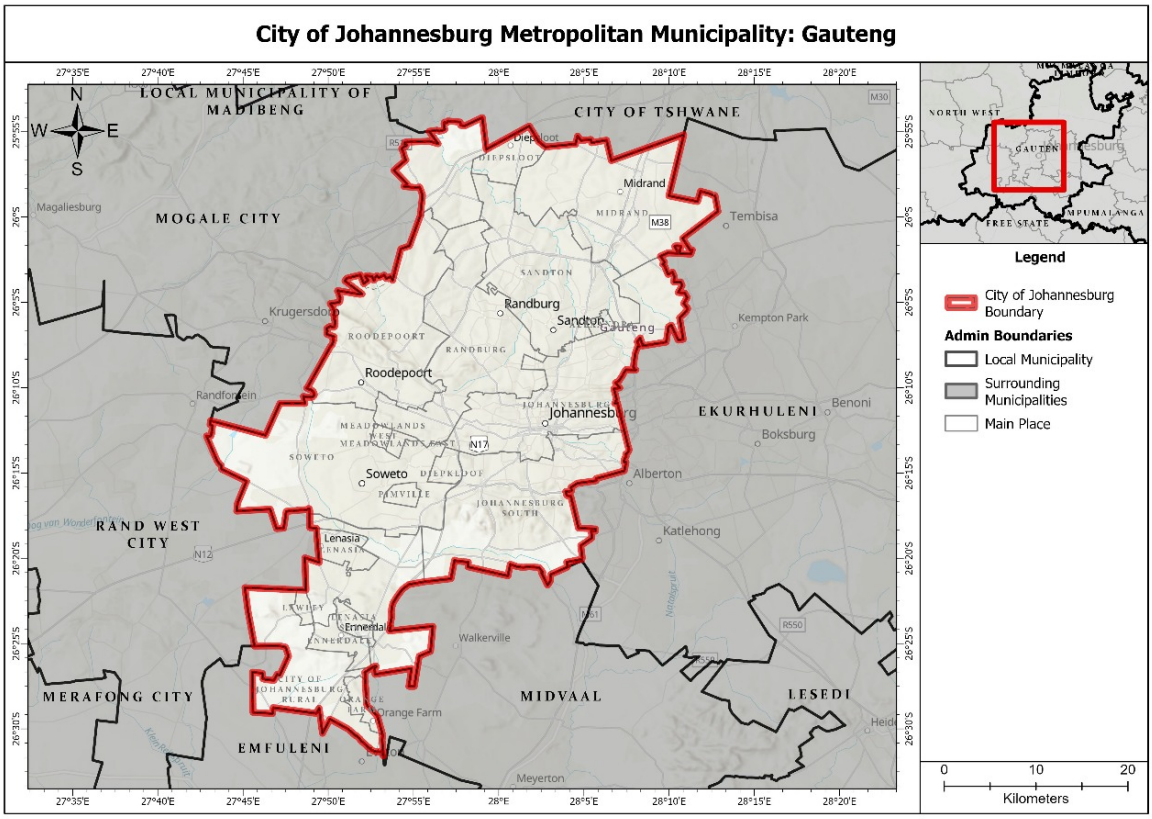

Fig. 1: Locality map showing the study area

Johannesburg has to reconcile its practices around urban development and spatial planning with a history of inequalities and the need to sustain urban growth. For example, the apartheid legacy in South Africa has heavily influenced the spatial configuration of cities characterised by segregation, uneven development, and poor access to resources for impoverished groups (Turok, 2016).To overcome the above-mentioned challenges, a plethora of policies which are referred tospatial development policies have emerged with the purpose of fostering spatial justice and integration. This study examined how these policies have fared in terms of inclusivity, equity, and balanced growth in the CoJ.

The spatial disposition of Johannesburg is informed by the sociopolitical landscape of South Africa, more specifically the apartheid era (1948–1994). This resulted in stark racial segregation, an apartheid tool for control and marginalisation of the non-white majority that informed the urban planning vision. Policies such as the Group Areas Act dictated people's residency in a segregated urban landscape, with separate public services available for each group, effectively creating a well-resourced, predominantly white city, next to townships that housed non-white communities (Creswell, 2013).This history has proven spatial injustices embodied in walls that segregate communities along racial and class lines, unequal allocation of resources, and large discrepancies in infrastructure, public amenities, and economic opportunities in disparate neighborhoods (Harrison and Todes, 2017). Moreover, the lack of an efficient model of public transport hinders disadvantaged communities from accessing their jobs and social services.

4 SPATIAL JUSTICE IN JOHANNESBURG'S SPATIAL TRANSFORMATION POLICIES

Scholars such as Harrison et al. (2019) and Robins (2018)stated that in Johannesburg, spatial transformation has been a key policy objective since the end of apartheid, as the city sought to address the spatial inequalities rooted by decades of racially discriminatory urban planning. Furthermore, in Johannesburg, spatial transformation has been one of the primary objectives of post-apartheid policy as the city strives to overcome and address the spatial inequalities that were compounded by years of racially discriminatory urban planning. The spatial planning of the apartheid state was manifestly evident through legislation such as the Group Areas Act of 1950 that forcibly segregated urban space, relocating non-white people into township peripheries, leaving the city centre and white northern suburbs for the whites(Makhura, 2020; Nleya, 2017; Turok, 2016). The end result is a deeply segregated city, marked by a geographic distribution of socio-economic opportunities and unequal access to essential services such as housing, jobs, and transport.However, post-apartheid space policy (for example, the IDP and the SDF) has sought to address the legacy of spatial inequality, mainly through the promotion of spatial justice via urban integration, mobility, and equitable access to services (Harrison et al., 2019). One such policy approach introduced was the Corridors of Freedom initiative, which aimed to dissolve the spatial restrictions of apartheid by establishing transit-orientated development corridors linking peripheral areas to economic centres, thus improving marginalised populations' access to jobs and services (Tomlinson, 2018). This was an effort to try to connect the direct economic regeneration of space back to the notion of social justice in space, to make sure the communities that had historically been excluded were brought into the socio-economic mainstream of the city.

Besides the IDP and SDF, the spatial development of Johannesburg was informed by various policies such as the Growing Gauteng Together 2030, the Gauteng Environmental Management Framework, the 25-year Gauteng Integrated Transport Master Plan, the Gauteng SDF 2030, and the Johannesburg Growth and Development Strategy 2040. The Growing Gauteng Together 2030 focused on the regeneration of townships and transit-orientated development, but does not radically change spatial inequalities. Also, the Gauteng Environmental Management Framework does guide land usage, referring to the structure of land used for the production of disclosure services, such as agriculture, tourism, and industry;however, it is not actually a tool for spatial restructuring but is more like a regulatory system. Moreover, there are the 25-year Gauteng Integrated Transport Master Planthat focusseson effective and efficient transport connectivity between residential and economic zones, and thestratigraphies of ecologies of scale: the SDF – Good Soil Development Facilitator. The Growth and Development Strategy 2040, however, is an aspirational document, and its plans for moving beyond deep inequalities are modest (SDF 2040, 2024).

Overall, these spatial plans are well linked to the national and provincial frameworks, but there are limits to their efficacy in enabling transformative spatial outcomes. According to Berrisford (2021), the CoJ'spolicies have had some positive impact, but fragmented governance, financial limitations, and market-mediated gentrification continue to limit their effectiveness. Gentrification, as an unintentional consequence, has been a significant driver of a central polemic in the spatial transformation–spatial justice nexus: the material enhancement of infrastructure can make neighborhoods more connected and accessible for some but can also increase property values, leading to the displacement of poorer neighborhood residents from areas activated for development (Tomlinson, 2018). Such displacement undermines the broader pursuit of spatial justice, whereby marginalised populations are pushed further outside of important spaces, reinforcing cycles of spatial exclusion.

Informality remains one of the most urgent concerns regarding the relationship between Johannesburg's spatial transformation and spatial justice. These include settlements such as Alexandra, Diepsloot, and Ivory Park, which accommodate a large percentage of the low-income population of Johannesburg and are typified by poor access to basic services, insecure land tenure, and limited access to economic opportunities (SACN, 2020). Johannesburg's spatial policies have sought to formalise and integrate these settlements into the wider urban fabric, but progress has been slow, and precarious living remains the default for many residents. The battle of informal settlements remains a key obstacle to spatial justice in Johannesburg. As asserted by Turok (2016), spatial justice will not be achieved without addressing the housing needs of those living in informal settlements, who are among the most spatially marginalised groups in the city. Meanwhile, efforts to regularise these settlements often meet resistance from both residents and the state: upgrading infrastructure and service provision involves a high cost, and many informal settlers would prefer to keep their homes if their settlements are regularised. This mimics broader tensions in spatial justice discussions, such as how to balance the short-term needs of marginalised communities (CoJ, 2020); and what spatial transformation should look like in the long run.

The plans are central tools through which the city confronts the structural challenges it faces and are updated over time to embody the city's changing strategic priorities. This means the city will address issues like spatial segregation, economic inequality, and equal access to essential public services, through these plans. Grounded in their location and their impatience to build a just society, the desire for integration and transformation from the heritage of apartheid, they were meant to unmake and remake Johannesburg as a more connected, spatially just, and integrated city. But the impact of these policies and strategies is contested; it is important to interrogate their effects on spatial justice and urban integration.

5 CONTENT ANALYSIS OF JOHANNESBURG'S SPATIAL PLANNING TOOLS

5.1 City of Johannesburg Integrated Development Plan 2016–2021

The IDP 2016–2021 was meant to tackle these spatial inequalities through interventions such as the Corridors of Freedom and transit-orientated development.These are strategies that aimed to change the apartheid-era settlement of the city by consolidating high-density housing and mixed-use developments around public transport corridors.Intended to enable accessibility and promote spatial justice by connecting historically disadvantaged communities to economic opportunity, the initiative sought to create equitable access to transport systems.These existing policies, overall, enhanced the urban fabric in terms of connectivity due to the investment in the Rea Vaya BRT (Bus Rapid Transit) systemand the Gautrain stations, although the spatial and socio-economic inclusiveness of such developments were not universally experienced across the entire landscape.

Housing development mentioned preceded focus, especially in places like Diepsloot, Zandspruit, and Soweto, over informal settlements and overcrowding. The IDP also aimed to expedite affordable housing delivery by using public–private partnerships as a funding supplement to the government. However, the strategy was incomplete as adequate infrastructure was not provided, while delivery rates were slow, which further restricted living standards.Many low-income communities ended up far from economic centres, aggravating spatial inequalities, not alleviating them. This was further compounded by the introduction of a small number of mixed-income housing projects that never attracted the level of private sector investment necessary to create fully integrated communities, resulting in continued segregation by status and race.The IDP also emphasised infrastructure investment in marginalised areas, especially Soweto, Orange Farm, and Diepsloot. These neighborhoods, which have in the past been excluded from essential services, had been marked for upgrades in transport, water, sanitation, and energy supply.While there was extensive investment and some gains were made, infrastructure development always played catch-up to population growth, decreasing the overall effectiveness of these investments. In Diepsloot, for instance, "rapid urban expansion outstripped service delivery", resulting in a "pervasive struggle for resources" and deteriorating living conditions.This disconnect of infrastructure in these regions resulted in the unreliability of electricity supply and road conditions, which hampered economic opportunities as they would not encourage business developments, infrastructure establishments, and investment.

The IDP also specifically concentrated on service delivery in Soweto, Alexandra, and Orange Farm, with the aim of boosting local economic development. Although these initiatives sought to incorporate townships into

the formal urban structure, inequalities persisted. Specifically, there was more development of the private sector in richer areas, such as Sandton, but less development of the private sector in townships.Such spatial inequalities were exacerbated as job opportunities and investments continued to cluster in areas that have always benefited from the machinery of planning, and the IDP, rather than ameliorating this inequity, perpetuated it. The absence of concrete land planning worsened these issues, as some of the people living in informal settlements still lacked any kind of formal development, increasing the vicious cycle of informality and marginalisation.

One of the main components of the IDP was to expand the public transport system as a way to improve the linkages between the peripheral townships and the economic centres. The Rea Vaya BRT system was expandedin an effort to be more accessible and help residents of low-income areas cut costs. However few routes were covered, which resulted in many areas being disconnected, such as Midrand, Lenasia, and Fourways.Even worse, without a fully integrated and expansive transit network, true spatial transformation for Johannesburg is unlikely to ever be achieved. Moreover, due to the inefficiencies and financial sustainability issues of public transport systems, they were also unable to induce substantial spatial restructuring, with many residents continuing to rely on informal and unreliable transport modes.

Figure 2 shows the number of land development applications within 1 km of each 400 m hexagon used in the Nodal Review policy. The figure also shows that formal development is limited in some areas, especially in previously Black-only townships like Soweto. It compares the location of land use applications over two periods: the six years before the 2016 SDF and the six years thereafter. This provides a visual representation of major trends, such as increased development around key urban nodes located in the already affluent northern parts of the city.

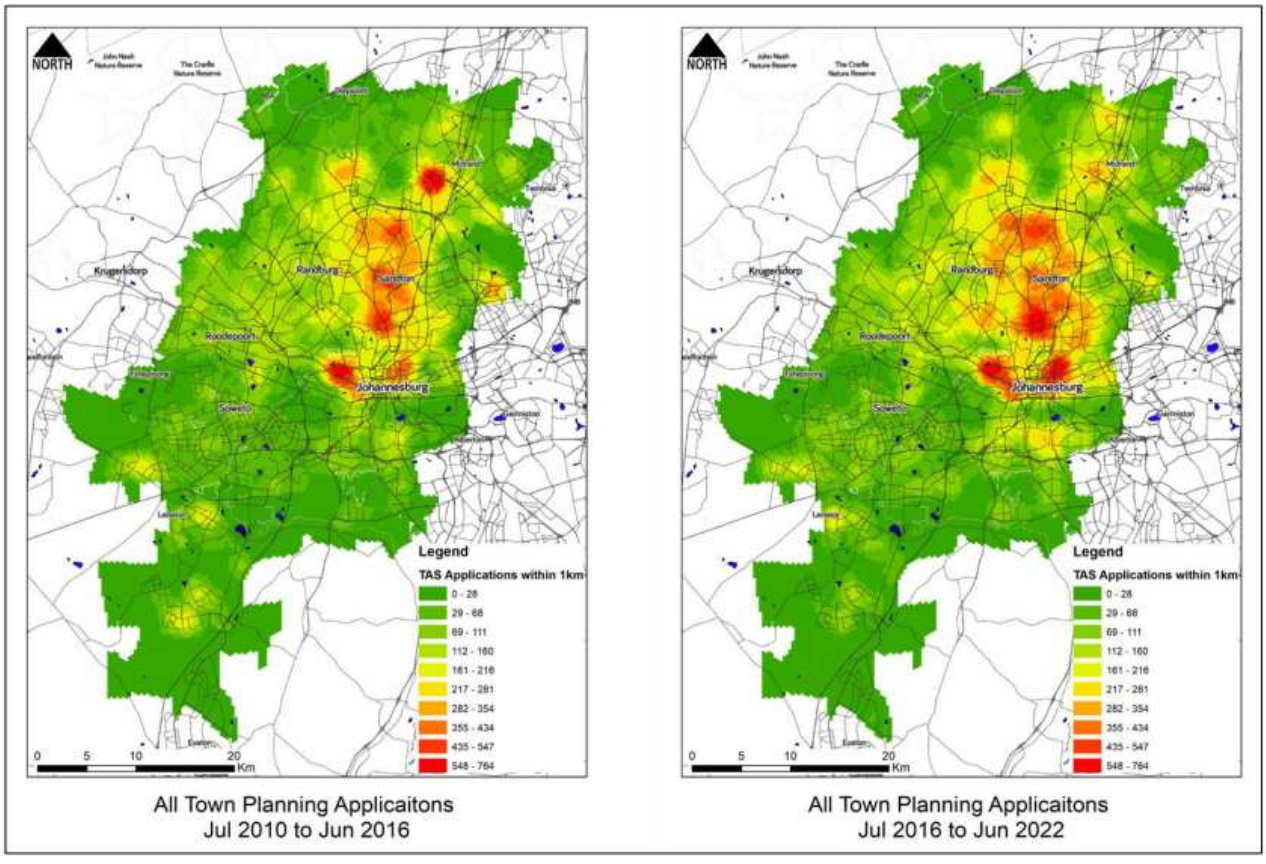

Fig. 2: All town planning applications within 1 km before and after the SDF 2016 (Source: CoJ 2040)

Long-term investments in the area, significant infrastructure developments, and the existence of major economic hubs have meant that Johannesburg's northern suburbs are still favored in terms of the spatial distribution of town planning applications.Northern areas continue to attract the bulk of development proposals, establishing an already prosperous part of the city while stifling growth in other parts.This trend persists despite demographic data indicating that population growth is quickening in the southern and other

historically marginalised areas of Johannesburg, including Ledwaba's cross between Soweto, Orange Farm, and parts of the inner city.Given this disconnect between growth and planning applications, there are difficulties in achieving spatial transformation for spatial justice.

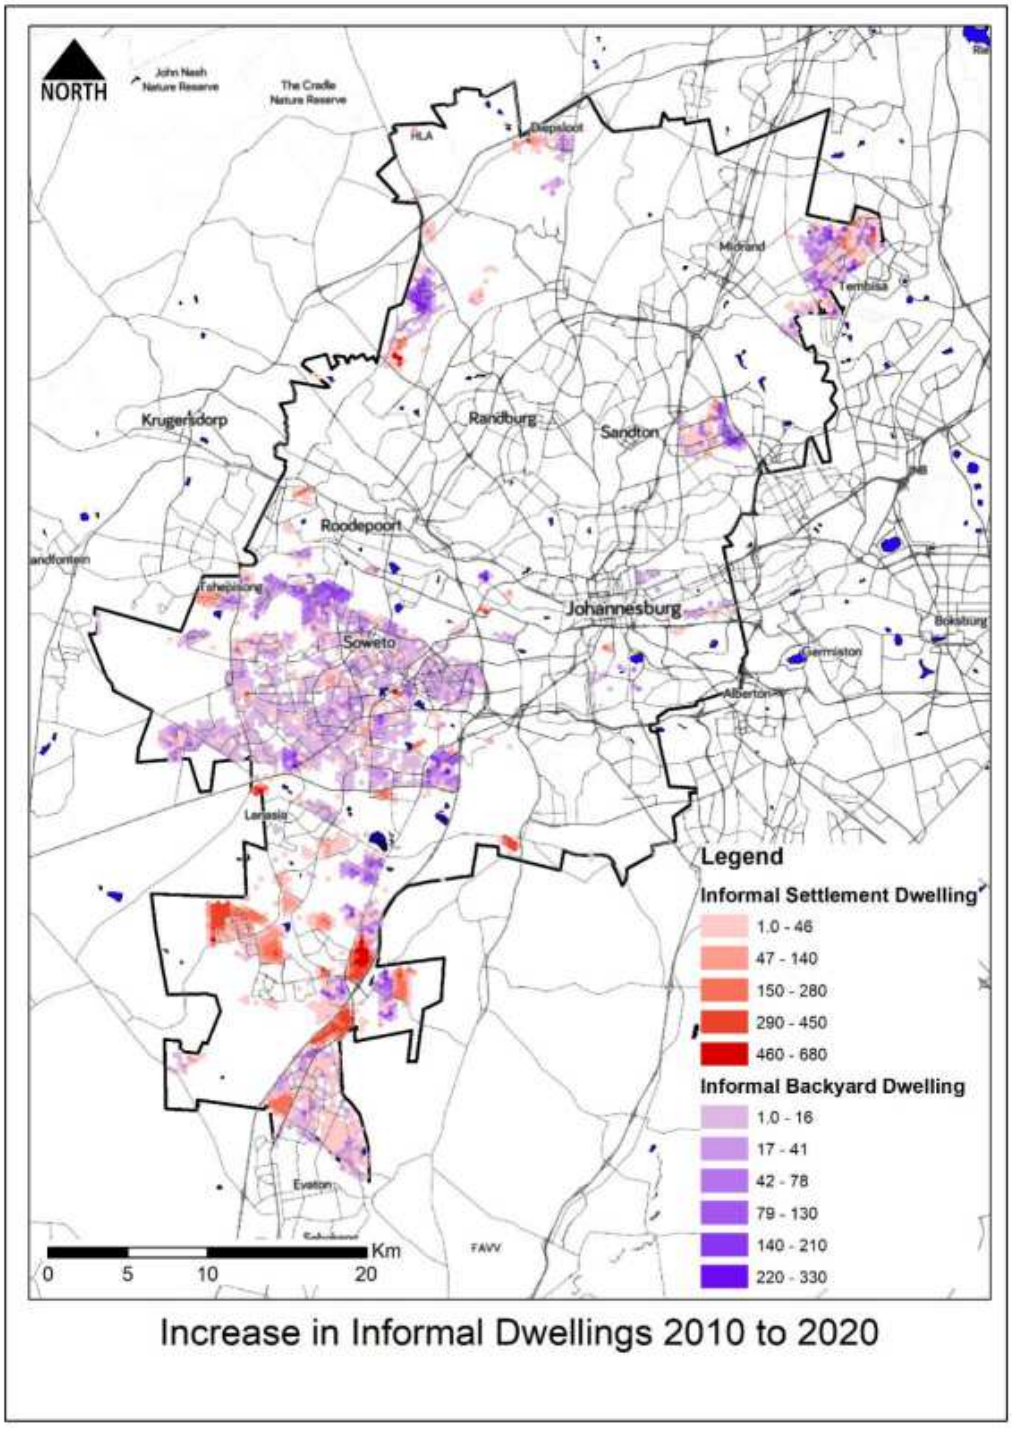

Fig. 3: Increase in informal dwellings 2010 to 2020 per 400 m hexagon (Source: CoJ, 2021).

The primarily northern nature of town planning applications is largely driven by economic and infrastructure benefits.The northern suburbs have historically served as the commercial and financial centres of Johannesburg and have attracted businesses, investors, and high-income residents. These areas tend to have better roads, efficient public transport systems such as the Gautrain, and far superior service delivery to that seen in the suburbs, making them a great option for real estate developers.The legacy of apartheid-era spatial planning also meant much greater investment in infrastructure and zoning in the north and underdevelopment in the south and west. This historical bias still informs investment decision-making, as developers view

projects north of Johannesburg as more financially viable due to stable property values and perceived security.

However, this trend has to be reversed since population data suggest that the strongest population growth has recently occurred in the southern and peripheral areas of the city. Soweto, for example, is still the largest township in Johannesburg and keeps growing, partly as a result of natural population growth and rural–urban migration.If the planning applications continue to be concentrated in the north, there is a danger that the city will become blind to where demand for housing, commercial diversity, and essential services is greatest. Also, pushing development north only exacerbates spatial inequity, entrenching economic and social divides within the city. A more balanced view of typed planning applications would call for town planning applications in historically deprived areas to be balanced with applications in historically wealthy areas.To that end, increasing infrastructural usage in underutilised zones of underdeveloped regions will also be critical to Johannesburg's long-term urban sustainability. Many areas in the south, like Lenasia and Orange Farm, for instance, have underutilised infrastructure that is needed as a population explosion is experienced (CoJ, 2021).A better way: Rather than swelling the already sprawling northern suburbs, invest more in enhancing and expanding services in these robustly growing regions to meet consumer needs (Harrison et al., 2019). Yet if the city does not change course, facilitating urban inefficiency, congestion, and informal settlements will continue. Economic decentralisation should be incentivised through investment in the south and west, forming new concentration areas of business out of over-reliance in Sandton and the central business district. Such part-time work would create jobs, facilitate access to services, and ensure an economically strong urban way of life.

CoJ should also work towards making town planning applications across the southern and western regions more conducive.Tax breaks for developers, fast-tracked rezoning, and prioritised upgrades to infrastructure in these areas are incentives that can help channel investment.Particularly, public–private partnerships must be encouraged to establish mixed-use development that combines housing with commercial and economic centres in emerging growth centres.Johannesburg can address those discrepancies in its urban strategies and ensure that they are tailored to their citizens in an inclusive way.

5.2 City of Johannesburg Integrated Development Plan 2022–2027

While the previous IDP covered a wide range of issues, the 2022–2027 IDP gives greater emphasis to urban regeneration and emphasises it as a solution for urban decay, a means for promoting economic growth as well as attracting investment.The plan focuses on the inner city with the same spirit in mind, with significant concentration on areas such as Hillbrow, Braamfontein, Newtown, and Jeppestown, which have been neglected, over-occupied, and have poor infrastructure.Although this regeneration is intended to make the area safer and with better infrastructure, and also to attract businesses, the gentrification of the area and the displacement of lower-income residents is still a major problem. This has been clearly articulated through the vision of the CoJ to transform Johannesburg into a world-class African city; however, this must extend to ensure that activities can be spatially just.Gentrification is a major issue surrounding urban regeneration, with price increases in housing and cost of living forcing long-term, low-income residents out of the area. Maboneng provides a case in which regeneration efforts have resulted in such steep rent increases that lower-income groups can no longer afford the area. Areas such as Hillbrow, which have significant low-income and immigrant populations, are especially vulnerable.While the IDP recognises these risks and suggests social housing and affordable rental units as potential solutions, the proposed actions remain policy-orientated rather than tangible steps toward addressing the issues at hand. This demonstrates that faster on-track usage needs more vigorous intervention to force urban renewal spreading to all residents, instead of just investors and upper-income groups.The IDP also includes projects that will deliver affordable housing to help address socio-economic segregation through the integration of different income groups within the same neighborhoods. The goal is a socially cohesive city with access to essential services, and better mixed-income communities.Land and construction costs in urban areas can be prohibitive, which remains one of the principal challenges to delivering affordable housing, often leading to new developments in the suburbs. Unfortunately, this means that the areas these people move to have even fewer access to the essentials of life, such as affordable and quality housing, quality education, health care, and jobs, which only amplifies the economic status of the area against achieving true equity in accessing housing.

As with the 2016–2021 IDP, infrastructure development is another important dimension of the IDP, with the focus on historically marginalised areas like Soweto, Alexandra, and Orange Farm. These regions have historically experienced poor access to basic services such as water, sanitation, electricity, and public transport along with the aforementioned challenges. Through investments in infrastructure upgrades, the city hopes to enhance the quality of life of its residents in ways that address long-term spatial inequality. It will facilitate more equitable living conditions and sustainable urban development to improve public services in these two areas.The focus on targeting those areas mentioned above is because these areas were historically marginalised under apartheid and were severely socio-economically disadvantaged, leading to the current socio-economic challenges we find ourselves in today. Soweto, for all the vibrancy of its community, still suffers from high unemployment and crumbling infrastructure. One of Johannesburg's most overcrowded areas, Alexandra, suffers from serious sanitation and housing problems. Orange Farm is not immune to the scourge of inadequate basic services and much of the population live in informal settlements. Concerned with past disparities in geographical development, the IDP aims to improve the social well-being of the people in these locales if properly operationalised.

5.3 Evolution and progress between the two 'generations' of integrated development plans

The IDPs of the CoJ for the years 2016–2021 and 2022–2027 mark two unique yet interrelated phases in the ongoing journey to tackle urban challenges and foster economic prosperity for the city. The previous IDP is characterised by ambitious, large-scale initiatives, while the latter reflects a shift to more pragmatic, incremental approaches, incorporating lessons learned from its precursor's successes and failures.

The 2016–2021 IDP set ambitious targets that promised exciting responses such as the Corridors of Freedom as well as growing the Rea Vaya BRT services. The Corridors of Freedom was a project around high-density mixed-use developments along major transport routes, tying previously disconnected areas like Orange Grove and Westbury into economic nodes like Sandton and Rosebank. As towns in the developing world grow, urban transport systems must keep pace; this was the broader rationale behind expanding the BRT system to link residents in peripheral townships such as Soweto and Diepsloot with the spatial and economic opportunities of the urban core.However, the conceptual nature of these initiatives posed major challenges. Those objectives, while consistent with advancing spatial justice and urban regeneration, faced a multitude of challenges due to a lack of capital investment, bureaucratic inefficiencies, and, above all, a lack of support from the local population. In Alexandra and Ivory Park, for example, residents resisted urban regeneration projects for fear of expulsion, while others complained about housing delivery in new developments in Kliptown and Jabulani being too slow. These challenges demonstrated the ambitious scope of the 2016–2021 IDP, with many of its goals proving difficult to meet in the given timeframe.

The 2022–2027 IDP provides a more pragmatic stance, drawing from the lessons of the preceding IDP, and containing more attached to what is realistic.Rather than focusing on big transformative projects as it did in the past, the updated plan signals a shift to creating incremental improvements, strengthening collaborations between the public and private sectors, as Curbelo (2023) added. Public–private partnerships are now viewed as crucial to solving the funding shortfalls that constrained the last IDP goals (Smith, 2022). One can clearly see this in how mixed-income housing projects in places such as Fourways and Randburg are developed, offering a mix of affordable and market-rate housing with the city receiving deliveries through private developers.

6 CONCLUSION

In a worst-case scenario, the IDPs from 2016–2021 to 2022–2027 reveal startling evolutions in focus and intention but also reveal repeating failures and unfulfilled promises. The lingering of certain risks, in particular those related to spatial justice, urban integration, and public transport, illustrate that many of the city's most pressing problems are still to be solved.Integration of informal settlements is probably the most visible sense of being repeated. These include informal settlements in areas of Zandspruit, Thembelihle, and Diepsloot, which have been identified in both the 2016–2021 and the 2022–2027 IDPs and the need to address them. These settlements, often remote from basic services and economic opportunities, were identified as major contributors to spatial inequality. The unfulfilled promises from the earlier IDP repeat themselves in the latter, the provisions in both plans promising the city better housing and infrastructure.

This marked a significant evolution in theIDPs, as they worked to learn from previous years, culminating in the 2022–2027 IDP being grounded in a strategic approach to address challenges and issues within the built environment. The 2022–2027 IDP acknowledges deficiencies in previous plans, placing greater emphasis on public–private partnerships which serve as an avenue for overcoming some of the challenges that led the 2016–2021 plan to fall short.The issues of spatial justice, integration of informal settlements, affordable housing, and public transport are still in the centre of attention for IDPs, but real progress on the ground remains limited. As such, the relevance and effectiveness of the 2022–2027 IDP hinges on the revelation of what went wrong, the reorientation towards attainable goals, and the resource mobilisation and utilisation towards enabling actions that achieve the spatial transformation objectives.Until these and other persistent challenges are addressed, the city runs the risk of slipping back into a cycle of unfulfilled promises, repeated goals, and continued obstacles to the realisation of spatial transformation.

Examining the Influence of 4IR Technologies in Urban Planning: A Case of the City of Johannesburg

Siphiwe Mbatha

(Dr Siphiwe Mbatha, University of Johannesburg, 37 Nind street Doornfontein Johannesburg 2028, gmbatha@uj.ac.za)

DOI: 10.48494/REALCORP2025.1068

1 ABSTRACT

There is rapid increase of new technologies that are being implemented in many fields benefiing their operations positively, and urban and regional planning is also slowly growing in deploying various tecbnologies. The Fourth Industrial Revolution (4IR) has introduced transformative technologies such as Artificial Intelligence (AI), Big Data, the Internet of Things (IoT), and Geographic Information Systems (GIS), which are reshaping urban planning and governance. The city of Johannesburg is located in South Africa which is in the developing world. The city is working towards becoming a world class city. To achieve this, there is a need of deploying advance technological tools in urban planning learning from developed countries. The aim of the study is to explore the influence of 4IR technologies that might have in the City of Johannesburg (CoJ), focusing on how these innovations enhance decision-making, optimize resource allocation, and improve urban efficiency. By analyzing real-time data, predictive analytics, and smart infrastructure solutions, the research analysis the potential of 4IR technologies in addressing urban challenges. With the adoption of a qualitative case study approach, through the use of literature, this research evaluates existing applications and applications that could be implemented of AI and Big Data in Johannesburg's urban planning strategies, as well as the challenges related to data privacy, and infrastructure readiness, The findings highlight the benefits of technology-driven urban management while also identifying barriers to widespread adoption. Therefore, the study recommends the integration of 4IR technologies into Johannesburg's urban planning framework to foster sustainable and inclusive city development.

Keywords: Smart Cities, Big Data, Artificial Intelligence, urban planning, 4IR

2 INTRODUCTION

Fourth Industrial Revolution provides techonological advancements that could bring solutions to urban planning challenges and drive the City of Johannesburg towards becoming a smart city. These technologies require to be deployed correctly to be functional, and effectively. Accordingly, there is a need for them to be well-utilized by both the governmnent and the city residents. The aim of the study is to explore the influence and impact of 4IR technologies that might have in the City of Johannesburg, focusing on how these innovations enhance decision-making, optimize resource allocation, and improve urban efficiency. By analyzing real-time data, predictive analytics, and smart infrastructure solutions, the research analysis the potential of 4IR technologies in addressing urban challenges. The city has been adopting various technologies in various aspects such as the CoJ municipality integrating e-services in their operations to ensure tha the city residents can easily obtain information, communicate and other related services, there has been smart mobility developments such as the Bus Rapid Transit system (Known as Rea Vaya system), High speed rail system (known as Gautrain system which includes Bus, train and midi-buses), rising number of ride e-hailing services, Free WiFi services in various neighbourhoods and parks for city residents to connect to the internet, usage of green energy such as the adoption of solar powers, Geographic Information System services used to assist in planning and also providing the city residents with real-time navigation information, CCTV networks to prevent crime, sensored waste management, and environment sensors monitoring conditions to prevent natural disasters, and other technologies. The use of more technological innovations can enhance the urban living leading to quality of life and promote sustainable development.

3 BIBLOMETRIC LITERATURE REVIEW

The use of biblometric mapping of literature has been adopted for this study. This is to identify suitable literature for this study and identify most of the common themes researched on related to fourth industrial revolution, Artificial intelligence, Big data, smart cities, urban planning and South Africa. Further, the results of the mapping network indicates a summary of themes that are most studied and or that need attention.

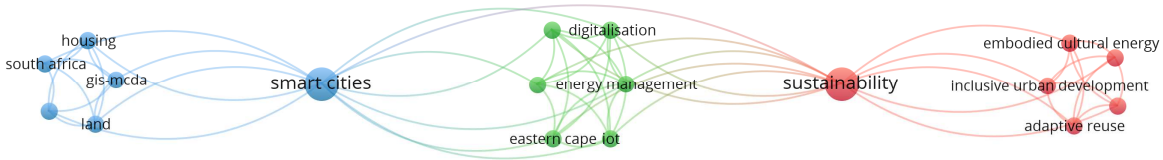

Figure 1: Keyword co-occurrence network visualisation

The above figure1 indicates a biblometric mapping of literature about authors keywords. These keywords indicate the most used keywords related to the study. There are 18 items (keywords), 3 clusters, 58 network links, 198 total link strength, and there is a total of 43 occurences. Only 18 keywords formed the network as 22 keyworkds could not connect to other keywords. Accordingly, links indicate the connection between various keywords in the biblometric mapping of literature, and the occurences shows how much a keyword has appeared in the networks. Furthermore, the total link strengths highlights that which keywords are most connected to other keywords indicating that most author's studies focuses on such themes. The authors keywords formed 3 clusters that are indicated by different colours. Each cluster has subfields that most authors work focuses on. In cluster 1, there are six keywords indicated by red node which include adaptive-reuse, cultural resilience, embodied cultural energy,inclusive urban development, sustainability, Tshwane/ Pretoria. The cluster indicate that some of the studies conducted are based on inclusive urban development with cultural resilience and embodied cultural energy. Accordingly, adaptive-reuse is a significant concept that needs to be implemnted for creating sustainabilty smart cities.

In cluster 2, there are six keywords represented by a green node which include Eastern Cape, digitization, enegry management, internet of things, urbanization, and smart municipalities. This cluster highlights that various studies conducted indicate that municipalities in the Eastern Cape are transitioning towards smart municipalities were there is deployment of internet of things and digitization for energy management and urbanization. In cluster 3 there are two keywords represented by a blue node which include gis-mcda, housing, land, smart cities, South Africa, and well-located. The cluster indicates that there are various studies conducted of identify suitable land location for housing development and smart cities development across South Africa using gis multi-criteria decision analysis. Further, there is a strong connection in the network for the keyword smart cities as it is strongly linked with cluster 2, cluster 3 and also with one keyword in cluster 1 which is sustainability. The keyword connects with Eastern Cape, digitization, enegry management, internet of things, urbanization, and smart municipalities in cluster 2 highligting that for successful smart cities development in the Eastern Cape there is a need for all the keywords in cluster 2 to be implemented or included in planning. Consequently, there is a need for gis multi-criteria decision analysis to identify suitable land location for succesful development of smart cities, which this will produce sustainable smart cities.

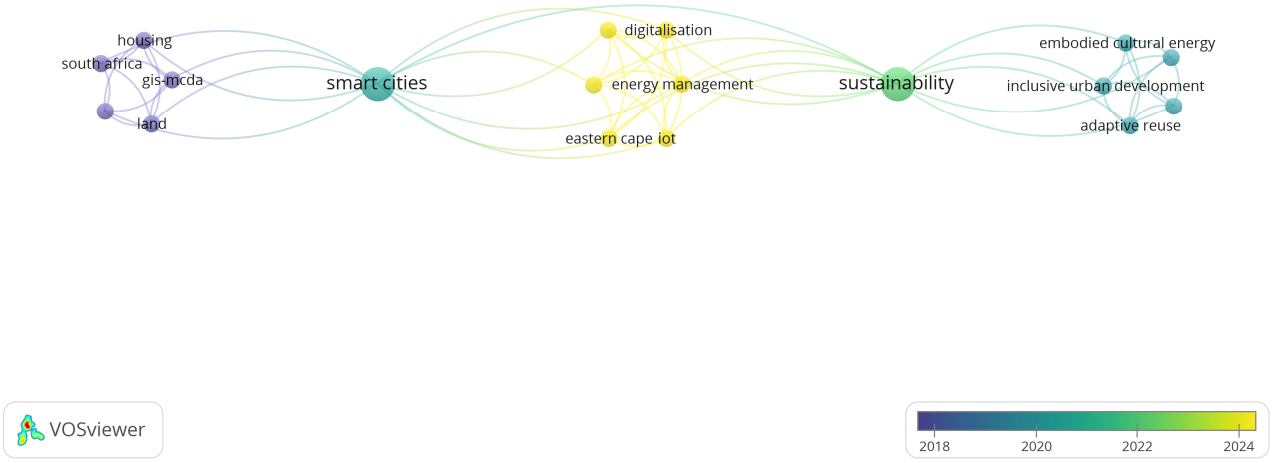

Figure 2: Keyword co-occurrence overlay visualisation

The above figure 2 highlights the publication themes that were most trending from the year 2018 to the year 2024. Consequently, this indicates that studies on smart cities, sustainability and technological innovations in urban and regional planning experience boost from late 2019 to 2024 in South Africa. However, there are very few studies conducted related to this study which highlights that there is more research that could be

done in this area. As seen on the above keyword co-occurrence overlay visualisation, there are few keywords that are creating a network of authors keywords, indicating that this research area in South Africa has not been explored sufficiently to assist provide positive impact using this approach in urban planning. During 2018, studies conducted related to the study focused on deployment of technology such as gis multi-criteria decision analysis to identify suitable locations for development of smart cities, suitable land for housing in South Africa. In 2020 to 2022, more studies were conducted on smart cities and sustainability. Accordingly, in 2023 to 2024, more studies were conducted on digitalization, internet of things, energy management, and sustainability.

4 APPROACH AND METHODOLOGY

The study deployed a case study research design were the City of Johannesburg was selected to explore how the 4ir technologies can influence urban planning. Accordingly, a qualitative approach is followed were variouss publications are examined related to the study through the use of biblometric mapping of literature. The use of biblometric mapping of literature assist to identify common research areas related to smart cities, urban planning, artificial intelligence, big data, digital mapping, Johannesburg and South Africa, and this allow the study to identify a literature gab. 12 publications were downloaded on scopus which included 4 conference papers, 6 journal articles and 2 book chapters. The keywords selected were urban planning, smart cities, and South Africa. Only three keywords were used to ensure that the study obtain most suitable publications and also if more keywords are added no publication is obtained. Which this indicates that there is a gab on studies conducted that include urban planning, 4IR, artificial intelligence, big data, smart cities, digital transformation, Johannesburg, and South Africa. Therefore, there is a need of more studies conducted to assist developing South African cities using advancement of technology which could assist producing smart cities where South African cities can go where they have never been.

During the data cleaning process, the abstracts of all publications generated were examined and all the publications were relevant to the study. Selected publications were exported to a excel sheet csv document to provide a suitable file that VOSviewer allow for biblometric mapping of literature. Accordingly, the excel sheet was inserted in the VOSviewer to start the process of biblometric mapping of literature. Accordingly, the type of analysis chosen is co-occurrence and the unit of analysis selected are authors keywords. Consequently, the threshold chosen is based on the number of occurrences of a keyword should appear which was once. 40 keywords were generated, and when the threshold was selected, 40 keywords meet the threshold. when the number of co-occerences were reduced to two, only three keywords meet the threshold which this will lead to poor network analysis produced. Therefore, the results produced figure 1 representing keyword of co-occurrence network visualisation and figure 2 representing keyword co-occurrence overlay visualisation.

5 RESULTS AND DISCUSSIONS

This section provides the results and analysis on the influences of 4ir technologies in urban planning, and how these technology could enhance the City of Johannesburg. There are various technologies that are developed in the City of Johannesburg to address urban challenges, development, governance, city operations and service delivery. Building information modelling are deployed for risk management. The technologies referred here include BIM, automatic rule checking, knowledge based systems, reactive and proactive safety systems based on information technology. There is a distinct difference between reactive and proactive safety systems for risk management. Forsythe (2014) and Teizer et al. (2010) pointed out reactive systems using information technologies such as VR, 4D CAD, and GIS seldom use real-time data and need a post data collection processing effort for analysis, while in contrast proactive technologies can collect and analyse real-time data, and provide real-time warning and immediate feedback to construction site about dangers in time. It has been found that BIM, on one hand, can be used as a systematic risk management tool in the development process and, on the other hand, can perform as a core data generator and platform to allow other BIM-related tools for further risk analysis, where most of these technologies can be used interactively in related investigations (Zou et al., 2017). The municipality of johanesburg use technology such as GIS for mapping to identifying suitable sites for development and identifying areas that need the provision of service delivery.

Accordingly, Big Data is the term being used to describe a wide spectrum of observational or "naturally-occurring" data generated through transactional, operational, planning and social activities.The major potential of big data applications is in four areas: (1) improved strategies for dynamic urban resource management, (2) theoretical insights and knowledge discovery of urban patterns and processes, (3) strategies for urban engagement and civic participation, and (4) innovations in urban management, and planning and policy analysis (Thakuriah et al., 2017). The city deploys such technology to collect real-time information to provide quality of services to the citizens. Prior to this era which we can loosely call the age of the smart city (Batty, 2020), describes that computers were mainly used to support plan-making functions, although data and information had become central to the operation of the routine planning system as well. This is best seen in planning skills which in the year 2000 were still organised around spatial representation through GIS and CAD, forecasting models from transportation to housing, the development of web pages to communicate ideas that might be organised digitally such as database access and the development of a national infrastructure for the archiving and transmission of data (Batty, 2021).

The IoT is considered the next large prospect for the world of the Internet, as it has come out of its early stages and is entering into the era of revolutionizing the traditional network infrastructure into a fully integrated future with the internet. Thus, this leads us to the concept of smart homes where different electronic appliances are interconnected with each other and achieve high-quality two-way interactive multimedia services. In such a system where a large number of devices are communicating with each other, a massive volume of data (called Big Data) is generated. To enrich smart home technology, the better analytics of Big Data could play a vital role in the advancement of Information and Communications Technologies (ICTs). This type of Big Data analysis provides a better understanding and useful information about the future as well as about planning and development, thus providing us insight into Big Data. This type of technology is used to enable a large variety of security as well as monitoring applications, and for urbanization, it is of utmost importance to comprehend the demand for service profiling to enhance efficiency and may advance city management (Rathore et al., 2016).

Smart city is a concept that encapsulates various technological innovation concepts into a single architecture (Alvi et al., 2016; Silva et al., 2018). The key concept of the smart city is to obtain the right information at the right place and on the right device to make a city-related decision with ease and to aid citizens more quickly (Rathore et al., 2016). According to Manville et al.(2014;7) 'it is in this context that smart cities emerge not just as an innovative modus operandi for future urban living, but as a key strategy to tackle poverty and inequality, unemployment and energy management'. Many cities around the world adopted smart urban technologies with an aim to become a smart city, maintain a scientific-technologic position of excellence via ensuring and expanding economic competitiveness to transforming and modernising their societies and cities, and sustain their growth and development. Examples of some the smart city initiated concepts; the Amsterdam Smart City initiative formed a collaboration between the citizens, government and businesses to develop smart projects to make a change by energy saving, which a concept more or less like this is initiated in CoJ as more solar power energy devopemnts are created such as solar power street light and more houses and companies generate electricity from solar power; the Southampton City Council utilised smart cards to stress the importance of integrated e-services, which this is similar to some of the CoJ city services of having one e-smart card for different purposes; the City of Edinburgh Council formed a smart city vision around an action plan for government transformation; the Malta Smart City formed a strategy to promote a smart business park as a way to leverage economic growth (Yigitcanlar, 2015), a similar strategy is implemented in Johannesburg were various city parks are provided with free WiFi for residents to use for various purposes such as work and entertainment.

Figure 3 indicates a concept of a technology driven City of Johannesburg supported by the 4ir technological innovations which can lead to a functional smart city. This demonstrate that 4IR technologies such as artificial intelligence, internet of things, big data, digital transformation can allow the provision of massive amount of data to provide efficient suitable response to urbanisation challenges and services delivery. Accordingly, optimization of land use zoning for areas across the city to function efficiently and sustainable. Consequently, more advance technologies could be integrated with the use of GIS to identify suitable locations that can provide affordable housing for the city residents and combat the challenge of the increasing informal settlements and optimize infrastructure planning ensuring that the city is resilient to natural disasters.

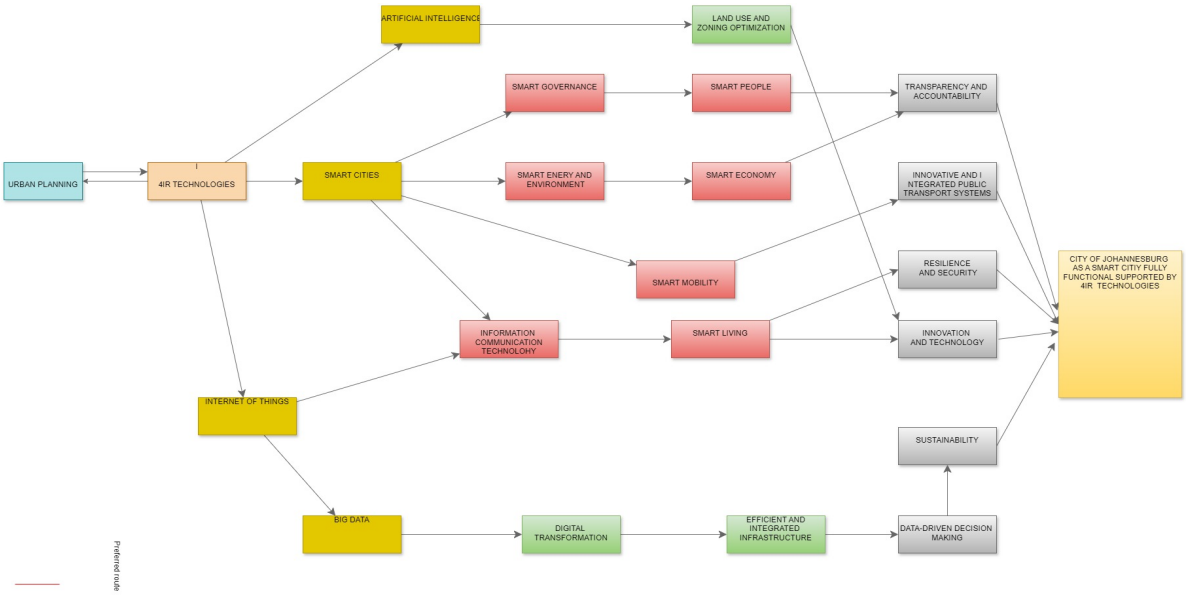

Figure 3: Concept of technology driven City of Johannesburg

Further, these technologies could assist with the vision of the city to become a world class city and becoming a smart city. This would include smart governance which will change governance and coordination processes as well as planning processes with public participation leading to transparency and accountability, smart people and smart economy were people are compatible with technology and assist in the development of the economy eradicating the levels of poverty. Accordingly, smart mobility were various innovative public transport systems such as Gautrain and bus rapid transit system (Rea Vaya system) and other modes could be integrated to ensure effective and reliable public transport systems, smart living ensuring that there is safe and security in all the neighbourhoods and 24hrs policing response services across the city. Consequently, smart energy and the environment were there could be provision of effcient solar-energy as the country is struggle with power provision and more technologies that could monitor the environment to provide in-time alert to communities and areas that are prone to disasters before hand.

In addition, innovative technologies afford opportunities for data-driven cities which is generated from various technologies that could assist with spatial transformation as informed decisions are taken and this is very important in Johannesburg neighbourhoods to transpire as there is spatial injustice and would create sustainability. All this can help transform the city and be resilience creating City of Johannesburg to be a functional smart city. However, the challenge of reaching this point lies in the tools and resources in the city and the policies and legislative frameworks to support this approach.

6 CONCLUSION

The City of Johannesburg is a transitional city working towards being a developed world class city. There are various types of infrastructure developed making the city functional, and with 4ir technological innovations being integrated towards enhancing the city. Enhancing the city towards being a smart city, there is a need of ensuring that the technological innovations that are deployed are functional and utilized by both the service providers and city residents. These various technologies such as internet of things, artificial intelligence, big data analytics, geographic information systems, smart infrastructure and digital twins, autonomous vehicles and smart transportation, renewable energy and smart grids, digital platforms for citizens engagement, automation, and virtual reality and augemented reality are suitable in urban planning which could enhance the city's functionality making the City of Johannesburg to go where no cities have gone before. Technological integration is critical in urban innovation to provide solutions that traditional urban planning systems struggle to provide. Lastly, technology could transform the city to be more data driven making it effective, efficient, functional , sustainable and provide a quality of life for the residents.

DOI: 10.48494/REALCORP2025.7070

1 ABSTRACT

The enduring legacy of spatial apartheid continues to shape the lived experiences of many South Africans, particularly in urban areas. Historical injustices have resulted in fragmented spatial configurations that exacerbate socio-economic inequalities. Galeshewe Township in Kimberley, Northern Cape province, South Africa, serves as a case study of a community grappling with these challenges. This study aims to investigate the socio-spatial injustices and inequalities experienced by Galeshewe residents. The research is motivated by the significant and ongoing impact of these issues on the community, as well as the dearth of scholarly research addressing this topic within the South African context. Ten key socio-economic factors were identified for analysis: income disparity, rural-urban divide, educational attainment, health outcomes, public service access, land tenure security, poverty, employment patterns, and spatial freedom. A qualitative research methodology, employing semi-structured interviews and a qualitative survey, was utilized to collect data. The sample comprised fifteen residents of Galeshewe and five professional planners. Purposive sampling and snowball sampling techniques were employed to select participants from the township. Thematic analysis was used to analyze the collected data. The findings revealed that the unequal distribution of societal benefits significantly contributes to economic deprivation and limited access to essential services. Based on these results, the study concludes by advocating for social cohesion, inclusivity, and equitable planning practices. This research contributes to the field of urban planning by highlighting the enduring impacts of historical injustices and the need for more equitable and socially just urban development.

2 INTRODUCTION AND BACKGROUND

Globally, stark disparities between different places and social groups characterize socio-spatial injustice and inequality (Brenner & Theodore, 2020). Wealthy areas boast well-maintained infrastructure, access to quality services, and green spaces, while marginalized communities often face overcrowded housing, limited sanitation, environmental hazards, and a lack of basic amenities (UN-Habitat, 2020). The African continent presents a particularly acute example of how these global trends intersect with specific regional challenges. Furthermore, the legacy of colonial land dispossession and racial segregation continues to shape spatial inequalities, with certain groups having limited access to prime land and opportunities (Watson, 2022). In South Africa, these inequalities are deeply intertwined with the nation's colonial and apartheid history. Discriminatory policies and practices systematically disadvantaged Black South Africans, resulting in a significant racial wealth gap that persists to this day (Wolff et al., 2018).

Townships, established under apartheid to segregate the Black population, often lack basic infrastructure, quality education facilities, and access to reliable transportation (Ballard & Desai, 2009). Conversely, wealthier suburbs, historically reserved for white residents, benefit from proximity to jobs, green spaces, and well-maintained public services (McDonald, 2021). This uneven distribution of resources perpetuates a cycle of disadvantage in marginalized communities, reinforcing social segregation and limiting opportunities for social mobility. Discontent and social unrest often arise in response to these inequalities, as residents struggle with inadequate healthcare, limited access to resources, and a lack of political representation (Satterthwaite, 2017). The ongoing challenge of spatial inequality is further amplified by the rise of gated communities within South African cities (Wu et al., 2020). These enclaves of privilege, often located in previously white suburbs, offer residents access to high-quality amenities and security. However, their exclusivity reinforces social segregation and limits opportunities for interaction and integration between different socio-economic groups. The latest data from Statistics South Africa (Stats SA) in 2024 indicated that the gini coefficient in South Africa remained high at 0.63 points in 2024, highlighting the persistent challenge of income inequality that spatial planning efforts must address.

The Spatial Planning and Land Use Management Act (SPLUMA) of 2013 marked a significant step towards redressing spatial inequalities in South Africa. Recognizing the enduring legacy of apartheid's discriminatory spatial planning, SPLUMA aimed to create a more inclusive and equitable urban landscape. As a means of restoring the unjust spatial configuration of the apartheid era, SPLUMA's distinguished principle of spatial justice, seeks to address the past spatial imbalances such as, improving access to land and the use thereof. However, SPLUMA's implementation faces significant challenges rooted in the enduring spatial form of apartheid South Africa. The fragmented ownership patterns within townships, with a mix of formal and informal settlements (Govender, 2016), pose a complex obstacle to integrated planning and development. While there are policies, plans and frameworks developed to address such imbalances, the greatest challege remains to be the implementation of the respective tools. The main objective of the study is to identify the causes and forms of socio-spatial injustice and inequality within the Galeshewe township, while exploring the perceptions of the residents on the socio-spatial injustice and inequality embedded in their daily lives, as well as identifying any gaps and limitations within the exisiting policies and frameworks in addressing the specific needs of the Galeshewe residents.

3 LITERATURE REVIEW

3.1 Conceptualizing socio-spatial injustice and inequality

This section lays the groundwork for understanding socio-spatial justice and inequality by establishing clear definitions of the key concepts that underpin the research. A precise grasp of these terminologies is crucial for effectively analyzing the lived experiences of residents in Galeshewe and the challenges they face. In order to get a meaningful insight on what the study focuses on, the key concepts pertaining this study are explained here below.

3.1.1 Socio-Economic Inequality

The concept of socio-economic inequality touches upon many factors which essentially covers the social disparities and inequalities to a greater extent. Socio-economic inequality denotes a state where there is unequal distribution of resources, services, opportunities, and social classes within a specific geographical space. This means that certain areas are provided with better access to social and economic opportunities than others. Furthermore, the concept of socio-economic inequality considers a number of factors ranging from education, health, income, and services disparities; therefore, presenting an economic and political challenge of many developed and developing countries.

3.1.2 Spatial Disparities

The concept of spatial justice has been discussed extensively by scholars since the coining of the two theories being, Lefebvre's Right to the City as well as Harvey's Social Justice and the City (Garnica-Monroy & Alvanides, 2019). It does not only refer to the unfair and unjust access of physical space, but also considers the change in which the quality of life of individuals in different geographical locations of the city should be pursued. Furthermore, spatial disparities concept does not anchor its focus on spatial patterns only, which shape the horizons of urban lives, but mobility, housing, and infrastructure quality (Bhan & Jana, 2015). The concept is further associated with the spatial distribution of resources and economic opportunities in urban centres or cities. Greenberg (2016) emphasized that spatial disparities are rooted on the notion of "who gets what and where". This refers to the limited resources availed to the community in accessing their essential services.

3.1.3 Socio-spatial Justice

Socio-spatial justice is understood as the equitable distribution of social resources in a given geographical space. This concept considers the involvement of equity, participation, and accessibility of societal resources over space. However, Cassiers & Kesteloot (2012), argue that there is a possibility of creating a socially unequal city without spatial inequality. Spatial justice lays ground for social justice. When thinking about space, we should remember that the society shapes the space in which they live. It is imperative to emphasize that when deliberating on the concept of socio-spatial justice, we need to understand how space is structured socio-economically, and that socio-spatial justice is derived from the spatial arrangement of economic activities (Han, 2022).

3.2 South Africa: The legacy of apartheid and spatial justice

The apartheid government of the Republic of South Africa passed pieces of legislation which were used as legislative tools to enforce the segregation of various races to specific areas within the urban spaces. It was during this era that South Africa was racially segregated; leading to the enactment and enforcement of a series of laws, which institutionalized white supremacy. The apartheid era in South Africa, which was controlled by the white ruled government, continued as an institutionalized policy in effect from 1948 to 1994. It was in 1948 after the National Party won elections and occupied the office. The racial segregation of people was legally governed by the Popular Registration Act 30 of 1950, and the Group Areas Act 40 of 1950 (Davies, 1981). The Population Registration Act of 1950 classified South African racial groups into 4, being the Whites, Blacks, Coloureds and Asians. The allocation of space and land was racially dependent which resulted in what was known as the apartheid city (See Fig.1).

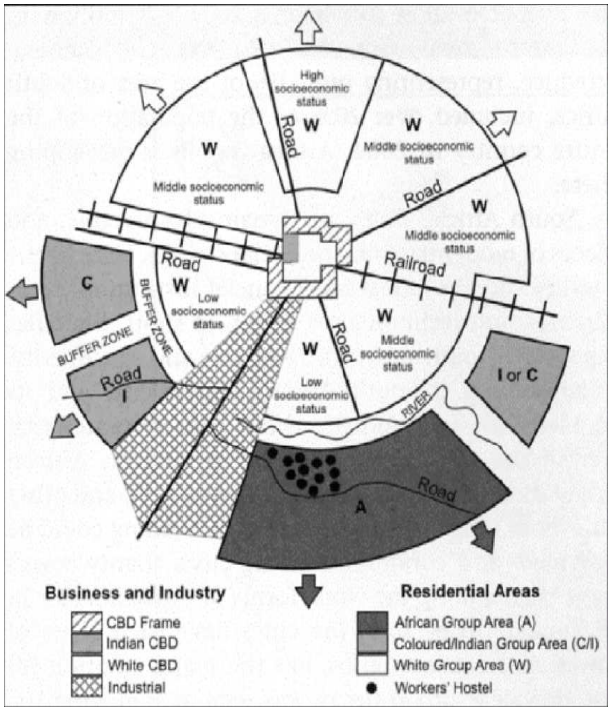

Fig. 1: Apartheid City Model. Source Davies (1981:69)

Through the regulations of this Act, (Population Registration Act, 1950), separation of residence, public facilities and transportation systems, labour market, education and health systems, were strictly enforced. The model (Fig 1) illustrates how the White dominated areas were located in a very close proximity to the central business district frame, whilst the African Blacks, Indians and Coloureds were placed on the outskirts of urban areas. The apartheid city model was contrary to the social justice theory coined by Henri Lefebvre in 1968. Lefebvre emphasized the effects that capitalism had on social collaborations contributing to the rise of spatial inequalities throughout cities across the world. Such effects led to a point where urban life became a commodity. Lefebvre called for man (citizens) to save the city which he had built and make a city an accessible meeting point for all; not an exclusive good.

Lefebvre's slogan was realized by social movements as the cities around the world saw a rise in the struggle for social justice and distinguished access to urban life. In support of Lefebvre's slogan about inhabitants having the right to the city, a British Geographer, David Harvey; emphasized that the right to the city is a collective right to have an all-inclusive participative democratic society, whereby the inhabitants have the power to be decisive in terms of the conditions that benefit and affect their livelihoods.

The right to a clean, healthy, safe and sustainable environment without excluding quality health is also a right to the city. The city inhabitants are also entitled to a safe and sound neighbourhood without any fear. Additionally, the right to the city should allow equitable access to housing, health facilities, education, and economic opportunities to citizens.

3.3 The context of Galeshewe Township

In 1871 a township called Galeshewe was established, which was named after the baTlhaping Chief, Kgosi Galeshewe. The township was inhabited by the black people who were mine workers. The areas surrounding the city were segregated based on skin colour where, the black people were meant to reside in Galeshewe; whilst the coloured people resided in Greenpoint, an area located outside of the city centre. Areas beyond the city centre were not serviced, only the white dominated areas received adequate municipal services. Following the opening of the mine, a large compound known as "The Greater No. 2" was established, located closer to the mine open pits which accommodated the black people employed as mine workers as they needed to reside closer to their workplace. After a while, the Greater No. 2 area expanded due to the high influx of people from various places seeking job opportunities (Sol Plaatje Integrated Development Plan, 2022). Furthermore, there was a law practice firm along the main street of Greater No. 2 known as Royal Street that was owned and managed by the first president of the Pan African Congress (PAC), Mr. Robert Sobukwe. It was during the apartheid period that the Greater No. 2 area became popularly known for many protests against the then system. The area therefore became known as the most violent part of Galeshewe.

On 8th November 1952, there were campaigns led by political and social activists raising their voices for poor housing, lighting, and public transport as well as "unfulfilled promises". These campaigns and uprisings led to the riots that transpired then. The city has considerable history due to its diamond mining activities in the past and the siege during the Second Boer War.

Post-apartheid, the Kimberley City Council was then renamed to Sol Plaatje Local Municipality, named after a prominent writer and activist who spent much of his life in Kimberley. Additionally, the District City Council which was then known as Diamantveld District Council was also renamed to Frances Baard District Municipality. The district municipality was accordingly renamed after a trade unionist, Frances Baard who was a resident of a 'coloured area' Greenpoint. The segregation of land based on race took effect pre-apartheid and led to the current spatial configuration present. Evidently, the community of Galeshewe are to date still experiencing the aftermath of apartheid regime socio-spatial imbalances. These imbalances are characterized by poor service delivery challenges, social and economic exclusion as well as spatial marginalization.

4 METHODOLOGY

This research forms part of the Masters study concerning the experiences of socio-spatial injustice and inequality within the residents of Galeshewe Township in Kimberley. This study adopts a qualitative research approach to understand the experiences of socio-spatial injustice and inequality within the community of Galeshewe township. A qualitative research approach is described as a holistic approach and an unfolding model applied to understand an experience of a phenomenon in a more natural way (Williams, 2007). Moreover, qualitative research approach can be understood as a model occurring in a more natural set-up, enabling the researcher to establish a detailed level of involvement in the actual experience (Khan, 2014). This study is designed as a case study. A case study research design considers an in-depth examination of a case, people or a group of people. When using this design, the researcher searches for themes and patterns. A case study research design assists the researcher to concentrate on keeping the focus of their research within the confines of space and time. Creswell et.al (2007) asserted that case studies focus predominantly on a specific case selected to understand the issues thereof.

Case study design is best suited for this study because it explores an understanding to a greater length of complexities of issues in the real-life context. The study employed semi-structured interviews and qualitative survey methods which allowed the researcher to gain deeper understanding of the experiences of the Galeshewe community. Fifteen community members, four professional town planners and one ward councillour formed part of this study during the data collection process. The study was sampled through purposive and snowball sampling techniques. Lastly, the results of this study were analyzed through the thematic analysis process.

5 FINDINGS AND DISCUSSION

This section of the study outlines findings and discussins to shape the data collection and analysis through the development of themes and subthemes. The presented findings emerged from the data collection process and was analyzed in order to guide the researcher in finding answers to the research questions of the study.

5.1 Identifying the causes and forms of socio-spatial injustice and inequality in Galeshewe

The apartheid era reflected the racial imbalances through spatial configuration. According to Tutu (2005), apartheid was a policy of exclusion. Racializing land significantly drew a line between the blacks and the whites in South Africa, and legalizing it through the Natives Land Act of 1913, took land tenure even a step further (Ramutsindela, 2012). The historical legacy of discriminatory land policies, such as the Natives Land Act of 1913 and the Group Areas Act of 1950, continues to shape the spatial and social realities of Galeshewe. These policies resulted in forced removals, spatial segregation, and restricted access to land and resources for Black South Africans. The spatial legacy of these policies is evident in the fragmented and marginalized location of Galeshewe. Participants in this study highlighted the ongoing impact of these historical injustices, emphasizing the unfair distribution of land and resources. One participant noted that "there is no fairness for as long as the township is known as an area for the previously disadvantaged." Another participant expressed their frustration with the discriminatory policies of the past, stating "the apartheid era was so discriminatory, and laws were suppressing us. We were forced to stay in townships yet work for the whites who were staying in urban suburbs. I really felt oppressed for the longest time, and here I am, still in the township." These firsthand accounts underscore the enduring impact of historical land policies on the spatial and social fabric of Galeshewe. This aligns with what Kloppers & Pienaar (2014) said when they outlined their perspective on the historical context of land reform in South Africa that: “the effect of this racially based segregation legislation was to force black people to be ‘perpetual tenants’ with very limited rights.” What Kloppers & Pienaar (2014) alluded links with the study through the identification of forms and causes of injustice and inequality where the legalized apartheid laws discussed in this study enforced strict racial segregation. Such pieces of legislation institutionalized racial discrimination, causing severe economic, social, and psychological harm to Black Africans. Considering land as a critical matter in the broader South African context, upon attainment of democracy in 1994, the government of South established policies and programmes which aimed at addressing the land issue. For the community of Galeshewe, attempting to purchase land is almost impossible because either “there is no land available” or it’s exorbitantly priced.

Evidently, the demand for land is currently high as citizens, particularly the under privileged and previously disadvantaged blacks want ownership of land in urban and sub-urban areas, closer to economic opportunities, hence the rapid urbanization leading to the mushrooming of informal settlements and illegal land invasion in and around urban areas. Mather (2002) argued that despite the passing of numerous legislations and policies aimed to redress the inequalities brought by the apartheid legacy, the success of overcoming such legacy is very limited. Although the government employed the ‘land reform programme’ after attainment of democracy in 1994, with the aim of addressing the past racial inequalities and social injustices, land will remain a greater challenge in South Africa. Zantsi & Greyling (2021) asserts that land reform is quite complex as it has social justice and equity features with which it encompasses. Land reform is made up of 3 pillars known as the land restitution, land redistribution and land tenure, and is considered a step in the right direction towards responding to land issues and claims. This aligns with a statement made by Hall (2004) that:

“Land reform was conceived as a means by which the South African state would provide redress for past injustice and promote development. It would pursue these twin goals by restoring land rights to those dispossessed by segregation and apartheid through a land restitution programme, securing and upgrading the rights of those with insecure rights to land through a land tenure reform programme, and changing the racially skewed land ownership patterns through a land redistribution programme.”

In support of the statement made by Hall (2004), the land reform programme has made strides toward addressing the legacy of apartheid but has also faced significant challenges that have perpetuated or even exacerbated socio-spatial inequality. Despite the land reform programme being designed to address these historic spatial inequalities, its slow pace, insufficient support for new landowners, and continued concentration of wealth and land in urban and commercial sectors have meant that spatial inequalities remain entrenched. For land reform to effectively reduce socio-spatial inequality, it will need to address not only

land redistribution but also broader issues of infrastructure, economic opportunities, and support for small-scale farmers, while ensuring that the benefits of land reform reach all South Africans, particularly those in rural and historically marginalized areas.

During the data collection process, one participant expressed their view on access to and security of land post 1994 when they said "we are in the democratic country right now, but the issue of land is still a topic for continuous discussion in government. It seems like the process of land will not happen in the near future because, the people leading the process also want a piece of land to themselves, and there's also political instability and corruption which generally affect the whole process." On the other hand, another participant indicated that "I believe that our government had good initiatives, policies and programmes in place which were meant to redress our challenges from the apartheid times. However, the problem became the implementation part, where the goals and objectives of such programmes were not achieved over the prescribed period, therefore delaying the whole process."

In addition to the land issue, municpal service delivery was identified as a key challenge for the community. They further emphasized that local government sector is the closest sphere of government to them; and should make services accessible to them easily; however, the respective sector still fails to render its services to the local community as mandated by the Constitution of the Republic of South Africa. In terms of Section 152 of the Constitution, the object of local government sphere is to render a provision of services to the communities in a sustainable manner and promote a social and economic development. The frustrations of the community was recorded where they highlighted that "we are just paying for services, but we struggle to get our value for money. If it's not water cut due to a burst pipe somewhere around the township almost every day, then it's electrical cable that are stolen or damaged." Another participant indicated that "poor service delivery has become a norm to us. If it's not water, then it's electricity or sewerage flowing down the streets." The dissatisfactions raised by the participants align with what was highlighted by Zondi & Nzimakwe (2017) when they indicated that:

"Municipalities are legally obliged to deliver services such as water and sanitation, and to involve communities in the formulation of developmental priorities. However, low levels of public satisfaction with government performance indicate that citizens are increasingly discontented with the state of local government."

In support of the statement made by Zondi & Nzimakwe (2017), the dissatisfaction with municipal service delivery in Galeshewe reflects deep-rooted issues such as inequality, corruption, poor governance, and resource mismanagement. Addressing these concerns requires a multifaceted approach that includes better planning, transparent governance, improved accountability, effective use of public funds, and stronger community engagement.

5.2 The perceptions of Galeshewe residents on socio-spatial injustice and inequality embedded in their daily lives

The economic growth of Kimberley as a financial hub has been gradually declining over the years. The town that is situated along the N12 treasure route has its economy largely concentrated on the tertiary sectors. The rise of economic difficulties put many businesses under pressure, therefore forcing the closure of some businesses, resulting in poorer economic growth and higher unemployment rate. The continued decline of business in private sector, exerts more pressure on the public sector to establish some employment opportunities. In terms of employment and income, it is mostly the dwellers of urban areas that are employed and can afford to properly sustain their livelihoods. Nonetheless, there are township residents who are employed, but the percentage is quite minimal; therefore, pressuring the dependency ratio. The inhabitants of the township are mostly unemployed, or discouraged job seekers, or even economically inactive. In essence, a society cannot not develop if they are not economically active.

While Kimberley remains the capital and economic hub of the Northern Cape, economic activities are drawn central to the city centre respectively and further disseminated to the eastern part (white dominated areas) of the town. The participants outlined their economic challenges when they said: "I have been unemployed for than 6 years now. I am a single mother of 2, residing in this shanty with my kids. I used to work on a contract job, and it ended in 2019, I have since been struggling to make ends meets. I had to resort to a being street vendor so that I can put food on the table." Another participant indicated that "unemployment is a serious problem that we especially the youth are faced with. We are advised to go to school, study and obtain

qualification to fit with the corporate market. However, once you're qualified, then the reality of unemployment kicks in. It is an overwhelming reality, but I remain positive and hopeful for a better outcome." According to the Sol Plaatje Integrated Development Plan (2022), the implications for the municipality as brought forth by the income gaps adversely affects the disposable income of households, exacerbating social unrest and crime. Furthermore, the purchasing power gets eroded, and the dependency of government grants increases. The participants of this study within the Galeshewe community are of the view that they are economically and socially excluded. Factors such as limited access to improved education quality other social services and facilities contribute to the socio-economic exclusion of such community.

5.3 Gaps and limitations within the existing policies and frameworks in addressing the needs of Galeshewe

Several policies and programmes established years ago post 1994, aimed at remedying the past spatial planning system that burdens the current planning system. It started in 1994 post attainment of democracy and the greatest predicament still presented to this day is lack of implementation of established policies. The most recent piece of legislation being Spatial Planning and Land Use Management Act, 2013 (SPLUMA) is tasked with guiding land use and land development across SA. The underlying problems from the past spatial planning leave a big challenge for SPLUMA and it will take a longer period to attain spatial justice as advocated for by the said Act respectively. The professional planners across sectors departments attest to the fact that yes, policies are in developed, but the non-implementation leads to the said policies not being effective. Despite all the policies, plans, acts and programmes; Galeshewe is still faced with socio-spatial inequality and injustice.

The one participant shared their opinion when they said: "yes, SPLUMA can redress past spatial imbalances if Urban Planners are given the space to lead the spatial transformation agenda in organizations without any hinderance (e.g. political interference). However, common in local government level, the challenge remains whereby there is no political-will and lack of departmental budget to support initiatives from the Urban Planning Section which seeks to fast-track spatial transformation in line with the SPLUMA Principles." Another participant highlighted that "socio-spatial injustice and inequality are practical in Kimberley. There are only two malls (North Cape Mall & Diamond Pavilion Mall) which are situated in areas previously classified for the minority population. Therefore, one proposal is for the local authority to stimulate investment by creating an enabling environment where private sector can develop malls with similar magnitude to the existing two malls in areas such as Galeshewe, Roodepan, Colville. This could stimulate social and economic spin-offs such as job creation, decrease unemployment, reduce travel time and spending on transportation for the poor and redress the current spatial inequalities experienced in areas classified as previously disadvantaged (i.e. coloured and black communities)".

The government must, especially at the municipal sphere ensure that there is suitable and sufficient capacity to implement the programmes and plans. Considering that land as source is central to development; the redistribution process by government should not only focus on peripheral areas; but should also in the urban areas so as to promote inclusivity and spatial reconciliation. One of the participants touched on the issue of prime land still being under the control of the elite when they said "land redistribution needs to be prioritized firstly to the previously marginalized. The reality on the ground is that the minority or elite still control the prime development land. Additionally, the rapid release of land is often in unserviced and inaccessible location. What then is the role of the private sector in ensuring spatial justice?"

6 CONCLUSION

The study has outlined how the spatial configuration of Galeshewe was formed as a result of racial segregation which transpired during the apartheid era. The concepts of spatial injustice and socio-economic inequalities have been in existence for decades, and in the context of South Africa, such injustices were legislated during the apartheid era. The study revealed that Galeshewe in still confronted with socio-spatial injustice and inequality despite the formulation of programmes and plans aimed at addressing socio-spatial imbalances. It is important to emphasize that although spatial justice may be understood as the form of equity in spatial distribution and allocation, it also encapsulates factors such as transportation, health, education and employment issues, which form a larger part of the socio-economic and spatial imbalances.

The study outlined the lived experiences and perceptions of the Galeshewe community in respect of socio-spatial inequalities and injustices and has discovered some common ground factors which are evidently affecting their lives. Legislative and policy framework non-implementation have been noted to be the catalyst in delayed development and poor service delivery. Therefore, it can be concluded that socio-spatial inequality and injustice in disadvantaged, impoverished communities will continue to occur because the strategic tools established to address such challenges are not effectively implemented.

DOI: 10.48494/REALCORP2025.8125

1 ABSTRACT

Urban heat islands are a spatial phenomenon characterized by increased temperatures in urban areas compared to their suburban and rural surroundings, driven by spatial patterns of built-up areas, land use, and land cover, as well as the absence of vegetation and variations in land surface temperature (LST). This study examines the relationship between built-up intensity, planned land use, and LST in the City of Zagreb, focusing on its core urban area. Utilizing Landsat-9 satellite data for LST extraction and urban spatial planning documents for vegetation classification, the study explores key spatial factors influencing the intensity and spatial distribution of urban heat islands. The methodological approach integrates Exploratory Spatial Data Analysis (ESDA), regression models, and spatial autocorrelation to determine the spatial dependencies between land use and temperature variation, conducted using the R programming language. The analysis identifies specific areas where built-up land use categories contribute most to temperature increases, while planned green zones have a significant cooling effect. Spatial regression highlights the varying impact of different planned land-use categories on local thermal conditions, particularly the role of designated green areas in mitigating urban heat accumulation. Spatial autocorrelation techniques confirm the presence of clustering effects in heat island distribution, emphasizing the spatial dependency of UHI formation. These results emphasize the need for an integrated urban planning approach to mitigate the negative effects of urban heat islands and improve the quality of life.

Keywords: Urban Heat Islands, Zagreb, R, Spatial Analysis, Land Use

2 INTRODUCTION

The Urban Heat Island (UHI) phenomenon, characterized by increased temperatures in urban areas compared to their rural counterparts, is a major issue in urban climate research. This temperature disparity arises due to a combination of factors, including land-use changes, impervious surface expansion, anthropogenic heat emissions, and reduced vegetation cover. As urbanization intensifies, cities across the world are experiencing heightened UHI effects, which pose significant environmental challenge thus making UHI mitigation an essential component of sustainable urban planning.

Recent advancements in remote sensing and geographic information systems (GIS) have provided valuable insights into the spatial and temporal distribution of UHI. Researchers have employed multi-temporal satellite analyses, thermal imaging, and statistical modeling to assess the impact of different land-use types on urban thermal environments. Studies on cities worldwide have consistently emphasized the role of vegetation in mitigating UHI effects, highlighting the importance of integrating green infrastructure into urban landscapes.

For Zagreb, the capital of Croatia, several studies have investigated the impact of urban expansion and land-use transitions on the city's thermal environment. This review synthesizes findings from recent research on UHI in Zagreb and other comparable cities, with a focus on land-use patterns, vegetation cover, remote sensing methodologies, and mitigation strategies.

3 LITERATURE REVIEW

Land use and urban morphology play a crucial role in influencing land surface temperature (LST) and the intensity of UHIs. The spatial distribution of built-up areas, green spaces, and water bodies significantly affects temperature variations. Research in Wuhan, China, revealed that industrial and commercial zones contribute extensively to elevated surface temperatures due to anthropogenic heat emissions (Lu et al., 2021). Similarly, a study in Izmir found that areas with high street network centrality exhibited intensified UHI effects, whereas increased street connectivity mitigated heat buildup (Erdem et al., 2021). Functional zones

such as commercial and industrial areas have been identified as UHI hotspots due to heat absorption by impervious surfaces and limited vegetation (Chen et al., 2022). Studies in European cities reinforce these findings. In Berlin, Germany, research demonstrated that densely built-up areas exhibit the highest temperatures, while green spaces provide cooling effects (Dugord et al., 2014). An assessment of urban temperature distributions across Europe found that industrial and commercial areas consistently exhibit higher LSTs than vegetated areas (Hellings & Rienow, 2021). In Seville, Spain, urban expansion and a reduction in agricultural land over 30 years have significantly increased LST (Halder et al., 2022). Nighttime UHI intensity has risen in Istanbul due to continuous urban expansion and reduced green cover (Ünal et al., 2020), while a study in Prishtina demonstrated a strong correlation between built-up intensity and increased surface temperatures (Isufi et al., 2021). Additionally, the growing urbanization of rapidly developing regions has exacerbated heat island effects, making mitigation efforts more urgent.

These findings underscore the strong relationship between urban development patterns and temperature variations, highlighting the need for effective mitigation strategies. One of the most effective approaches to counteracting the UHI effect is the integration of vegetation, which plays a crucial role in cooling urban environments.

Vegetation plays a crucial role in mitigating the UHI effect by providing shade, enhancing evapotranspiration, and reducing heat absorption. The correlation between the Normalized Difference Vegetation Index (NDVI) and LST has been widely studied, with consistent findings that higher vegetation cover results in lower temperatures (Guha & Govil, 2018). A study in Bochum, Germany, confirmed a strong negative correlation between LST and green volume, indicating that increasing urban greenery can effectively mitigate heat stress (Schmidt & Lawrence, 2022). Research in Andalusia, Spain, further supports these findings, emphasizing that urban planning strategies incorporating green spaces are essential for maintaining a balanced thermal environment (Hidalgo García & Díaz, 2023). Case studies in Naples and Florence found that UHIs predominantly formed in built-up and bare land areas, while regions with dense vegetation exhibited significantly lower temperatures (Guha et al., 2018). Similarly, research in Dubrovnik, Croatia, revealed a rising trend in maximum summer temperatures from 1961 to 2019, with urbanized surfaces heating up more than vegetated areas (Boras et al., 2022). The cooling effect of tree cover is further highlighted in studies conducted in Italy, where increased impervious surface density led to higher UHI intensity, while inland cities suffered more than coastal cities due to a lack of cooling from nearby water bodies (Morabito et al., 2020). The findings highlight the necessity for large-scale tree planting initiatives, green corridor development, and the protection of existing green infrastructure.

These studies collectively emphasize the critical role of vegetation in regulating urban temperatures, reinforcing the need for strategic urban planning focused on expanding green infrastructure. To accurately assess and monitor these thermal dynamics, remote sensing and GIS methodologies have emerged as essential tools, enabling researchers to analyze UHI patterns with greater precision and develop targeted mitigation strategies.

Remote sensing and GIS methodologies have become indispensable tools for analyzing UHI spatial patterns. The use of Landsat satellite imagery and geospatial indices like NDVI and the Normalized Difference Built-up Index (NDBI) enables researchers to quantify UHI intensity and identify mitigation strategies. A study in Hefei, China, used Landsat 8 OLI_TIRS data to explore how spatial scale impacts UHI intensity, finding that smaller spatial scales provide more precise insights into the urban thermal environment (Lin et al., 2024). The integration of spatial regression models, clustering techniques, and spatial autocorrelation has been effective in identifying heat island clusters and their driving factors (Erdem et al., 2021). European studies confirm the efficacy of remote sensing in UHI analysis. In Skopje, North Macedonia, Landsat 8 data revealed a strong negative correlation between NDVI and LST, reinforcing the cooling effect of vegetation, while built-up areas significantly intensified UHI (Kaplan et al., 2018). In Andalusia, Sentinel-3 satellite data demonstrated that daytime urban heat hotspots are primarily located in rural areas with minimal vegetation, whereas nighttime hotspots cluster in highly impervious urban zones (Hidalgo García & Arco Díaz, 2023). In Ahvaz, Iran, bare lands and built-up areas were directly correlated with UHI intensity (Amindin et al., 2021). The continued advancement of satellite-based analysis provides increasingly accurate assessments.

Addressing the UHI effect requires a multi-faceted approach, including increasing green spaces, implementing high-albedo surfaces, and enhancing urban ventilation. Studies show that increasing albedo

through reflective surfaces significantly reduces surface temperatures (Hidalgo García, 2023). The strategic placement of water bodies and green corridors enhances local microclimates and reduces urban heat stress. Urban planning policies should prioritize sustainable design principles, such as tree canopies, green roofs, and urban parks, to counteract UHI effects.

Research in Granada, Spain, emphasizes that increasing impervious surfaces has led to a significant rise in LST, highlighting the need for proactive land-use planning (Hidalgo-García & Arco-Díaz, 2022). Studies in various European cities indicate that UHI mitigation strategies must be tailored to local climatic and urban conditions, considering factors such as wind flow, surface permeability, and spatial planning frameworks (Hellings & Rienow, 2021). In Sivas, Turkey, urban expansion and the reduction of barren land contributed to rising LST over a 26-year period, with urbanized areas exhibiting the highest temperatures (Karakuş, 2019).

Urban green infrastructure (UGI) has been widely recognized as a key strategy for reducing urban temperatures. A study on European functional urban areas found that UGI can lower city temperatures by an average of 1.07°C, with tree cover playing a crucial role in microclimate regulation (Marando et al., 2022). The study recommended that at least 16% of urban land should be covered by trees to achieve effective temperature reduction. Green infrastructure investments not only mitigate temperature extremes but also contribute to improved air quality and public health outcomes (Chen et al., 2022). Additionally, the implementation of green roofs and vertical gardens has proven effective in high-density urban areas where open green space is limited.

Building upon these broader insights, the Urban Heat Island (UHI) effect in Zagreb, Croatia, reflects similar patterns observed in other urban environments, with land use changes, urban morphology, and anthropogenic activities playing a decisive role in temperature variations. As urbanization intensifies, the spatial and temporal characteristics of UHI in Zagreb have become increasingly evident, necessitating a deeper examination of its driving factors and mitigation strategies.

Long-term satellite-based monitoring has provided valuable insights into the distribution and intensity of UHI in Zagreb. Analysis of Landsat 8 imagery from 2013 to 2022 revealed that built-up areas consistently exhibited higher land surface temperatures (LST), whereas vegetated zones, particularly forested areas, maintained significantly lower thermal anomalies. These findings underscore the importance of green infrastructure in reducing urban heat stress and maintaining thermal balance within the city (Seletković et al., 2023). Further research using multi-temporal Landsat datasets has demonstrated a strong negative correlation between LST and vegetation indices such as the Normalized Difference Vegetation Index (NDVI), reinforcing the critical role of urban greenery in mitigating heat accumulation (Krtalić et al., 2020).

Urban morphology has also proven to be a key determinant of UHI intensity in Zagreb. A temporal analysis spanning from 1984 to 2014 highlighted that densely built-up areas – including the city center and industrial districts – experience the most pronounced temperature increases. In contrast, areas with higher vegetation cover, such as parks and tree-lined streets, demonstrate a measurable cooling effect, aligning with global findings on the role of green spaces in urban heat mitigation (Krsnik, 2024). Additionally, research assessing spatial heterogeneity in UHI patterns has identified commercial hubs and transportation corridors as persistent heat hotspots, primarily due to their high concentration of impervious surfaces and anthropogenic heat emissions (Krtalić et al., 2020).

Beyond the influence of land use, remote sensing methodologies have been instrumental in evaluating Zagreb's thermal environment and identifying vulnerable areas. The Environmental Criticality Index (ECI), derived from satellite thermal data, has pinpointed districts with extreme temperature anomalies, highlighting the disproportionate impact of UHI on commercial and industrial zones. These areas, characterized by low vegetation density and high impervious surface coverage, exhibit the most significant heat retention, emphasizing the urgent need for mitigation interventions (Krsnik, 2024). Comparative analyses of different types of green infrastructure in Zagreb further confirm that urban forests, public parks, and interconnected green corridors offer the most effective cooling benefits, with temperature reductions of up to 2°C recorded in densely vegetated areas (Seletković et al., 2023).

Seasonal and diurnal variations further shape Zagreb's UHI intensity. Studies have shown that summer months exhibit the most pronounced heat buildup due to higher solar radiation and reduced

evapotranspiration in built-up environments, whereas winter periods present less thermal contrast due to lower solar input and seasonal vegetation loss (Krtalić et al., 2020).

Mitigation strategies for UHI in Zagreb emphasize the need for integrating urban greenery into city planning. A study on urban green space effectiveness in climate regulation found that tree cover, green roofs, and permeable surfaces significantly contribute to reducing surface temperatures, particularly in high-density neighborhoods (Krsnik, 2024). Furthermore, the role of large-scale green infrastructure was explored through scenario modeling, demonstrating that a 16% increase in tree cover could lead to a temperature reduction of approximately 1.5°C across the city (Seletković et al., 2023). These findings are aligned with European urban sustainability studies, which advocate for policy-driven initiatives to expand urban vegetation and enhance climate resilience.

4 MATERIALS AND METHODOLOGY

4.1 Research scope

This research builds upon and extends the existing body of knowledge on Urban Heat Islands (UHIs) by providing spatially explicit analysis of UHI intensity in the city of Zagreb, focusing on the relationships between land surface temperature (LST), planned land-use categories, built-up intensity, and vegetation cover. While previous studies have examined the impact of urban form on UHI, few have integrated spatial regression modeling with high-resolution Landsat-9 imagery and urban planning data. This study bridges that gap by quantifying the statistical influence of zoning regulations on temperature variations. While they also have examined general trends in UHI formation, vegetation's cooling effects, and urban expansion's role in heat accumulation, this study takes methodological approach by integrating multiple spatial analysis techniques to identify and quantify factors driving temperature variations. Research emphasizes the importance of urban planning decisions in shaping local microclimates and investigates how different land-use types, contribute to spatial patterns of heat intensity. The spatial scope of this research is limited to the area covered by the General Urban Plan (GUP) of the city of Zagreb, rather than the entire administrative territory of the city. This delineation ensures a more precise analysis of temperature variations within the core urban area, where land-use planning and built-up intensity have the most significant impact on UHI formation. By focusing on the GUP-defined urban zones, the study effectively captures localized temperature fluctuations.

The primary objective is to establish statistically correlations between LST and planned urban land-use categories as well as built-up intensity parameters to assess the extent to which specific urban planning and development strategies influence temperature distribution. A crucial extension of previous research is the incorporation of a composite UHI index, constructed by integrating both LST and the Normalized Difference Vegetation Index (NDVI) to refine the identification of heat-prone areas. Unlike conventional studies that solely rely on thermal remote sensing, this research defines UHI zones based on two critical criteria: (1) LST values exceeding the daily mean temperature, which highlights localized heat anomalies, and (2) NDVI values below 0.2, which indicate areas with minimal vegetation cover and, therefore, limited natural cooling capacity. This combined approach ensures a more precise delineation of heat islands by incorporating both thermal and vegetation-based factors, offering a nuanced representation of urban heat stress zones in Zagreb.

The research further builds on previous findings by examining the spatial clustering of UHIs through spatial autocorrelation analysis, enabling a better understanding of how heat islands are distributed across the urban landscape and whether specific spatial patterns emerge due to land-use planning and built-up intensity.

4.2 Materials

Core datasets used in this research consist of high-resolution remote sensing data, urban planning documentation, and spatial statistical modeling techniques. The study relies primarily on Landsat-9 satellite imagery from July 10, 2024, which provides thermal infrared data to assess land surface temperature (LST) and multispectral data for NDVI calculations, allowing for the evaluation of vegetation cover. The integration of LST and NDVI data enables the identification of heat-prone areas where a lack of vegetation correlates with elevated surface temperatures. Additionally, the study utilizes the General Urban Plan of the City of Zagreb (GUP) and its 2024 amendments, which define planned land-use categories and provide spatial constraints for urban development. The GUP outlines different types of planned green spaces,

including; protective green areas (Z), public parks (Z1), urban park-forests (Z2), thematic parks (Z3), and public green zones (Z4), which are analyzed in relation to their effectiveness in mitigating high temperature effects. Furthermore, the study incorporates urban planning regulations that specify built-up intensity parameters, allowable plot coverage, which is some of key determinants of urban density and surface heat retention. By analyzing the spatial distribution of these regulatory parameters, the study assesses how different levels of urbanization impact LST. The use of spatial datasets from official planning documents allows for an in-depth evaluation of how zoning regulations influence temperature dynamics.

4.3 Methodology

Methodological framework employed in this research represents an advancement over prior studies that relied solely on thermal remote sensing or statistical temperature analysis. Previous Zagreb-based UHI assessments, such as those by Krtalić et al. (2020) and Seletković et al. (2023), primarily focused on broad-scale thermal imagery analysis and identified general UHI patterns. By integrating Exploratory Spatial Data Analysis (ESDA), this research moves beyond descriptive analysis to establish causal relationships between land-use categories and temperature anomalies.

This research is structured around three core analytical stages:

- Correlation and regression analysis between LST, planned land-use, and built-up intensity;
- Integration of NDVI and LST to define UHI areas;
- Spatial autocorrelation analysis to assess the clustering of heat islands.

First stage involves correlation analysis which is used in this step to examine the strength and direction of relationships between temperature and urban features, helping to identify whether built-up intensity is positively associated with higher LST, while planned green areas contribute to temperature reduction. Then regression analysis is used to quantify the impact of planned land-use categories and built-up density on LST, where land surface temperature (LST) serves as the dependent variable, while independent variables include land-use type, built-up intensity, and vegetation cover.

Second stage focuses on constructing the UHI index, which is defined by combining LST values higher than the daily mean temperature with NDVI values below 0.2, ensuring that heat islands are classified based on both thermal excess and lack of vegetation. The NDVI threshold of 0.2 was selected based on prior studies that define low vegetation cover in urban settings as NDVI < 0.2 (Guha et al., 2018). This threshold ensures that areas classified as UHI zones are those with minimal vegetation cover. This approach refines conventional UHI identification by distinguishing between areas where temperature anomalies result from built-up density rather than other environmental factors.

Third stage applies spatial autocorrelation analysis to evaluate the spatial clustering of heat islands, using Moran's I to measure global clustering patterns of UHIs across Zagreb and Local Indicators of Spatial Association (LISA) to identify localized hot spots and cold spots, highlighting districts where temperature accumulation is most pronounced. Spatial autocorrelation methods help determine whether high-temperature zones are randomly distributed or whether they form significant clusters due to specific urban planning characteristics.

This analytical approach enables a systematic assessment of how planned green spaces and built-up areas influence temperature distribution and whether heat islands are spatially clustered in areas of high-density urbanization. The combination of these methods provides a robust, evidence-based framework for urban planners and policymakers to develop targeted climate adaptation strategies, such as optimizing the distribution of green infrastructure, adjusting zoning regulations to mitigate heat retention, and improving urban design strategies to enhance thermal comfort. By integrating geospatial analysis, spatial statistics, and urban planning data, this study advances the scientific understanding of UHIs in Zagreb.

5 RESULTS

Building upon the outlined methodological framework, the results of this research provide a detailed examination of the relationships between land surface temperature (LST), built-up intensity, and planned green spaces, offering insights into the drivers of Urban Heat Island (UHI) intensity in Zagreb. The first stage of the analysis focuses on statistical correlations and regression modeling to quantify how built-up

areas and green spaces impact LST. By evaluating the strength and direction of these relationships, the analysis highlights the degree to which urban planning decisions influence local microclimates. This is followed by the construction of a UHI index in the second stage, integrating LST and NDVI to refine the identification of heat-prone areas and differentiate zones where elevated temperatures are primarily attributed to built-up density or lack of vegetation. Finally, the third stage applies spatial autocorrelation techniques, including Moran's I and LISA, to identify spatial clustering of high-temperature zones and assess whether these clusters align with specific urban planning characteristics. Together, these results provide a comprehensive understanding of how urban planning variables such as built-up intensity and planned green spaces affect UHI patterns, forming a basis for evidence-based urban climate adaptation strategies.

The correlation and regression analysis provide insights into relationships between land surface temperature (LST), built-up intensity, and the total area of planned green spaces. The findings reveal a moderately strong positive correlation (0.68) between built-up intensity, and mean temperature. This confirms that higher built-up intensity significantly contributes to elevated LST, emphasizing the role of impervious surfaces, such as asphalt and concrete, in retaining and amplifying heat.

On the other hand, the total area of planned green spaces demonstrates a moderate negative correlation (-0.32) with mean temperature, highlighting the critical cooling effect of vegetation in mitigating LST. Areas with greater coverage of planned green spaces exhibit lower temperatures, reinforcing the importance of greenery in reducing UHI effects.

These findings align with the hypothesis that built-up surfaces exacerbate urban heating, while green spaces serve as an effective countermeasure. From a planning perspective, the analysis underscores the urgent need for urban regulations to balance high-density development with the integration and preservation of green infrastructure. Planned green zones (Z, Z1, Z2, Z3, Z4) are essential in reducing urban heat, while high-density areas require targeted interventions, such as green infrastructure, to mitigate localized heating effects (Figure 1).

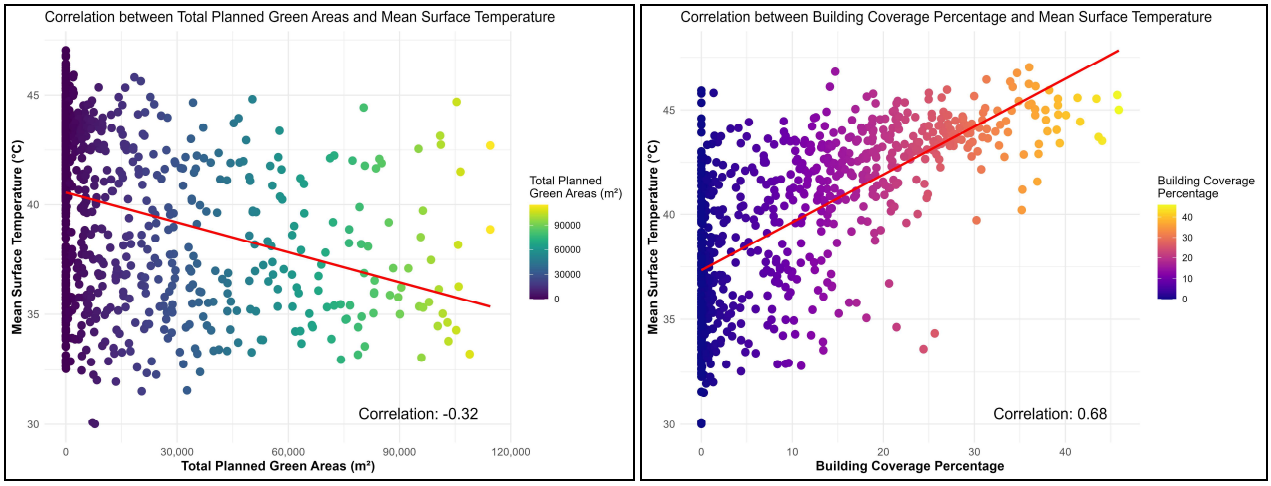

Fig. 1: Correlation analysis between planned green areas and built-up intensity and LST

Analysis provides critical insights into the relationship between land surface temperature (LST) and various land-use categories defined in the General Urban Plan (GUP) of Zagreb. The results reveal that park-forests (Z2) and protective green areas (Z) have a statistically significant cooling effect on LST, with coefficients of -3.11×10^{-6} and -3.29×10^{-6}, respectively, highlighting their effectiveness in mitigating the heat effects. The overall model is statistically significant (F-statistic = 7.25, $p < 0.001$), though it explains a modest proportion of variance in LST (adjusted R-squared = 0.064), reflecting the complexity of factors influencing urban heat dynamics.

Building upon the statistical correlation and regression analysis, the construction of the composite Urban Heat Island (UHI) index represents the second stage of the methodological framework. This composite index integrates land surface temperature (LST) and Normalized Difference Vegetation Index (NDVI) to refine the identification of areas most affected by hight temperature effects. The threshold for LST > 39°C, chosen based on the average land surface temperature on the day the satellite images are dated, which ensures that regions experiencing significant heat accumulation are highlighted. Simultaneously, the threshold of NDVI <

0.2 identifies zones with minimal vegetation cover. This dual-filtering approach enables the differentiation of heat-prone areas primarily driven by built-up intensity from those influenced by the absence of vegetation (Figure 2).

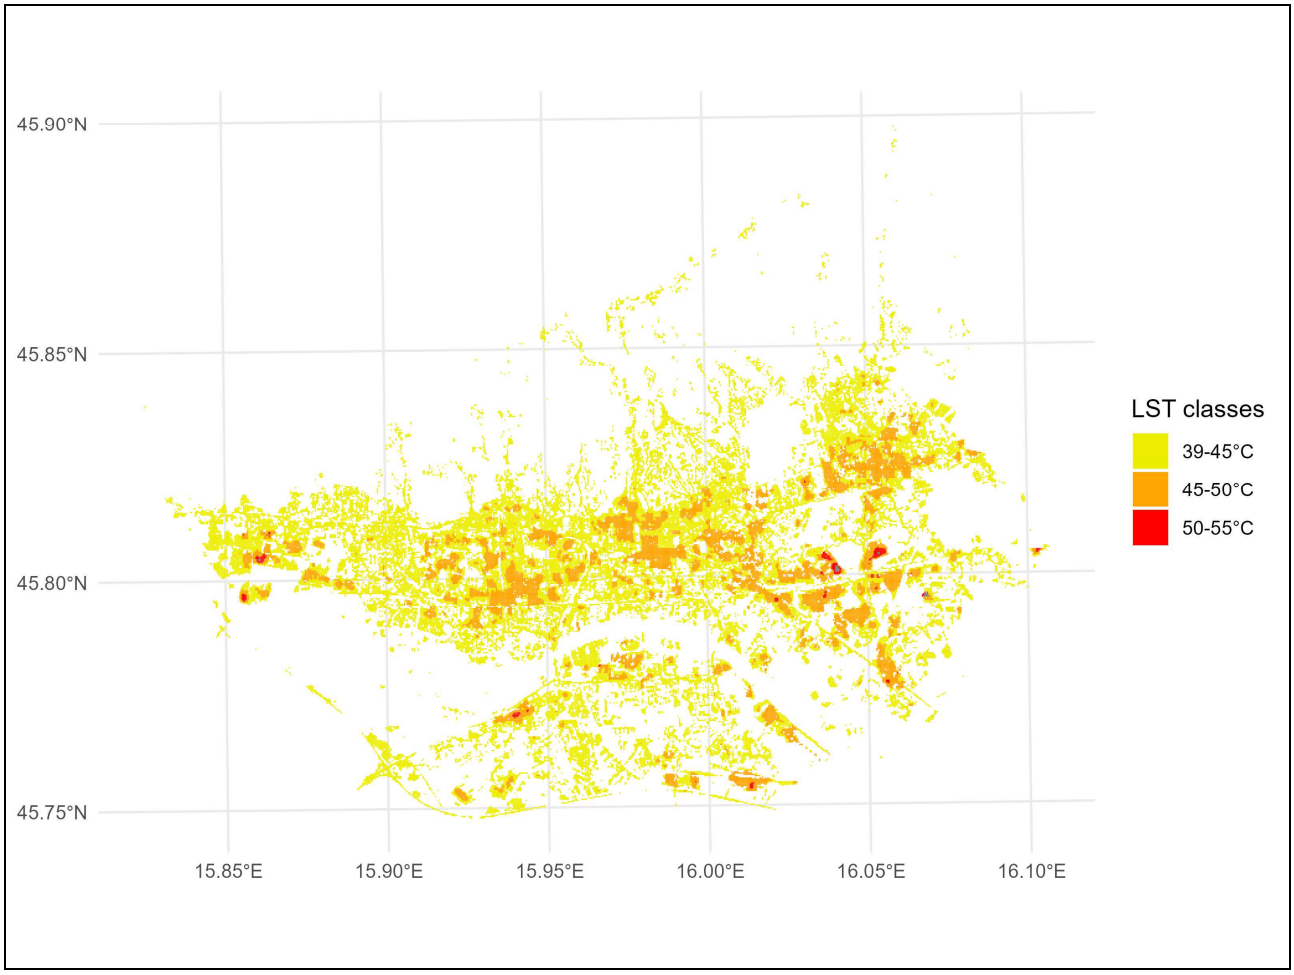

Fig. 2: Distribution of Land Surface Temperature

Building upon the statistical correlation and regression analysis, the spatial autocorrelation analysis represents a critical step in identifying and understanding the spatial clustering of Urban Heat Island (UHI) hotspots. Utilizing Moran's I and Local Moran's I (LISA), this stage examines the spatial patterns of high land surface temperature (LST) values to determine whether they are randomly distributed or form statistically significant clusters. The key focus of this analysis is to identify hotspots, or areas where elevated temperatures are spatially concentrated.

The Moran's I test under randomization indicates a highly significant positive spatial autocorrelation (Moran I = 0.920, p-value < 2.2×10^{-16}), confirming that high LST values are strongly clustered rather than randomly dispersed. This result validates that UHI effects in Zagreb are driven by systematic spatial processes rather than random temperature variations, underscoring the role of urban planning and land-use patterns in shaping heat accumulation. The Moran I statistic's standard deviation deviate (394.04) further supports the strength of this clustering, highlighting the robustness of the identified patterns.

Local Moran's I (LISA) refines this global insight by pinpointing the exact locations of statistically significant hotspots. These hotspots are areas where high LST values are not only concentrated but are also surrounded by other high-temperature zones, creating pockets of intense heat accumulation (Figure 3).

The ability of the spatial autocorrelation tools to statistically identify these clusters makes them indispensable for understanding UHI dynamics. Hotspot detection enables urban planners to spatially delineate the areas most vulnerable to heat accumulation, providing a clear foundation for targeted mitigation strategies..

By focusing exclusively on hotspots, this analysis emphasizes the power of spatial modeling in addressing urban heat challenges. The integration of Moran's I and LISA with high-resolution LST data provides a

comprehensive tool for modeling heat distribution and highlighting areas of concern. This approach moves beyond descriptive analyses to deliver statistically validated insights, reinforcing the need for evidence-based interventions in urban planning. In doing so, it not only enhances the scientific understanding of UHI effects but also equips stakeholders with precise spatial intelligence to prioritize climate adaptation measures effectively.

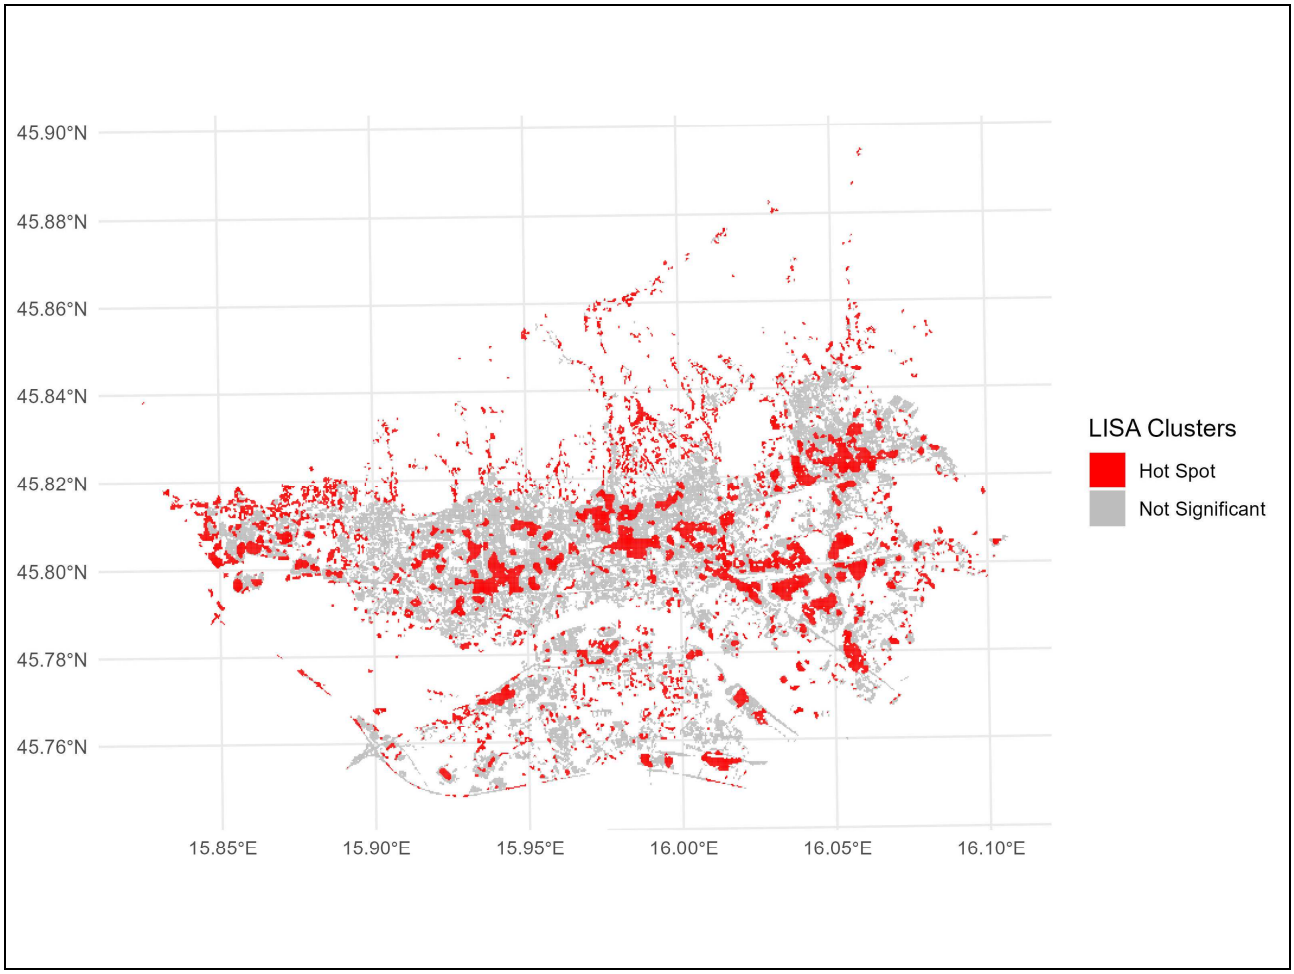

Fig. 3: Spatial Autocorrelation of UHI

6 CONCLUSION

This study provides significant insights into the spatial dynamics of Urban Heat Islands (UHIs) in Zagreb by employing a methodological framework that integrates correlation, regression, and spatial autocorrelation analyses. The findings reveal that built-up intensity is a key driver of elevated land surface temperature (LST), while planned green spaces, such as park-forests (Z2) and protective green areas (Z), play a critical role in mitigating UHI effects.

The spatial autocorrelation analysis, using Moran's I (Moran I = 0.920, p-value $< 2.2 \times 10^{-16}$) and Local Moran's I (LISA), identifies statistically significant UHI hotspots that are spatially clustered in high-density urban zones characterized by impervious surfaces and minimal vegetation. This precision in hotspot detection underscores the spatial dependency of UHI formation and validates the influence of urban planning and land-use patterns on the thermal environment.

The study advances UHI research by moving beyond traditional descriptive methods, employing spatial autocorrelation techniques to validate clustering patterns and incorporating regulatory zoning frameworks (GUP) to contextualize thermal patterns. By integrating high-resolution Landsat-9 satellite imagery from July 10, 2024, the research provides a snapshot of UHI intensity on an extreme temperature day, ensuring accurate identification of heat-prone areas. However, this single-day analysis does not capture seasonal or annual variations, and future research could incorporate multi-temporal analysis to assess UHI evolution over time and the effectiveness of mitigation strategies. Additionally, expanding the methodological framework to include broader climatic influences, such as wind circulation, humidity levels, and

anthropogenic heat emissions, could further refine the understanding of UHI drivers in an urban environment.

The identification of UHI hotspots in high-density zones provides a foundation for targeted urban interventions, such as expanding green infrastructure, increasing vegetation density, and implementing reflective surfaces, particularly in areas most affected by heat accumulation. Furthermore, the preservation and enhancement of planned green spaces (Z1, Z2, Z3, Z4) emerge as vital components for sustainable urban design, reinforcing the importance of climate-adaptive policies in city planning.

However, the primary objective of this study was not necessarily to propose direct solutions for mitigating UHI effects but rather to conduct a systematic spatial analysis to identify the zones most vulnerable to negative temperature impacts and to assess the extent to which planned land-use categories influence temperature variations. By establishing a spatially explicit understanding of UHI formation, the findings serve as a foundation for integrating urban heat mitigation strategies into spatial planning frameworks. Based on these analyses, conclusions can be incorporated into urban planning policies and regulatory documents, ensuring the protection of green areas, strategic tree planting, and improved zoning regulations to enhance climate resilience.

Future research should incorporate multi-temporal analysis to assess long-term trends in UHI intensity and evaluate seasonal variations in land surface temperature. Expanding the study to include meteorological factors such as wind patterns, humidity, and anthropogenic heat emissions would provide a more comprehensive understanding of UHI drivers. Additionally, refining statistical models by integrating urban geometry indices (e.g., building height, albedo, sky view factor) could enhance the explanatory power of UHI predictions. Further investigation into the effectiveness of different types of green infrastructure – such as tree canopy density, water bodies, and rooftop gardens – would offer targeted strategies for mitigating urban heat. These advancements would strengthen the link between geospatial analysis and urban planning, ensuring more effective climate adaptation strategies.

This research contributes to UHI analysis by:

- Advancing the methodological framework for UHI studies by integrating remote sensing, regression modeling, and spatial autocorrelation techniques.
- Providing statistically validated evidence for the role of built-up intensity and green spaces in temperature regulation.
- Utilizing spatial clustering methods to precisely identify UHI hotspots, strengthening the case for targeted mitigation efforts.
- Aligning findings with urban planning regulations (GUP), bridging the gap between geospatial analysis and policy implementation.

Overall, this research highlights the critical role of spatial modeling in addressing urban heat challenges and offers a replicable framework for integrating geospatial data with urban planning to support climate-resilient cities. By leveraging advanced spatial statistical tools, this study provides a robust evidence base for designing effective UHI mitigation strategies, ensuring that urban policies align with climate adaptation objectives to enhance the long-term sustainability of urban environments.

1 ABSTRACT

Gender equality is a critical yet often overlooked aspect of urban planning and sustainability. Urban environments significantly shape social, economic, and environmental dynamics but frequently fail to account for the distinct needs, experiences, and challenges faced by women. This systematic review examines the intersection of gender equality, urban planning, and sustainability, highlighting how traditional urban planning practices, when developed without a gendered perspective, perpetuate existing inequalities, particularly in areas such as access to public spaces, safety, and essential services. The study aims to fill a gap in the literature by exploring the integration of gender-sensitive approaches into urban sustainability practices. Bibliometric analysis will be conducted using VOSviewer to map and analyse research trends in gender equality, urbanism, and sustainability. The PRISMA protocol for systematic reviews will be followed to ensure a rigorous and transparent methodology in selecting and analysing relevant publications. This review provides an overview of the current state of research and offers insights for future studies and policy development aimed at integrating gender-sensitive approaches into urban planning to promote sustainability and social equity.

Keywords: Gender Equality, Urban Planning, Sustainability, Gender-Transformative Urbanism, Bibliometric Analysis

2 INTRODUCTION AND BACKGROUND

Cities are not neutral spaces – they reflect and reproduce social hierarchies, including gender inequalities. Despite growing global commitments to gender equality, urban environments often remain designed for an assumed universal user who is typically male, able-bodied, and economically mobile (Jabeen, 2020). This oversight in urban planning has far-reaching implications, particularly for women, who face challenges related to safety, mobility, and access to public spaces. Sustainable cities cannot be achieved without addressing these disparities and ensuring that urban environments are inclusive and equitable for all. This study is significant because it highlights the critical intersection of gender equality, urban planning, and sustainability, offering a systematic review of how gender-sensitive approaches can transform urban environments. While research on gender and urbanism has expanded in recent years, much of it remains fragmented, and the implementation of gender-inclusive planning remains inconsistent (Rampaul & Magidimisha-Chipungu, 2022). This study conducts a bibliometric analysis to identify key research trends, gaps, and thematic developments in the field. The literature provides a background for the study, highlights perspectives on gender equality, and points out the significance of this research. It emphasises the underrepresentation of gender considerations in urban planning practices and examines global and regional frameworks related to gender equality. The study also reflects on key theoretical frameworks, particularly feminist urbanism, gender mainstreaming, and sustainable urban development informing the research. Furthermore, it discusses the challenges and opportunities associated with gender-inclusive urban planning, aiming to contribute to a clearer and more structured understanding of gender-responsive urban planning.

3 LITERATURE REVIEW

Gender equality is a critical yet often overlooked aspect of urban planning and sustainability. Urban environments significantly shape social, economic, and environmental dynamics but frequently fail to account for the different needs, experiences, and challenges faced by women (UN-Habitat, 2022). Traditional urban planning practices, when developed without a gendered perspective, perpetuate existing inequalities, particularly in areas such as access to public spaces, safety, and essential services (Westendorp, 2021). In many African cities, deeply entrenched patriarchal systems and the lasting socio-economic and spatial impacts of colonialism further marginalise women in urban spaces (Parnell & Pieterse, 2019). Addressing

these challenges requires alignment with international frameworks such as Agenda 2063 and the Sustainable Development Goals (SDGs), specifically Goals 5 and 17, which advocate for gender equality and collaborative implementation strategies (United Nations, 2023). This study reviews existing literature at the intersection of gender equality, urban planning, and sustainability, specifically focusing on women's experiences and needs. The review synthesises key insights and identifies research gaps that hinder the development of truly inclusive urban environments.

3.1 Underrepresentation in Urban Planning

While gender-based marginalisation in urban planning is a key focus, the paper argues the broader issue of underrepresentation extends to other marginalised groups, including low-income communities, ethnic minorities, people with disabilities, and LGBTQ+ individuals (Fainstein & Servon, 2005; Sandercock, 1998). Urban planning literature increasingly highlights how exclusionary policies and planning frameworks have reinforced social hierarchies and spatial inequalities (Soja, 2010). Historically, city development has prioritised economic growth over inclusivity, often neglecting the voices of those who are most affected by inadequate infrastructure, housing insecurity, and unsafe public spaces (Miraftab, 2009). Examining gender alongside these intersecting forms of marginalisation, this review contributes to a more comprehensive understanding of urban inequities and the necessity of inclusive planning approaches.

3.2 Global and Regional Frameworks on Gender Equality in Urban Planning

Moreover, the global significance of gender equality, urban planning, and sustainability is firmly embedded within international development frameworks such as the SDGs and the New Urban Agenda (United Nations, 2016). SDG 5 emphasises achieving gender equality and empowering all women and girls, recognising that sustainable development cannot be achieved without addressing women's needs and rights (United Nations, 2015). Research has demonstrated a positive correlation between gender equality and improvements across various sectors, including economic growth, public health, and social cohesion (Duflo, 2012). Simultaneously, SDGs 11 and 17, as outlined in Agenda 2063, emphasise the need for urban planning to create inclusive, safe, resilient, and sustainable cities through collaborative implementation strategies (United Nations, 2015). The African Union's Agenda 2063 calls for gender-sensitive urban policies that rectify historical injustices and ensure equal access to urban resources, services, and decision-making structures (African Union, 2015).

3.3 Theoretical Frameworks and Key Debates in Gender and Urban Planning

The interdisciplinary nature of this research is rooted in three core theoretical frameworks: feminist urbanism, gender mainstreaming, and sustainable urban development. Feminist urbanism critically examines why gender-sensitive planning is necessary, challenging traditional male-centric urban design (Kern, 2020). Gender mainstreaming provides a structured approach to institutionalising these changes by ensuring gender perspectives are integrated into urban policy and decision-making (UN-Habitat, 2022). Additionally, sustainable urban development places gender equity within the broader goal of long-term urban resilience and sustainability, ensuring that cities address the needs of all citizens, particularly women and other marginalised groups (Campbell, 2016).

3.4 Challenges and Opportunities in Gender-Inclusive Urban Planning

Historically, urban planning has overlooked women's unique experiences, often reinforcing societal biases (Spain, 2016). This has resulted in urban spaces designed primarily for men, neglecting the realities faced by women in terms of mobility, safety, and access to essential services (Kern, 2019). Feminist urbanism serves as a key theoretical lens in this study, critiquing traditional urban planning and advocating for gender-sensitive design approaches that enhance inclusivity. Research increasingly highlights the benefits of incorporating gender considerations into urban planning, leading to safer, more accessible, and equitable cities (UN-Habitat, 2016). Inclusive urban design that considers women's needs – such as well-lit streets, safe public transport, and accessible childcare facilities – can enhance social cohesion and create vibrant, livable communities (Sandilands, 2020).

Beyond gender, urban planning scholarship highlights the need for an intersectional approach that considers race, class, disability, and other factors in city design (Crenshaw, 1989; Parnell, 2020). Cities that fail to consider these factors risk perpetuating inequality through exclusionary infrastructure and policy decisions

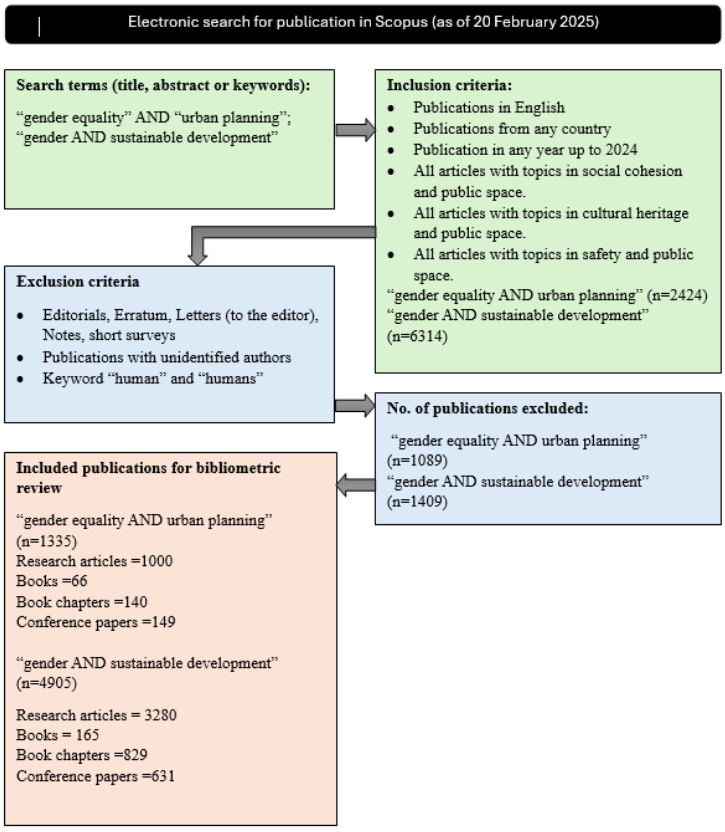
(Robinson, 2016). Gender mainstreaming ensures that women's perspectives are embedded in all levels of urban planning and decision-making (UN-Habitat, 2022). However, research also highlights the challenges of implementing gender-inclusive strategies, emphasizing the necessity of institutional support and policy integration. Furthermore, gender-inclusive policies can enhance sustainability outcomes by addressing the specific needs and challenges faced by women, leading to more effective and equitable urban solutions (UN Women, 2016). As African cities plan for future development, sustainability becomes a key priority, necessitating gender equality within broader urban sustainability goals, such as those outlined in Agenda 2063 and the SDGs. This perspective aligns with social, economic, and environmental sustainability, advocating for cities that are inclusive, resilient, and equitable (Campbell, 2016).

4 METHODOLOGY

This study employs a bibliometric review methodology to explore the intersection of gender equality, urban planning, and sustainability, with a particular focus on integrating gender-sensitive approaches into urban development practices. Intersectionality recognises that women's experiences are shaped by multiple social categories such as race, class, and geographic location, creating unique challenges of marginalisation and privilege (Crenshaw, 1989). The Scopus database was selected as the primary source for this study due to its extensive coverage of peer-reviewed literature across various disciplines, including urban planning, architecture, sociology, and cultural studies (Bass et al.,2020). The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol was used to ensure a rigorous and transparent process for selecting and analysing relevant publications. These findings provide valuable insights for researchers, policymakers, and urban planners, ensuring that gender-sensitive urban planning is a core component of sustainable development. This is particularly crucial in African contexts, where historical and socio-cultural dynamics have shaped spatial inequalities that disproportionately affect women and other marginalised groups.

4.1 Selection criteria

On 20 February 2025, a Scopus database search was conducted to access and evaluate the body of research on gender equality, urban planning, and sustainability.



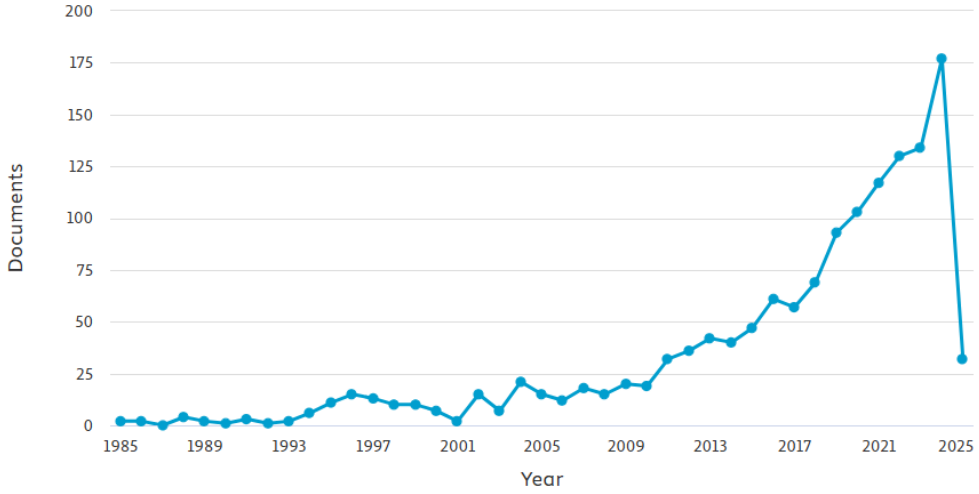
To ensure a comprehensive review, no specific time frame was imposed. The search terms included "gender equality AND urban planning" and "gender AND sustainable development". The inclusion criteria focused

on English-language publications from any country and any year up to 2025. Exclusion criteria eliminated editorials, errata, letters, notes, short surveys, publications with unidentified authors and books, book chapters, reviews, and conference papers not published in English. To ensure rigorous selection, titles and abstracts were screened to confirm eligibility, guided by the PRISMA protocols, which provide a robust and systematic framework for literature reviews, minimising bias, increasing the reliability of results, and ensuring clear and organized presentation (Selcuk, 2019; Page et al.., 2021). The analysis includes network maps, graphs, and tables to demonstrate key trends, influential authors, and emerging themes in gender equality and urban sustainability. This approach will allow for the identification of research gaps and key scholarly trajectories in the intersection of these fields (Jia and Mustafa, 2022). Furthermore, the review will synthesise the findings, highlighting the contributions of leading scholars and tracking the evolution of research topics. By addressing these disparities, this study contributes to the discourse on fostering truly inclusive and sustainable urban futures that prioritise women's needs and create equitable urban environments for all.

5 RESULTS AND DISCUSSIONS OF THE BIBLIOMETRIC ANALYSIS

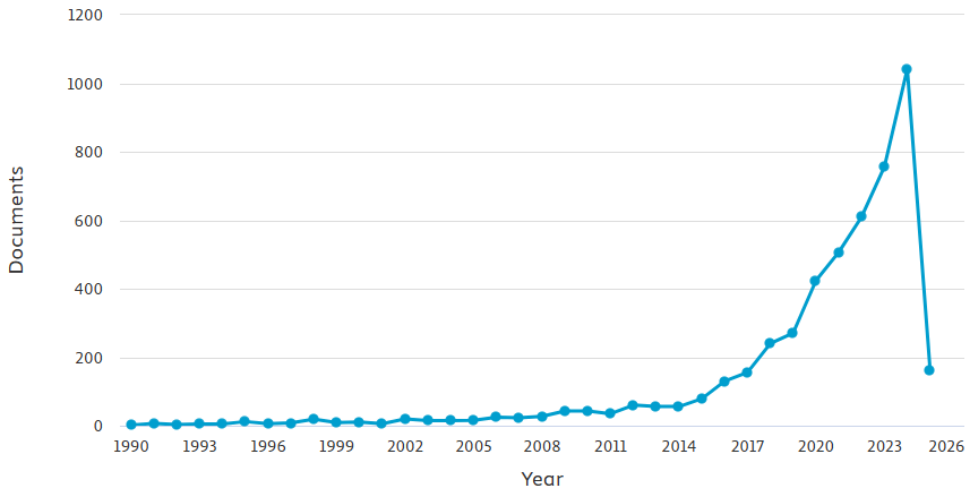
5.1 Publication trends

The analysis of the publication trends at the intersection of "gender equality" and "urban planning" reveal a significant increase in scholarly interest, particularly from 2010 onwards. This surge aligns with global initiatives emphasizing gender equality and sustainable urban development, such as the Sustainable Development Goals (SDGs) adopted in 2015. Specifically, SDG 5 aims to achieve gender equality, while SDG 11 focuses on making cities inclusive, safe, resilient, and sustainable. The heightened research activity post-2015 suggests that these international frameworks have catalyzed academic exploration into how urban planning can address gender-specific needs (Rampaul and Magidimisha-Chipungu, 2022; Yu-an Chung and Grichting Solder, 2024).



Graph 1: Publication trends for research on gender and urban planning (Authors, 2025)

The peak in publications observed in 2024, exceeding 175 documents, indicates that gender-sensitive urban planning has become a well-established research area. This trend may be attributed to increased policy shifts, funding opportunities, and a heightened academic focus on integrating gender perspectives into urban studies (Melin and Levonen, 2024). However, the sharp decline in 2025 could be due to incomplete data for that year, as academic databases often experience delays in indexing newly published articles. Alternatively, it might reflect a saturation point in the literature or a shift towards emerging themes within the field. These findings underscore the evolving recognition of the importance of incorporating gender-sensitive approaches in urban planning to promote sustainable and equitable cities. The growing body of research highlights the necessity for urban policies that consider the unique experiences and challenges faced by different genders, aiming to create inclusive public spaces and infrastructure that cater to all community members (Barker, et al. 2024).



Graph 2: Publication trends for research on gender and sustainable development (Authors, 2025)

The graph depicts a significant upward trend in publications related to gender and sustainable development over the past three decades, indicative of a growing scholarly interest in the intersection of these two critical areas. The steady increase from 1990 to the mid-2010s suggests a gradual recognition of the importance of gender considerations in sustainability discourses. However, the dramatic surge in publications from 2017 onwards points to a more recent and pronounced emphasis on this nexus. This escalation likely reflects the increasing awareness of gender's pivotal role in achieving the Sustainable Development Goals (SDGs), particularly Goal 5 on Gender Equality, and its interconnectedness with other goals. The spike could also be attributed to increased funding opportunities, progressive policy frameworks, and a broader societal push for inclusivity and equity in sustainable development initiatives. While the graph illustrates a positive trajectory in research output, it also underscores the need for continued scholarly engagement to translate research into tangible impacts on policy and practice, ensuring that gender perspectives are effectively integrated into sustainable development agendas globally (UN Women, 2018). Furthermore, future research should focus on addressing existing knowledge gaps, exploring the nuances of gender dynamics across diverse cultural contexts, and promoting intersectional approaches that consider the interplay of gender with other social categories in shaping sustainable development outcomes (Broome and Ranford, 2021).

5.2 Keyword Analysis

The keyword analysis of “gender” AND “urban planning” using VOSviewer reveals three major thematic clusters shaping scholarly discourse in this field. The first cluster (red) focuses on the direct relationship between gender and urban planning, emphasizing key topics such as urban areas, perception, surveys, women’s status, and greenspace, highlighting how women experience and interact with urban spaces in terms of access, safety, and mental well-being. The second cluster (green) centers on transportation planning, urban transport, roads, streets, and micromobility, indicating that gender-sensitive urban planning research heavily intersects with mobility and accessibility concerns, particularly in regions like the United Kingdom and Catalonia, where progressive transport policies may influence research. The third cluster (blue) addresses socioeconomic and policy dimensions, linking public policy, economic factors, employment, and urbanization in developing countries, with strong geographic connections to Africa, Bangladesh, and Southern Asia.

The presence of terms related to health, psychology, and marital status suggests an intersectional approach, linking gender disparities in urban planning to broader sociopolitical and behavioral factors. These findings underscore that traditional urban planning has largely overlooked gender-specific needs, leading to inequities in mobility, accessibility, and economic opportunities (Harrison et al., 2022). The transport and mobility cluster reinforces existing research indicating that women face greater transport insecurity, limited mobility options, and gendered constraints in urban transport systems, necessitating more inclusive policies (Ng et al., 2020). The prominence of policy and economy-related keywords suggests that gender disparities in urban planning are not just about infrastructure but are deeply tied to broader governance and development structures, particularly in the Global South (Kabeer, 2021). As global urbanization accelerates, integrating

gender-sensitive policies into urban planning becomes crucial for achieving sustainable and equitable cities (UN-Habitat, 2022). This bibliometric analysis highlights key research gaps in gender-sensitive urban planning, particularly in mobility, accessibility, and policy-driven inclusivity, reinforcing the urgent need for more intersectional and gender-responsive urban governance frameworks.

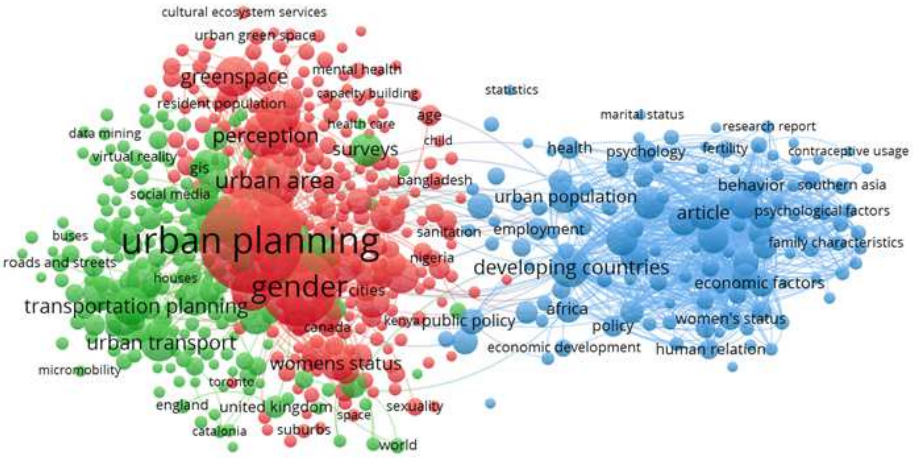


Figure 1: A co-occurrence network analysis of keywords on gender and urban planning research (Authors, 2025).

5.3 Top countries publishing in gender equality, urban planning, and sustainability

The global research landscape on gender, urban planning, and sustainability in the table below shows that the United States and the United Kingdom are the leading contributors, with substantial publications, citations, and total link strength, indicating both academic dominance and global influence. Total link strength reflects the level of international collaboration and the impact of research beyond national borders (Van der Heijden, 2016). Countries like China and India, though producing a significant number of documents, have lower citation counts and link strengths, suggesting more localized research. Meanwhile, countries like Canada, Spain, and Germany show moderate output with a strong regional focus. Emerging nations, such as India, and smaller contributors like Italy and the Netherlands, reflect a growing interest in gender-sensitive urban planning but may not yet have the same global recognition. Overall, the research highlights a dynamic global conversation, with the U.S. and U.K. at the forefront, but increasing contributions from other countries that address diverse urban challenges, such as gender equity, sustainability, and public space design (Parnell and Robinson, 2012; UN-Habitat, 2019).

No	Country	Documents	Citations	Total Link Strength
1	United States	262	7087	87
2	United Kingdom	159	3769	76
3	China	130	1999	44
4	Canada	85	1862	36
5	Spain	63	1067	36
6	Germany	63	967	29
7	India	94	784	28
8	Italy	42	1080	23
9	Netherlands	35	587	20
10	Australia	66	1509	18

Table 1: Top ten countries publishing on urban planning, gender, and sustainability

5.4 Top authors publishing in gender equality, urban planning, and sustainability

The field of gender, urban planning, and sustainability has seen significant contributions from a diverse range of scholars, each focusing on unique aspects of gendered urban spaces.

Leading this academic discourse is Tiziana Campisi, an Italian author with extensive publications on gender-sensitive urban design and accessibility, whose recent work explores gendered perspectives in sustainable urban development. Campisi's research emphasizes the importance of creating inclusive urban environments that prioritize safety and accessibility for women (Campisi, 2023). Donna Asteria, an academic from Brazil, examines urban governance and social inclusion, with her most recent work focusing on gender-responsive

governance and urban resource distribution (Asteria, 2022). While Asteria's citation count is lower, her contributions are still valuable in promoting gender equity through urban policy reform. Socrates Basbas, from Greece, has published research on gendered mobility in transportation systems, and his latest article, "Does Gender Matter in Daily Urban Mobility? Exploring Travel Perceptions, Attitudes, and Behaviours," advocates for transportation policies that address the needs of women and marginalized groups. Giovanni Tesoriere, an Italian researcher, focuses on public space design and social inclusion with his recent research on designing gender-inclusive public spaces. Tesoriere's work stresses the role of public spaces in promoting gender equality. Dyah Utari, from Indonesia, has written extensively on gender issues in informal settlements, with her latest work exploring urban informality and gender in Southeast Asia. Jo Beal and Alison Todes are both South African scholars whose work primarily addresses the intersection of gender, race, and transformation in urban planning. Collectively, these authors highlight the crucial need for gender-responsive urban planning practices that empower women, address gender inequalities in urban spaces, and ensure equitable access to resources and opportunities.

Author	Documents	Citations	Total Link Strength
Tiziana Campisi	9	317	8
Donna Asteria	6	19	5
Socrates Basbas	4	222	5
Giovanni Tesoriere	4	279	5
Dyah Utari	5	18	5
Jo Beal	6	137	2
Alison Todes	4	93	2
Doris Damyanovic	5	24	1
Ines Sanchez De Madariaga	4	55	1
Liisa Horelli	4	54	1

Table 2: Top ten authors publishing on urban planning, gender and sustainability

One interesting takeaway from this analysis is the geographic diversity of scholars contributing to gender and urban planning research. While European researchers like Tiziana Campisi (Italy), Giovanni Tesoriere (Italy), and Socrates Basbas (Greece) dominate in terms of citations and international influence, scholars from the Global South, such as Donna Asteria (Brazil), Dyah Utari (Indonesia), and Jo Beal (South Africa), bring critical perspectives on gender and urban equity in developing contexts. This suggests a growing recognition of gender disparities in urban planning across different socioeconomic and cultural landscapes. Another key takeaway is the focus of their research. While European scholars tend to emphasize gender-sensitive urban design, public space accessibility, and transportation equity, those from the Global South highlight informal settlements, urban governance, and the intersectionality of race, class, and gender in urban development. This highlights how gender-related urban issues are not universal but rather shaped by local contexts, governance structures, and socioeconomic conditions.

Moreover, the varying total link strength among these researchers suggests differing levels of international collaboration. Highly cited authors like Campisi and Basbas likely engage in global research networks, while others with lower citations and link strength may have regional or localized impacts. This underscores the need for more cross-regional collaboration to bridge knowledge gaps and create inclusive urban policies that are globally informed but locally relevant. Finally, a common thread among these scholars is the call for participatory urban planning that includes women and marginalized groups in decision-making. Whether addressing transportation, public space, or informal settlements, their work reinforces the argument that gender-responsive planning is not just about inclusion but about fundamentally reshaping cities to be more equitable, safe, and accessible for all.

6 CONCLUSION AND RECOMMENDATION: TOWARDS A CONCEPTUAL FRAMEWORK ON GENDER-RESPONSIVE URBAN PLANNING

In conclusion, the analysis of research trends in gender equality and urban planning highlights the growing scholarly focus on integrating gender-sensitive perspectives into urban development. The increase in publications post-2010 aligns with global initiatives such as the Sustainable Development Goals (SDGs), particularly SDG 5 (Gender Equality) and SDG 11 (Sustainable Cities and Communities). The peak in publications in 2024 indicates that gender-sensitive urban planning has become a well-established research

area, largely influenced by international policy shifts and funding opportunities. However, variations in research output across countries and the diverse thematic focus among scholars suggest that gender disparities in urban planning are shaped by local governance structures, socioeconomic conditions, and cultural contexts (Yu-an Chung and Grichting Solder, 2024). The dominance of the United States and the United Kingdom in publication output and citations reflects their well-established research networks, while emerging contributions from China, India, and South Africa highlight increasing scholarly engagement from the Global South. Despite the significant progress in gender-focused urban planning research, critical gaps remain. The keyword analysis reveals strong research clusters around urban accessibility, transportation equity, and policy frameworks, yet more attention is needed on the intersectionality of gender with race, class, and disability in urban environments (Ng et al., 2020; Kabeer, 2021). Additionally, the lower total link strength of many Global South researchers suggests limited international collaboration, which may hinder knowledge exchange and policy translation.

There lies an opportunity, therefore, to develop a conceptual framework that incorporates the works of the top scholars and key gaps identified and discussed in the findings section of this paper. This framework serves as a key recommendation and unique contribution to policy in ensuring that cities adopt gender-responsive urban governance and urbanism. The Gender-Responsive Urban Planning Framework (GRUPF) is structured around four key dimensions: policy and governance, participatory and inclusive planning, gender-sensitive urban design, and data-driven decision-making.

Figure 2: Gender-Responsive Urban Planning Conceptual Framework (GRUPF) (Authors, 2025).

The policy and governance dimension emphasizes institutionalizing gender-sensitive policies, multi-stakeholder collaboration, and legal reforms to ensure gender equity in urban planning. By embedding gender considerations into planning regulations, decision-making processes become more inclusive and accountable. The participatory and inclusive planning dimension highlights the need for co-creation with communities, grassroots empowerment, and gender-responsive governance structures. Women and marginalized groups must actively shape urban policies and infrastructure through participatory budgeting, design workshops, and policy dialogues. The gender-sensitive urban design dimension focuses on integrating gender-responsive mobility planning, safe and inclusive public spaces, and mixed-use zoning. This involves designing cities that accommodate the unique mobility patterns of women, ensuring adequate lighting, safe sidewalks, and accessible transportation systems that enhance safety and convenience. Lastly, the data-driven decision-making dimension underscores the importance of gender-disaggregated data collection, urban equity audits, and the use of digital tools such as GIS and smart city technologies. This ensures that planning interventions are based on evidence, enabling continuous assessment and improvement of gender equity in urban development. Collectively, these dimensions offer a comprehensive and systematic approach to embedding gender equity in urban planning, fostering more inclusive, accessible, and sustainable cities.

The Gender-Responsive Urban Planning Framework (GRUPF) offers a comprehensive approach to promoting gender equality and inclusivity in urban development. By embedding gender-sensitive policies,

fostering participatory planning, and integrating gender-responsive urban design, it ensures that cities are safer, more accessible, and equitable for all residents, especially women and marginalized groups. The framework's focus on data-driven decision-making and institutional accountability enhances the effectiveness of urban policies while encouraging global collaboration, particularly from the Global South. Ultimately, GRUPF supports sustainable, resilient, and inclusive urban environments, contributing to the broader goals of gender equality and sustainable development.

Exploring the Property Values of Logistics Facilities in the Vicinity of Cape Town International Airport

Masilonyane Mokhele

(A/Prof Masilonyane Mokhele, Cape Peninsula University of Technology, PO Box 652, Cape Town 8000, mokhelem@cput.ac.za)

DOI: 10.48494/REALCORP2025.4066

1 ABSTRACT

Amid the growing logistics processes, numerous studies analyse the placement of economic activities near airports á la the models of airport-led development. However, to deepen the knowledge on the catchment of airports, further research is required to analyse logistics spaces near airports compared to other logistics clusters in a territory. The paper, therefore, aims to analyse property values of logistics facilities in the vicinity of Cape Town International Airport relative to six other main logistics clusters within the City of Cape Town municipality, South Africa. These clusters are Philippi, Paarden Eiland, Epping, Parow Industrial, Montague Gardens/Milnerton, and Blackheath, wherein 15 randomly identified properties were analysed in each area. The identification of logistics firms in the seven focus areas involved examining company details on Google Maps, and verifying their locations on the company websites. The property details were then searched on the City of Cape Town's cadastral GIS shapefile, which was overlaid on the Google Satellite in QGIS 3.32.0. Three key attributes were captured from the cadastral shapefile and recorded on an Excel spreadsheet: property/land parcel extent, street address, and property number. The latter two attributes were used to extract the 2022 property market values from the City of Cape Town's valuation roll, available on the municipal website. Statistical analysis was then conducted in the IBM's statistical package for social sciences (SPSS), version 29. The results showed that the mean property values in the vicinity of the airport ranked sixth among the seven focus areas, with Montague Gardens/Milnerton having the highest value and Blackheath the lowest. In terms of the range, the airport environs ranked fourth, with Montague Gardens having the widest and Epping the narrowest. Regarding the property value relative to extent, the mean in the vicinity of the airport ranked second, following Paarden Eiland. The findings show that from the perspective of property values, the area near the airport does not significantly stand out compared to other logistics nodes in the municipality. Holding other locational factors constant, it can be argued that logistics firms near the airport could potentially be located in various zones within the broader airport catchment area.

Keywords: Cape Town International Airport, property values, logistics facilities, airport catchment, Planning

2 INTRODUCTION

The relationship between airports and the geographical distribution of economic activities has become a key focus in academic and policy discourse (Mokhele, 2022). This interest is epitomised by the popularity of the normative models of airport-led development, notably the airport city and aerotropolis. Although the airport city encompasses various categories (Conway, 1993), it is largely used to promote urban development in the immediate vicinity of airports (Kasarda, 2009). As the airport city evolves, development is expected to radiate outward, eventually shaping the spatial form of aerotropolis, which could extend for miles beyond the airport (Kasarda & Lindsay, 2011). Policymakers, spatial planners and airport authorities, inter alios, employ these models to market and guide the economic activity mix and spatial form of development that is understood to have a reciprocal relationship with airports.

The significance of airports in the contemporary economy is best understood against the backdrop of logistics processes. The logistics industry, which is a wide-ranging sector encompassing, inter alia, transportation, warehousing, storage, handling, processing, and delivery (Lan, Yang & Huang, 2017), facilitates the flow of goods between points of origin and consumption globally (Verhetsel, 2015). Among the various transport modes used in logistics, air cargo/airfreight is one of the backbones of global trade (Schwarz, 2006). According to the International Air Transport Association (n.d.), air transport accounts for about 35% of the value of global trade, highlighting the crucial role of airports in global supply chains and logistics processes. The airfreight market continues to expand, driven by the rapid growth of e-commerce, and the associated advantages of a timely delivery of goods (Kim & Lee, 2019). The rise of global supply

chains and e-commerce has, therefore, contributed to the development of a dynamic logistics estate market worldwide (de Oliveira, Dablanc & Schorung, 2022).

While airport-related literature has traditionally focused on the spatial economic characteristics of the immediate surrounds of airports, covering topics such as logistics sprawl, logistics parks, and the concentration or clustering of logistics facilities (Mokhele, 2022), a growing body of research examines airfreight catchment at different geographical scales (for instance, see Rodrigue, 2003; Hesse, 2010; Mokhele & Mokhele, 2023). To enhance our understanding of the catchment of airports, further research is needed to compare logistics spaces near airports with other logistics zones. The paper, therefore, aims to explore the property values of land used for logistics facilities near Cape Town International Airport compared to other logistics clusters within the City of Cape Town municipality, South Africa. The findings are expected to offer insights for strategically guiding the location of logistics firms within the airport's catchment area.

3 LITERATURE REVIEW

To contextualise the discussion on the property market values of land used for logistics facilities near the airport compared to other logistics nodes in the City of Cape Town municipality, this section reviews the literature on the real estate valuation methods, and the factors that influence the location of logistics firms.

3.1 Factors influencing the location choice of logistics firms

Identifying and analysing factors that influence the location of logistics facilities is essential for developing appropriate logistics-related land-use planning policies, strategies and guidelines (Sakai, Beziat & Heitz, 2020). As noted by Verhetsel et al. (2015), the location choices of logistics firms are influenced by a wide array of factors, including land availability and affordability, availability and quality of transport infrastructure, the level of economic development, the availability of labour, and land-use planning.

As the relationship between transport and the placement of logistics firms has been extensively examined in the literature (e.g. Heitz & Dablanc, 2015; Kang, 2018), the paper focuses specifically on the aspect of land affordability. The literature suggests that, due to the limited supply of land for development in the urban core, logistics facility development shifts toward peripheral areas where land is more readily available (Yang et al., 2022). At a micro level, land price plays a crucial role in location decisions, driving logistics development away from dense urban centres (Heitz et al., 2018). Unlike office and retail developments, it is argued that logistics firms can only afford smaller land rents (Verhetsel et al., 2015). As a result, Heitz et al. (2018) observe that logistics operators or their real estate investors search for areas with cheaper land/rent, typically at the periphery of urban areas. Fernández, Caralt & Valcarce (2023) emphasise that peripheral nodes near airports, for instance, consequently attract space-intensive activities such as warehousing.

Several studies have empirically analysed the connection between the location of warehouses and land value or rent. In the study exploring, among others, the hypothesis that the placement of warehouses is closely related to the land value of logistics facilities, de Oliveira, Dablanc and Schorung (2022) found a statistically significant evidence that the location of warehouses and average rent prices were dependent. In the Sao Paulo Metropolitan Region, Brazil, zones with the highest number of warehouses were those with the lowest real estate values (Guerin et al., 2021). In another Brazilian study, de Oliveira et al. (2022) found land cost to be one of the critical factors influencing warehouse location decisions in Belo Horizonte.

The paper intends to empirically test the foregoing literature's assertion that land values are relatively lower in the vicinity of airports, a factor attracting the development of space-intensive logistics facilities like warehouses.

3.2 Real estate valuation methods

The value of land is influenced by various factors, including physical, economic, social, environmental, and legal considerations (Bencure et al., 2019). Dale et al. (2002) as cited in Thontteh (2013) expounded that the factors affecting a property's financial worth include location, size, condition, the type of construction, the type and security of tenure, permitted land use, and the state of the economy. Additionally, the dynamics of demand and supply play a crucial role, showing that the equilibrium between demand and supply, along with the purchasing power, influences property values (Demetriou, 2016).

Land valuation is the process of estimating the value of land, which can be expressed in relative or absolute terms (Bencure et al., 2019). The process is intended to provide an unbiased assessment of a property to establish its value (Kartikasari et al., 2023, cited in Wentzel & van der Merwe, 2024). Valuation exercises can be performed manually or through automated techniques. The latter involve collecting market values that serve as a sample, which are then calibrated to develop a valuation model for a given area (Bencure et al., 2016).

Mass valuation techniques have been widely adopted in various countries, either as components of land administration systems or as part of fiscal systems that utilise land cadastre data for taxation and other purposes (UNECE, 2001; Wang & Li, 2019). Consequently, mass valuation models form part of a property attribute system, such as a cadastre or land registry, which is used for various land management purposes (Grover, 2016).

Mass valuation is a systematic assessment of a large number of properties performed on a certain date utilising uniform procedures and statistical analyses, which is in contrast to individual valuations, which focus on determining the value of individual properties (UNECE, 2001). Therefore, mass valuations are utilised when a large number of properties have to be valued simultaneously on a single date. As alluded to above, this approach relies on standardised procedures, common sets of data, usually derived from a property attribute system, and statistical models of the relationship between value and property attributes. These involve estimating the relationship between the market price (the dependent variable) and the varied characteristics of properties that influence the price (Grover, 2016).

As discussed further in the research methods section, the study that the paper reports on was based on the City of Cape Town's market property values, compiled by the municipality through mass valuation processes.

4 STUDY AREA

The study explored the market property value patterns of land used for logistics facilities near Cape Town International Airport (CTIA) compared to selected other industrial/logistics clusters in the City of Cape Town municipality, South Africa. CTIA is the second busiest airport in South Africa, which handled about 10 million passengers during the 2023/2024 financial year (https://www.airports.co.za/airports/cape-town-international-airport/statistics/passenger). The City of Cape Town municipality is also home to the country's second-largest seaport, the Port of Cape Town, positioned approximately 17 km to the north-west of CTIA, an expansive passenger rail infrastructure and roads of regional and national significance.

The analysis focused on the following seven logistics clusters in the City of Cape Town: the airport and its environs (encompassing Airport Industria and Airport City), Philippi, Paarden Eiland, Epping, Parow Industria, Montague Gardens/Milnerton, and Blackheath (Fig. 1). In light of the propensity of logistics firms to locate in industrial areas, these zones represent some of the densest clusters of logistics facilities in the City of Cape Town (Mokhele & Mokhele, 2023; Mokhele & Fisher-Holloway, 2023). From a geographical perspective, the selected nodes are diverse in terms of, among others, proximity to the central business district, the seaport and the airport (Fig. 1).

Regarding the study's reference point of the airport and its environs, it is important to note that during the 1970s and 1980s, the government strategically and actively promoted industrial development in the area (Mokhele, 2017); and by 1993, a growing trend in warehousing and storage facilities had begun to emerge in the vicinity of the airport (Mokhele & Fisher-Holloway, 2024).

5 RESEARCH DESIGN AND METHODS

This section outlines the research design, the units of analysis, as well as the data collection and analysis methods used in the study.

5.1 Research design

The study was based on an exploratory quantitative design to analyse the market values of land used for logistics facilities in the environs of Cape Town International Airport compared to other logistics clusters in the City of Cape Town municipality.

5.2 Units of analysis

The study's units of analysis were the land parcels used for logistics facilities within the selected industrial areas in the City of Cape Town municipality. It should, therefore, be noted that the units of analysis were not individual logistics buildings, as a single land parcel could accommodate several buildings. The study considered land parcels housing at least one of the following categories of logistics facilities: warehousing, storage, distribution (including shipping container yards), self-storage, courier services, freight forwarding, and recycling depots (a component of reverse logistics).

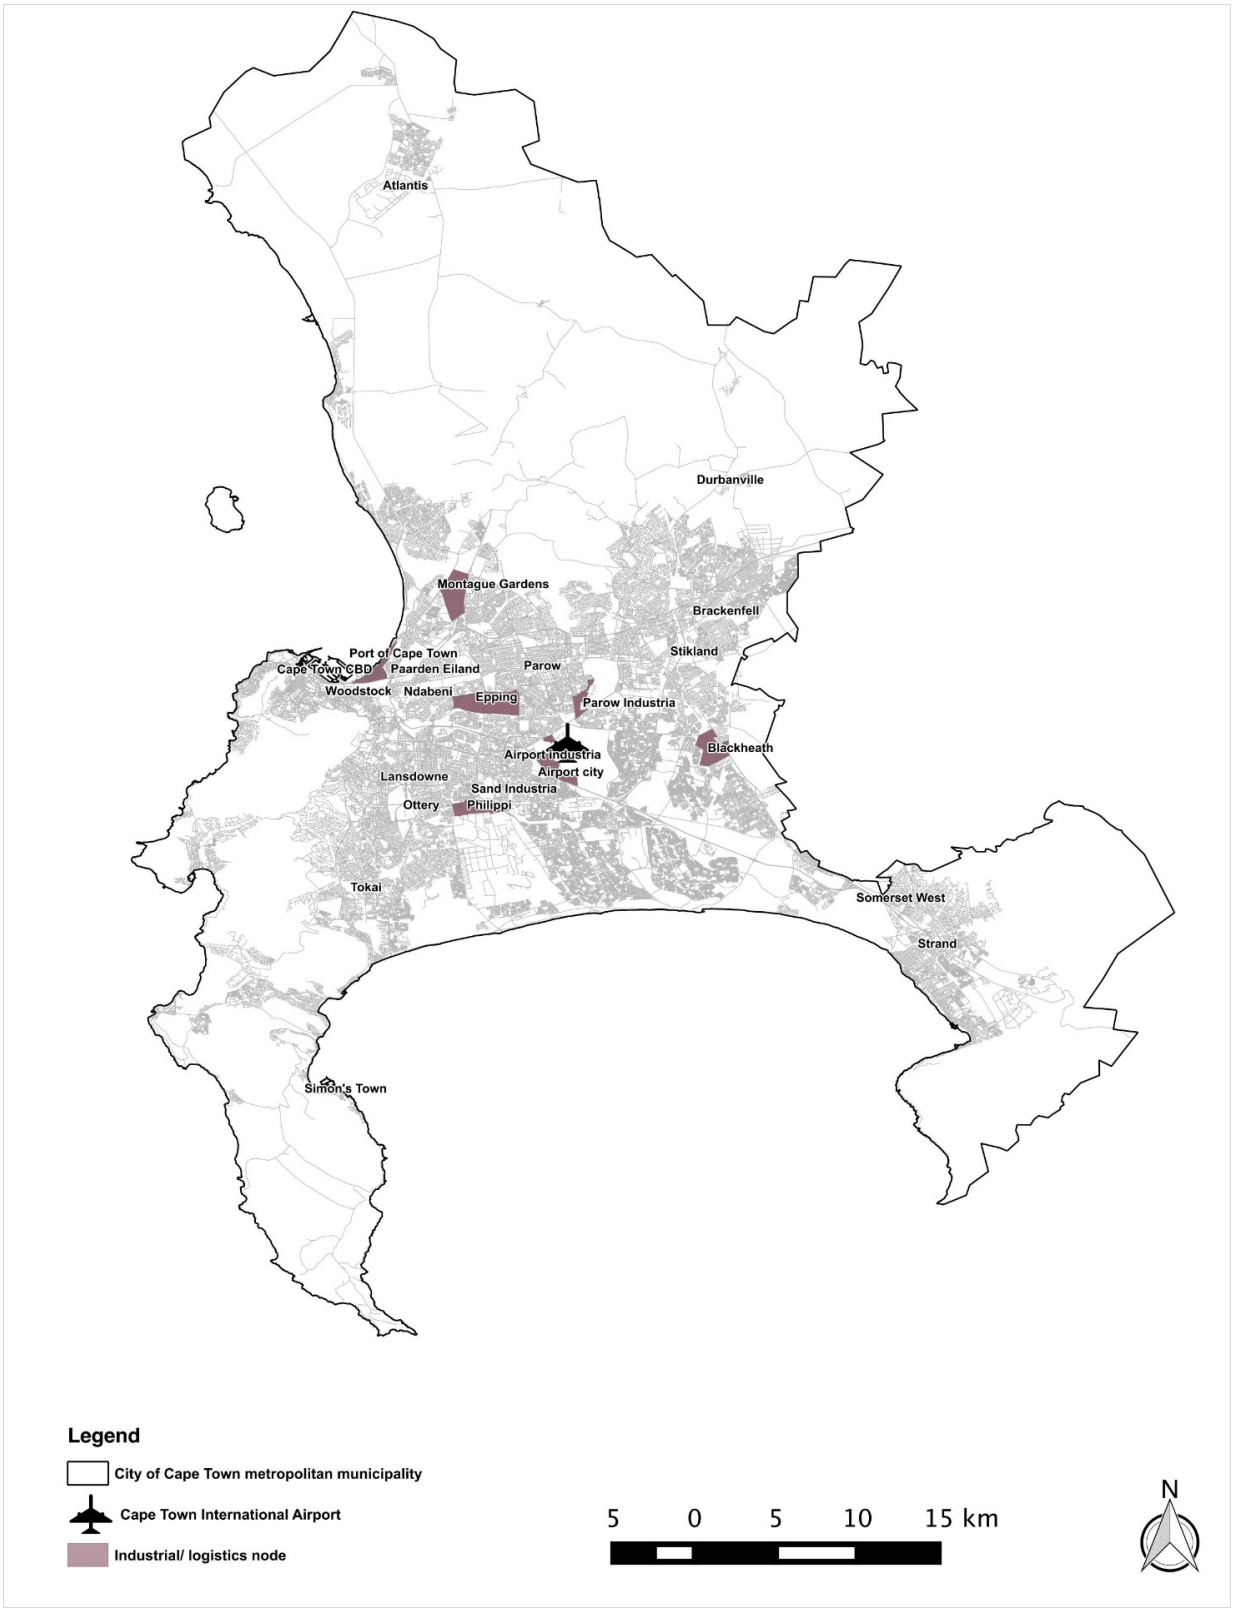

Fig. 1: The location of Cape Town International Airport relative to other selected industrial/logistics clusters.

5.3 Data collection methods

According to Heitz, Launay and Beziat (2017), a growing body of research highlights the acute lack of geo-spatial data on urban freight, resulting in a lack of a dedicated and accurate database on the geography of logistics firms (Heitz et al., 2018). Due to this lack of secondary information accurate at a land parcel level, alternative approaches were, à la Heitz, Launay and Beziat (2017), Heitz et al. (2018), and Mokhele (2018), employed to identify the applicable land parcels in preparation for the analysis of the property market value patterns. The identification of logistics firms involved examining the applicable company details on Google Maps, viewing the company names on the signage in Street View, and verifying their locations on the respective business websites where available. Per Heitz, Launay and Beziat (2017), several visual indicators were also important in identifying and validating logistics infrastructure and buildings like warehouses, terminals, and shipping container yards. These indicators included the shape and size of the building, large parking and manoeuvring areas for trucks (Heitz, Launay & Beziat, 2017), row buildings typical of the traditional self-storage facilities, and a rectangular shape and distinctly small size of shipping containers.

A total of 15 land parcels used for logistics facilities were randomly identified in each node per the process above. For comparability purposes, it was decided to analyse the same number of properties across the seven industrial/logistics zones. All in all, 105 land parcels housing logistics facilities were identified. It is intended that this exploratory study provides a foundation for the development of a geo-spatial dataset of logistics facilities in the City of Cape Town municipality, which can be continuously updated.

The unique property details of each identified land parcel were searched on the City of Cape Town's cadastral GIS shapefile, which was overlaid on Google Satellite in QGIS 3.32.0. Three key attributes were obtained from the cadastral shapefile and recorded on an Excel spreadsheet: land parcel extent (in m2), street address, and property number. The data for each logistics node was recorded on a separate tab in the spreadsheet.

The street addresses and property numbers were then used to extract the 2022 property market values from the City of Cape Town's valuation roll, available on the municipal website. The website makes provision for the values to be searched using either the unique property reference, sectional title, street address, and erf (property/parcel) number. The latter was primarily used in the study, and triangulated with the street address information. The property value information was extracted in December 2024. At the time of the study, the 2022 property market value data (as at 01 July 2022) were the latest available information for the City of Cape Town municipality. The City of Cape Town utilises a computer-assisted mass appraisal (CAMA) system to generate property values across the municipality (City of Cape Town, 2024) (also refer to the literature review section).

5.4 Data analysis methods

The information for the airport environs and other six industrial/logistics clusters (including the name of the applicable industrial area, property/land parcel extent, and market value) were collated into a single spreadsheet and loaded to IBM's statistical package for social sciences (SPSS), version 29, for analysis. Basic statistical analysis was then conducted to identify property market value similarities and differences between the area in the vicinity of the airport and other key logistics nodes in the City of Cape Town municipality.

6 RESULTS

This section presents the results of the statistical analysis conducted to compare the environs of Cape Town International Airport with selected other logistics clusters.

6.1 Descriptive statistics

The results showed that the mean property values of land used for logistics facilities in the vicinity of the airport (at R37 965 333) ranked sixth among the seven logistics clusters analysed. The mean property values were highest in Montague Gardens/Milnerton at R128 286 666, followed by Parow Industria, Philippi, Paarden Eiland, Epping, and the airport environs. Blackheath had the lowest mean of R33 464 133. In terms of the range, the land used for logistics facilities near the airport ranked fourth, with Montague Gardens having the widest range of approximately R706 million, followed by Philippi, Parow Industria, Blackheath,

and Paarden Eiland. Like the relatively low mean property values, Epping had the narrowest range of R101 300 000 (Table 1).

A land parcel with the highest market value in 2022, at R712 million, was situated in the Montague Gardens/Milnerton area, followed by properties in Philippi, airport environs, Parow Industria, Blackheath, and Paarden Eiland. Epping had the lowest maximum value of R1.08 million. The 2022 standard deviation for the zone near the airport and other six logistics clusters show that the figures ranged significantly above and below the mean values, implying the moderate to high variability of the market property values of land housing logistics facilities across the municipality.

		Airport environs	Blackheath	Epping	Montague Gardens/Milnerton	Paarden Eiland	Parow Industria	Philippi
N	Valid	15	15	15	15	15	15	15

Maximum		284 000 000	163 800 000	108 400 000	712 000 000	155 400 000	206 000 000	310 000 000

Table 1: Statistical patterns of the values of land used for logistics activities. Values are in South African Rand (ZAR).

6.2 Average market property values

To gain a more meaningful and disaggregated understanding of the property values, it was essential to analyse them in relation to the extent of each land parcel. Regarding the property value relative to extent, the mean values in the vicinity of the airport ranked second, following Paarden Eiland. Notably, Paarden Eiland had three land parcels with top average values relative to extend i.e. R9 507/m², R9 206/m² and R7 656/m², with a land parcel near the airport following at R5 960/m2. A land parcel with the lowest average value, at R509/m², was in Blackheath.

Table 2 presents the values of the 15 land parcels analysed in the vicinity of the airport, including the average market value per property extent. Although the highest value was R284 million (Land Parcel 10), the average was R3 509/m2 due to the large extent of the land parcel (Table 2). This expansive business park houses various logistics establishments, including courier companies and storage facilities. The land parcel with the lowest market value near the airport was R598/m2. In terms of the physical extent, this was the second- largest land parcel in the vicinity of the airport.

	Extent (m^2)	Market value (2022)	Average value/m^2 (2022)
Land Parcel 1	30 208	65 400 000	2 165
Land Parcel 2	2 097	6 800 000	3 243
Land Parcel 3	2 836	6 480 000	2 285
Land Parcel 4	2 075	6 300 000	3 036
Land Parcel 5	1 287	5 100 000	3 963
Land Parcel 6	4 454	12 600 000	2 829
Land Parcel 7	1 503	5 100 000	3 393
Land Parcel 8	4 970	16 700 000	3 360
Land Parcel 9	1 054	3 300 000	3 131
Land Parcel 10	80 941	284 000 000	3 509
Land Parcel 11	76 859	46 000 000	598
Land Parcel 12	8 510	38 100 000	4 477
Land Parcel 13	5 668	19 600 000	3 458
Land Parcel 14	10 812	32 000 000	2 960
Land Parcel 15	3 691	22 000 000	5 960

Table 2: Values of land used for logistics near Cape Town International Airport. Values are in South African Rand (ZAR).

7 DISCUSSION

The findings presented in the preceding section show that, in terms of the 2022 market property values, the land used for logistics facilities near Cape Town International Airport did not significantly differ from those in other logistics nodes within the City of Cape Town municipality. This challenges the literature suggesting that land values around airports are significantly lower, a factor attracting space-intensive activities such as warehouses (for instance, refer to Fernández, Caralt & Valcarce, 2023). The placement of logistics firms near

the airport are, therefore, potentially influenced by a combination of other factors beyond merely property values.

These findings show that, holding other locational factors constant, logistics firms near the airport could potentially locate in various zones across the broader airport catchment area. As noted by Mokhele and Mokhele (2023), the possible airfreight catchment of Cape Town International Airport can extend to approximately a 20 km radius of the airport. In light of the findings, the authorities are urged to, in the spatial planning efforts, take cognisance of the potential extent of the catchment, in which airfreight-related firms do not necessarily locate geographically near the airport (Mokhele & Mokhele, 2023).

Two logistics nodes in the City of Cape Town municipality (out of the seven analysed) stood out in terms of the highest land parcel values and average values. A land parcel with the highest market value in 2022 was in Montague Gardens/Milnerton at a staggering R712 million while the highest value near the airport was a relatively lower R284 million. Notably, in the 2000s, Montague Gardens was regarded as the fastest-growing industrial area in the City of Cape Town since 1985 (Mokhele & Fisher-Holloway, 2024). In terms of the average market values, Paarden Eiland, situated near the Port of Cape Town, had the highest average of R9507/m2 compared to the airport environs' highest average of 5960/m2. This provides evidence that Paarden Eiland has maintained a historical trend of relatively high property values. For instance, back in 1996, the area had a prime industrial rental rate that was three percent higher than the municipal average (City of Cape Town municipality, 2002).

8 CONCLUSION

To supplement the literature on the possible logistics catchment of airports, the paper explored the market values of the land used for logistics facilities in the vicinity of Cape Town International Airport compared to other six selected main industrial/logistics clusters in the City of Cape Town municipality, South Africa.

It was found that the patterns of land values near the airport did not significantly stand out, either at the highest or lowest end of the spectrum, compared to the other logistics clusters analysed. Therefore, it can be deduced that the values in the area are not a potential primary centrifugal or centripetal factor, showing that other factors might influence the placement of logistics facilities near the airport. From the perspective of land values, it can therefore be argued that, ceteris paribus, the logistics firms near the airport could locate in various areas within the municipality and vice versa.

A main shortcoming of the study is that it focused solely on market property values in comparing the land used for logistics facilities near the airport with other logistics nodes, and analysed the values for one year, 2022. It is, therefore, recommended that further research be conducted to analyse the market value patterns over time, and to examine additional factors influencing the location of logistics facilities within the catchment area. A more comprehensive analysis could also extend to a sub-regional scale, transcending administrative municipal boundaries.

1 ABSTRACT

Gentrification is a process of urban development in which an area undergoes redevelopment, which raises the cost of housing, rent, and standard of living, attracting middle-class and other higher-income earners to move in, which in turn leads to the displacement of lower-income residents, changing the composition of neighborhoods and generating population replacements. This study takes Taipei City as the study area, utilizing Multiple Criteria Decision Making (MCDM) to synthesize the data on socioeconomic indicators and overlapping them into a Geographic Information System (GIS). The overlapping results identify the areas that meet the screening criteria of each indicator to recognize the gentrification areas in Taipei City and analyze the characteristics of the areas. The results were used to indentify gentrification area in Taipei City and explore relationship between gentrification and social vulnerability.

Keywords: Planning, social vulnerability, Geographic Information System (GIS), Multiple Criteria Decision Making (MCDM), gentrification

2 INTRODUCTION

Gentrification is a process of urban development in which an area undergoes redevelopment, which raises the cost of housing, rent, and standard of living, attracting middle-class and other higher-income earners to move in, which in turn leads to the displacement of lower-income residents, changing the composition of neighborhoods and generating population replacements[1], [2], [3], [4], [5], [6], [7]. In addition to changing the physical environment, gentrification also affects the existing social structure, culture, economy, and industries. Many scholars have put forward different research explanations on gentrification, such as “New-Build Gentrification”, “ Rural Gentrification”, “Greentrification”, “Studentification”, “Commercial Gentrification”.

According to the research on gentrification, the change in the physical environment will generate suction and thrust, which will make the existing residents move out and the new residents move in. This will lead to the replacement of social classes in gentrification areas and change the composition of residents in these areas. In order to cope with the population replacement caused by gentrification, the current strategy is to minimize the displacement of disadvantaged groups such as low-income households. To this end, relevant measures include rent control to avoid excessive rents and eviction restrictions to protect tenants from forced evictions. Regulating land ownership and development through taxation provides public or affordable housing and promotes the regeneration of local communities. [10], [11].

An effective gentrification strategy should be based on a certain understanding of the development of gentrification. Therefore, the results of gentrification analysis should be used as an important reference for the formulation of various mitigation strategies. The government should be able to assess the impact of gentrification on different regions and provide the relevant departments with the necessary information to formulate a response to the specific situation. The development of tailor-made mitigation strategies [12] can effectively mitigate the potential negative impacts of gentrification, especially in the protection of disadvantaged groups.

The application of quantitative analyses to explore neighborhood changes derived from gentrification is still much debated. For example, Rent Gap is often applied to compare actual and potential rent differences [13], [14], or the application of census data to study socioeconomic changes [15], [16]. Huynh & Maroko (2014) used 1990 Census data and 2005 to 2009 American Community Survey (ACS) estimates to assess changes in economic status across communities. Three variables were chosen to construct indicators of community economic status: the number of people over the age of 25 with a college degree, the number of residents living below the federal poverty line, and Median Household Income (MHI). The study examines the

association between gentrification and preterm birth (PTB) and analyzes the effects of maternal race and educational attainment. Millard-Ball (2002) used income and residential mobility to study gentrification using Stockholm as the study area. Many communities have experienced significant changes in their economic and social structures that may have impacted the health of their residents, with particular differences in the impact on different ethnic groups (e.g., low-income groups, and minority groups).

Vulnerability refers to the propensity and predisposition to negative impacts. The United Nations Office for Disaster Risk Reduction (UNISDR) points out that vulnerability is a disaster-sensitive characteristic formed under the interaction of natural, social, economic and environmental factors; the United Nations University – Institute for Environment and Human Security (UNU-EHS) points out that vulnerability is a disaster-sensitive characteristic formed under the interaction of natural, social, economic and environmental factors; UNU-EHS points out that vulnerability is a disaster-sensitive characteristic formed under the interaction of natural, social, economic and environmental factors. UNU-EHS, on the other hand, recognizes that vulnerability is determined by the interaction of natural, social, and environmental factors that determine the expected loss from a disaster.

The Sixth Assessment Report (AR6) of the Intergovernmental Panel on Climate Change (IPCC) states that the level of risk will depend on the latest trends in vulnerability, exposure, socio-economic status, and adaptive capacity, with vulnerability being an important factor affecting human and socio-ecological systems, and age, Vulnerability is an important factor affecting human and social ecosystems, while age, medical resources, and social deprivation, as well as working and living conditions combine to determine human vulnerability [19].

The existence of vulnerability is widely recognized by various international organizations, and many studies have pointed out that vulnerability is often expressed in a negative and passive form, that is, the degree of sensitivity to disasters. Past research on vulnerability can be divided into three main orientations: (1) vulnerability is a condition that exists before a disaster occurs; (2) vulnerability is a key factor affecting the ability to adapt and respond to a disaster; and (3) vulnerability can have a certain degree of impact on a specific site. Turner et al. (2003) defined “vulnerability” as a condition consisting of natural hazards, including exposure, resistance, and vulnerability to natural hazards. Turner et al. (2003) defined “vulnerability” as being caused by natural hazards, including Exposure, Resistance and Resilience. With the development of disaster-related research, more and more studies have shown that different traits and capabilities reflect the degree of impact after an environmental shock [21], [22].

Over the past 30 years, vulnerability has become a fundamental concept in local, national, and international disaster research and the development of mitigation strategies [23], [24]. In this context, social vulnerability refers to the analysis of factors that are known or unknown to produce certain outcomes of an event. Yiing-Jenq et al. (2004) analyzed the social vulnerability of different segments of society based on the characteristics of age, gender, health, social welfare, and economy, as well as the coping strategies of social groups in response to emergencies. The study showed that children, the elderly, the sick, and the disabled may react to risk quite differently from the young and healthy. Evans & Kantrowitz (2002) also pointed out that characteristics such as income level, occupation, and household size determine socioeconomic status, which in turn determines the place of residence, its quality of life, and infrastructure, and ultimately the impact of risk.

Social vulnerability is recognized as a consequence of existing social inequalities, and many studies have shown that poor health, physical and mental impairments, and poverty are strongly associated with vulnerability [27], [28], [29]. In addition, social inequality determines an individual's living space and the nature of that living space. The vulnerability of the living space (including the means and empowerment of the dwelling, the neighborhood, and the infrastructure of neighborhood) can also effectively determine socio-economic vulnerability, which is closely related to the characteristics of the individual. Factors such as the degree of urbanization, population growth and density can further increase the vulnerability of living space.

The northern part of Taiwan has been developing rapidly in the past few decades, however, there is a relative lack of research on gentrification in Taiwan. As urban development accelerates, real estate prices continue to rise. Many areas with low socio-economic status have gradually attracted middle-class and high-income groups, leading to the replacement of social classes and changes in local characteristics. It is worthwhile to discuss how to reduce or even avoid the impact of gentrification on communities and disadvantaged groups.

Therefore, this study is expected to take Taipei City as the research field and use socioeconomic indicators to identify gentrification areas and explore the relationship between gentrification and social vulnerability.

2.1 Conceptual Model

This study is divided into two parts. First, the socio-economic indicators were integrated using a multi-criteria decision-making approach based on the key factors related to gentrification. This was then overlaid onto the GIS to identify areas that met the screening criteria for each indicator. The social vulnerability indicators were organized to create a vulnerability map. Next, this study attempts to analyze the spatial correlation between gentrification and social vulnerability variables and explore the relationship between gentrification and vulnerability (fig. 1).

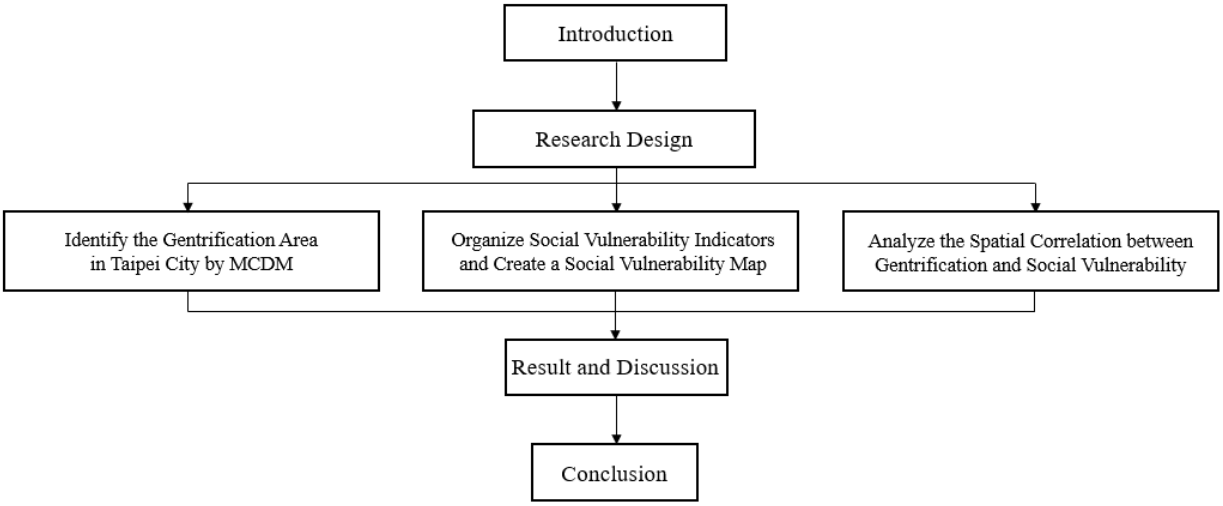

Fig. 1: Conceptual framework.

Fig. 2: Study Area (Source: generated by the authors).

2.2 Intro of Study Area

The northern part of Taiwan has developed rapidly over the past few decades and is the economic capital of Taiwan. It has many job opportunities, well-developed transportation facilities, abundant education and medical resources, and the most significant commercial development. As urban development accelerates, real estate prices continue to rise. Many areas with low socioeconomic status are gradually attracting middle-class and high-income groups, leading to a shift in social class and a change in the character of the area. Therefore, the scope of this study was chosen to be Taipei City (fig. 2), and the village was used as the unit of statistics and analysis. Multiple criteria decision aking (MCDM) was used to synthesize the socio-economic indicators and apply them to the GIS. To identify the areas that meet the screening criteria of each indicator, we identified the areas of gentrification in Taipei City and explored the relationship between gentrification and social vulnerability.

2.3 Methods

2.3.1 Multiple Criteria Decision Making (MCDM)

In this study, Multiple Criteria Decision Making (MCDM) was adopted for the first time for the gentrification indicators and the subsequent field screening. MCDM is an analytical tool used to measure multiple criteria or to make decision choices for multiple scenarios. MCDM is widely used by the planning community to solve problems in various fields because of its ability to consider multiple functions, attributes, criteria, objectives, and problems simultaneously [30], [31], [32]. Seo & Sakawa (2012) categorized the process into six stages: identifying decision objectives, determining decision preferences, evaluating alternatives, selecting weighting methods, aggregating, and making decisions. In this process, the broad and abstract objectives are transformed into more specific goals, and the weights of each factor are evaluated to compare the advantages and disadvantages of the alternatives so that the most suitable and practical alternatives can be selected to effectively help solve the decision-makers problem. In this way, the most suitable and practical solution can be selected to help the decision-maker solve the problem effectively. Different objectives and weights may affect the solution.

2.3.2 Spatial Autocorrelation Statistics

The purpose of spatial autocorrelation statistics is to examine the similarity between spatial units based on spatial distance. This approach is summarized in the “First Law of Geography”: everything is related, but proximity is more related [33]. If there is significant positive spatial autocorrelation, spatial units with similar spatial properties tend to be close to each other. In addition, spatial autocorrelation can also be used to measure geographic proximity between units or binary events [34]. Spatial autocorrelation statistics apply to the whole region (global) or neighboring regions (local). While global spatial autocorrelation explores whether there is spatial clustering among spatial units, local spatial autocorrelation explores the spatial variability of spatial autocorrelation at the local scale [35]. In this study, we will explore the degree of similarity between objects in the space, examine the aggregation or dispersion of spatial phenomena in the space due to different attributes, and analyze the correlation between the two variables (gentrification & social vulnerability) to explore the spatial correlation between the two variables.

2.4 Measurement Indicators of the Survey

This study focuses on the relationship between gentrification and vulnerability. Based on the literature review, five socioeconomic indicators of gentrification were selected: income, working-aged population, high degree population (university education or above), real estate sales, and house rent. The rate of change from 2012 to 2021 was used to identify gentrification areas. Based on the literature review, three indicators of social vulnerability were selected from 2021: the proportion of the elderly population, the proportion of the low-income population, and the proportion of disability (table 1). The indicators of gentrification and vulnerability were then standardized to obtain a map of gentrification and a map of social vulnerability.

Type	Indicators	Period
Socioeconomic	Income	2012 to 2021
	Working-aged population	2012 to 2021
	High degree population	2012 to 2021

	Real estate sales	2012 to 2021
	House rent	2012 to 2021
Social vulnerability	Proportion of aged population	2021
	Proportion of low-income population	2021
	Proportion of disability	2021

Table 1: Indicators of this study.

3 RESULT AND DISCUSSION

3.1 Socioeconomic Features of Gentrification in Taipei City

The rate of change in high degree has the highest value (1.08%) in Sanchong Vil., Nangang Dist., and the lowest value (-0.15%) in Xuefu Vil., Daan Dist. (fig. 3). The Rate of change in working-age has the highest value (0.35%) in Sanchong Vil., Nangang Dist., and the lowest value (-0.38%) in Longfu Vil., Zhongzheng Dist. (fig. 3). The rate of change in income has the highest value (16.68%) is located in Chongyang Vil., Nangang Dist., and the lowest value (-0.99%) in Laoquan Vil., Wenshan Dist. (fig. 3). The highest value of rate of change in real estate sales (2.18%) was found in Daan Dist., while the lowest value (0.25%) was found in Nangang Dist. (fig. 4). The highest value of rate of change in house rent (0.22%) was found in Wenshan Dist., while the lowest value (-0.11%) was found in Datong Dist. (fig. 4). The Gentrification map is obtained by standardizing and adding up the values of the above indicators. The highest value (15.15) is distributed in Sanchong Vil., Nangang Dist., while the lowest value (-8.48) is distributed in Longfu Vil., Zhongzheng Dist. (fig. 4).

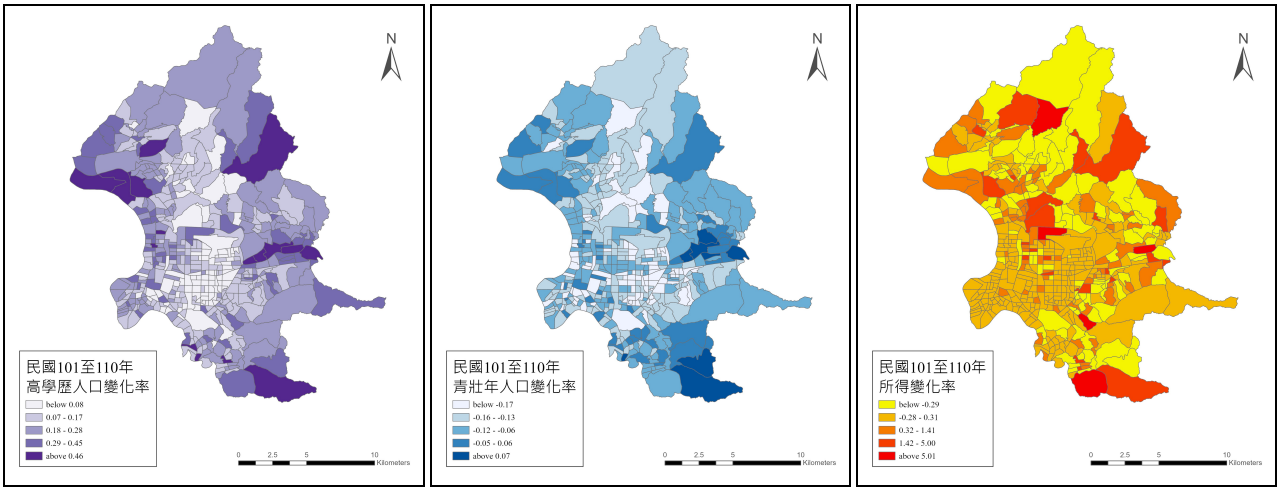

Fig. 3: Rate of change in high degree/Rate of change in working-age/Rate of change in income.

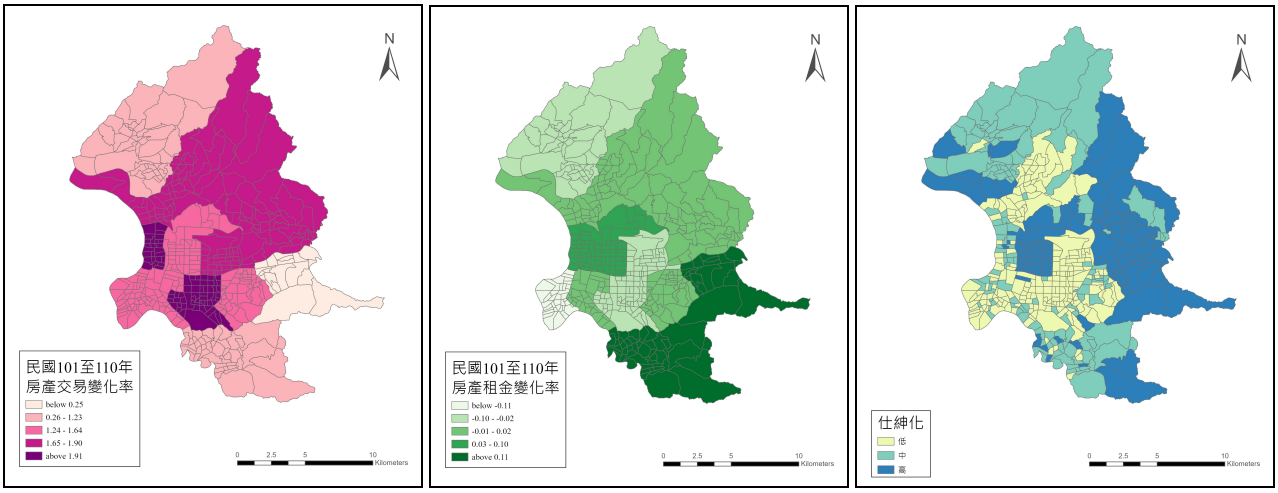

Fig. 4: Rate of change in real estate sales/Rate of change in house rent/Gentrification map.

3.2 Distribution of Social Vulnerability in Taipei City

After standardizing and adding up the values of the social vulnerability indicators (proportion of aged population, proportion of low-income population, and proportion of disability), the highest value (3.42) was found in Changlong Vil., Daan Dist., while the lowest value (-3.63) was found in Chongyang Vil., Nangang Dist. (fig. 5).

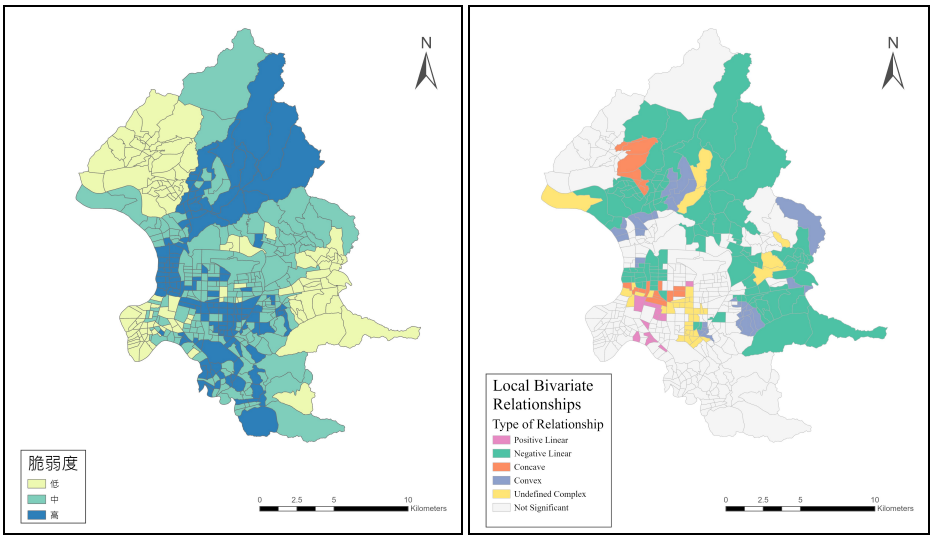

Fig. 5: Social vulnerability map/Result of Local Bivariate Relationships.

3.3 Relationship between Gentrification and Social Vulnerability

Positive linear is mostly found in ZhongZheng Dist., probably due to the fact that it has a smaller population of highly educated and young adults. The rate of change also shows a negative growth trend. The vulnerability level is more in the middle to high range, which results in a positive correlation between gentrification and social vulnerability. 11 of features are not significant, about 2.41%. The negative linear is mostly distributed in Nangang, Shilin, and Beitou Dist. The higher degree of gentrification and lower degree of vulnerability in Nangang District resulted in a negative correlation between the degree of gentrification and the degree of social vulnerability in this district (fig. 5). 107 of features are not significant, about 23.46%. Not significant means that the relationship between two variables are not significant or other explanatory factors need to be considered. 257 of features are not significant, about 56.36%.

4 CONCLUSION

This study synthesizes the relevant literature on the definition, causes, and observable characteristics of gentrification, and identifies the key influencing factors as the basis for analysis. Using Taipei City as the study area, this study utilized a multi-criteria decision-making approach to synthesize the socio-economic indicators. This was then overlaid onto the GIS to identify areas that met the screening criteria for each indicator. To identify the areas of gentrification in Taipei City and to explore the relationship between gentrification and social vulnerability. Provide references for the government to formulate follow-up policies. This study suggests that the government can target the less vulnerable areas and provide substantial social welfare to reduce the impact of gentrification in these areas.

1 ABSTRACT

Similar to other regions in Europe, the strategic positioning of medium-sized and small towns in Serbia has not yet been developed to its full extent. At the same time, its potential to contribute to sustainable, balanced territorial development and cohesion at national, regional, and local levels has been recognized through planning documents, strategies, and academic literature. The role of urban identity in the sustainable development of small and medium-sized towns has been especially emphasized. Therefore, there is a need to explore the complex concept of urban identity through analyzing the relevant literature dealing with its definition and practical use in planning. The main goal of the identity analysis is to highlight the specific characteristics of the selected settlements and value them as spatial, material, and immaterial elements that should be at the same time protected and developed. This implies the application of a place-based approach in planning and developing strategies to include the concept of identity as an important parameter for the qualitative assessment of planning solutions. The resulting conceptual framework consists of material and immaterial elements of identity that can be grouped into sets of specific characteristics. Secondly, the sustainable development policy framework for small urban areas in Europe has been investigated, resulting in a set of key thematic fields applicable in general practice and all contexts. The third step subsumes relating the elements of identity with the key thematic fields and creating the framework for measures and strategic directions that would enable simultaneous protection of existing and creation of new place values. This methodology has been applied to the study of identity of five territorially connected municipalities in Western Serbia, that already share a number of common characteristics. Consequently, not only their individual but also their common identity, compared to other regions in Serbia, can be examined. The uniqueness of the individual towns affects the sustainable development policies at the urban level – for regeneration and revitalization of urban centers, their specialization, and positioning. The uniqueness of the common territory opens up possibilities for sustainable development policies at the regional level, for catalyzing economic growth and reinforcing polycentric development at the national level.

Keywords: urban identity, sustainable development, planning strategies, medium-sized and small cities and towns, Serbia

2 INTRODUCTION

Strategic positioning of medium and small towns in Serbia is still not fully developed. At the same time, their potential to contribute to sustainable, balanced territorial development and cohesion at the national, regional, and local levels has been recognized through planning documents (NARS, 2010), strategies (NARS, 2019), and scientific literature (Spasić, 1995, Kokotović Kanazir, 2016, Manić, Niković, 2014). The role of urban identity in the sustainable development of small and medium-sized urban settlements is highlighted in this paper. It explores the complex concept of urban identity through an analysis of relevant literature that deals with the definition and practical application of the urban identity concept in sustainable development strategies and planning.

The position of the urban identity concept in recent European legislation (EUI, EC, 2020, UN, 2017) is examined, as well as in the legal, planning, and strategic documents in Serbia (NARS, 2010, 2013, 2019, 2020, 2023). Key determinants and opportunities for applying this concept in urban planning practice are identified based on a review of theoretical research (Mansour et al., 2023, Duan et al., 2021, Rifaioglu, Güçhan, 2007, etc.). A methodology is proposed that can be applied to study the identity of urban areas with the aim of formulating strategic guidelines for their sustainable development. This methodology has been

used in a study of the identity of five territorially connected municipalities in Western Serbia, which is currently being developed at the Institute of Architecture and Urban and Spatial Planning of Serbia – IAUS (GOA, 2024-2025). Due to their territorial connection, these municipalities already share a number of common characteristics. Therefore, not only can their individual identities be examined, but also their collective identity, in comparison with other regions in Serbia. The implementation of the results of the identity study through strategic projects, using various financial instruments for urban development, contributes to the affirmation of urban areas as active advocates of sustainable and integrated urban and territorial development.

3 THE ROLE OF URBAN IDENTITY IN SUSTAINABLE DEVELOPMENT OF SMALL AND MEDIUM-SIZED TOWNS IN RECENT EUROPEAN LEGISLATION

In 2006, ESPON (European Observation Network for Territorial Development and Cohesion) conducted a study titled "The Role of Small and Medium-Sized Cities," which highlighted the issue of insufficient research and development policies for this type of settlement compared to large cities and metropolises. The role of small and medium-sized cities is defined in relation to: a) two complementary areas: spatial organization and urban governance; and b) three levels of policies: urban policies related to the regeneration of urban centers; regional policies, which focus on opportunities for improving economic development; and spatial development policies, aimed at polycentric urban development, strengthening urban-rural links, and controlling the urban growth of large cities (ESPON, 2006). Research presented in this paper assumes that the network of small and medium-sized cities represents a key framework for achieving the goals of sustainable polycentric spatial development at all levels (Zavodnik et al., 2008, Kokotović Kanazir, 2016).

The concept of identity within the framework of the recent European legislation plays a significant role, whether directly or indirectly mentioned, through policies for sustainable, inclusive, and just cities that must respect cultural and social differences. In this context, identity refers to how cities and communities are recognized and how they connect with their cultural heritage, tradition, and face contemporary global challenges. In addition to social and cultural aspects, the physical aspects of urban identity (spatial organization, public spaces, urban form, etc.) gain a special role within the guidelines for sustainable development in these documents.

The New Urban Agenda (NUA) emphasizes that culture and cultural diversity should play an active and unique role in development initiatives, including the promotion of new sustainable consumption and production patterns that contribute to the responsible use of resources and the mitigation of harmful effects of climate change. The NUA highlights the following transformative commitments to sustainable development: 1) social inclusion and poverty reduction, with a particular role for spatial organization; the structure and arrangement of urban space; 2) sustainable and inclusive urban prosperity and opportunities for all, where urban form, infrastructure, and architectural design play a special role as drivers of efficient and sustainable resource use; urban planning that ensures appropriate compactness and density, polycentricity, and mixed land uses; 3) environmentally sustainable and resilient urban development, where a special role is played by increasing the resilience of urban centers as areas that are particularly vulnerable to the harmful effects of climate change, disasters, and all forms of pollution and environmental degradation; the smart city approach, which takes advantage of digitization, clean energy, technology, and innovative transportation technologies (UN, 2017).

The Territorial Agenda of the European Union until 2030 advocates for territorial cohesion and the use of the specificities/diversities of places (in the context of this study: identity) as a comparative advantage and development potential. The natural and built environment are viewed as parts of territorial capital and identity. Major threats to territorial development are identified as the neglect or degradation of ecological values, environmental quality, and cultural assets, which are exacerbated by urbanization, globalization, and uncoordinated spatial activities. The Territorial Agenda addresses higher spatial levels – regions and functional areas – through a place-based approach, sectoral policy coordination, and multilevel governance. It emphasizes the need for interventions in the areas of: 1) improving quality of life – through access to public services, enhancement of urban mobility and healthcare, creating resilient built environments, and high-quality architecture; 2) improving public services – through accessibility, user-friendliness, affordability, and quality that directly impact higher quality of life and economic development; 3) addressing

demographic and social inequality challenges; 4) digitalization and the 4th industrial revolution; 5) employment and economic development (EC, 2020).

The New Leipzig Charter promotes integrative and sustainable urban development. Like the Territorial Agenda, it advocates for a place-based approach, multilevel governance, and participation (multi-level and multi-stakeholder approach). In the context of urban development, the place-based approach involves recognizing the transformative potential of European cities – small, medium, and large – through their diversity. It emphasizes that cities are unique civilizational creations and key elements of European urban heritage and citizens' identity. This further emphasizes the importance of architectural heritage, the necessity of its protection, and its simultaneous activation as a resource for sustainable development. Special emphasis is placed on the capacity of cities for social interactions at various levels, making them an active part of the polycentric urban system, as well as an adequate platform for social innovations and testing new ways to solve urban development problems. The New Leipzig Charter highlights the need for coordination of measures across three key spatial levels: 1) the neighborhood level – where urban challenges are most prominent, directly relating to local community issues, requiring specific neighborhood policies; 2) the local government unit level – strategic guidelines and specific rules for the entire urban area, serving as a formal link between the neighborhood level and higher spatial levels, and are particularly important for improving the quality of life in small and medium-sized cities, establishing connections with the environment and rural hinterland; 3) the functional area level – regional and metropolitan context based on a complex network of functional interdependencies and partnerships, premised on the idea that cities must collaborate and coordinate development policies and instruments with their rural and suburban environments (EC, 2020).

The European Urban Initiative (EUI) is part of the new EU cohesion policy for the 2021-2027 period. The EUI is a key tool to support cities of all sizes, build capacity, support innovation, and develop solutions for urban challenges, applicable in different environments and scales. The new EU cohesion policy for 2021-2027 sets five main goals that guide investments in urban areas: 1) Smart Europe – innovation, digitalization, economic transformation, and support for small and medium enterprises; 2) Green Europe – implementation of the Paris Agreement on climate change; 3) Connected Europe – strategic transport and digital networks; 4) Europe for Society – support for social rights, quality jobs, education, skills, social inclusion, and access to services; 5) Europe Closer to Citizens – support for local development strategies and sustainable urban development across the EU. Although all the goals are interconnected and inseparable, the concept of identity in this work is most closely related to the fifth goal, which is achieved through territorial instruments: integrated territorial investment (ITI), community-led development (CLLD) (EC, 2021, EUI, https://www.urban-initiative.eu).

4 THE ROLE OF URBAN IDENTITY IN SUSTAINABLE DEVELOPMENT OF SMALL AND MEDIUM-SIZED TOWNS IN LEGISLATIVE, PLANNING, AND STRATEGIC DOCUMENTS IN SERBIA

Recent planning and strategic documents in Serbia define the basic principles of spatial development, in line with the recent European legislation suppoting sustainability, territorial cohesion, strengthening competitiveness, public participation, polycentric territorial development, strengthening urban-rural links, etc. In the context of the research of urban identity discussed in the paper, the following principles are of particular importance: functional specialization, respecting comparative advantages in terms of the development potential of regional units; forming and strengthening networks of cities and settlements (clusters) that can provide the development of complementary functions; improving transportation accessibility as a dominant factor for exploiting territorial potentials and balanced development; developing cultural identity and territorial recognizability; strict adherence to the protection of public interest, public goods, and public spaces; improving and protecting natural and cultural heritage as development resources (NARS, 2010). This chapter examines the role of urban identity advancement and its underlying principles in supranational and national policies relevant to the sustainable development of urban areas in Serbia, to provide guidance on implementing these principles at the local level.

In accordance with European documents reffering to the sources of financing sustainable urban development (EC, 2021) and the application of territorial instruments, the national strategy for sustainable development (NARS, 2019) and several local strategies (GOA, 2023) have been adopted. These strategies emphasize strengthening the identity of urban areas by defining priority areas for urban interventions and directing

financing towards priority projects. The methodology for developing and implementing territorial strategies encourages the application of key principles of good governance in urban and territorial development, such as urban policy as a public good (public interest), integrated approach, participation and co-creation, multilevel governance, and a place-based approach (EC, 2020, UN, 2017).

The Law on Planning and Construction (NARS, 2009-2023) bases the planning, regulation, and use of space on the following principles: 1) Sustainable development through an integrated approach in planning; 2) Balanced territorial development; 3) Rational use of land by encouraging urban and rural renewal and reconstruction measures; 4) Rational and sustainable use of non-renewable resources and optimal use of renewable resources; 5) Protection and sustainable use of natural and immovable cultural goods;... 10) Public participation; 11) Preservation of customs and traditions; 12) Preservation of environmental values, integrity, and the uniqueness of landscapes; 13) Horizontal and vertical coordination (Article 3). Sustainable development, as defined by this law, is "the alignment of economic, social, and ecological aspects of development, the rational use of non-renewable resources, and ensuring conditions for greater use of renewable resources, thus enabling present and future generations to meet their needs and improve their quality of life." (NARS, 2009-2023). Regarding the study of the role of urban identity in this document, the broad definition of sustainable development leaves room for discussion about diverse human needs, including psychological, aesthetic, and so on, as well as quality criteria, which certainly encompass the identity of a place. The law does not specify the term "integrated approach," and terms like "identity," "character," "sense of place," etc., are not mentioned as potentially valuable qualitative parameters, while quantitative parameters are precisely defined. These concepts are only indirectly addressed through the principles of planning, regulation, and use of space.

Through recent amendments and additions to the Law on Planning and Construction, two overarching strategies have been incorporated into spatial and urban planning documents, which provide an opportunity for a more operational interpretation and application of the concept of urban identity in development projects. The Sustainable Urban Development Strategy of the Republic of Serbia until 2030 (NARS, 2019) applies a participatory and integrated approach, considering the spatial dimension of sustainable urban development and the organization of processes that ensure coordination and cooperation. The integrated approach involves the inclusion of relevant thematic areas and tools/resources from various sectoral policies, actors, and institutions at different spatial and administrative levels (local, regional, national, supranational), in order to achieve a comprehensive (holistic) approach to urban development planning and management. The strategy contributes to strengthening the identity of urban areas by defining priority areas for spatial intervention, identifying development issues, and linking them to specific locations. In this way, local integrated urban development strategies are directed toward priority projects for financing. The strategy specifically highlights spatial units with cultural and architectural heritage, which are important landmarks in the cultural and historical development of urban settlements and groups of urban settlements (NARS, 2019).

The National Architectural Strategy for the period 2023-2035 (NARS, 2023) represents a document through which the state establishes a course of action aimed at: creating a high-quality built environment and space, protecting and improving the quality of the living environment, and, within that, preserving natural and cultural heritage. Some of the goals of architectural policy are: the valorization of real architectural values, protection, and improvement of spatial and environmental parts and units, protection of architectural heritage as one of the most important aspects of cultural identity and heritage of a state and its people; affirming the importance of architecture as a key factor in the economic development of the state and the stimulation of overall economic growth; raising awareness among the professional, scientific, and wider public about the significance of architecture and urban planning as one of the most important elements of the quality of life and work (NARS, 2023).

5 THEORETICAL AND METHODOLOGICAL FRAMEWORK FOR EXPLORING THE CONCEPT OF URBAN IDENTITY IN SUSTAINABLE DEVELOPMENT

A review of recent European and national documents indicates the presence and affirmation of the concept of urban identity and its role in sustainable development. However, there is a lack of concretization in the application of this concept, particularly through more precise definition and linking to action points. Comprehensive studies on urban identity highlight its theoretical foundation in psychology, environmental studies, and urbanism (Mansour et al., 2023), as well as its insufficiently precise definition, which calls for

its differentiation from related concepts such as place identity, sense of place, attachment to place, authenticity, and character (Jiven and Larkham, 2003).

5.1 Key Determinants of the Concept of Urban Identity in Theory: Complexity, Multifacetdness, and Dynamic Nature

An analysis of contemporary theoretical contributions on the topic of urban identity reveals three key characteristics of this concept: complexity, multifacetdness, and dynamism.

Complexity: This characteristic implies that urban identity is composed of various elements, which can be identified through content analysis. It is not a simple, singular concept, but rather a combination of many factors acting in synergy. It is emphasized that urban identity is a complex, composite concept containing both material (built and natural environment) and immaterial elements (people, culture, activities etc.), where a specific combination of characteristics produces a spatial and visual effect, i.e., urban identity, which makes places recognizable (Rifaioglu and Güçhan, 2007; Kropf, 1996). We perceive urban areas because they distinctly differ from the surrounding natural or undeveloped environment, or from other places we carry in our memory (Kropf, 1996).

Multifacetdness: This characteristic emphasizes that urban identity can be linked to different aspects of the spatial context. These could include regional, urban, ecological, landscape, social, and other aspects that reflect the diverse layers that constitute the identity of urban space. The extended definition of urban spatial identity becomes a subject of interpretation through three paradigms: landscape, culture, and economy (Duan et al., 2021). In the landscape paradigm, urban spatial identity refers to the cumulative effect of heterogeneous spatial characteristics. In the culture paradigm, the component of cultural values to be protected is added exclusively to the physical component of the landscape paradigm. In the economy paradigm, existing spatial values, comparative advantages, and local resources are viewed as drivers of urban development with positive economic effects. Furthermore, the authors add a fourth, humanistic paradigm, considering the experiences, needs, behaviors of inhabitants, local practices, and culture (Duan et al., 2021).

Dynamism: The concept of urban identity is dynamic, depending on the observer and time, which are not static categories. It constantly changes and develops based on interactions between people and space over time. Urban identity is explained as the relationship between people and their environment; a dynamic interaction of tangible and abstract elements, where the environment encompasses not only built structures but also economic practices and social interactions (Mansour et al., 2023). The relationships between space users and the physical, social, and cultural aspects of that space shape urban identity over time (Rifaioglu and Güçhan, 2007).

5.2 Application of the Concept of Urban Identity in Urban Planning Practice and Sustainable Urban Development Strategies through an Analytical Approach to the Complexity, Multifacetdness, and Dynamism of the Concept

In contemporary research, urban identity is considered a conceptual tool for developing strategic thinking about sustainable urban development, as a response to the processes of globalization, rapid urbanization, and homogenization. Its application is especially significant in historical urban areas, but also in all processes of urban renewal in general (Mansour, 2023; Duan et al., 2021; Rifaioglu and Güçhan, 2007; Appendino, 2017; Salah Ouf, 2001; Taşçioğlu and Sirel, 2020). The application of urban identity in formulating policies and strategies for sustainable development involves addressing the three key determinants of the concept: complexity, multifacetdness and dynamic nature.

The analytical approach to the complexity of the concept involves identifying the elements of urban identity within a specific spatial context: breaking down the complex concept into components, both material and immaterial (Mansour et al., 2023; Rifaioglu and Güçhan, 2007). Complexity is emphasized as a key determinant for describing identity, which underlies every theory of built form. The analysis of complexity involves deconstructing the whole into parts and observing their connections, hierarchy, and patterns of organization (Kropf, 1996).

The analytical approach to multifacetdness involves linking elements of urban identity with various aspects of sustainable development. This includes considering how identity can contribute to or enhance ecological, social, economic, and cultural sustainability in urban areas. The main hypothesis is that every context possesses a unique identity that arises from physical, social, cultural, and historical aspects and elements.

Understanding and taking urban identity into account should be the starting point for policies and decision-making. In urban conservation projects (Rifaioglu and Güçhan, 2007), the identity study encompasses three phases: 1) documentation, which includes literature research, fieldwork, and workshops with local residents; 2) evaluation, which includes conducting a SWOT analysis and selecting identity components for different levels of intervention, considering the goals of sustainable development; and 3) the decision-making phase, which defines several thematic areas to ensure an integrative, sustainable, and manageable conservation process (Rifaioglu and Güçhan, 2007).

The analytical approach to the dynamism of the concept involves stepping out of the comfort zone of an exclusively expert approach – through the engagement of various stakeholders, particularly local residents, to ensure that urban identity is shaped by those who live in the observed area as its direct users. According to Kropf's research, understanding urban identity/character involves a dynamic approach between people and the urban area, namely, the observer and what is observed. Observers are experts who are part of a collaborative study that includes expertise from different fields: spatial planning, demographics, urbanism, urban protection, architecture, environmental protection, sociology, etc. The observed area is the territory on which experts focus, and whose spatial elements are subject of their expertises. The methodological approach balances the perspectives of conservation and planning, protection and development. It includes careful and systematic documentation, analysis, and evaluation of data related to territorial, administrative, ecological, urban, historical, and socio-economic aspects of a given area, to make informed decisions regarding the protection of existing and the creation of new spatial values (Kropf, 1997).

In addition to the analytical approach to the three key determinants of urban identity, to define a particular territory and target population is also important for the application of the concept of urban identity. Although the concept is not solely composed of material factors, its perception is conditioned by the physical framework, as well as by the users of the space. It is not in the observed or the observer, but in the response to a specific place, where conceptual tools are needed to construct the idea of urban identity (Kropf, 1996). Therefore, Duan posits urban spatial identity as a methodology for structural thinking about space as an instrument for planners, conservators, and architects when facing the pressures of globalization (Duan, 2021). The authors propose an integrated, systematic, and consistent methodology for assessing urban identity that addresses the complexity and diversity of urban systems, enabling planners, decision-makers, and communities to develop more resilient, just, and sustainable cities. The main goals are to understand cities as a whole, develop strategies that are economically viable, socially inclusive, ecologically sustainable, and culturally aware. The methodology for exploring urban identity does not use quantification, but rather the analysis of the state-of-the-art and needs assessment through participatory approach, in order to provide a comprehensive understanding of the phenomenon and inform policies and decision-making processes (Mansour et al, 2023).

6 STUDY OF URBAN IDENTITY OF FIVE LOCAL GOVERNMENTS UNITS IN WESTERN SERBIA

Western Serbia is considered one of the regions in Serbia where depopulation and unfavorable demographic structure are particularly evident, which calls for strengthening human and social capital, as well as increasing the attractiveness of the area for living and working. Additionally, Western Serbia faces the serious issue of fragmentation due to the geomorphological characteristics of the hilly and mountainous area, which is interspersed with waterways. Special emphasis is placed on the physical arrangement of space and the protected environment, which should increase the area's appeal to investors and tourists, as well as strengthen the local residents' identification with their living environment. Key priorities include solutions to the problem of illegal construction, urban planning and revitalisation of cities, rural revitalization, and areas with protected, well-arranged, and properly presented cultural heritage as factors of attractiveness (NARS, 2010). The region is marked by significant socio-economic and territorial polarization, primarily between the northern and southern parts of the area. In terms of development, 5 local government units presented in this research are compared to the national average: one is above average (the municipality of Užice); one is between 80-100% (the municipality of Čajetina); two are underdeveloped, at 60-80% (Bajina Bašta and Požega); and one is below average (the municipality of Priboj). The structure of the economy is dominated by the industrial sector, with a preserved competitiveness of several successful companies, agricultural

means of production, along relatively developed tertiary sector activities (trade, transportation, tourism, etc.) (NARS, 2013).

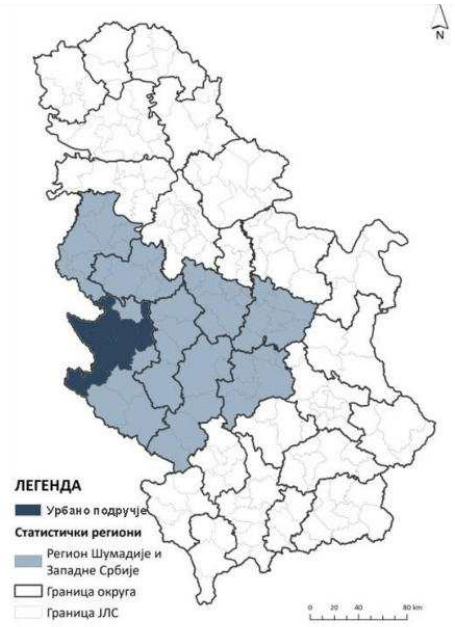

Fig. 1: The position of the targeted territory of five municipalities within Serbia and Western Serbia.

For the integrated territory of the five local government units (Fig. 1), a Development Strategy for the Urban Area has previously been adopted, which defines one of the thematic goals as "strengthening urban identity and the revitalization of the urban area by promoting sustainable and integrated urban development" (GOA, 2023). The Study of the Unique Identity of Urban Environments within the territory of the Development Strategy for Urban Area of Užice, Priboj, Bajina Bašta, Čajetina and Požega local government units (GOA, 2024-2025) elaborates on this goal through three phases/steps: 1) state-of-the-art analysis, 2) defining directions for action, and 3) gathering project ideas. All three phases include expertises from various areas of sustainable urban development and a participatory process. The introductory (zero) step, which is the subject of this paper, covers the initial considerations for the operationalization of the concept of urban identity in order to formulate methodological guidelines, approaches, and steps for the development of the Study.

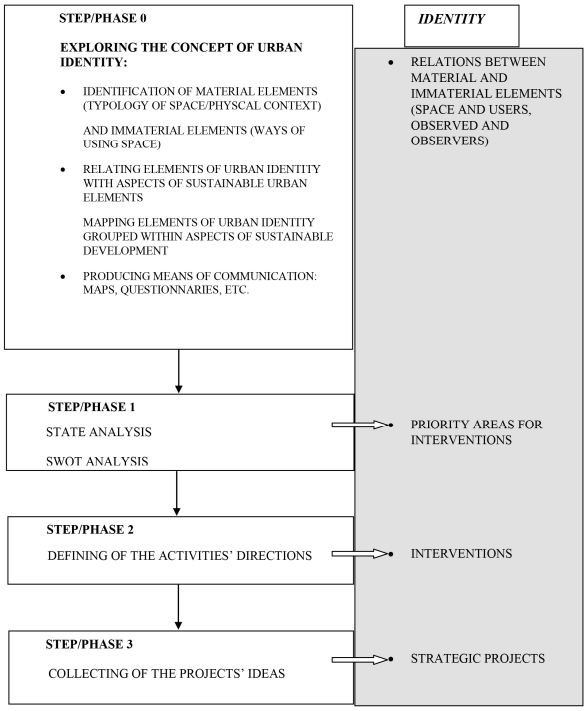

Fig. 2: Steps in the development of the urban identity study.

6.1 Operationalization of the Concept of Urban Identity

6.1.1 Identification of Identity Elements: Analytical Approach to the Complexity of the Concept

In this study, identity is viewed as a complex concept composed of material elements (aspects of the natural and built environment, systematized according to the scope and complexity of spatial organization) and immaterial elements (qualities of space that arise from its interaction with users: the way it is used, perceived, and experienced in real-time and historically) – Table 1. Identity is considered a dynamic concept that depends on the local context and is constructed through the creation of relationships between material (physical environment) and immaterial elements (forms of interactions between physcial environement and users).

Material elements	**Immaterial elements**

Natural Heritage
• City in nature – natural environment and determinants
• Nature in the city
• Routes – connections between settlements
Architectural Heritage (including cultural heritage under institutional protection)
• Archaeological sites
• Industrial and military heritage
• Modern heritage (socialist and post-socialist)
• Monuments
• Fountains
• Bridges
• Public and shared spaces
  • Squares
  • Plazas
  • Passages
  • Urban pockets
  • Streets and sidewalks
  • Roof terraces
  • Shared courtyards
  • Shared spaces in buildings
• Vernacular
  • Private houses and buildings
• Public buildings
  • Municipality
  • Library
  • Theatre
  • Gallery
  • Museum
  • Bus station
  • Railway station
  • Stadium
  • Educational institutions
  • Nursing homes etc.
Partially Built and Unbuilt Areas
• Unbuilt land within construction areas
• Landfills and waste sites
• Agricultural land and farms/land for urban farming
• Infrastructure corridors
	Activities
	• Housing
	• Commercial and Production
	• Education
	• Culture
	• Sports and recreation
	Urban History, Memory, and Perception
	• Notable personalities
	• Significant events
	• Urban landmarks
	• Meeting places/points, hubs
	• Places of memory/demolished buildings, etc., oriental past, etc.
	• Everyday routes/paths
	• Everyday routines/walks, gatherings, etc.
	• Vistas and viewpoints/within the settlement, from the settlement to the surroundings, from the surroundings to the settlement
	• Connection with the wider environment
	Intangible Cultural Heritage (according to official classification, whether or not under institutional protection)
	• Oral traditions and expressions, including language as a bearer of intangible cultural heritage
	• Performing arts
	• Social practices, rituals, and festive events
	• Knowledge and practices related to nature and the universe
	• Traditional craftsmanship

Table 1: Material and immaterial elements of urban identity

6.1.2 Positioning Identity Elements within the Framework of Sustainable Development: Analytical Approach to Multifacetdness of the Concept:

To connect the elements of identity with aspects of sustainable development and to engage the professional capacities of the 18-member IAUS working team in the study's preparation, the following aspects of identity in the context of sustainable development were defined: regional, urban, environmental, social, economic, and governance aspects.

- Regional Aspects: Considers demographic changes, relationships between settlements, infrastructural corridors, and the functional integration of the territory.
- Urban Aspects: Include architectural heritage, including immovable cultural heritage under institutional protection; design guidelines and rules in urban planning documents; the use and performability of public spaces; safety and accessibility of public spaces; the usage modalities of

buildings by function and housing; and the use of shared spaces with a particular focus on multi-family residential buildings.

- Environmental Aspects: Include nature in the city, greenery, water, landscape design, and climate change; natural heritage and tourism infrastructure; waste management and municipal services; environmental quality aspects; underutilized land, agricultural land, urban agriculture, and the circular economy.
- Social Aspects: Manifested through social well-being and the availability and quality of public services.
- Economic Aspect: Refers to recognizing the territory's potential in terms of economic development, employment, and innovation.
- Urban Governance Aspects: Relate to multi-level governance, inter-municipal cooperation, co-creation, participation, and innovative civil governance systems.

Cartographic analyses and presentations of the aspects and factors of identity are important tools for communication throughout the participatory process thoughout all phases of the Study's preparation. On the maps of regional and urban levels, the elements of urban identity have been mapped according to the classification in Table 1 and then linked to the aspects of sustainable development of the territory (Fig. 3).

Fig. 3: Workshop in one of the municipalities (Bajina Bašta). Discussing and mapping.

6.1.3 Participatory Process: Analytical Approach to the Dynamism of the Concept

In line with previous research, the concept of urban identity is dynamic depending on time and observers. By applying a dialectical approach to the analysis of existing elements of urban and physical structures, permanent elements are identified, which testify to the continuity of the existence of settlements and territories, as well as changing elements. Permanent elements are designated as urban landmarks and may or may not be declared cultural heritage sites.

Another powerful tool for addressing the dynamism of the concept is the participatory process, which involves workshops (Fig. 3), surveys, and various forms of communication with a wide range of stakeholders: representatives of local governments, public enterprises, professionals from various fields, especially architects, urban planners, and ordinary citizens.

The foundation for applying participation and co-creation in the development of the Study lies in the theoretical premises of collaborative planning, where participation is based on the belief that social groups

and individuals are capable of learning from one another, and that this knowledge has a positive impact on problem-solving and defining frameworks for activities in space. The main characteristic of these ideas is the view of planning/governance as an active process in which social meanings emerge through discussion, and where social (including professional) practice is formed and gains legitimacy (Healey, 2003).

Planning for sustainable and integrated urban and territorial development involves action, not just a response to problems – it provides a framework for activities. When conducted in a participatory manner, it can contribute to developing the knowledge and relations between actors, fostering joint reasoning, organizing around common issues, and formulating ideas on how to improve the space (Čolić et al., 2021).

In all stages of the development of the Study, a series of events and thematic workshops are organized. Their goal is to transparently and participatively verify, supplement, and rephrase the results of research on the identity of the territory and individual areas, define action directions, and gather project ideas. Informing the broader public about the participatory process of developing the Study is carried out through local media, municipal web portals (Fig. 4), and the Zlatibor Regional Development Agency, as well as social networks used for promoting the project.

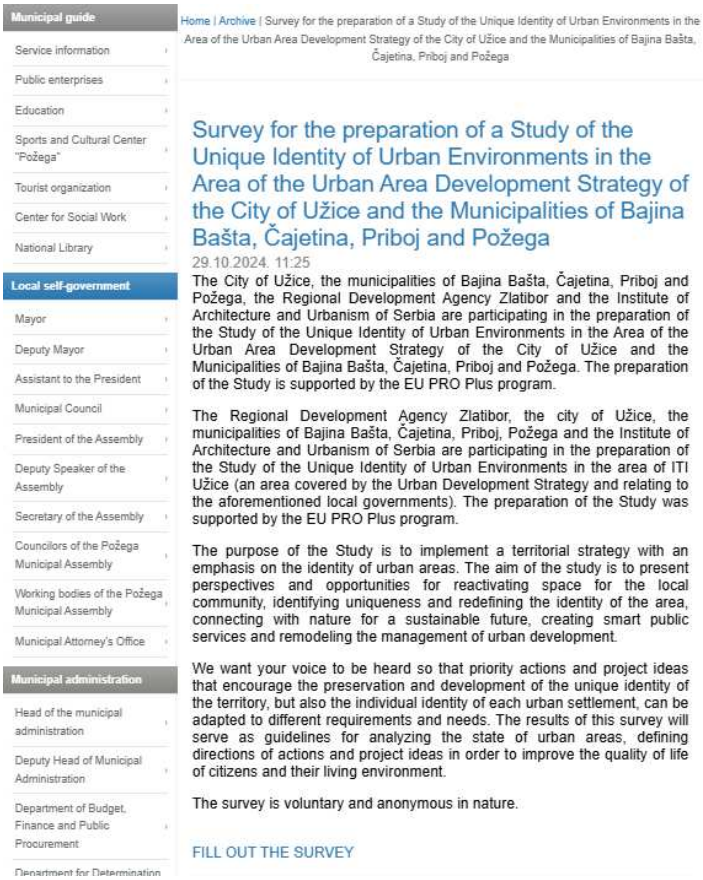

Fig. 4: The survey for citizens "Let Your Voice Be Heard!" on the municipality of Požega's web portal.

7 CONCLUSION

The concept of urban identity has a significant role in strategies for sustainable and integrated urban development. This role is particularly important for the development of small and medium-sized cities, both in the European Union and in Serbia – for their strategic positioning in balanced territorial development and for strengthening territorial and social cohesion (Table 2).

As stated, the urban identity is a complex, multifaceted and dynamic concept that requires an analytical, multidisciplinary and multi-stakeholder approach, which is also place-based, i.e. conditioned by phyical context (Table 3). The synergy of all these approaches produces a conceptual framework for structural thinking and decision-making, which can be aligned with sustainable development aspects.

In the case of the Study on the Unique Identity of Five Municipalities in Western Serbia, the applyied methodology has raised awareness among all participants about the important elements of urban identity that

should be protected and/or used as a trigger for development projects. It has also enhanced the capacitites of local government units to improve strategic thinking, balance between conservation and development, and introduce planning guidelines based on existing territorial and human capital. The up-to-date workshops have shown a lack of awareness among participants regarding the common identity of the entire territory, mostly due to poor traffic connectivity, socio-economic challenges, and territorial polarization. In the next steps of the tudy, by introducing the five key thematic fields of sustainable development – rediscovering uniqueness, reactivating spaces for local communities, reconnecting with nature, reinventing smart public services, and remodelling governance and partnerships (EC, 2023) – a futher wide debate will be opened. This debate should result in specific strategic projects tailored for applying financing instruments, aiming at the creation of sustainable, inclusive, and vibrant urban environments.

Document	**Main points relevant for the urban identity concept**
The New Urban Agenda (UN, 2017)	Relating transformative commitments to sustainable development with: spatial organization, structure and arrangement of urban space; urban form; architectural design; urban planning.
The Territorial Agenda of the European Union until 2030 (EC, 2020)	Refers to the regional level and advocates for territorial cohesion and the use of the specificities/diversities of places (natural and built, with territorial capital and identity) as a comparative advantage and development potential.
The New Leipzig Charter (EC, 2020)	Refers to the urban level and advocates a place-based approach, which involves recognizing the transformative potential of European cities – small, medium, and large – through their diversity.
The Spatial Plan of the Republic of Serbia (NARS, 2010)	Developing cultural identity and territorial recognizability; strict adherence to the protection of public interest, public goods, and public spaces; improving and protecting natural and cultural heritage as development resources.
The Law on Planning and Construction (NARS, 2009-2023)	Public participation; Preservation of customs and traditions; Preservation of environmental values, integrity, and the uniqueness of landscapes; Horizontal and vertical coordination.
The Sustainable Urban Development Strategy of the Republic of Serbia until 2030 (NARS, 2019)	Strengthening the identity of urban areas by defining priority areas for urban intervention, identifying development issues, and linking them to specific locations.
The National Architectural Strategy for the period 2023-2035 (NARS, 2023)	Architectural heritage as one of the most important aspects of cultural identity and heritage of a state and its people; a key factor in the economic development and achieving higher quality of life.

Table 2: The role of the urban identity concept in the recent European and national documents.

The key determinants of the urban identity concept	**A conceptual tool for exploring the urban identity concept in sustainable development**
Complexity	Analytical decomposition of the concept into material and immaterial elements.
Multifacetdness	Multidisciplinary approach – observing the urban identity concept from various aspects of sustainable development.
Dynamism	Multi-stakeholder approach through various channels of communication and participation processes.

Table 3: Analytical approaches to complexity, multifacetdness and dynamism of the urban identity concept.

1 ABSTRACT

Illegal land use presents intricate challenges with far-reaching socio-economic and environmental implications. This study investigates the dynamics of unlawful land use in Louis Trichardt, Makhado Local Municipality. Employing a mixed-methods approach, the research synthesizes insights from 270 respondents, including municipal employees, supplemented by primary data from comprehensive surveys and community observations. A SWOT analysis revealed key strengths, such as community awareness and potential for localized solutions, but also weaknesses, including insufficient municipal resources and individual resistance to regulations. Identified opportunities include public awareness campaigns, improved housing accessibility, and stronger regulatory enforcement. However, significant threats such as environmental degradation and limited access to formal economic activities pose ongoing risks. The findings highlight unauthorized rental structures, illegal spaza shops, informal shack settlements, and unapproved businesses as prevalent forms of illegal land use. Respondents identified critical drivers behind these practices, including limited access to affordable housing, economic hardships, and unemployment. The study recommends bolstering municipal capacity, enhancing community awareness initiatives, and prioritizing affordable housing programs to address these issues effectively. Suggested areas for future research include examining the long-term impacts of community-driven solutions, evaluating the effectiveness of municipal campaigns, fostering public-private partnerships, advancing sustainable land use planning, and conducting comparative studies with similar municipalities.

Keywords: Land use, spatial, environment, socio-economic, Makhado Local Municipality

2 INTRODUCTION

Illegal land uses, or the unauthorized occupation and use of another person's property, were common worldwide (Machete et al., 2021). This was due to factors like population expansion, urbanization, and poverty, which were especially prevalent in developing nations. Illegal land use was a serious issue in South Africa, impacting both urban and rural areas (eNCA, 2021). The Constitution of the Republic of South Africa 1996, Section 25, only safeguarded a landowner from the arbitrary deprivation of property; it did not provide an absolute property right. One area that felt the negative effects of illegal land use was Louis Trichardt town in Makhado, a local municipality in the Limpopo Province. Like many other South African rural areas, Louis Trichardt struggled with the negative effects of unauthorized land use. Furthermore, according to the South African Human Rights Commission 2000, all citizens could take advantage of their fundamental rights to access land and housing, where necessary and given the available resources. The government also had a responsibility to help private landowners defend their property in cases of widespread invasions, i.e., "Use the Prevention of Illegal Eviction From and Unlawful Occupation of Land Act, 1998 to obtain a swift court eviction order in the event of a trespass on your private property. Alternatively, if the invasion was connected to a requirement for access to agricultural land, ask for help from the Department of Agriculture, Land Reform, and Rural Development" (Carnie, 2022).

Many social, economic, and environmental issues were associated with illegal land use (Masilela, 2022; Mokoena et al., 2017). These issues affected people's livelihoods and general well-being and could have long-term effects on social structures and the environment. In the Makhado Local Municipality, South Africa, there had been an increase in illegal land use over time (Makhado IDP, 2022/23). The area's ecological balance was in danger due to illegal land use, which also affected the socio-economic development of the area. This study aimed to evaluate Louis Trichardt town's illegal land uses from 2017 to 2022 and offer suggestions for addressing this issue.

Firstly, illegal land use was a widespread problem in many South African rural areas and had a significant impact on these places' socio-economic growth and ecological balance (Sinthumule et al., 2020). To create efficient policies and strategies to address it, it was essential to comprehend the scope of this issue and how it affected the study area (Sithole et al., 2021). Secondly, there was a dearth of studies on illegal land use in South African rural areas, especially in Makhado's local municipality. This study added to the body of knowledge on this subject and shed light on the reasons behind and effects of illegal land use in the community (Manakane et al., 2022). Thirdly, the findings of this study could be used by the local government and other stakeholders to develop interventions that addressed the underlying causes of illegal land use, such as poverty and unemployment. This could improve the living conditions of residents in the town and promote sustainable development. Lastly, determining Louis Trichardt's illegal land uses assisted in achieving the Sustainable Development Goals (SDGs) established by the United Nations (Zwane et al., 2020). This research aimed to help achieve SDGs, i.e., "11 and 15". Accordingly, SDG 15 aimed to protect, restore, and promote the sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, stop and reverse land degradation, and stop biodiversity loss (Walz et al., 2022); hence, targets 15.9, 15.A, and 15.B of the SDGs aligned with this study because they promoted the protection of biodiversity, investment, and the integration of natural ecosystems into planning, development, and poverty alleviation programs in developing countries. Moreover, SDG 11 aimed to make cities and human settlements inclusive, safe, resilient, and sustainable (Ebbesson et al., 2022). In this case, it was important because inclusive human settlements were being promoted. To address these reaserch gap, the study investigates the dynamics of unlawful land use in Louis Trichardt, Makhado Local Municipality.

3 LITERATURE REVIEW

Illegal land use, also called illegal land occupation, was the taking of land without the required authorisations or legal rights (Khumalo, 2019). Moreover, it could have involved a variety of actions, such as the erection of structures or habitations, the farming of crops, or the unauthorised use of land for other purposes. Hence, it was frequently fuelled by social, economic, and environmental issues like deprivation, unemployment, the lack of affordable housing, and restricted access to land (Palm, 2021).

Furthermore, illegal land use had both good and bad societal, economic, and environmental consequences (Ntshidi, 2020). On the one hand, it provided a way for marginalized groups to gain access to land and shelter when they did not have formal alternatives for obtaining land rights (Dlulane, 2020). It could also have facilitated entrepreneurship, innovation, and societal growth. In addition, it resulted in conflict, bloodshed, and adverse environmental consequences such as deforestation, land degradation, and species loss (Thaw, 2020). It could also have had fiscal consequences, such as lost property tax income and reduced investment in the official real estate market.

Some of the causes included housing shortages, i.e., people turned to occupying land unlawfully to get a place to live in locations where there was a dearth of affordable housing. Another reason was landlessness, that is, people who lacked access to land invaded it to take advantage of resources like agricultural or grazing land (Sakala, 2016, & Adedamola et al., 2022). Additionally, rapid urbanisation led to encroachment and informal settlements due to the need for houses and land. Moreover, poor people invaded other people's land to secure a place to reside, or to engage in illegal activities that brought in money. Weak land governance led to illicit land acquisition and selling, which resulted in conflicts and invasions of private property (Khumalo, 2019).

Theory of Relative Deprivation

According to Neely (2020), this theory stated that people's actions and behaviours were influenced by how they perceived their rights and what they possessed. According to the theory, when people felt their rights to access and own land had been violated, they engaged in collective action, including illegal land use. Longley (2021) stated that when income was insufficient to maintain a standard of living that included food and shelter, absolute deprivation or absolute poverty developed. The theory assisted in explaining why people engaged in illegal land occupation. In South Africa, many people struggled with poverty, unemployment, and a lack of accessible housing (Marutlulle, 2021; Gumbo et al., 2022). According to this theory, individuals felt a sense of relative deprivation about their access to land, especially if they believed that land was being unfairly allotted to others or was being withheld from them.

Furthermore, Ted Robert Gurr's 1970 book, Why Men Rebel, explored the relationship between relative deprivation and political violence. Moreover, the author argued that the frustration-aggression mechanism, triggered by a sense of relative deprivation, was a major contributor to the human tendency for violence (De Kock, 2021). Although not all individuals or groups experiencing relative deprivation engaged in violent acts, Gurr maintained that the longer they endured such frustration, the more likely it was that their anger would escalate into violence (Walker et al., 1984).

The relative deprivation hypothesis also shed light on why urban areas were frequently the scene of illegal land uses (Zulu, 2020). The demand for housing increased because of urbanisation, but many people could not afford the high price of formal housing. People felt relatively deprived because they believed they were entitled to decent housing but could not obtain it (Pillay, 2020). Overall, the relative deprivation theory contended that to combat illegal land use effectively in South Africa, it was necessary to address the root causes of relative deprivation, such as poverty, inequality, and the lack of affordable housing. It might have been possible to lessen illegal land use and encourage a more equitable and sustainable land use method in South Africa by addressing these issues.

4 METHODOLOGY

Employing a mixed-methods approach, the research synthesizes insights from 270 respondents, including municipal employees, supplemented by primary data from comprehensive surveys and community observations. The questionnaires were administered to members of the public who were residents of Louis Trichardt. The researcher utilized Ward's proportional representation to select the respondents. The distribution of the questionnaires was outlined in Table 1:

Total	Population no.	Households no.	NQD	% distributed	NQR	% returned
Ward 21 Louis Trichardt Town	25 360	7 129	379	100%	270	71.2%

Table 1: Questionnaire administration. Sources: Author's Field Data 2023 SA census (2016). Key: NQD = Number of questionnaires distributed, NQR = Number of questionnaires returned.

Table 1 showed that 379 questionnaires were distributed based on population proportions. Only 71.2% of those questionnaires were returned. The appropriate number was determined using the Raosoft sample size calculator online with a margin of error of 5%, a confidence level of 95%, and a response distribution of 50% results.

Purposive sampling was utilized to select key informants. According to Nikolopoulou (2022), this sampling was frequently employed in qualitative and mixed methods research. Seven of the key informants interviewed, were, the Town Planner (processing land use applications and approvals), Geographic Information System (GIS) Officer, GIS Specialist (responsible for capturing and updating all spatial data), EIA Officer (assessment of environmental impacts and authorizations), Town Planner (assess and authorize land uses and issues approvals), Senior Property Administrator (who dealt with municipal land acquisition processes), and Senior Administrative Officer: Valuations (deals with valuation and appraisal of properties land values).

5 FINDINGS AND DISCUSSION

Understanding the varying length of residency within the municipality was crucial in comprehending the perspectives and experiences that informed residents' responses to questions about illegal land use, its consequences, and potential solutions. This diversity in residency duration contributed to a comprehensive analysis of the local community's viewpoints and needs. Figure 1 depicted the years respondents had stayed in Louis Trichardt town.

A significant factor influencing residents' viewpoints regarding various aspects of Louis Trichardt, Makhado Local Municipality was the duration of their residency within the region. The data collected from the respondents revealed a diverse distribution in terms of residency duration, shedding light on the distinct experiences and perspectives of the population. Approximately 11% of the respondents had reported having resided in Louis Trichardt for less than a year. Being relatively new to the area, these individuals might have had a fresh and perhaps less informed perspective on land use and community dynamics issues. Around 17% of the respondents had a residency duration spanning one to five years. This group likely had a somewhat

intermediate familiarity with the municipality, potentially having witnessed changes and developments during their time in Louis Trichardt. The largest cohort, constituting roughly 32% of the respondents, had resided in the area for six to ten years. This population segment likely possessed a more established understanding of the municipality's dynamics and may have witnessed significant changes over their prolonged residency. Finally, 40% of the respondents had been residing in Louis Trichardt for more than ten years. This group, characterized by long-standing residency, was expected to bring a wealth of experience and in-depth knowledge of the region's history and evolution.

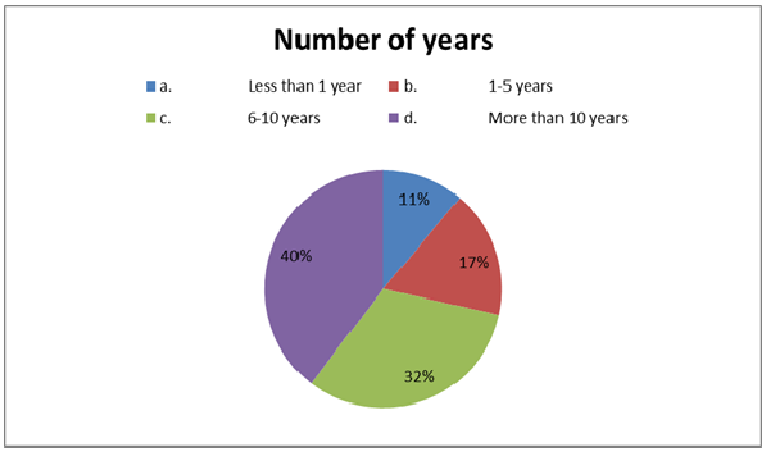

Figure 1: Residency duration. Source: Author's construct/field data (2023)

Awareness of Illegal Land Use in the Vicinity: Perceptions and Observations of Respondents

A substantial majority, comprising approximately 240 respondents, demonstrated a keen awareness of illegal land use. They acknowledged the presence of such issues and offered notable insights into specific instances. Examples of their observations included cases of unauthorized land occupation in residential areas, where individuals had erected structures or established dwellings without following the proper legal procedures. In some instances, respondents pointed to land zoned for specific purposes, such as residential or commercial use, being utilized for purposes that did not align with the designated zoning. These observations reflected a community acutely attuned to the realities of illegal land use, directly impacting their neighborhoods and the broader community. The respondents' ability to identify and provide examples of such instances underscored the significance of addressing this issue to ensure compliance with land use regulations and preserve community well-being. Moreover, key informants "also identified instances of illegal land use, such as unauthorized occupation of residential areas and illegal building conversions''.

Social and Economic Implications of Illegal Land Uses: Insights from Respondents

Respondents' opinions on the social and economic consequences of illegal land use varied. Many (about 72%) expressed concerns about newcomers (less than one year) who might have been unintentionally unaware of zoning regulations. The high demand for housing prompted some residents to occupy land without following proper procedures, resulting in resource and infrastructure strain. Economic hardships and the lack of affordable housing could have driven individuals to engage in illegal land use for survival. Similarly, the study conducted by Mutero and Makwara (2018) revealed that the impetus for illegal land occupation was propelled by the absence of government support in furnishing accommodation for trespassers. Key informants "highlighted the socio-economic consequences of such activities, including reduced property values, increased crime, and potential loss of government revenue''. Additionally, some individuals resorted to illicit land occupation to compel the government to provide them with housing. Furthermore, it was observed that individuals engaging in unauthorized land occupation experienced property loss during an eviction, and the use of force during eviction was identified as a deterrent against subsequent land invasions. In areas with limited access to formal economic activities, joblessness might have made illegal land use seem like a viable alternative. A common thread in their narratives was the belief that the municipality's inadequacy in addressing housing needs might have motivated some to resort to illegal land use.

Perceptions of Ecological Impact: Respondents' Views on Illegal Land Use and the Environment

Respondents generally expressed concerns about the ecological impact of illegal land use. They believed that unauthorized land occupation could lead to deforestation, causing harm to the local ecosystem. In support of this, key informants stated that " The ecological impact included environmental degradation such as land, water, and air pollution, deforestation, and habitat disruption. The municipality's measures to address these issues involved inspections, meetings, contravention letters, warnings, and formal settlement implementation." Issues like improper waste disposal and sanitation in informal settlements were mentioned as factors that could have resulted in the pollution of natural resources, particularly rivers. Land degradation and soil pollution might have resulted from unauthorized activities. The strain on resources due to illegal land use further exacerbated environmental issues. According to Troisi (2022), illegal land use was a noteworthy environmental concern progressively garnering attention.

Impact of Illegal Land Use: Personal Experiences and Community Effects

A significant portion of respondents, roughly 220 out of 270, reported experiencing or observing adverse effects of illegal land use on their community. They mentioned increased congestion and overcrowding in their neighborhoods, which made it challenging to access essential services. Additionally, there was a perceived increase in crime rates in areas with illegal land use, affecting safety and overall quality of life. According to the Makhado IDP, 2022/23, illegal land use was identified as one of the top issues concerning safety and security. The third most frequently reported offenses included property-related crimes such as burglary, stock theft, and similar incidents. Numerous police stations and satellite stations served the study area. Notably, the Makhado police station recorded the highest number of reported crimes, totaling 1,736 cases. Respondents' narratives highlighted a range of consequences, encompassing both tangible and perceived impacts.

Regarding increased congestion and overcrowding, respondents expressed concerns about the palpable effects of illegal land use on their immediate surroundings. They described scenarios where unauthorized land occupation had led to increased congestion and overcrowding in their neighborhoods. The proliferation of informal settlements and structures in areas not designated for housing notably altered the landscape. This, in turn, made it challenging for residents to navigate their local environments and added strain to the existing infrastructure.

Several respondents highlighted difficulties in accessing essential services in areas of illegal land use. These areas often lacked adequate infrastructure, such as roads, sewage systems, and waste management. This resulted in challenges related to waste disposal, safe sanitation, and accessibility to healthcare facilities. Residents in such areas confronted daily obstacles in securing basic services that many others might have taken for granted.

In tandem with the physical transformations brought about by illegal land use, there was a noticeable perceived increase in crime rates in areas with unauthorized land occupation. Respondents pointed to a correlation between the expansion of informal settlements and increased criminal activities within their communities. Examples included theft, vandalism, and general unrest in neighborhoods affected by illegal land use. These observations contributed to a growing sense of insecurity and compromised residents' overall quality of life.

Key informants within the community echoed these sentiments, emphasizing the importance of addressing the adverse effects of illegal land use. They highlighted the need for enhanced security measures, improved infrastructure development, and efforts to mitigate the negative consequences on community well-being. As articulated by respondents and key informants, the impact of illegal land use underscored the urgency of addressing this issue to safeguard the community's quality of life and safety.

Municipal Initiatives to Address Illegal Land Use: Community Awareness and Participation

Unfortunately, the majority of respondents, approximately 210 out of 270, were unaware of any initiatives or programs the municipality undertook to address illegal land use. This indicated a potential lack of public awareness or engagement on the part of the municipality in this regard. Respondents who indicated their lack of awareness suggested that the municipality might not have effectively communicated its initiatives to combat illegal land use. This raised concerns about the need for improved dissemination of information to the public. In their view, the community should have been better informed about the steps local authorities had taken to address this pressing issue.

The absence of public knowledge also underscored missed opportunities for community engagement. Respondents noted that had they been aware of municipal programs, they might have been more inclined to participate actively in initiatives to curb illegal land use. They felt the lack of information had hindered their ability to contribute to the solution. Masenya and Kgobe (2023) argued that land use planning within the municipality held significant implications, particularly in addressing challenges related to human settlement, promoting citizen participation in determining needs and objectives, and rectifying historical spatial inequalities resulting from apartheid spatial planning. Consequently, despite its importance, the implementation of land use planning had encountered various hurdles, such as insufficient collaboration in areas governed by traditional authorities, illicit land occupation, and political interference. In essence, the study posited that achieving spatial justice and rectifying past imbalances in South Africa hinged on effective integration and coordination of land use planning. However, it highlighted persistent discontent within communities regarding their level of engagement. Despite the overall success of many municipalities in fostering citizen participation, an outstanding backlog in civic interaction existed due to unethical practices, financial constraints, a lack of capacity, and misguided targeting.

Key informants echoed these concerns, emphasizing that community involvement was vital in tackling illegal land use effectively. Furthermore, Enaifoghe and Adetiba (2018) uncovered that within most local municipalities, community involvement in decision-making had not been effectively executed. They suggested that the municipality prioritize public awareness campaigns and engage with local residents to encourage active participation. Key informants also highlighted the need for more transparent communication from the municipality regarding its initiatives, fostering a sense of shared responsibility in addressing this critical issue. Moreover, respondents believed that community members could play a pivotal role in preventing and reporting illegal land use. They suggested raising awareness within the community about the legal procedures for land use, encouraging residents to report illegal land use to the authorities, and promoting community engagement and neighborhood watch programs to deter illegal activities.

Community-Driven Solutions: Recommendations to Address Socio-Economic and Ecological Impact

The respondents, cognizant of the challenges posed by illegal land use, offered a spectrum of community-driven solutions to address its socio-economic and ecological impacts in Louis Trichardt, Makhado Local Municipality. These recommendations were rooted in their collective understanding of the problem and their aspirations for a better future.

A common suggestion from respondents was the need for comprehensive municipal awareness campaigns. They believed these campaigns could be pivotal in educating residents about legal land use and the importance of adhering to zoning regulations. By enhancing public understanding, the community anticipated a reduction in illegal land use. Chen et al. (2021) explored the notion that increasing the policing and robustness of land law enforcement contributed to a decrease in the occurrence of illegal land use cases. However, they speculated that this increase in enforcement measures might have prompted offenders to engage in more severe violations out of desperation, thereby increasing the overall degree of illegal land use. In contrast, reducing the difficulty of enforcing land law was associated with significantly reducing the extent of illegal land use.

Furthermore, respondents emphasized the significance of improving access to affordable housing options. According to Yongyang et al. (2018), such informality was a reaction to dysfunctional land institutions, particularly the prohibitively high costs of obtaining land property rights in many developing countries. Mennen (2016) stated that land tenure informality remained one of the most prevalent occurrences, with nearly 75% of the world's population lacking access to formal procedures for registering and safeguarding their property rights. Hence, respondents believed that one of the driving factors behind illegal land use was the lack of accessible and affordable housing. By creating more opportunities for residents to secure suitable housing, they aimed to mitigate the socio-economic consequences of illegal land use.

Respondents identified the critical role of law enforcement in preventing and addressing illegal land use. They stressed the need for stronger enforcement of land use regulations to act as a deterrent and ensure compliance. An effective legal framework would curb illegal activities and contribute to community safety. The community, aware of its collective potential, proposed community-driven initiatives to address the housing and economic challenges that could lead to illegal land use. Examples included forming neighborhood watch programs to enhance security and community projects to provide affordable housing

solutions. Respondents recognized the importance of sustainable land use planning to mitigate the ecological impact of illegal land use. They suggested that comprehensive planning would help allocate land for various purposes, reducing the strain on natural resources and preventing ecological degradation. The community's ecological concerns led to recommendations for conservation efforts. Respondents were keen on initiatives to protect the local environment from degradation. Examples included reforestation programs, waste management solutions, and campaigns to promote responsible land use.

Key informants echoed the community's recommendations, emphasizing the need for community involvement and active participation in implementing these solutions. They highlighted the role of local governance in initiating and supporting these efforts. Additionally, key informants stressed the importance of public-private partnerships to facilitate the creation of affordable housing options.

In summary, the recommendations put forward by the community, coupled with the insights of key informants, highlighted a collaborative and multifaceted approach to addressing the socio-economic and ecological impact of illegal land use. These solutions reflected the community's resilience and commitment to building a more sustainable and secure future for Louis Trichardt, Makhado Local Municipality.

Municipal Respondents Regarding Illegal Land Use

The following sections presented, analyzed, and interpreted the data collected from municipal respondents regarding illegal land use in Louis Trichardt, Makhado Local Municipality. The survey encompassed various aspects, including the roles of municipal employees, instances of illegal land use, socio-economic consequences, ecological impacts, measures taken to address illegal land use, the effectiveness of these measures, challenges encountered, support and resources required, the role of public awareness, and policy recommendations.

Theme 1: Human Settlement

Illegal land use affected the availability of adequate housing in the municipality, as unauthorized occupation reduced the land available for residential purposes. The strain on basic services like water, electricity, and sanitation also led to service disruptions in illegal settlements. Informal land use contributed to overcrowding, straining existing infrastructure. Residents perceived these informal settlements as congested and lacking resources compared to formal housing. The lack of legal land tenure in these areas further led to criminal activities and instability. According to the UN-Habitat 2021 report, "Shelter served as the foundation for personal and familial stability and security. It stood at the core of our social, emotional, and economic experiences, a sanctuary providing a haven for individuals and families to live in tranquility, safety, and respect." Hence, housing played a crucial role in achieving sustainable urbanization, acting as a catalyst for development, peace, and enhanced living standards for everyone.

Theme 2: Informality

Informal land use disrupted the legal and regulatory framework governing land ownership and development, leading to delays in development and a lack of compliance with legal procedures and municipal by-laws. It also affected the formal land market by lowering property values in the vicinity. The informal economy associated with illegal land use might have increased the local economy due to population growth but could have resulted in competition and unsafe working conditions. The provision of public services in informal settlements was often inadequate, affecting healthcare and infrastructure. Moreover, social exclusion was a concern as it could have led to limited access to services and higher crime rates.

Theme 3: Access to Economic Activities

Illegal land use negatively affected residents' access to formal economic activities and employment opportunities, as businesses avoided informal areas, leading to economic instability for residents. The informal economy associated with illegal land use might have stimulated the local economy but often operated under unsafe conditions. The lack of legal land tenure might have made formal businesses less attractive, potentially hindering economic growth. Additionally, illegal land uses affected land available for agricultural and productive activities, increasing poverty levels due to limited opportunities.

Illegal land use not only hampered residents' access to formal economic activities and employment opportunities but also introduced a range of challenges that rippled through various aspects of community life. The reluctance of businesses to establish themselves in informal areas, driven by uncertainties related to illegal land use, not only caused economic instability but also perpetuated a cycle of limited growth and

opportunity for local residents. The informal economy associated with illegal land use, while contributing to local economic stimulation, often operated under unsafe conditions, posing risks to the well-being of those involved.

Moreover, the absence of legal land tenure could have diminished the attractiveness of formal businesses, potentially acting as a deterrent to investment and impeding overall economic growth. The resulting economic disparities might have exacerbated existing social inequalities, affecting the overall prosperity of the community. Beyond the urban landscape, illegal land uses also encroached upon land designated for agricultural and productive activities. This encroachment limited the available space for cultivation and production, subsequently increasing poverty levels by restricting opportunities for sustainable livelihoods. The intricate web of challenges stemming from illegal land use highlighted the need for comprehensive strategies that addressed the immediate issues and contributed to sustainable economic development, social equity, and improved living conditions for affected communities.

Theme 4: Land Uses

Illegal land uses had a negative impact on the availability and conservation of natural resources, including land, water, air pollution, deforestation, and habitat disruption. Unauthorized land occupation disrupted land use planning and urban development initiatives, hindering the implementation of sustainable practices. Such informal land use also contributed to environmental degradation and loss of biodiversity. Residents stressed the importance of fairness and transparency in land resource management. Furthermore, the lack of legal land tenure might have led to land disputes and hindered the implementation of sustainable land use practices in the area.

These responses shed light on the multifaceted challenges and consequences of illegal land use within Louis Trichardt, Makhado Local Municipality. The insights provided by municipal employees offered a comprehensive understanding of the issues at hand and served as a basis for potential policy development and community engagement initiatives to address these challenges.

6 CONCLUSION

The study on illegal land use in Louis Trichardt, Makhado Local Municipality, provides valuable insights into the challenges and potential solutions regarding this multifaceted issue. The community's awareness, concerns, and recommendations, combined with municipal perspectives, emphasize the need for collaboration, community engagement, and effective policy measures. By implementing the recommended strategies and addressing the identified weaknesses, Louis Trichardt can move towards a more sustainable and secure future while ensuring the well-being of its residents and protecting its environment. The findings highlight the economic, social, and environmental consequences of illegal land use, reflecting similar impacts observed in the Lwandle informal settlement in Cape Town. The study also draws parallels with international cases, such as the ongoing struggles with illegal land use and evictions in South Africa and the exploitation of indigenous lands in Brazil.

The community's awareness, concerns, and recommendations, combined with municipal perspectives, underscore the need for collaboration, community engagement, and effective policy measures. Addressing illegal land use requires a multifaceted approach that includes strengthening municipal resources, enhancing public awareness, and improving access to affordable housing. The study underlines the importance of a coordinated effort involving government, civil society, and affected communities to effectively address illegal land use and its repercussions. This approach not only tackles immediate challenges but also contributes to long-term sustainable urban development.

1 ABSTRACT

The 21st century is the era of continuous rapid and high levels of urbanisation, particularly in cities of the developing world. Projections show that by 2050, over half of the global population will reside in urban areas. It is estimated by the United Nations (UN) that 71.3% of South Africa's population will live in urban areas by 2030, increasing to nearly 80% by 2050. This study explores the diverse challenges hindering sustainable urban development in South Africa. The paper identifies key barriers through a systematic literature methodology, including the ripple effects of apartheid, the sheer prevalence of urban informal settlements, unemployment, and limited citizen engagement. However, it does not stop at identifying the problems. It also proposes an innovative approach: "Formalising the Informal" through a multi-stakeholder lens. It argues that achieving this goal requires addressing the informal sector's complexities, often viewed as a problem rather than a potential asset. The approach stresses collaboration between government, communities, and the private sector to integrate the informal sector into the urban fabric, supporting secondary cities and further tackling societal concerns such as unemployment and inadequate housing, adversely affect urban sustainable development. The study argues that recognising informal actors' ingenuity and economic contributions can pave the way for more sustainable and inclusive cities in South Africa.

Keywords: urban development, informality, formalising, multi-stakeholder, secondary cities

2 INTRODUCTION

The rapid and high levels of urbanization in the 21st century presents significant challenges and opportunities for sustainable urban development, particularly in South Africa. The United Nations projects that by 2050, over half of the global population will reside in urban areas, with an estimated 71.3% of South Africa's population living in urban centres by 2030 and nearly 80% by 2050 (United Nations, 2018). As urban populations swell, so too do the complexities associated with managing these growing cities, particularly in South Africa's unique socio-political history. South Africa's urban landscape is deeply shaped by the legacy of apartheid, which has left a lasting impact on city planning, housing, and economic opportunities. One of the most visible manifestations of this legacy is the prevalence of informal settlements, which have become a prominent feature in the country's urban areas. These settlements are often characterized by inadequate infrastructure, a lack of basic services, and precarious living conditions, highlight the persistent inequalities within South African society (Harrison, Todes & Watson, 2008).

Despite these challenges, informal settlements are not merely a symbol of urban failure; but represent a complex and dynamic aspect of urban life. The informal sector, which includes these settlements, is often viewed as a problem to be eradicated rather than a potential asset that could contribute to urban sustainability. This study challenges this conventional perspective by proposing a multi-stakeholder approach to "Formalising the Informal." Smit, (2018), argues that sustainable urban development in South Africa can be better achieved by integrating the informal sector into the formal urban fabric, rather than sidelining it. The multi-stakeholder approach involves collaboration between government entities, local communities, and the private sector. This collaborative effort is essential for addressing the diverse challenges faced by secondary cities, which are often overshadowed by larger metropolitan areas yet are crucial to the broader urbanization process. UN-Habitat (2019), formalising the informal sector, there is the potential to tackle critical societal concerns such as unemployment and inadequate housing, which are key barriers to sustainable urban development.

Moreover, this approach recognises the ingenuity and economic contributions of informal actors. These individuals and communities, who operate outside the formal economy, play a vital role in the functioning of cities. Their inclusion in urban planning and policy-making processes can pave the way for more inclusive

and resilient urban environments. As South Africa continues to urbanize, embracing the informal sector through a multi-stakeholder framework may be key to achieving long-term sustainability and equity in urban development. This paper contributes to the ongoing discourse on sustainable urban development by highlighting the importance of a more inclusive approach. Formalizing the informal, South Africa can move towards a future where its cities are not only more sustainable but also more just and inclusive for all its inhabitants.

3 LITERATURE REVIEW

Sustainable urban development is broadly understood as the process of encouraging urban growth while balancing economic, social, and environmental considerations (James, 2024). The United Nations Sustainable Development Goal 11 (SDG 11) stresses making cities and human settlements inclusive, safe, resilient, and sustainable. This entails providing access to adequate housing, improving infrastructure, ensuring participatory urban governance, and stirring economic opportunities while mitigating environmental degradation (United Nations, 2018). However, globally, achieving this vision faces challenges such as urban sprawl, resource depletion, socio-economic inequalities, and inadequate planning frameworks (Kanchana, 2022).

Developing countries often rely on centralised, top-down urban planning frameworks that exclude meaningful participation by local communities (Mokoele, 2023). This approach fails to address the needs of marginalised populations, particularly those in informal settlements, leading to urban environments that are inequitable and unsustainable (Watson, 2009). Without grassroots engagement, urban policies often exacerbate disparities rather than resolve them (Muggah and Wahba, 2020). Informal settlements often lack basic infrastructure and services, yet they house a significant proportion of the urban population (Huchzermeyer, 2011). Similarly, the informal economy provides critical employment opportunities where formal economies fall short, particularly in sectors such as construction, retail, and services (Chen, 2012). Despite their importance, informal settlements and economies are often sidelined in planning processes, further marginalising vulnerable communities. Another prominent feature of impediment to sustainable urban development in the developing world is corruption. Resources intended for infrastructure development and public services are often misallocated, and public-private partnerships may prioritize profit over equity and sustainability (Pattanayak and Verdugo-Yepes, 2020). Corruption undermines trust in governance structures and inhibits the implementation of inclusive urban development policies. Secondary cities, often eclipsed by larger metropolitan areas, play a fundamental role in regional development and can serve as laboratories for innovative urban policies for achieving urban sustainable development. They function as vital hubs that connect local production, movement, and exchange of goods, people, trade, information, and services between various urban systems, demonstrating industry agglomerations, localized supply chains, diverse economic bases, and a range of housing options (Roberts and Hohmann, 2014).

South Africa's urban development strategies have evolved over the years, shaped by the socio-political and economic challenges inherited from the apartheid era. Several policies and frameworks have been introduced to address the deep-seated inequalities in urban areas, improve living conditions, and promote sustainable urban development. Following the end of apartheid in 1994, the South African government introduced the Reconstruction and Development Programme (RDP) as a comprehensive policy framework aimed at addressing the historical inequalities of apartheid. The RDP focused on providing basic services, including housing, water, and sanitation, to previously marginalised communities (Marutlulle, 2021). This was part of the government's broader goal to promote socio-economic integration through infrastructure development. While the RDP made significant strides in improving living conditions for many South Africans, particularly in informal settlements, it also faced criticism. The approach was often seen as insufficient in addressing long-term sustainability and urban planning issues, with a focus on quantity over quality, which sometimes led to poorly planned settlements (Lefuwa, 2016). Additionally, the RDP's focus on the delivery of housing failed to fully integrate other aspects of urban sustainability, such as economic development and environmental resilience. In response to the persistent challenges of informal settlements, the South African government launched the Upgrading of Informal Settlements Programme (UISP) in 2004. This policy aimed to improve the living conditions of residents in informal settlements by providing secure tenure, basic infrastructure, and services. The UISP encouraged a more integrated and sustainable approach to upgrading informal settlements rather than merely demolishing or relocating residents (Maganadisa, Letsoko, and

Pretorius, 2021). However, the program did not fully address the broader socio-economic factors affecting urban sustainability, such as unemployment and local economic development. While not specifically urban-focused, the Integrated Sustainable Rural Development Programme (ISRDP), launched in 2001, aimed to integrate rural and urban development efforts to create more balanced regional development (Public Service Commission, 2010). The Urban Development Framework (UDF), introduced in 1997, sought to address the specific needs of South Africa's urban areas. The framework set out a vision for integrated, sustainable, and equitable urban development by focusing on promoting urban efficiency, social equity, and environmental sustainability (Department of Provincial and Local Government, 2009). The framework underlines the importance of a balance between housing and employment, urban regeneration, and sustainable environmental practices. While the UDF made strides toward these objectives, it struggled to shift the national urban development paradigm away from large-scale, top-down approaches, often failing to fully incorporate informal sector dynamics and local-level participation in urban development. In 2004, South Africa introduced Breaking New Ground (BNG), a landmark policy that sought to transform the country's approach to housing and urban development. The BNG policy emerged as a response to the limitations of previous housing policies, such as the RDP, by highlighting the need for sustainable human settlements rather than just housing provision (Baloyi, 2014). BNG introduced a more holistic approach by considering aspects such as job creation, poverty reduction, and environmental sustainability in housing development. It promoted mixed-use developments, better access to services, and the creation of communities that were more self-sustaining (Osman and Herthogs, n.d.). However, BNG also faced implementation challenges, including slow delivery of services, financial constraints, and the complexity of integrating informal settlements into the formal urban fabric. Despite the significant efforts made through these programs and frameworks, gaps remain in achieving truly sustainable urban development in South Africa.

In response to the challenges posed by informal settlements, the informal sector, and poor engagements, there has been growing interest in multi-stakeholder approaches to urban development. These approaches state the importance of collaboration between government, communities, and the private sector in addressing urban challenges and achieving urban sustainable development. Watson (2009) argues that inclusive urban governance is essential for creating sustainable and equitable cities, particularly in areas with high levels of informality. Multi-stakeholder approaches have been implemented in various forms across the Global South, with varying degrees of success. In South Africa, as already argued earlier, initiatives such as the (UISP) have sought to formalise informal settlements through partnerships between government and communities (Socio-Economic Rights Institute of South Africa [SERI], 2018). However, these initiatives have often been hampered by bureaucratic inefficiencies, lack of resources, and insufficient community engagement.

4 METHODS AND MATERIALS

This section outlines the methodological approach adopted to guide the research process, ensuring a systematic and coherent investigation of the study objectives. The study employed a systematic literature review (SLR) methodology to explore the challenges and opportunities related to sustainable urban development in South Africa. The primary objective is to understand the role of informal settlements and the informal sector in the urbanisation process and to propose a multi-stakeholder approach for integrating these elements into formal urban development strategies.

The SLR methodology is chosen for its robustness in synthesising existing knowledge and identifying gaps in the literature. A comprehensive search of electronic databases, including Scopus, Web of Science, and Google Scholar, was conducted. Keywords that include "sustainable urban development," "informal settlements," "multi-stakeholder approach," "South Africa," and "urban governance" were used to identify relevant literature. The search initially identified 778 documents, which were screened through a two-step process involving title and abstract review followed by full-text assessment. This rigorous selection process, guided by inclusion and exclusion criteria, narrowed the pool to 33 high-quality and relevant studies. The search was limited to peer-reviewed journal articles, conference papers, and relevant policy documents published between 2000 and 2023. To ensure the relevance and quality of the data, specific inclusion and exclusion criteria were applied. Articles were included if they focused on urban development in South Africa, addressed the role of informal settlements or the informal sector, or discussed multi-stakeholder approaches to governance. Articles that did not meet these criteria, were not peer-reviewed, or were focused on regions outside South Africa were excluded.

5 UNDERLYING OBSTACLES TO ACHIEVING SUSTAINABLE URBAN DEVELOPMENT IN SOUTH AFRICA

5.1 Unsupported Secondary Cities

Urbanisation, the shift of population from rural to urban areas, is a global trend with profound implications for sustainable development. As cities grow, they often face challenges such as increased resource consumption, pollution, and social inequality (Kanchana, 2022). However, South Africa's urbanisation process is complicated by its unique historical and socio-political landscape. South Africa's struggle to achieve urban sustainable development can be equally attributed to its limited support for secondary cities, which plays a crucial role in addressing urbanisation challenges. These challenges, including chronic poverty, unemployment, job creation, infrastructure provision, small business development, and education and skills development, are likely common to most, if not all (Pillay, n.d.). Supporting these cities with targeted investments, infrastructure, and governance reforms would help alleviate urbanisation challenges, reduce inequalities, and promote more balanced development.

5.2 The Legacy of Apartheid on Urban Development
