REAL CORP 2026 took place under the patronage of the Mayor of the City of Vienna, Dr. Michael Ludwig, and under the patronage of the Federal Minister of Education Christoph Wiederkehr, MA.

PREFACE

Manfred SCHRENK

Conference Director,
President CORP – Competence Center of Urban and Regional Planning

WELCOME to REAL CORP 2026, the 31st International Conference on Urban & Regional Development and Spatial Planning in the Information Society!

As urban and regional landscapes become more complex, planning is no longer a linear process. It is adaptive, participatory, and often unpredictable. In urban and regional development, planning is both a discipline and a gamble. This conference gathers thinkers and doers to navigate the space between vision and reality – shaping futures one decision at a time.
For three decades, the REAL CORP conference series has been at the forefront of exploring the profound impact of information and communication technologies (ICT) on urban and regional development. As we navigate an era of unprecedented change, marked by rapid technological advancements, evolving societal structures, and pressing environmental challenges, REAL CORP 2026 invites researchers, practitioners, experts, activists and policymakers to contribute to the discourse on "Cherish Heritage, Plan Now, Create Future!"

We are witnessing a paradigm shift in how our cities and regions function, are planned, and are experienced. From the pervasive influence of artificial intelligence and big data analytics to the imperative of climate resilience and inclusive governance, urban and regional landscapes are undergoing continuous metamorphosis. REAL CORP 2026 provides a vital platform to critically examine these transformations, share innovative solutions, and collectively envision sustainable and equitable futures.

The REAL CORP 2026 research question is: does technology and especially AI really revolutionise everything? Even CITIES, the biggest invention of mankind?

New technologies and especially AI lead to many changes in all aspects of life, including in cities and regions and, of course, in planning processes. Still cities and regions are not primarily a playground for "new technologies" but the main goal is to have sustainable, resilient and above all livable environments. The soul of a livable future often lies in adequate density, adaptive reuse, green infrastructure, and places where communities thrive, with eco-conscious urban design, human-scale architecture, and inclusive public spaces!
All this has to be planned, created, maintained and eventually renewed.

Planning is always an effort of many contributors and planners have to be part of all urban planning efforts – be it as experts, visionaries, strategists, co-ordinators, moderators and mediators, advocates and sometimes opposers. LET'S PLAN TOGETHER!

Welcome to Vienna! Welcome to Austria! Have a great conference!
Manfred SCHRENK, Clemens BEYER & the REAL CORP Team

Dear participants of REAL CORP 2026!

On behalf of the City of Vienna, I would like to extend a warm welcome to you all! I am delighted that such important topics as urban planning and regional development are on the agenda of such a high-profile conference. International exchange is the best way to tackle global challenges that affect us all equally.

This applies in particular to the impact of revolutionary modern technologies and AI in particular. It is no coincidence that the central research question of REAL CORP 2026 is whether these innovations will really change everything, including modern metropolises such as Vienna.

We are already feeling this change in our everyday lives: for example, more and more administrative procedures in Vienna can be completed digitally; the BRISE project, for example, is making building permit procedures paperless, faster, more efficient, more sustainable and more transparent. In addition, Vienna has become an AI innovation centre.

This process is guided by the principle of "digital humanism" – in other words, progress should make everyday life easier. The focus is on people, not progress.

In this context, education will become a key resource. Our industrial societies are transforming into knowledge societies. That is why it is so important to set the course now for the best possible preparation of our children and young people so that they are ready for the growing challenges of the digital world.

In addition, it will be important to focus even more than before on international exchange. Especially in times of national solo efforts and protectionism, it is important to keep multinational forums for communication and cooperation open. After all, science and innovation are only truly stimulated by encounters on an equal footing and by learning from each other.

That is why I am very pleased that REAL CORP 2026, a major international conference, is taking a close look at the characteristics and effects of these fundamental transformations. Especially now – when change is already becoming apparent – it is important and necessary to develop ideas about where and how far we as societies want to go. We must not allow ourselves to be driven by this innovation process, but must shape it ourselves with social awareness and clear objectives.

REAL CORP 2026 is making an invaluable contribution in this regard. I am very excited to see the results and wish you all a successful and, above all, insightful conference!

Michael Ludwig, Mayor and Governor of Vienna

Vision Education warmly welcomes participants to REAL CORP 2026!

Vision Education is honored to support the 31st International Conference on Urban Planning, Regional Development, and the Information Society in Vienna, Austria, in collaboration with CORP – Competence Center of Urban and Regional Planning. This important partnership reflects a shared commitment to advancing global dialogue and fostering academic and practical cooperation in the fields of urban planning, regional development, and the information society. As an institution committed to strengthening education and research in the Kurdistan Region of Iraq, Vision Education supports both private and public institutions while empowering citizens to contribute to positive change. Vision Education recognises the critical role of knowledge exchange, international collaboration, and interdisciplinary research in addressing the complex challenges facing contemporary cities and regions.

Sustainable urban growth, climate resilience, and technological innovation require forward-looking approaches that integrate education, policy, and practice at both regional and local levels. Through engagement with global academic networks and institutions, Vision Education seeks to contribute to the development of informed leadership, innovative research, and practical solutions that support sustainable and inclusive urban futures.

Partnerships such as this collaboration with CORP exemplify the value of building bridges between regions, institutions, and stakeholders to foster shared expertise, mutual understanding, and long-term cooperation.

We are proud to support this leading international conference, bringing together distinguished scholars, professionals, and policymakers in Vienna, and we look forward to the continued exchange of ideas that will help shape more resilient, sustainable, and intelligently planned cities for generations to come.

Idris Nechirvan Barzani, Chairman of Vision Education

Dear participants of REAL CORP 2026!

Our cities and regions stand at the threshold of a profound transformation. Climate change, demographic shifts, digitalisation, and evolving patterns of work and mobility are reshaping how we live, work, and move. Cities and regions are therefore central arenas for safeguarding quality of life, advancing sustainability, and strengthening social cohesion for all citizens.

Our shared goal is to create resilient, inclusive, and liveable urban environments. Research, technology, and innovation play a key role in achieving this objective. They provide essential tools for integrated spatial planning, enable evidence-based decision-making, and support sustainable solutions in areas such as energy, mobility, infrastructure, and public spaces. Strategic investment in research and innovation is indispensable to steering this transformation in a forward-looking and responsible manner.

Integrated neighbourhood and district development is a particularly powerful lever in this context. By linking spatial, social, ecological, and economic dimensions, it enables complex challenges to be addressed holistically and makes the benefits of transformation tangible for citizens. Well-designed integrated neighbourhoods can serve as showcases for innovation, foster social cohesion, and act as key building blocks for sustainable urban and regional development.

In this spirit, I warmly welcome REAL CORP 2026 to Vienna. With its focus on integrated urban and regional development, the conference provides an important platform for international exchange and brings the discussion to the Vienna Otto-Wagner-Areal – a place that exemplifies transformation, innovation, a vibrant architectural culture, and the close connection between research, technology, and urban planning.

Table of contents – Inhaltsverzeichnis:

PREFACE 5

3D City Models as Simulation Infrastructure: Open Tools, Proprietary Gaps and Application Scenarios in Everyday Planning 19
Peter Zeile, Daniel Broschart

A Digital Transformation Assessment on the Role of Building Information Model Training in Built Environment Institution Programmes: Lessons from South Africa 29
Nkosinathi Dube, Thembani Moyo, Thulisile Mphambukeli

A Governance Framework for Planning Approval of Housing Developments to Enhance Growth in the Economy 39
Nonhlanhla Bongiwe Charity Buthelezi, George Onatu, Clinton Aigbavboa

A Green(er) Roof over the Head: Reflecting on Strategies Targeting Homelessness with Urban Agriculture for Cape Town, South Africa 45
Louis Lategan, Charné Erasmus

A Spatiotemporal Analysis of Duhok's Urban Growth (2010–2025): A Narrative Review of the Duhok Master Plan 57
Haval Bankin Qasim Kittani

A Stakeholder-Driven Needs Assessment: Identifying Urban Challenges and Requirements for Satellite-Based Services Supporting Climate-Resilient Austrian Cities 63
Romana Berg, Martin Jung, Eliza-Maria Link, Diana Silvestru, Heinz Gallaun, Isabella Hinterleitner, Anna Kozlowska, Jan Peters-Anders, Katharina Köglberger, Viktoria Mentin, Daniel Deutsch

A Systematic Living Lab Approach for Community Engagement for Urban Regeneration – the S.M.I.L.E. Methodology 75
Caroline Cheng, Judith Thomsen, Anandasivakumar Ekambaram

A Systematic Review of Policy and Legislative Gaps in Advancing Sustainable Human Settlements in Small Rural Towns: A Case of South Africa 87
Lungile Mkhize, Trynos Gumbo

A Toolbox to Analyse Sustainable Mobility in Land-Use Planning Processes: Methodological Challenges and Approaches for Residential Developments in Rural Areas 93
Nazanin Zahabkar Aghdam, Jochen Eckart, Christian Rickert, Catharina Lutz

Accelerating instead of Waiving Planning: Opportunities and Challenges of Digital Building Land Cadastres in Urban Digital Twins 105
Stefan Fina, Florian Rack, Antonia Finger, Martina Königbauer

Affordable Housing in Emerging and Developing Economies: Exploring the Role of Urban Planning and Policy in African Countries 117
Parsa Arbab

An Analysis of the Role of Spatial Planning in Enhancing Rural Resilience to Flooding: A Case Study of South Africa 125
Takalani Mugada, Trynos Gumbo, Retsepile C. Kalaoane, Thembani Moyo

An Assessment of the Clean Air Zones (CAZ) Implementation in Developing Contexts: Social Equity Report for the City of Johannesburg 135
Abdulrasaq Ajadi Ishola, Trynos Gumbo, Tafadzwa Clementine Maramura

An Educational Approach to Planning the Future Spatial Development of a Small Town: The Case of Čakovec, Croatia 145
Lea Petrović Krajnik, Damir Krajnik, Tamara Zaninović

Analysing the Logistics Space near Cape Town International Airport in Comparison to the Seaport and Dry Port Environments 157
Masilonyane Mokhele

Analysing Urban Development Patterns: A Spatio-Temporal Analysis and Predictive Scenarios around Major Railway Stations/Terminals 167
Rohit Koiri, Ashly Augustine, Ankhi Banerjee

Architectural Rehabilitation of Charasteen Cave in Duhok: A Locally-Led Accessibility and Heritage Intervention within the UNESCO–EU MADAD Framework with Support from the Kurdistan Regional Government 179
Mahmood Albrifkany

Assessing Pedestrian Accessibility to Urban Land Surface Temperature Cold Spots in Bavarian Cities 191
John Friesen, Sarah Heinz, Ariane Droin, Michael Wurm, Tobias Leichtle, Mattia Marconcini, Hannes Taubenböck

Beyond Informality: Middle-Class Urbanisation, Hybrid Governance, and Resilience Challenges in African Peripheries 203
Lindokuhle Matshika, Trynos Gumbo, Karen Puren

Beyond Municipal Boundaries: Rethinking Public Amenities in Eswatini's Peri-Urban Transformation 211
Mhlalisi Mndzebele, George Onatu

Cherishing Human-Elephant Landscapes with GIS-LBS: A LUCIS-Based Negotiation Framework for Human-Elephant Coexistence in Sri Lanka **217**
Chethika Abenayake, Amila Jayasinghe, Kaveesha Lahiru, Sandaruwan Sankalpa, Gayesha Diwyanjali, Sandali Kangara, Chathura De Silva, Günther Retscher, Jelena Gabela Majic

Childhood Mobility Socialisation: The Influence of Social Environment, Infrastructure and Perception of the School Route on Active Mobility Modes **223**
Hans Peter Ellmer, Vanessa Weiß, Sebastian Seebauer, Irene Bergmann, Karlheinz Gürtl, Elisabeth Oswald

Co-Creating Urban Resilience by Community Engagement in Central Asia **231**
Madina Junussova, Chynarkan Saparova

Co-Productive Project Development in Urban and Regional Planning **239**
Sarah C. Schreiner

Combining Social Aspects of Climate Change with Urban Heat Stress Modelling – a Case Study from Bremerhaven, Germany **247**
Markus Groth, Steffen Bender, Ricarda Klafka

Community Perceptions of Municipal Stormwater Management in Durban, KwaZulu-Natal: Evaluating Progress and Challenges **259**
Basiiraa Moosa, Trynos Gumbo, Thulisile Mphambukeli, Thokozani Simelane

Condition Assessment of Cycling Infrastructure – A Step towards a Systematised Approach in Austria **269**
Karin Markvica, Stefan Portisch, Dominik Wieser, Christian Fürstler, Manuela Stögerer, Peter Saleh

Constitutional Energy Mandates and Local Governance in Post-Apartheid Spatial Planning **279**
Khatliso Simon Baas, Thulisile Ncamsile Mphambukeli

Critiquing the Implementation of the New Urban Agenda in Sub-Saharan Africa: A Systematic Review of Housing Policies and the Challenge of Upgrading Informal Settlements **291**
Mhlalisi Mndzebele, George Onatu

Digital Participatory Rural Appraisal Approach for Smart Sustainable Rural Development **297**
Papiya Bandyopadhyay Raut, Sandeep Kumar Raut, Vivek Kumar

Digital Systems Audit and Policy Alignment in the City of Johannesburg **305**
Thandekile Khumalo, Aurobindo Ogra

District Sub Centres as Foundational Elements in the Implementation of the 15 Minute City Model: Case Study of Albertfalva **315**
Boróka Szarvák

Earth Observation and Open Geodata for Sustainable Urban Planning – A Practical Case Study from the City of Munich, Germany **327**
Tobias Leichtle, Marlene Kühnl, Jeroen Staab, Dorothee Stiller, Stefan Gamperer, Klaus Martin, Robert Behringer, Michael Wurm, Hannes Taubenböck

Enhanced Communication Systems with Reconfigurable Intelligent Surfaces in Smart Cities: Bridging Wireless Connectivity and Urban Sustainability **337**
Y. E. Mohammed Ali, Abdulrahman Kh. Alhafid, Sedki Younis, Joan Atheel Ahmed

Enhancing Safety Perception for Disabled Users of BRT System through Closed-Circuit Television Cameras in Johannesburg **347**

3D City Models as Simulation Infrastructure: Open Tools, Proprietary Gaps and Application Scenarios in Everyday Planning

Peter Zeile, Daniel Broschart

(Dr.-Ing. Peter Zeile, Karlsruhe Institute of Technology KIT, peter.zeile@kit.edu)
(Dr.-Ing. Daniel Broschart, City of Landsberg am Lech, daniel.broschart@landsberg.de)

1 ABSTRACT

Digital Twins are increasingly used as analytical frameworks in urban planning, supporting spatially explicit assessments of climate, energy and environmental risks. Based on interoperable 3D city models (e.g. CityGML/CityJSON) and shared geodata infrastructures, they enable scenario-based evaluations across multiple planning domains. This paper examines how Digital Twin workflows can support planning-oriented simulation tasks, with a particular focus on the interplay between open-source and proprietary tools.

Using the city of Landsberg am Lech as an applied case study, four thematic applications are investigated: solar framework planning in a protected historic ensemble, urban heat screening, pluvial flood risk assessment, and environmental noise scenarios. The workflows combine open data – most notably LOD2 building models and digital terrain models – with a hybrid toolchain including QGIS, GRASS GIS, Honeybee, ICETools, H-Risk, as well as proprietary environments such as Rhino/Grasshopper and ArcGIS Pro.

The results demonstrate that Digital Twins function most effectively as shared spatial reference systems for planning-oriented screening and orientation analyses, rather than as fully integrated simulation platforms. While physically based models such as PALM-4U represent the state of the art in urban climate modelling, simplified tools proved suitable for early-stage planning and comparative scenario evaluation. Overall, the study shows that hybrid workflows combining open and proprietary tools currently represent best practice, balancing transparency, methodological robustness, and planning relevance.

Keywords: Digital Twin, Open-Source Planning Tools, Hybrid Simulation Workflows, Noise, Urban Climate Simulation

2 INTRODUCTION

Contemporary urban planning is increasingly challenged by a set of highly complex, mutually dependent issues related to climate change, efficient resource use, and risk governance. Heat stress, pluvial flooding, noise exposure, and energy transition processes interact spatially and temporally, often exceeding the analytical capacity of traditional two-dimensional planning instruments. In this context, digital technologies have become central to contemporary planning practice. While the concept of the Smart City has primarily been associated with sensor-based, real-time optimisation and proprietary platforms (BATTY, 2018, p. 2; GRIEVES, 2014), the notion of the Open Digital Twin (DEMBSKI et al., 2020; KETZLER et al., 2020) emphasises a different paradigm: the creation of interoperable, transparent, and reproducible digital representations of urban space based on open standards and open data.

Open Digital Twins are not primarily visualisation tools but analytical infrastructures (ZIEHL et al., 2023). They integrate 3D city models, geospatial datasets, and simulation environments to support scenario-based planning, early-stage decision-making, and interdisciplinary collaboration. Their growing relevance is closely linked to the increasing availability of open geodata, such as Level of Detail 2 (LOD2) building models, digital terrain models (DTM), and open-source geographic information systems.

This paper investigates the role of Open Digital Twins in urban planning with a specific focus on climate-related applications. It addresses two central research questions:

- Which planning-relevant simulations can already be conducted entirely with open-source tools?
- In which areas do proprietary software solutions remain necessary due to regulatory, methodological, or institutional constraints?

Using the city of Landsberg am Lech as a case study, the paper demonstrates how a hybrid toolchain combining open-source and proprietary software can be implemented in practice. The contribution aims to provide both a conceptual framework and empirical insights for planners, municipalities, and researchers working with digital urban models.

3 STATE OF THE ART: SIMULATION-BASED URBAN PLANNING WITH DIGITAL TWINS

3.1 3D City Models as Analytical Infrastructure

The application of digital twins in urban planning has expanded significantly over the last decade, driven by advances in geospatial data availability, 3D city modelling, and simulation technologies. Rather than constituting a single methodological approach, digital twins increasingly function as integrative frameworks that support multiple thematic analyses (JEDDOUB et al., 2023). In current research and planning practice, four application domains are particularly prominent: solar energy assessment, urban climate modelling, hydrological risk analysis, and environmental noise evaluation (ZHU & JIN, 2025).

3.2 Solar Potential Analysis and Urban Solar Frameworks

Solar potential analysis represents one of the most mature and widely applied use cases of 3D city models in urban planning. The availability of LOD2 building data enables the calculation of roof orientation, inclination, shading effects, and annual solar irradiation with high spatial resolution. Numerous studies demonstrate that solar cadastre systems based on 3D city models provide reliable decision support for municipal energy strategies (BROSCHART et al., 2024).

Recent research increasingly emphasises strategic, city-wide solar planning beyond parcel-based assessments. Solar framework plans (Solarrahmenpläne) translate technical potential analyses into spatially differentiated planning instruments that integrate urban morphology, heritage protection, densification strategies, and policy objectives (ZEILE et al., 2025).

Methodologically, these approaches rely on reproducible GIS-based workflows. While open-source tools support transparent modelling of solar radiation and scenario comparison (ROUDSARI et al., 2013), proprietary software remains relevant for detailed economic or grid-related assessments. The solar framework plan presented at REAL CORP 2025 (ZEILE et al., 2025) illustrates how Digital Twins can serve as spatial decision-support systems that link energy analysis and urban planning.

3.3 Urban Climate and Heat Stress Modelling

Urban climate modelling has become increasingly important due to rising heat stress and the need for climate adaptation. Digital twins support this domain by providing detailed representations of urban form, which strongly influence radiation balance, airflow, and thermal comfort (LOPEZ-CABEZA et al., 2025).

Current approaches range from simplified surface-based models to entirely physical, three-dimensional atmospheric simulations. Open-source tools such as Ladybug/Honeybee enable accessible, iterative assessments of solar exposure and shading, while the PALM-4U model system represents a state-of-the-art, physically based approach to urban climate simulation (BAKLANOV et al., 2020; HELDENS et al., 2020).

Proprietary tools such as ENVI-met remain widely used for detailed microclimatic studies (BRUSE, 2000), although recent literature highlights the suitability of simplified models for planning-oriented, comparative analyses.

3.4 Pluvial Flooding and Surface Runoff Analysis

Hydrological risk analysis, particularly pluvial flooding, has become increasingly relevant in urban planning due to the rising frequency of extreme rainfall events. Digital twins enable the integration of terrain models, surface characteristics, and built structures to analyse runoff pathways and accumulation zones.

Open-source GIS environments such as GRASS GIS and QGIS provide robust tools for surface runoff analysis (SCHNEIDER, 2025; “SplashTool”). These methods support transparent, reproducible modelling and are widely applied in municipal risk mapping and climate adaptation planning. Proprietary platforms such as ArcGIS Pro offer extended functionalities and are often embedded in administrative workflows, while the underlying modelling principles remain transferable across software environments.

3.5 Environmental Noise Modelling

Environmental noise assessment constitutes an established application of digital spatial models. Noise exposure is strongly influenced by building geometry, street layout, and traffic volumes, making 3D city models particularly suitable for spatially differentiated analysis.

Recent developments in open-source GIS plugins, such as H-Risk (TAGUSARI, 2024), demonstrate that scenario-based noise modelling can support early planning stages by enabling relative comparisons of urban form, traffic management, and mitigation measures. For legally binding noise assessments, proprietary software remains dominant; however, the literature increasingly acknowledges simplified tools as complementary instruments in planning practice.

3.6 Synthesis

Across all four domains, the literature indicates a convergence towards scenario-based planning workflows supported by Digital Twins. While thematic priorities differ, shared methodological requirements – interoperable data models, reproducible simulations, and spatial transparency – are evident. Solar framework planning emerges as a particularly effective interface between technical simulation and strategic urban planning, highlighting the broader potential of Digital Twins as decision-support systems.

4 LANDSBERG AM LECH TEST-SITE

4.1 The (Open) Digital Twin of Landsberg am Lech

The city of Landsberg am Lech serves as a case study demonstrating how Open Digital Twin workflows can be implemented in municipal planning practice. As a medium-sized city with accessible open geodata, a heterogeneous building stock, and increasing challenges related to climate adaptation and energy transition, Landsberg am Lech represents a typical and transferable European planning context.

The digital twin used in this study follows a planning-oriented interpretation of the Digital Twin concept, as discussed in recent contributions (BROSCHART et al., 2025). Rather than aiming at real-time monitoring or sensor-driven control, the model focuses on spatial analysis, scenario development, and decision support for strategic and early-stage planning processes, aligning with research that positions urban digital twins as integrative spatial frameworks rather than purely operational systems.

The data basis consists primarily of open and municipal datasets, including a Level of Detail 2 (LOD2) building model, a high-resolution digital terrain model (DTM), land use information, and thematic layers related to vegetation, mobility infrastructure, and environmental constraints. These datasets were harmonised within a GIS environment using interoperable data models, enabling consistent use across multiple analytical domains.

Crucially, the digital twin is not conceived as a monolithic model but as a shared spatial reference system connecting different simulation tools and thematic analyses. In this sense, the model represents a planning-oriented digital twin, designed to support scenario-based analysis, comparative evaluation, and interdisciplinary workflows. This structure allows diverse planning questions – such as solar energy potential, urban heat mitigation, surface runoff, and noise exposure – to be addressed using a common geometric and semantic foundation while retaining methodological flexibility.

By emphasising openness, reproducibility, and thematic integration, the Landsberg am Lech Digital Twin demonstrates how municipalities can operationalise digital twins as practical planning instruments that support both technical analysis and strategic discourse.

4.2 Solar Framework Planning using the Digital Twin

Solar energy assessment constitutes a particularly relevant application of Digital Twins in historic urban contexts, where technical potential alone is insufficient as a planning criterion. In Landsberg am Lech, the Digital Twin was applied to develop a solar framework plan (Solarrahmenplan) explicitly addressing the challenges of solar energy deployment within a protected historic ensemble. The central planning question was not whether solar energy is technically feasible, but which types of solar installations are compatible with heritage protection requirements and urban visual integrity.

4.2.1 Planning Context: Solar Energy in Historic Ensembles

The historic core of Landsberg am Lech is characterised by a dense building fabric, heterogeneous roof typologies, and strict heritage protection regulations. In such contexts, conventional solar cadastres reach their limits because they typically identify technically suitable roof surfaces without accounting for visual exposure, material compatibility, or monument-preservation objectives.

The solar framework plan, therefore, reframes solar potential analysis as a spatial governance instrument. Its purpose is to support differentiated planning decisions by identifying zones where solar installations are permissible, conditionally acceptable, or to be avoided, and by distinguishing between different photovoltaic and solar thermal technologies. This approach follows the logic presented in recent CORP research (ZEILE et al., 2025), positioning solar framework planning as an interface between energy transition and urban heritage management.

4.2.2 Digital Twin as Analytical and Visual Reference

Solar irradiation analysis was used as a supporting layer within the framework plan, but did not constitute its primary decision criterion. Instead, irradiation values were interpreted in combination with roof typologies, visibility conditions, and conservation guidelines. This enabled the classification of roof surfaces into differentiated categories, such as suitable for non-visible installations, ideal for visually integrated systems, or unsuitable due to heritage sensitivity.

The analytical workflow combined GIS-based processing with parametric modelling environments. While open-source tools were used to prepare and structure the LOD2 data, subsequent analyses and visual evaluations were conducted in commercial software environments, including Rhino/Grasshopper and ArcGIS Pro (Fig. 1). This hybrid setup reflects planning practice, in which analytical requirements rather than licensing models guide tool selection.

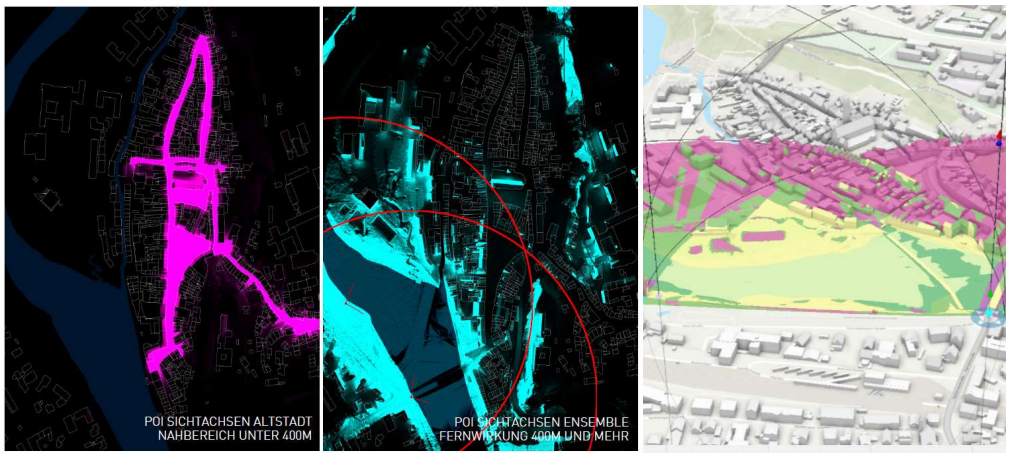

Fig. 1: Various approaches to visibility analysis using Rhino and ArcGISPro (left& middle: Herm & Benkeser 2025, right: own source)

4.2.3 Modelling Solar Suitability under Heritage Constraints

Solar irradiation analysis was used as a supporting layer within the framework plan, but did not constitute its primary decision criterion. Instead, irradiation values were interpreted in combination with roof typologies, visibility conditions, and conservation guidelines. This allowed the classification of roof surfaces into differentiated categories, such as suitable for non-visible installations, ideal for visually integrated systems, or unsuitable due to heritage sensitivity.

The analytical workflow combined GIS-based processing with parametric modelling environments. While open-source tools were used to prepare and structure the LOD2 data, subsequent analyses and visual evaluations were conducted in commercial software environments, including Rhino/Grasshopper and ArcGIS Pro. This hybrid setup reflects planning practice, where analytical requirements rather than licensing models guide tool choice.

4.2.4 Differentiation of Solar Technologies

A key contribution of the solar framework plan lies in its explicit differentiation among solar technologies. Rather than treating photovoltaic systems as a homogeneous category, the framework distinguishes between conventional PV modules, building-integrated photovoltaics (BIPV), solar tiles, and solar thermal systems. Each technology exhibits distinct visual characteristics and degrees of compatibility with historic roofscapes.

By linking technology categories to spatial zones within the Digital Twin, the solar framework plan provides concrete guidance for planners, heritage authorities, and property owners. In this role, the Digital Twin acts

as a mediating instrument, translating abstract conservation principles into spatially explicit planning recommendations.

4.2.5 Planning Relevance and Strategic Value

The Landsberg am Lech solar framework plan demonstrates how Digital Twins can support nuanced planning decisions in sensitive urban contexts. Rather than maximising energy yield, the framework prioritises contextual appropriateness and visual integration, thereby reducing the potential for conflict between energy policy and heritage protection.

Importantly, the Digital Twin does not replace detailed architectural design or approval procedures. Instead, it provides strategic orientation at an early stage, supports transparent communication among stakeholders, and increases planning certainty.

4.3 Urban Heat and Microclimate Assessment

Urban heat stress represents a critical challenge for cities, particularly in dense urban areas with limited vegetation and high surface sealing. Within Open Digital Twin workflows, microclimate assessment functions as an essential analytical layer for evaluating the spatial effects of urban form, materiality, and vegetation on thermal comfort. In the Landsberg am Lech case study, urban heat assessment was implemented as a planning-oriented screening and orientation tool, rather than as an entirely physical climate simulation.

4.3.1 Reference Framework: Physically Based Urban Climate Models

From a scientific perspective, physically based urban climate models such as PALM-4U represent the state of the art in microclimate simulation. PALM-4U enables high-resolution modelling of air temperature, radiant heat fluxes, airflow, vegetation–atmosphere interactions, and human thermal comfort, and its integration into Digital Twin environments is increasingly discussed in research and municipal climate adaptation studies (BENDER et al., 2023).

However, despite its methodological advantages, PALM-4U requires substantial computational resources, specialised expertise, and extended setup times. In the Landsberg am Lech case study, PALM-4U served as a conceptual reference model but was not applied operationally. Instead, simplified and more accessible approaches were selected to support exploratory planning questions.

4.3.2 Applied Tools: Honeybee and ICETools

Urban heat assessment in Landsberg am Lech was conducted using a combination of Honeybee (Grasshopper/Rhino) and ICETools (QGIS). These tools were selected to balance analytical relevance with practical feasibility in a planning context, as demonstrated in accompanying academic exercises.

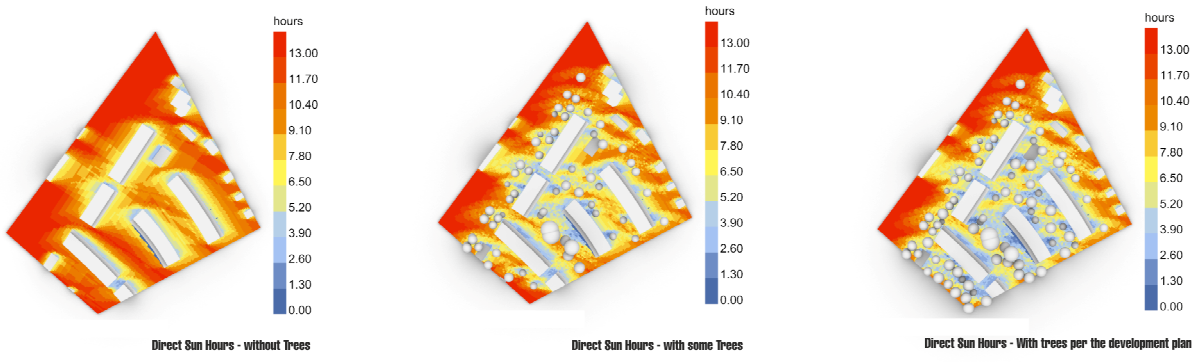

Fig. 2: Heat development in the xy new development area in Landsberg with varying vegetation densities, simulated in Heneybee. The areas with reduced heat stress due to vegetation are clearly visible. (Flores & Zumholte 2025)

Honeybee was used to analyse solar radiation exposure, shading patterns, and surface-related thermal indicators using the LOD2 building model and selected scenarios. Its parametric structure supports rapid iteration and comparison of spatial configurations, particularly regarding vegetation placement and building geometry. While Honeybee does not simulate atmospheric dynamics, it provides valuable insights into radiation-driven heat loads (see Fig.2).

ICETools was used as a complementary method to estimate surface temperature patterns based on simplified energy balance calculations. By integrating land cover, vegetation, and shading information, ICETools enables reproducible, low-threshold heat assessments that are well-suited for early-stage planning and scenario comparison.

4.3.3 Methodological Limitations of Tool Integration

Despite increasing tool availability, the integration of urban climate simulations into Digital Twin workflows remains methodologically fragmented. Tools such as ICETools and ENVI-met require substantial model reconstruction, as existing Digital Twin geometries cannot be used seamlessly. Buildings, vegetation, surface materials, and boundary conditions must be newly parameterised within each simulation environment, limiting reproducibility and increasing modelling effort.

Parametric environments such as Honeybee offer greater interoperability, as 3D city models can be imported directly. However, practical experience shows that combining LOD2 building geometries with digital terrain models (DTMs) poses significant challenges. At building–terrain interfaces, geometric inconsistencies may occur, leading to artefacts such as implausible surface temperature anomalies ("cold spots").

These issues are primarily caused by geometric and semantic mismatches between datasets generated for different purposes. Without careful preprocessing and validation, such inconsistencies can propagate into simulation results. Consequently, current Digital Twin workflows should be understood as loosely coupled toolchains, reinforcing the need for staged modelling approaches in which simplified tools support early decision-making and more complex models are applied selectively.

4.4 Pluvial Flood Risk and Surface Runoff

Pluvial flooding constitutes a recurring challenge in urban planning, particularly in compact settlement structures with high degrees of surface sealing. In the case of Landsberg am Lech, surface runoff analysis was implemented as a planning-oriented screening tool to rapidly identify spatial patterns, flow paths, and potential accumulation zones relevant to urban development and climate adaptation.

4.4.1 Data Basis and Digital Twin Integration

The analysis was based on a Digital Terrain Model (DTM) and the LOD2 building model, both of which could be directly integrated into the Digital Twin environment. The DTM provided the basis for modelling surface gradients and runoff directions, while LOD2 buildings served as physical obstacles that influenced flow paths and accumulation areas.

A key advantage of this approach is the flexibility in data preparation. Terrain data can be rapidly adjusted using grayscale heightmaps, enabling quick testing of alternative surface conditions or simplified scenarios. This allows planners to explore assumptions about surface sealing, microtopography, or redevelopment with minimal preprocessing effort, while ensuring consistent representation of terrain and built structures.

4.4.2 Modelling Approach and Tools

Surface runoff modelling was conducted using QGIS Splash Tools and ArcGIS Pro flow path analysis, both of which support direct use of terrain and building data without complex model reconstruction. The tools calculate flow directions and accumulation zones based on terrain gradients and produce visually intuitive results.

The modelling approach focuses on relative flow behaviour, highlighting areas where water is likely to concentrate during intense rainfall events. Rather than simulating exact water depths or temporal dynamics, the analysis identifies structural vulnerabilities in the urban fabric. While terrain and building data can be ingested directly, the modelling process remains loosely coupled to the Digital Twin and requires tool-specific parameterisation.

4.4.3 Visualisation and Interpretability

A central strength of the applied method is the visual clarity of the results. Flow paths, accumulation areas, and potential impact zones can be visualised directly within the Digital Twin, supporting intuitive interpretation by planners and non-technical stakeholders. As both tools operate on raster-based height models, results can be rapidly updated, enabling iterative scenario evaluation.

The pluvial flood analysis is explicitly coarse and exploratory. It does not account for underground drainage systems, sewer capacities, or time-dependent rainfall scenarios. Accordingly, results are interpreted as orientation maps for planning, not as regulatory flood hazard maps. Embedded within the Digital Twin, the analysis supports prioritisation and complements other thematic assessments in a holistic planning context.

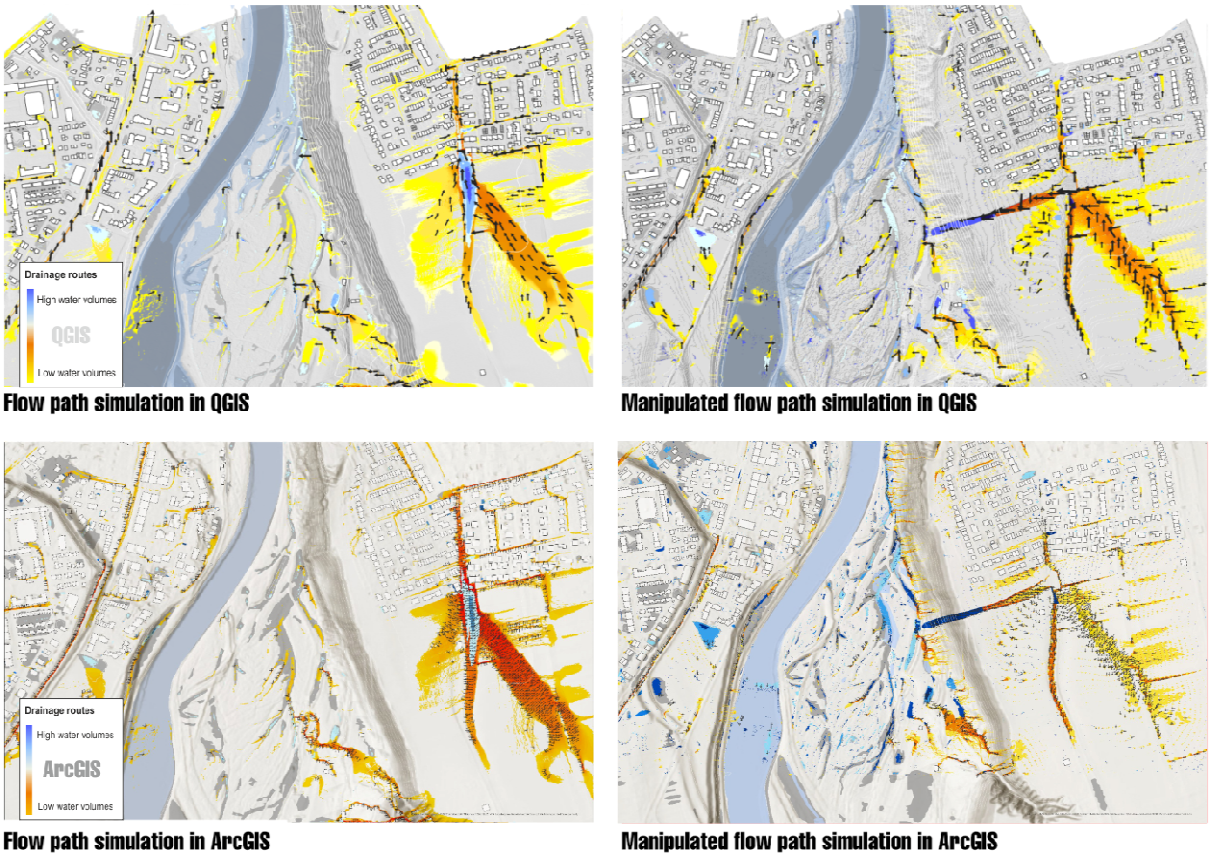

Fig.3: Comparison of the stream path simulation in QGIS and ArcGIS in the inventory (left side) and diverted water flow through terrain adaptation on the right (Kappeler & Schwarz 2025)

4.4.4 Planning Relevance and Limitations

The pluvial flood analysis conducted for Landsberg am Lech is explicitly coarse and exploratory. It does not account for underground drainage systems, sewer capacities, or time-dependent rainfall scenarios. Nevertheless, its value lies in its ability to quickly identify potential problem areas and support strategic planning discussions.

In line with the approach presented here, the results are interpreted as orientation maps for planning rather than regulatory flood hazard maps. They provide a robust basis for prioritising areas where further, more detailed hydrological or engineering analyses may be required. Embedded within the Digital Twin, the pluvial flood assessment complements other thematic analyses and contributes to a holistic understanding of spatial vulnerability in urban planning.

4.5 Environmental Noise Scenarios

Environmental noise represents an established but methodologically demanding field within urban planning. While norm-based proprietary software solutions often dominate noise assessment, recent work demonstrates that planning-oriented noise scenarios can also be explored within Digital Twin environments using simplified, transparent approaches. In the Landsberg am Lech case study, environmental noise modelling was therefore included as a supplementary analytical layer, in accordance with established methodological principles.

4.5.1 Planning-Oriented Noise Assessment

From a planning perspective, early-stage noise assessment focuses less on legally binding exposure values and more on relative spatial patterns. Key questions include the location of noise-sensitive uses, the influence

of urban form on sound propagation, and the potential effects of alternative planning scenarios. Digital Twins provide a suitable spatial framework for addressing these questions, as building geometry, street networks, and land use are already integrated.

4.5.2 Applied Tools and Workflow

In Landsberg am Lech, noise scenarios were explored using H-Risk in QGIS, integrating open street data, traffic assumptions, and building geometries. The LOD2 building model served as the geometric basis for modelling reflecting and shielding effects, while OpenStreetMap (OSM) road network data provided the source structure for noise emission modelling (Fig. 4).

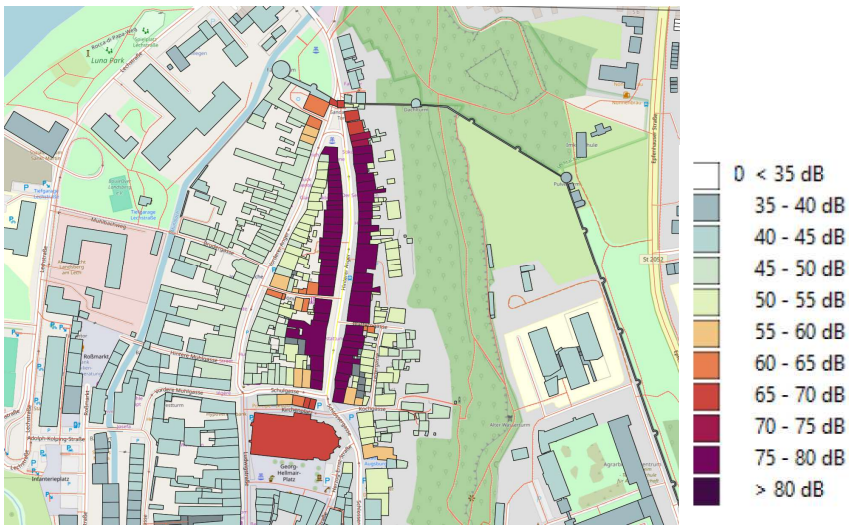

Fig. 4: Noise level at the facade 30km/h in QGIS/H-Risk (Strifler & Daum, 2025)

The workflow follows a simplified approach: traffic volumes and speed assumptions are parameterised, and resulting noise levels are calculated and visualised as spatial distributions. This enables rapid comparison of alternative scenarios, such as changes in traffic routing or street hierarchy. The Digital Twin ensures spatial consistency with other thematic analyses, while the noise analysis itself operates on a tool-specific abstraction rather than a fully integrated twin model.

4.5.3 Interpretation and Limitations

The applied noise modelling approach is explicitly non-normative. It does not replace standardised noise mapping procedures required for regulatory compliance. Still, it serves as a planning-oriented screening and orientation tool, highlighting areas where noise exposure may become critical under certain assumptions. Such simplified models are particularly valuable in early planning stages, where they support spatial awareness and informed discussion rather than final verification. For legally binding assessments, proprietary tools such as CadnaA or SoundPLAN remain necessary.

5 CONCLUSIONS, SYNTHESIS AND OUTLOOK

Taken together, the four applied use cases illustrate that the Digital Twin of Landsberg am Lech functions less as a fully integrated simulation environment and more as a shared spatial reference for planning-oriented screening analyses. This hybrid use of open and proprietary tools forms the basis for the comparative synthesis presented in this chapter.

5.1 Synthesis of Findings

This paper explores how Open Digital Twin workflows can support simulation-based urban planning, using Landsberg am Lech as a case study. Across the four thematic domains – solar framework planning, urban heat assessment, pluvial flooding, and environmental noise – the results demonstrate that the Digital Twin functions most effectively as a shared spatial reference system, rather than as a fully integrated simulation environment. The applied examples confirm that Digital Twins are particularly valuable for planning-oriented screening and orientation analyses. Their primary contribution lies not in predictive accuracy or regulatory compliance but in structuring complex spatial questions, enabling scenario comparison, and

supporting interdisciplinary communication. This finding aligns with recent research that positions urban digital twins as integrative planning infrastructure rather than operational control systems.

A central insight from the Landsberg am Lech case is that thematic simulations do not require monolithic or fully synchronised models. Instead, loosely coupled workflows, anchored in a consistent geometric and semantic base, allow planners to address different questions with appropriate tools.

5.2 Open-Source and Proprietary Tools: A Comparative Perspective

A key objective of this study was to assess the role of open-source and proprietary software within Digital Twin workflows. The results indicate that tool choice is primarily driven by planning objectives and methodological requirements, rather than by licensing models.

Open-source tools play a crucial role in early-stage planning and exploratory analysis by supporting transparency, reproducibility, and rapid iteration. Proprietary tools remain relevant where standardised procedures, normative requirements, or advanced physical modelling are required. Table 1 summarises the complementary roles of both tool categories across the four thematic domains.

Planning Domain	Open-Source / Accessible Tools	Proprietary Tools	Role within the Digital Twin
Solar Planning	QGIS, GRASS GIS, parametric modelling (data preparation)	Rhino/Grasshopper, ArcGIS Pro	Strategic spatial differentiation (Solar Framework Plan)
Urban Heat	Honeybee, ICETools	ENVI-met, PALM-4U (reference)	Screening and comparative scenario analysis
Pluvial Flooding	QGIS Splash Tools, GRASS GIS	ArcGIS Pro	Identification of flow paths and accumulation zones
Environmental Noise	H-Risk (QGIS)	CadnaA, SoundPLAN	Orientation and scenario comparison

Table 1: Open-Source and Proprietary Tools in Planning-Oriented Digital Twin Workflows

Rather than competing alternatives, open-source and proprietary tools form complementary components of hybrid workflows, with open data – particularly LOD2 buildings and terrain models – providing the stable foundation for both.

5.3 Methodological Implications for Digital Twin Use

The applied workflows highlight several methodological implications. First, full integration of simulation tools into a single Digital Twin environment remains limited, as climate, hydrological, and noise models typically require tool-specific abstractions of geometry and attributes.

Second, geometric and semantic mismatches – particularly at building–terrain interfaces – represent a persistent challenge across simulation domains. Acknowledging these limitations is essential to avoid overinterpretation and to maintain methodological transparency.

Third, a staged modelling approach emerges as a pragmatic strategy: lightweight, planning-oriented tools support early decision-making, while advanced, physically based models can be applied selectively when higher accuracy or regulatory compliance is required.

5.4 Outlook

Future developments in semantic data modelling, improved terrain–building integration, and the maturation of open-source simulation frameworks such as PALM-4U may reduce current interoperability barriers. At the same time, institutional learning and capacity building will be critical for responsible and effective Digital Twin use. Rather than striving for fully integrated, all-encompassing platforms, planning practice may benefit more from robust, modular Digital Twins that support thematic extension and methodological flexibility. The Landsberg am Lech case demonstrates that such an approach is already feasible and can meaningfully contribute to climate-responsive, context-sensitive urban planning.

1 ABSTRACT

Digital transformation in the Built Environment is increasingly underpinned by the adoption and maturity of Building Information Modelling (BIM), a critical tool for enhancing technological skills and addressing complex infrastructure and service delivery challenges. However, the availability of comprehensive BIM training programs in higher education remains inadequate, limiting graduates' and practitioners' capacity to apply and integrate BIM effectively in professional contexts. This study adopts a mixed-methods approach to evaluate the maturity and integration of BIM training in South African Built Environment higher education programmes. The findings reveal that most available programs focus on introducing basic BIM concepts and adoption strategies, advanced training necessary for higher levels of BIM maturity is largely absent. While short learning programs have been developed to upskill industry practitioners, formal curricula face persistent barriers, including limited access to state-of-the-art facilities, software and licensing costs, and structural rigidities within module offerings. The study argues that these challenges undermine both the digital transformation within the Built Environment and the competitiveness of graduates entering professional practice. Ultimately, the findings underscore the urgent need for policy and institutional reforms to accelerate digital transformation and ensure that the Built Environment workforce is equipped with the skills required to meet the demands of contemporary urbanisation and infrastructure development.

Keywords: Digital transformation, training, higher institutions, Building Information Modelling, Built environment

2 INTRODUCTION

Adoption and maturity of revolutionary technologies such as Building Information Modelling (BIM) are critical in the Built Environment (BE) for improving project performance and enhancing infrastructure delivery. Digital Transformation (DT), driven by the principles of Industry 4.0, has advanced building systems significantly since the industrial revolution towards hybridised, intelligent and interconnected systems (Hazrat et al., 2023). Within the BE, Industry 4.0 technologies including big data analytics, artificial intelligence, virtual modelling and integrated project delivery are reshaping traditional infrastructure management approaches. This shift is particularly relevant in contexts facing infrastructure backlogs, rapid urbanisation and service delivery pressures, such as South Africa.

BIM occupies a central position within this digital transformation agenda. It provides innovative, effective and collaborative digital processes and management tools that equip professionals with the technological skills required to address complex infrastructure and service delivery challenges (Akintols et al., 2020; Omar & Dulaimi, 2023; Obi et al., 2024). According to McAuley and Behan (2019), BIM can be utilised for multiple analyses and performance predictions, particularly in projects requiring collaborative three-dimensional design applications. It reshapes and simplifies the BE by enhancing professional roles and responsibilities across the planning, design, construction, operation, and maintenance phases (Whyte & Hartmann, 2017). Furthermore, DT interventions contribute to notable productivity gains by supporting professionals with comprehensive, accurate, and real-time information for day-to-day decision-making (Kaushalya et al., 2024).

Numerous scholars argue that the evolution of DT has contributed significantly to mitigating climate and sustainability challenges in the BE by moving beyond traditional infrastructure management approaches (Muzi et al., 2022; Samuelson & Stehn, 2023). The shift from fragmented, time-consuming and financially costly traditional techniques towards multidisciplinary, digitally enabled processes enhances value creation across the infrastructure chain (Hajj et al., 2021). The adoption of DT further supports sustainable strategies

and green practices in urban BE contexts experiencing considerable environmental and social pressures (Stroumpoulis & Kopanaki, 2022). For example, large volumes of social and environmental data can be modified and virtualised in real time to identify potential threats, simulate predictive scenarios and recommend resilient infrastructure interventions (Daniotti et al., 2020; Muzi et al., 2022; Saka, 2022). Understanding information through data analytics thus provides multiple pathways for improving infrastructure performance and service delivery (Whyte & Hartmann, 2017).

Despite these advantages, graduates' and practitioners' capacity to effectively apply and integrate BIM in professional contexts remains constrained. Training programmes on BIM adoption are more critical than ever in responding to the demands of big data and rapid urban development. However, many higher education institutions experience inadequate BIM integration within their curricula, resulting in graduates who are insufficiently prepared for digitally enabled practice. Rather than expecting industry to shoulder the responsibility of upskilling graduates, scholars argue that students should be trained during their educational journey to become BIM-ready professionals, thereby avoiding additional financial and time burdens on industry (Iqbal et al., 2022; Olowa et al., 2022; Hazrat et al., 2023). At the same time, Yusuf et al. (2017) highlight that higher education institutions face challenges related to limited knowledge, skills, finances, and resources, which constrain the development of a high-standard BIM workforce. Iqbal et al. (2022) therefore advocate for stronger industry participation in collaborative seminars, workshops and international engagements to facilitate skills transfer to educators.

In developing countries, the adoption and maturity of DT, including BIM, big data analytics, virtual modelling, artificial intelligence, and green building technologies, remains comparatively slow (Saka, 2022). Although university–industry research collaboration is recognised as a key driver of technological innovation and BIM maturity (Iqbal et al., 2022), limited attention has been given to systematically evaluating the scope, depth and maturity of BIM training within university programmes, particularly in the South African context. This gap has significant implications for digital transformation and graduate readiness within the BE sector.

Accordingly, this study aims to evaluate the maturity and integration of BIM training in South African BE higher education programmes. To achieve this aim, the study employs a mixed-method approach comprising a literature review, surveys and semi-structured interviews involving students, academics and professionals in Urban and Regional Planning, Construction, Civil Engineering and Architecture. Through this investigation, the research seeks to provide empirical insights into strengthening BIM education as a strategic enabler of digital transformation in the South African Built Environment.

3 LITERATURE REVIEW

3.1 Digital Transformation in the Built Environment

In recent years, DT has increasingly differentiated performance across industries within BE, particularly in infrastructure construction and service delivery. Improvements in organisational capabilities and production efficiency have largely been driven by the integration of digital technologies (Samuelson & Stehn, 2023). Globally, regions such as the European Union have capitalised on the growth potential of DT technologies, including artificial intelligence (AI), robotics, advanced manufacturing, blockchain technologies, three-dimensional (3D) printing and the Internet of Things (IoT), particularly in managing and extracting value from big data (Daniotti et al., 2020). These technologies strengthen sustainable strategies across supply chains, enable real-time operational monitoring, and support resilience-oriented green practices (Stroumpoulis & Kopanaki, 2022). Consequently, the adoption of Information Technology (IT) is no longer optional but necessary to enhance stakeholder performance and infrastructure delivery outcomes (Kaushalya et al., 2024).

In developed countries, higher education institutions have increasingly aligned curricula with Industry 4.0 technologies, producing graduates who are digitally competent and responsive to evolving BE industry demands (McAuley & Behan, 2019; Daniotti et al., 2020; Stroumpoulis & Kopanaki, 2022; Hazrat et al., 2023). This alignment has strengthened the dominance of digital approaches in many developed contexts. However, the transition is not universally consistent. For example, in Italy, traditional construction management practices still dominate certain stages of the BE operational cycle despite the availability of DT technologies (Muzi et al., 2022). In developing countries, adoption is generally slower and more fragmented.

Although DT technologies form part of contemporary industrial discourse, higher education institutions in many developing contexts continue to lag in implementation (Benavides et al., 2020; Badran et al., 2022). Structural challenges, including corruption, weak governance, limited funding, and shortages of skilled personnel, restrict institutional capacity to modernise curricula and infrastructure (Hannan, 2023). In extreme cases, geopolitical instability further constrains digital adoption, as illustrated in conflict-affected contexts such as Syria (Habib, 2023).

These global dynamics resonate with realities in South Africa, where higher education institutions operate under financial constraints, uneven digital infrastructure and significant student enrolment pressures. While national policies promote digital innovation and infrastructure development, practical implementation within BE programmes remains uneven. As a result, digital transformation in the South African BE sector continues to be characterised by pockets of excellence rather than systemic maturity.

3.2 BIM Adoption and Training in Higher Education

Contemporary research positions BIM as a central enabler of digital transformation in the BE. Increasingly, BIM is integrated with emerging technologies such as IoT, augmented and virtual reality (AR/VR), AI, drones, robotics, 3D printing, and laser scanning (Prabhakaran et al., 2021; Liu et al., 2021). When integrated effectively, these technologies extend BIM beyond three-dimensional modelling into a dynamic decision-support ecosystem. For instance, IoT sensors embedded within buildings enable real-time data collection on structural performance, energy consumption, and environmental conditions. When linked to BIM platforms, these datasets support predictive maintenance and lifecycle optimisation. Similarly, AR/VR technologies enhance stakeholder engagement by enabling immersive visualisation of design alternatives prior to construction, reducing costly revisions. AI and machine learning algorithms applied to BIM datasets improve risk identification, detect design inefficiencies, and optimise scheduling processes (Bunse et al., 2025). Drone and laser scanning technologies facilitate the development of accurate as-built models, improving monitoring and quality control.

Despite these advances, the integration of BIM with advanced technologies remains uneven across regions and sectors. While BIM research continues to expand ranging from design coordination improvements to automation and robotics integration (Jayasena et al., 2024; Adegoke et al., 2026) the field has evolved in an incremental and fragmented manner, often lacking a coherent digital transformation narrative (Azhar, 2011; Volk et al., 2014; Yalcinkaya & Singh, 2015). Much of the literature focuses on adoption strategies, implementation barriers and best practices, yet comparatively limited attention has been given to educational maturity and curriculum integration, particularly in developing country contexts.

A recurring challenge identified in the literature is the difficulty of integrating BIM into existing organisational systems and workflows (Volk et al., 2014; Schroeder et al., 2020). Technical interoperability constraints, institutional resistance to change, and insufficient digital infrastructure frequently inhibit progress. These challenges are amplified in resource-constrained environments, where managing large-scale, data-intensive models places significant demands on hardware, software licensing, and specialist expertise.

The concept of BIM maturity provides a useful framework for evaluating implementation depth. Maturity models generally conceptualise BIM development along progressive levels:

- Level 0: A pre-BIM environment dominated by two-dimensional CAD drawings and paper-based documentation, with minimal digital collaboration. In many South African small and medium-sized enterprises, this level still characterises routine practice, particularly in municipal infrastructure projects.
- Level 1: Partial digitalisation through isolated 3D modelling tools. While visualisation improves, collaboration remains siloed, and data exchange is limited. Some South African universities introduce BIM at this level through standalone modelling modules without interdisciplinary integration.
- Level 2: Collaborative workflows supported by standardised data exchange formats (e.g., Industry Foundation Classes, IFC). Stakeholders share coordinated models, improving clash detection and reducing errors. Larger South African firms involved in commercial developments increasingly operate at this level, although adoption is inconsistent across sectors.

- Level 3 (and beyond): Fully integrated digital environments linking design, construction and operation across the entire project lifecycle. Cloud-based platforms, real-time collaboration, AI-driven analytics and automated processes define this level. In South Africa, examples remain limited and are typically confined to high-budget or multinational projects.

These maturity levels highlight that BIM adoption is not solely a technical issue but also an organisational and educational one. Institutional readiness, curriculum design, educator competence and industry collaboration are critical determinants of progression across levels. Although numerous studies examine BIM implementation in practice, fewer critically assess the scope and maturity of BIM training within higher education institutions, particularly in developing contexts. Existing research often assumes that educational institutions are adequately preparing graduates for digital transformation, yet empirical evidence from resource-constrained settings suggests otherwise. In South Africa, limited curriculum integration, insufficient interdisciplinary collaboration, and uneven access to digital infrastructure may hinder the production of BIM-ready graduates.

Therefore, a clear research gap exists in systematically evaluating the scope, depth, and maturity of BIM training within BE programmes in developing country contexts. This study addresses that gap by assessing BIM training across disciplines, identifying curricular and institutional barriers, and analysing implications for digital transformation and graduate readiness within the South African Built Environment sector.

4 METHODOLOGY

This study adopted a mixed-methods research design to systematically examine the role, delivery, and perceived effectiveness of BIM training BE programmes offered by higher education institutions. The use of a mixed-methods approach was justified on the basis that BIM adoption and maturity encompass both measurable structural elements (such as training exposure, curriculum content, and resource availability) and experiential dimensions (such as perceptions of competence, institutional readiness, and preferred learning platforms). Integrating quantitative and qualitative data, therefore, enabled triangulation, enhanced validity, and provided a more comprehensive understanding of BIM training dynamics (Whyte et al., 2017; Badran et al., 2022). While quantitative data offered measurable indicators of BIM maturity and training scope, qualitative insights contextualised these findings by capturing stakeholder experiences and institutional realities.

An online survey was administered in 2025 to capture patterns of BIM training provision, utilisation, associated challenges and levels of BIM maturity across professional and academic groups in the BE sector. The survey instrument was structured around four key thematic areas, namely Exposure to BIM training, Scope and content of BIM training, BIM maturity and advanced digital skills and Resources and institutional support. The development of the questionnaire followed a multi-stage process to ensure contextual relevance and methodological rigour. Initially, a draft instrument was developed based on a review of existing literature on BIM adoption, maturity models and digital transformation in higher education. Thereafter, the instrument was refined through consultation with key stakeholders from government departments, professional councils, industry associations and academic institutions. To enhance reliability and content validity, a series of focus group discussions were conducted prior to full deployment. These discussions served to verify the clarity of questions, align terminology with industry standards, and ensure that the instrument reflected both educational realities and professional expectations. Feedback from the focus groups informed revisions to question wording, response scales, and thematic categorisation, thereby strengthening the robustness of the final survey tool.

A total of 90 respondents participated in the study. Participants were purposively selected to reflect the multidisciplinary nature of the Built Environment sector. The sample comprised of Undergraduate and postgraduate students enrolled in BE programmes, Academics involved in curriculum development and BIM instruction and Industry professionals, including practitioners from Urban and Regional Planning, Construction Management, Civil Engineering and Architecture, as well as representatives from professional bodies and government departments. This distribution ensured representation across the education–industry continuum, enabling the study to assess both training provision and professional expectations regarding graduate readiness.

Data collection was conducted in 2025. The study adhered to established ethical standards and received formal approval from the University of Johannesburg Ethics Committee prior to commencement. Participation was voluntary, and informed consent was obtained from all respondents before completing the survey and participating in the focus group. Respondents were assured of confidentiality and anonymity, and data were securely stored in accordance with institutional research governance policies. Quantitative survey data were analysed using descriptive and inferential statistical techniques. Descriptive statistics (including frequencies, percentages and mean scores) were used to assess levels of BIM exposure, training scope and perceived maturity. Comparative analysis across participant groups (students, academics and professionals) was undertaken to identify alignment or discrepancies in perceptions of BIM competence and institutional readiness.

Qualitative data derived from open-ended survey responses and focus group discussions were analysed using thematic analysis. Responses were coded inductively to identify recurring themes relating to curriculum gaps, institutional barriers, infrastructure constraints and training needs. These themes were then compared with quantitative findings to enable triangulation and deepen interpretation. By integrating quantitative indicators with qualitative insights, the mixed-methods design provided a holistic evaluation of BIM training maturity, institutional barriers and implications for digital transformation and graduate preparedness within the Built Environment sector.

5 FINDINGS

5.1 Exposure to BIM Training

The survey findings indicate limited and uneven exposure to BIM training within Built Environment (BE) programmes. Approximately 60% of respondents reported that BIM is insufficiently integrated into core curricula and is often offered only as an elective or introductory module (see Figure 1). This suggests that BIM is not yet positioned as a foundational competency within many institutions. Early-stage exposure remains particularly limited, with students typically encountering BIM concepts late in their academic trajectory.

This delayed introduction restricts the progressive development of competence and confidence, undermining cumulative skills acquisition. The quantitative results therefore indicate that BIM training remains peripheral rather than embedded within programme structures.

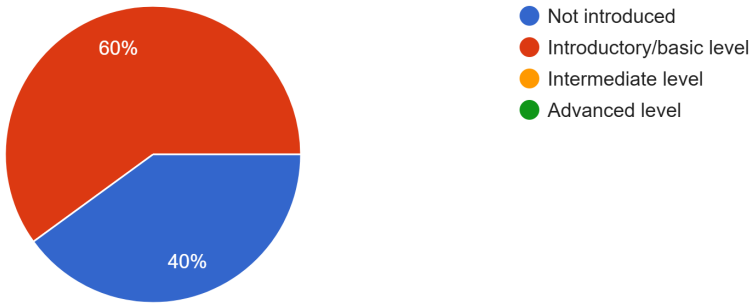

Fig. 1: Student Exposure to BIM Training

5.2 Scope and Content of BIM Training

Approximately 60% of respondents indicated that current BIM training is narrow in scope and insufficiently aligned with industry practice (see Figure 2). Training was reported to be predominantly software-centric, focusing on basic modelling functions rather than process integration across the full project lifecycle. Furthermore, respondents highlighted limited interdisciplinary collaboration within modules. This restricts students' understanding of coordinated workflows between architecture, civil engineering, construction management, and urban planning, a core requirement of BIM-enabled environments.

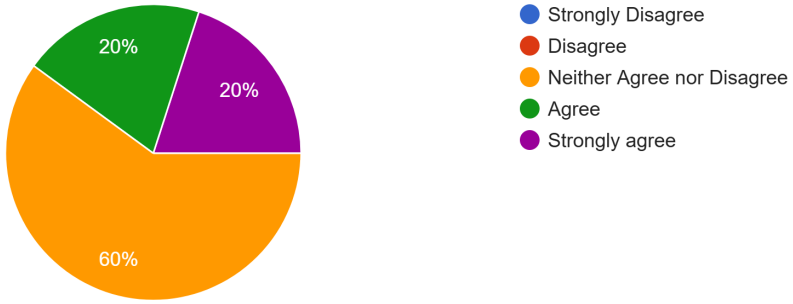

Fig. 2: Level of Training Resources and Curriculum Integration

These findings align with previous studies that identify fragmentation and incremental adoption in BIM education (Azhar, 2011; Volk et al., 2014). While institutions may introduce modelling tools, they often fail to integrate BIM as a collaborative, lifecycle-oriented process consistent with digital transformation narratives (Yalcinkaya & Singh, 2015).

5.3 BIM Maturity and Advanced Skills

Survey responses revealed generally low levels of BIM maturity, particularly in relation to advanced competencies such as:

- Multidisciplinary coordination
- Data management and interoperability
- Lifecycle integration
- Collaborative digital workflows

Although basic modelling skills were reported, progression towards Level 2 and Level 3 maturity (collaborative and fully integrated environments) remains limited. This finding echoes literature highlighting persistent institutional and technical barriers to BIM integration (Volk et al., 2014; Schroeder et al., 2020). The quantitative evidence, therefore, suggests a substantial disconnect between academic training and industry expectations, where BIM increasingly supports integrated decision-making and performance optimisation.

5.4 Resources and Institutional Support

Qualitative findings strongly emphasised institutional constraints. Figure 3 shows several participants cited High software licensing costs limiting student access, Outdated computer laboratories unable to support large BIM datasets, Limited cloud-based collaboration platforms and Insufficient continuous professional development for lecturers

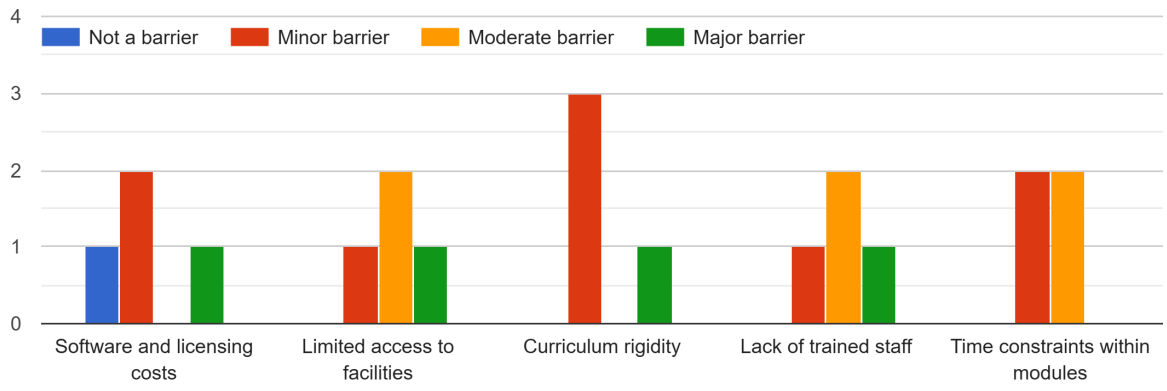

Fig. 3: Key barriers to BIM training

However, examples of good practice were identified. The University of Johannesburg Virtual Lab was highlighted as a valuable platform that provides students with remote access to BIM software and collaborative tools. This initiative demonstrates how targeted institutional investment can mitigate infrastructure constraints and enhance training quality. Participants further recommended dedicated BIM laboratories, structured lecturer upskilling programmes, stronger university and industry partnerships, and the development of national or regional BIM education standards. Such measures would align educational outcomes with industry expectations and strengthen digital transformation pathways.

6 DISCUSSION AND IMPLICATIONS

The findings confirm that BIM integration within BE curricula remains limited, uneven and insufficiently mature. This aligns with literature highlighting fragmented adoption and institutional resistance (Azhar, 2011; Volk et al., 2014; Schroeder et al., 2020). In the South African context, limited BIM integration has significant implications for graduate readiness and industry competitiveness. As infrastructure projects increasingly demand collaborative digital workflows, graduates lacking advanced BIM competencies may struggle to meet employer expectations. This perpetuates a skills gap and increases training burdens on industry.

Moreover, the dominance of software-centric training constrains deeper understanding of BIM as a process-driven digital transformation tool. Without interdisciplinary and project-based learning, students fail to develop competencies in coordination, data exchange and lifecycle management – all essential for higher maturity levels. Addressing these gaps requires systemic curriculum reform, sustained institutional investment and stronger alignment between academia and industry. By embedding BIM progressively across programmes, investing in digital infrastructure and enhancing educator capacity, higher education institutions can play a transformative role in advancing digital maturity within the South African Built Environment sector.

7 CONCLUSION

This study examined the role and effectiveness of Building Information Modelling (BIM) training within Built Environment (BE) programmes and identified significant gaps between current educational practices and the evolving demands of industry. The findings reveal that BIM integration within higher education remains limited, uneven and largely software-centric. Exposure is often delayed and insufficiently embedded within core curricula, while advanced competencies related to collaboration, coordination and lifecycle integration remain underdeveloped. Resource constraints, including high software licensing costs, inadequate digital infrastructure, and limited lecturer capacity, further inhibit progress. Collectively, these challenges weaken graduate readiness and constrain broader digital transformation efforts within the BE sector.

The study underscores the urgent need for policy reform and sustained institutional investment. Curriculum restructuring is required to embed BIM progressively across academic programmes, ensuring interdisciplinary and project-based learning that reflects real-world industry workflows. Institutions must prioritise investment in digital infrastructure, including dedicated BIM laboratories, cloud-based collaboration platforms, and updated software environments. Equally important is structured professional development for educators to ensure that teaching remains aligned with industry innovation. Strengthening industry–academia collaboration is critical to closing the identified gaps. Partnerships with professional councils, government departments, and private-sector firms can facilitate knowledge transfer, curriculum co-design, internship pipelines, and access to real-world project datasets. In addition, the development of national or regional BIM education standards would promote consistency in competency development, clarify expected graduate outcomes and align higher education outputs with industry benchmarks. Such standards could support coordinated digital transformation strategies at the sectoral level.

Future research should extend this work by exploring the effectiveness of university–industry partnership models in enhancing BIM competency development. Longitudinal studies tracking students from entry into higher education through to professional practice would provide valuable insights into how BIM skills mature over time and how curriculum interventions influence career readiness. Comparative studies across institutions or provinces could further illuminate structural inequalities and identify scalable best practices within the South African context. Ultimately, BIM training is not merely a technical curriculum component but a strategic enabler of digital transformation. Strengthening BIM education is essential to enhancing

graduate competitiveness, improving infrastructure delivery, and supporting sustainable urban development. In the South African context, characterised by rapid urbanisation, infrastructure backlogs, and pressing sustainability challenges, robust and integrated BIM training will play a pivotal role in accelerating digital maturity and equipping the Built Environment workforce to meet the complex demands of the future.

1 ABSTRACT

This research investigates the components of a governance framework for planning approvals of housing developments in Johannesburg, South Africa, with a focus on its linkages to economic growth. Through qualitative research, including interviews with 25 experienced professionals and analysis of municipal reports, the study identifies the roles of key stakeholders – such as municipal officials, technical experts, and community representatives – in the planning approval for housing development. Findings reveal that while multiple digital and administrative systems support planning approvals, their lack of integration hampers effective monitoring and reporting. The research highlights spatial disparities in development activity and demonstrates a correlation between certain approval types and economic growth datasets. However, fragmented governance structures and inconsistent reporting practices limit the ability to align planning approvals with broader economic and spatial goals. The study proposes a collaborative governance framework that incorporates standardized indicators, improved integration of digital systems, and multi-level oversight to enhance transparency, accountability, and turnaround times. While the framework may be tailored to the city of Johannesburg, the methodology and recommendations offer valuable insights for other metropolitan areas regionally and internationally.

Keywords: planning approvals, governance, housing, development, frameworks

2 INTRODUCTION

This research examines the planning approval processes for housing development.It highlights the challenges posed by fragmented and inefficient planning approval processes. The research investigates the stakeholders involved in planning approvals for housing developments in Johannesburg.It analyses historical trends in reported approvals alongside South Africa's Gross Domestic Product data set as one of the measures of economic growth and establishes a correlation between the types of planning approvals and economic growth. It proposes a governance framework to improve coordination, monitoring, and reporting of outcomes. The research is organised into background explanations, a problem statement, a literature review, key role players, input for the thematic governance framework, and a conclusion.

3 BACKGROUND

Nearly half of South Africa’s population resides within eight metropolitan municipalities, which function as principal centres for economic activity and administer substantial budgets. These metros – Nelson Mandela Bay, Johannesburg, Tshwane, Cape Town, Buffalo City, eThekwini, Mangaung, and Ekurhuleni – are responsible for governing significant urban areas. South African municipalities are categorised as Category A (metropolitan), B (local), or C (district), with Category A municipalities exercising exclusive authority within their regions. Johannesburg, one of the nation’s largest metropolitan areas, accommodates approximately 6.45 million residents, as reported in the 2022 census The city draws the highest levels of domestic and international investment nationwide and encompasses an area of about 1,644 square kilometres. In recent years, Johannesburg has prioritised considerable investment in digital infrastructure, particularly during the COVID-19 pandemic, to improve service delivery. Furthermore, Johannesburg has hosted prominent international events including the UN Global Summit (2002), FIFA World Cup (2010), and G20 and U20 Mayoral Summits (2025), establishing the city as a key venue for global urban dialogue.

4 PROBLEM STATEMENT

Governance and reporting within South African metropolitan municipalities are characterised by specialisation, fragmentation andnot too strong coordination arrangements, resulting in inefficiencies in both housing development and service delivery. While initiatives such as National Treasury’s Municipal Finance

Management Act Circular 88 have been introduced, legislative complexities arising from statutes like the Spatial Land Use Management Act (2013) and the National Environmental Management Act (1998) continue to complicate data management and administrative processes. Research indicates that convoluted procedures, overlapping reporting requirements between province and national governments, elevated system costs, and constrained regulatory capacity impede the effective assessment of economic growth. Stevens (2025) identifies regulatory overlaps, procedural complexity, high system costs, and limited regulatory resources as significant challenges. Similarly, Mokoele (2022) observes that multi-authority reporting leads to redundant and inconsistent data, thereby restricting evidence on how efficient planning approvals contribute to economic development, despite cities being recognised as engines of economic and employment growth. The City of Johannesburg (2022:150) highlights additional issues such as delays in processing planning applications, slow response times regarding requirements, inadequate bulk infrastructure, technological difficulties, and insufficient integration with related systems like billing. In 2023, the City of Johannesburg (2023:144) announced intentions to digitise manual planning procedures to improve transparency and efficiency; however, the effectiveness of these measures has yet to be determined. A key obstacle remains the absence of a cohesive governance framework capable of integrating planning data, building control, and economic growth metrics, which hampers the ability to accurately evaluate the impact of ongoing reforms.

5 LITERATURE REVIEW

Countries use planning and policies to promote development and need collaboration across government and sectors for effective results.de Visser &Poswa (2019) highlightthat in South Africa, the Integrated Urban Development Framework (IUDF) and the National Spatial Development Framework (NSDF) are used to guide infrastructure investment. The NSDF isa mandated in terms of Spatial Land Use Management Act of 2013 to direct national development. In addition, there are funding-related frameworks such as the Medium-Term Revenue and Expenditure Framework (MTREF) and the Integrated Financial Framework for Greening South African Metropolitan Cities (IFFGSAMC). These frameworks aim to align budgets with sustainability goals. South Africa also employs a Scenario-Based Planning Framework (SBPF), which introduces flexible planning through three growth scenarios: Nayi le Walk, Isibhujwa, and Gwara Gwara. The Nayi le Walk scenario envisions a positive future where the country moves toward achieving National Development Plan (NDP) targets. In contrast, the Isibhujwa scenario represents a continuation of existing trends, marked by low economic growth and high inequality. The Gwara Gwara scenario depicts a "struggling false dawn," where aspirations remain unfulfilled.

Furthermore, to these national frameworks, international approaches also offer valuable insights. For example, the Major Infrastructure Delivery Framework (MIDF) in England focuses on climate adaptation in water infrastructure and leverages expertise in procurement and engineering. Meanwhile, the National Planning Policy Framework (NPPF) of England aims to increase housing delivery, although it has faced critiques regarding its overall effectiveness (National Treasury: 2025; Sedighi,et al: 2025; Upton: 2019).

Despite the range of frameworks available, a significant challenge remains: these frameworks often lack amechanism of showing a clear connection between planning approvals for housing development and economic growth. For instance, despite the implementation of the NPPF, recent studies have shown that increases in housing approvals have not consistently resulted in measurable economic growth in several regions (Sedighi et al: 2025).

Recent studies by Mhlongo, Gumbo, and Musondo (2022) highlight ongoing challenges in South Africa's low-income housing sector, such as limited stakeholder involvement, weak accountability, and transparency issues. Despite multiple governance frameworks, these problems persist, underscoring the need for collaborative co-production models as proposed by Maila, Malan, and Mazenda (2024: 10), and Maila (2025), which require shared legislative understanding and active stakeholder participation. Irtyshcheva et al. (2023) stress the importance of clear objectives and robust tracking systems due to concurrent national and provincial responsibilitiesdepited by Mathonsi (2020), while Ndevu and Muller (2018) emphasize the critical role of local governments. Carter, Klein, and Day (2002) call for performance-driven, accountable public sector management. Although National Treasury (2017) introduced standardized performance indicators (MFMA Circular 88),continues to refine them, gaps remain in stakeholder coordination and evidence linking planning approvals to economic and spatial outcomes. The researchers have crafted the conceptual framework in figure1 below to emphasize the need for improved integration and monitoring, provide clarity

on stakeholder roles, reporting practices, and their connection to economic development, focusing on housing development context in Johannesburg. The conceptusal framework visually structures these concepts and variables and provides a basis for further research.

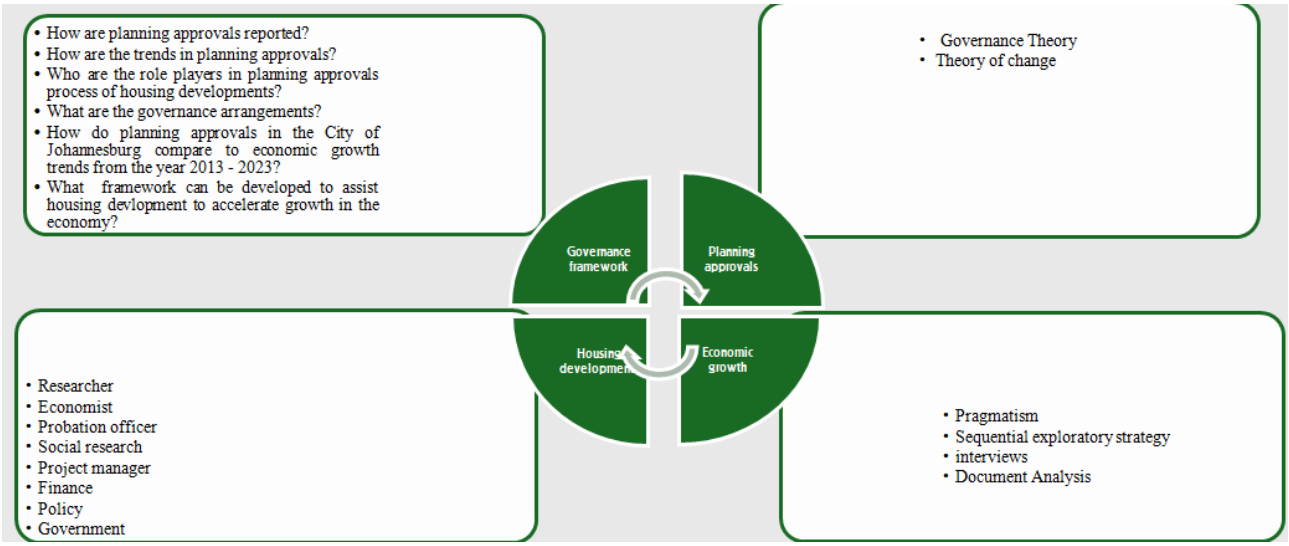

Figure 1: Conceptual Framework (Own diagram)

This study is grounded in Foucault's concept of governmentality (Kerr, 1999) to examine the governance frameworks shaping planning approvals for housing developments, with a particular focus on stakeholder roles and their links to economic growth. The researchers also acknowledge that post-2024 municipal planning in South Africa is now influenced by coalition governance, which necessitates balancing diverse interests alongside economic and spatial development (Kariuki & van der Waldt, 2025). Furthermore, this research draws upon Dean's (2010) refined concept of governmentality, which encompasses citizens' collective perceptions of governance. Notably, Stoker (1998), in conceptualising governance theory, clearly distinguishes between authority (government) and coordination (governance). The researchers also reference the work of Munzhedzi (2021), who asserts that effective governance involves both public and private service delivery. These considerations inform the formulation of the research questions.

6 RESEARCH QUESTION

The main question in this study is who the roleplayers are in the planning approval for housing development in Johannesburg, and what are the governance arrangements?

7 RESEARCH APPROACH AND METHODOLOGY

The study used a qualitative method, selecting around 25 experienced professionals for semi-structured virtual interviews about planning approval. Document analysis drew from city trend reports, annual reports, and systems from relevant agencies. The research focused on planning approval applications in Sunninghill, Inner City of Johannesburg, Kyalami, and Sandton.

8 FINDINGS

The study revealed the following: Reporting Practices: Planning approvals are recorded in annual and trend reports, as well as digital systems; reporting varies by application type and region. There are differences in how planning approvals are reported in the annual reports and no integrated national tracking mechanisms to better inform economic growth discussions. The study recommends further research and comparative analysis across metropolitan areas, emphasizing that current reporting gaps hinder effective monitoring and calling for greater integration at the national level.

Systems Supporting Planning Approvals: The main systems identified are as per table 1 below. At present, these systems are not fully integrated, which restricts the ability to conduct comprehensive monitoring and reporting.

System Name	Administrators
Town Planning Application System (TAS)	City of Johannesburg
Housing Subsidy System (HSS)	Provincial and National Departments of Human Settlements
Geographic Information System (GIS)	City of Johannesburg, Provincial and National Departments
Strategic Innovation Hub (SIH)	Provincial and National Human Settlements, National Cooperative Governance

Table1: Systems Supporting Planning Approvals

Trends in Planning Approval Applications within the City of Johannesburg: The planning approval process includes applications for rezoning, township establishment, subdivision/consolidation, special consent, site development/building plans, and township establishment. Outcomes are approved, refused, withdrawn, or appealed. From 2006 to 2023, the highest number of applications was in Johannesburg's inner city, followed by Sandton, Sunninghill, and Kyalami. See Table 2 for more details.

Application Type	Sunninghill	Sandton	Kyalami	Inner City
Rezoning	58	426	23	2323
New Township	8	0	12	33
Consent	42	188	22	1342
Subdivision / Consolidation	42	171	12	2644
Site Development	65	257	44	1337

Table 2: Development applications approved from 2006- 2023. Source: Own table extracted from the City Of Johannesburg development planning trend report for 2023/24Financial Year

The figures in table 2 illustrate spatial disparities in development activity across the city of Johannesburg. However, does not provide an explanation of why is it the case and what factors inform decision making.

Planning Approvals vs Gross Domestic Product in Johannesburg (2013–2023) Trends:Using data from Johannesburg's development trends report and GDP figures from Statistics South Africa, this analysis examines links between development application types and economic growth. Over the past decade, township establishment applications have shown a correlation with GDP, while zoning applications followed a different pattern. Figure 2 illustrates these findings.

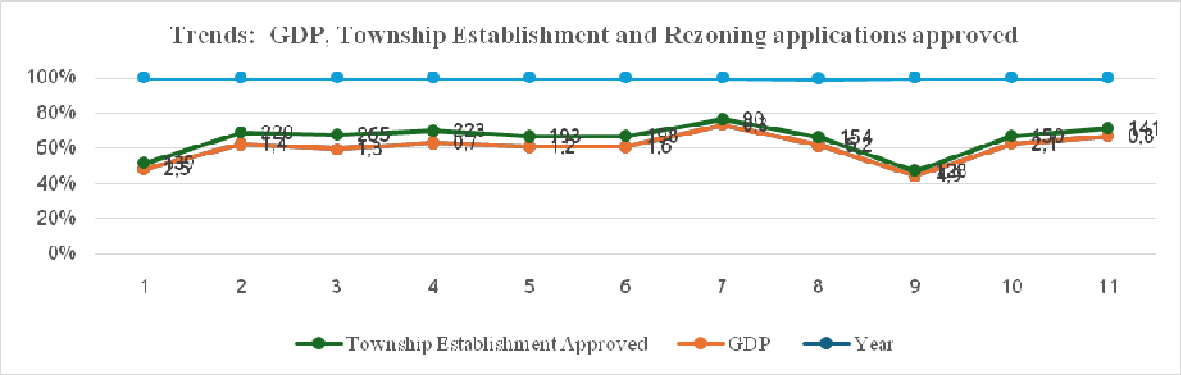

Figure 2: Graph comparison of trends in GDP, Township establishment applications approved and rezoning approcations approved (Source: Authors own diagram using City of Johannesburg data and Stats SA data sets on GDP Period from 2013-2023)

Key role players in planning approval for housing developments: The approval process involves consultants or developers who coordinate applications, and municipal officials who review and approve plans. Key professionals – town and regional planners (Planning Profession Act, 2002), engineers (Engineering Profession Act, 2000), conveyancers (Deeds Registries Act, 1937), land surveyors (Land Survey Act, 1997), community facilitators (Municipal Systems Act, 2000; Housing Act, 1997), project managers, valuers, and architects – all ensure compliance, safety, legal accuracy, inclusivity, and sustainability (Oladiran et al., 2025). Citizens, especially marginalized groups, also participate through objections and consultation. Researchers emphasize governance frameworks to enhance social inclusion and address spatial inequities.

The Governance Arrangements: The city has a solid governance system for development planning, guided by frameworks such as the MSDF, RSDF, Land Use Scheme, Bi laws, Nodal Policies, council-approved delegations, business processes, and procedural manuals with checklists. Delegated officials process applications, while tribunal members handle appeals and objections, supported by a secretariat that maintains records and follows the monthly scheduleof meetings. This promotes transparency, efficient project

approvals, and coordinated planning in Johannesburg. However, the connection between planning approvals and economic growth remains weak. Housing stakeholders include developers, officials, and experts, but economic growth is mainly discussed informally, with no formal forum. Early assessments consider land, infrastructure, transport, heritage, and socio-economic factors. City managers track economic growth, but resource constraints limit broader integration of these discussions.

Proposed components of the Framework for Planning Approval Monitoring: Respondents identified these key elements: 1) Municipal planning approvals require inputs such as rezoning and township establishment applications submitted by qualified experts. 2) Main activities involve processing, analysing, managing objections, and reporting on applications. 3) Outputs are assessed using transparent metrics and economic valuations. 4) Desired outcomes include improved environments, spatial transformation, job creation, and economic growth. Success depends on system maintenance, timely subsidies, and regular meetings to monitor progress and resolve application issues.

9 RECOMMENDATIONS

The study advises government to collaborate for greater transparency, accountability, and better alignment of housing planning approvals with economic and spatial goals. It calls for a governance framework that includes young, tech-savvy professionals to address youth unemployment, revised planning indicators, coordinated governance structures involving political and administrative leaders, and a digital platform to improve tracking and performance evaluation.

10 CONCLUSION

The study finds that current planning approval monitoring is fragmented and poorly linked to economic growth. It recommends integrated national and local tracking, updated indicators, and governance structures combining political and administrative oversight. It recommends the use of digital tools to address the technical complexity, improve transparency, accountability, and speed. These steps can strengthen housing developments in Johannesburg and similar cities.

A Green(er) Roof over the Head: Reflecting on Strategies Targeting Homelessness with Urban Agriculture for Cape Town, South Africa

Louis Lategan, Charné Erasmus

(Dr Louis Lategan, Cape Peninsula University of Technology, Hanover Street, Cape Town/North-West University, Unit for Environmental Sciences and Management, Hoffman Street, Potchefstroom, South Africa; lateganl@cput.ac.za)

1 ABSTRACT

The homeless face desperate socio-economic challenges, not in the least, food insecurity. Vulnerabilities are intensified by changing climatic conditions, macroeconomic constraints, limited sanitation and poor nutrition resulting from restricted access in urban food deserts. Social support programmes and shelters mitigate some risks, with several adopting urban agriculture (UA) in developmental strategies to yield longer-term benefits. Examples are especially prominent in the global North, where non-profit organisations (NGOs), research collaborations and cooperatives have engaged in partnerships to target UA-based interventions for the homeless. Such strategies emphasise the provisioning and cultural ecosystem services (ES) delivered by UA as green infrastructure (GI). Framing UA as multi-functional GI and acknowledging additional regulating and habitat ES empowers advocacy in urban planning to advance UA practices in urban centres where space is at a premium and market forces favour more competitive land uses. Although UA is increasingly applied in the global South, approaches remain largely productivist and economic, prioritising food security, poverty alleviation and entrepreneurship. Very few published case studies link UA and homelessness in developing contexts. This is evident in Cape Town, South Africa, regarded as a leader in UA in Africa and home to a substantial homeless population, where information on such strategies remains limited. In response, this paper explores international precedents from the global North and turns to a case study of Cape Town to investigate which organisations integrate UA into interventions for the homeless and how. A qualitative approach is applied following semi-systematic literature reviews. The first examines international cases in the academic literature as part of the literature screening section. The second, under the paper's empirical component, reviews grey literature on Capetonian examples identified from an official database of registered homeless shelters in the city (n = 29). The literature on international cases revesals the dominace of the USA and emphasises intergovernmental involvement, multidisciplinary collaboration, securing long-term tenure, linking UA sites with supportive uses, using liminal open spaces such as rooftops, remediating brownfields, subsidising infrastructure, embedding volunteerism and co-production, providing training and identifying access points to markets. Findings from Cape Town–based shelters indicate that 17.2% of organisations have implemented UA-related interventions, most primarily focused on production and subsistence, with an auxiliary recognition of therapeutic benefits. Many of the operational characteristics identified in Northern case studies are also pertinent in interventions in Cape Town, underscoring their significance and contextualising their application. By identifying evidence-based principles from global North and Capetonian precedents, the paper highlights critical opportunities to embed UA within strategies addressing homelessness through more developmental approaches, facilitated by urban planning, to encourage cultural and other multi-functional ES beyond (ir)regular sustenance or a temporary roof for the destitute.

Keywords: Homelessness, Urban agriculture, Urban farming, Ecosystem services, Non-profit organisations

2 INTRODUCTION

Homelessness constitutes an extreme manifestation of urban vulnerability, modelled by intersecting economic, spatial and social exclusions that are particularly pronounced in cities of the global South (Pitt, 2022; Hopkins et al., 2024). Within this condition, food insecurity emerges not merely in episodic hunger but as a persistent and multi-dimensional deprivation that constrains health, autonomy and dignity. For the homeless, food insecurity is embedded in everyday urban relations. As such, limited purchasing power, restricted access to food storage and preparation and a dependence on charitable donations collectively undermine both nutritional adequacy and agency over food choices (Greene, 2019; Campagnaro et al., 2023). In Cape Town, South Africa, where deep income inequality, spatial fragmentation and uneven food environments persist (Haysom, 2021; Kanosvamhira et al., 2023), food insecurity among the homeless reflects broader failures in urban governance and social protection. Accordingly, food insecurity operates as

a critical lens through which the lived realities of homelessness and the limits of conventional relief-based responses, may be interrogated.

Urban agriculture (UA) has increasingly been positioned as a response to urban food insecurity, specifically within low-income and marginalised communities, where it is most often justified in terms of food provision. However, beyond this productivist framing, UA is also recognised internationally as an element of urban green infrastructure (GI) capable of generating a wider array of ecosystem services (ES), including social, cultural and health-related benefits (van Zyl et al., 2021). Research has shown that engagement with cultivation and green spaces can support psychological wellbeing, social connection and skill formation, outcomes that may be especially salient in contexts of profound vulnerability (Soga et al., 2017; Gibbens, 2019). Despite the increasing visibility of UA policy in Cape Town (Smit, 2016; Cilliers et al., 2020; Kroll, 2021), its relevance to homelessness and to food insecurity as a relational and structural urban condition, remains poorly conceptualised. This gap raises critical questions regarding the way food-based interventions are framed, valued and integrated within urban planning and social development. Against this background, this paper sets two research questions: Firstly, what good practice principles can be derived from international case studies of UA interventions in homelessness? Secondly, which organisations addressing homelessness in Cape Town include UA in their approach and what lessons are provided by these institutions for broader application?

The paper proceeds with the next section unpacking homelessness as a concept, its drivers and lived impacts, with a particular emphasis on food insecurity and dignity. This is followed by a discussion of UA as a multi-functional, nature-based developmental intervention and unpacking ES in UA in Section 4. International case studies of UA in homelessness interventions are then reviewed in Section 5 to distil key principles. Cape Town is subsequently introduced as the empirical case study, followed by a methodology section detailing the desktop review and dataset used. The results and discussion sections (8 and 9) examine the nature, scale and significance of UA initiatives linked to homelessness in Cape Town. The paper concludes with reflections and planning-oriented recommendations to integrate UA more systematically into homelessness responses in the city, also of value to other contexts in the global South and North.

3 COMING TO TERMS WITH HOMELESSNESS

Homelessness is a worldwide phenomenon affecting countries in the global North and South (Pitt, 2022). It is estimated that 150 million people, or 2% of the world population suffer from homelessness (Lidzhade and Mphambukeli, 2025), with the figure expected to increase under globalised neoliberal urbanism ruled by market forces. Within this system, prolific homelessness jars with aspirations for progressive world-class cities principled on rational order, the rule of law and codified planning to protect private interests. As such, the homeless are othered and stereotyped as perpetrators who increase crime, litter and dump, practice poor hygiene and contaminate, beg and devalue property by their presence as agents of the 'broken window syndrome' (Michaels, 2022). Such narratives bound in aversion from powerful private investors and fear amongst the voting public politicise the issue as an emotive challenge for local authorities framed by deep difference, professional and personal conflict (Hopkins et al., 2024). Broad brush condemnation of the homeless as a class of 'social failure, dysfunctionality and unproductivity' (Gerrard and Farrugia, 2015; Pitt, 2022:2) easily rationalises blunt political intervention. Yet even a shallow exposition of personal narratives or a frank confrontation of systemic drivers, may uncover accounts opposing freeloading by choice or deliberate ill intent. Rather, testifying to precarity of circumstance and last resort, aggravated by external factors beyond individual control. These include structural unemployment, migration, domestic violence and dysfunctional home environments, adverse childhood experiences, substance abuse and health challenges (Makiwane et al., 2010; Pitt, 2022; Hopkins et al., 2024; Lidzhade and Mphambukeli, 2025). In realisation, acknowledging that the homeless are often exposed to property threat, isolation, misconception, stigmatisation, harassment and violence and may face substance dependence, physical disability and disease (Rankin, 2019; Hopkins et al., 2024). Health concerns may be far reaching, including injuries, mental health challenges, sexually transmitted infections, respiratory ails like tuberculosis and other co-morbidities (UN-Habitat, 2020). These issues are severely impacted by changing climatic conditions and seasonality, lacking sanitation and ablution facilities and food insecurity in urban food deserts (Greene, 2019; Hopkins et al. 2024).

Food deserts do not reference the type, size and number of food retailers established locally, but rather lacking access to affordable healthy food amongst the poor even when retailers are plentiful (Smith et al., 2010). For the homeless, who often dwell in well-served urban areas, challenges include limited financial means and restrictions in preparing or storing food. This is especially problematic for perishable fruits and vegetables (Greene, 2019). Food insecurity overshadows basic hunger to include spatial, social, cultural, political and emotional aspects of food access (ibid), including the act and place of consumption (Campagnaro et al., 2023). Eating is often an undignified experience for the homeless as many scavenge for sustenance in bins, beg or are handed leftovers to consume publicly. Such meals are often nutritionally deficient, even hazardous, consisting of calorie rich processed foods or expired products. Alternatively, more nourishing meals may be accessed through soup kitchens and homeless shelters that may also provide temporary accommodation, sanitation and ablution facilities, clothing, blankets and possibly rehabilitation and developmental services (Brothers et al., 2020). Shared accommodation and meals may foster social cohesion in conviviality and camaraderie, but the interim nature of shelter support does not necessarily advance food security, nor do charitable services instil pride, self-confidence, self-esteem or self-reliance (Mjema et al. 2023). In addressing issues of nutrition, advancing food security, training and dignity in parallel, several organisations incorporate UA in developmental strategies addressing homelessness.

ES Category	Definition	Potential UA examples
Provisioning ES	Protection and restoration of natural resources and the capability of natural (e.g., rivers, biomes) or semi-natural (e.g., community gardens) green spaces to contribute physical products, materials or goods consumed directly by humans.	Community gardens, rooftop farms and alike produce fresh vegetables, fruits, eggs, honey, herbs and other food products often consumed by proximate residents, improving urban food security and reducing food miles. Urban gardens may cultivate medicinal and aromatic plant species used in traditional remedies or small-scale commercial products.
Regulating ES	The regulation of ecosystem processes that moderate natural and artificially induced environmental conditions. Benefits derive from capacities to control, reduce, or buffer ecological, climatic and biological processes alternatively requiring technical or engineered solutions.	UA vegetation contributes to local cooling through evapotranspiration and shading to reduce the urban heat island effect. Plants in UA systems capture particulate matter and contribute to pollutant removal from urban atmospheres. Soil enhancement is promoted via organic matter and reduced compaction, also preventing surface erosion. There are further contributions to nutrient cycling and soil quality stabilisation. UA systems can enhance pollinator habitat and activity and support populations of beneficial insects that regulate pests.
Cultural ES	The non-material benefits humans derive from ecosystems meeting cultural or spiritual needs when visiting, living in or enjoying views of green areas.	UA spaces provide green venues for recreation, passive enjoyment and aesthetic engagement with nature, especially valued in dense urban contexts. UA sites are often used for environmental education and gardening training, generally increasing ecological literacy and food system awareness, ultimately advancing skill development and employment opportunities. Shared involvement in UA projects fosters cultural expression, social interaction, networking, inclusion, community organisation and stronger sense of community identity. Exposure to green UA spaces, participation in gardening and contact with nature are linked with mental health improvements in decreased depression and anxiety, enhanced cognitive abilities, increases in attentional capacity, increases in life satisfaction and the benefits of physical activity like strength, fitness and flexibility.
Habitat services (or supporting services)	ES that conserve natural ecosystems and enhance urban biodiversity do not directly benefit humans but facilitate the fulfilment of all other ES by providing natural habitats.	UA sites, especially diversified gardens, increase urban biodiversity as habitats for flora, pollinators, insects and fauna often uncommon in built environments. Soils in urban horticulture systems regularly present enhanced biological diversity and nutrient cycling compared to non-vegetated landscapes. UA systems presenting diverse crops, including rare or heirloom cultivars, support the conservation of genetic resources in urban areas. Through green cover, flowers and sheltered microhabitats, UA supports the lifecycles of beneficial organisms, enhancing general ecological functions in urban areas.

Table 1: ES categories and potential examples in UA. Source: Constructed from Draper and Freedman (2010); Gonzalez et al. (2010); Soga et al. (2017); Gibbens (2019); Górna and Górny (2021); Lategan et al. (2021); van Zyl et al. (2021)

4 URBAN AGRICULTURE AS A NATURE-BASED SOLUTION AND DEVELOPMENTAL TOOL

UA is defined as the production of food and non-food crops and/or animal husbandry at micro and meta scale within and on the peripheries of urban areas (Hardman et al., 2022). UA includes all activities from cultivation to the entrepreneurial components of agri-processing, marketing and distribution (Cilliers et al., 2020; Chari et al., 2022). UA is acknowledged as a nature-based solution and element of GI, defined as a strategically planned, designed and managed urban network, consisting of various natural, semi-natural and man-made green and blue spaces that conserves ecosystem functions, contributes to biodiversity conservation and provides social, economic and health benefits through multiple ES (van Zyl et al., 2021). ES are the direct and indirect benefits all living species derive from the capacity of ecosystems to provide goods and services that satisfy needs (De Groot et al., 2010). ES have been classified according to provisioning, regulating, cultural and supporting/ habitat services. These categories are not mutually

exclusive, with multiple benefits derived simultaneously by GI elements like UA (van Zyl et al., 2021). Table 1 captures ES categories and potential manifestation examples in UA.

Recognising numerous ES (Table 1), highlights multi-functionality as a critical GI characteristic, which has provided planners with significant motivation and leverage to advance implementation internationally (Tsegaye et al., 2018; Cilliers et al., 2021). Yet, an overly naïve perspective should be avoided. A balanced approach recognises latent ecosystem disservices (ESD), acknowledging that ecosystem functions may deliver contrasting negative impacts (Davoren and Shackleton, 2021; Lategan, et al., 2021). For UA, examples may include invasive species or clearing indigenous remnants, continuous maintenance, operating expenses, security concerns of theft, squatting and vandalism. The threat of cultivation on urban sites contaminated by proximate pollutants like lead, arsenic from pesticides and polyaromatic hydrocarbon from exhausts, as well as residue and littering from discarded items related to substance abuse are noted (Bryld, 2002; Lategan et al., 2021). Fresh produce is also associated with microbial foodborne disease deriving from cats and birds, composting materials and fertilizers from livestock (Kaiser et al., 2015). Additionally, limited funding, skills and knowledge, staff shortages and a reliance on volunteer labour, limited markets and lacking consensus regarding success metrics often limited to biased cost-benefit analyses in favour of economic sustainability, are concerning (Biewener, 2016). Such challenges are exacerbated by limited research focused on UA benefits for vulnerable stakeholders like the homeless (Gibbens, 2019), with reflections limited to reports on disparate case studies. Section 5 attempts to relay some of these cases from the global North to evidence their general approach and distil potential lessons of practice.

5 REVIEWING SELECT GLOBAL NORTH CASE STUDIES OF URBAN AGRICULTURE IN HOMELESSNESS INTERVENTIONS

The examples summarised in Table 2 were derived from the academic literature on UA interventions targeting the homeless.

Project / Initiative	Organisational Type	Key Partners & Stakeholders	Approach & Model	Produce, Cultivation Methods & Facilities	Engagement with Homeless	Outcomes & Impacts
The Food Project/ Dudley Street Neighbourhood Initiative, Boston, MA & suburbs (1991)	Community-based nonprofit network	Foundations; municipalities; schools; hunger relief orgs	Youth employment, food donation, farmers markets. Food justice–oriented, educational UA integrating production, donation and market sales	Mixed vegetables; open-field cultivation; greenhouses; suburban farms (16 ha total); internships organic soil-based production; community gardens, farm, aquaculture facility, greenhouses and bioshelters, processing facilities and marketing outlets	Direct: produce and meals for homeless shelters and soup kitchens.	Food access, youth leadership, social cohesion
San Francisco County Jail – Garden Project, San Francisco, CA (1992 -2018)	Nonprofit re-entry programme	County jail; municipalities	Rehabilitative UA linking incarceration, skills and community service	Vegetables; tree planting; soil-based cultivation on institutional land	Indirect: food for homeless and elderly	25% lower recidivism
Sea Change, Inc. Philadelphia, PA (1993)	Nonprofit economic development corp.	Philadelphia Redevelopment Authority	Entrepreneurial and ecological UA as neighbourhood regeneration	Organic vegetables, herbs, flowers; 0.2 ha site; eco-village systems; organic farming, traditional and innovative technologies	Direct: employment and training	Skills, food production
Cook County Sheriff's Garden.Chicago, IL (1993)	Correctional UA programme	Univ. of Illinois Extension Urban Gardening Programme	Prison-based farming. Institutional rehabilitative UA	Vegetables; 557 m² prison garden; soil-based	Indirect: food for homeless; inmate rehabilitation	Reduced recidivism; food donations
Growing Home. Chicago, IL (1998)	Nonprofit social enterprise	City of Chicago; Community Development Block Gant; Coalition for the Homeless	Greenhouse farming; phytoremediation. Employment-focused UA with environmental remediation	Greenhouse, vegetables; raised beds; 0.4–1.2 ha brownfield site; phytore-mediation	Direct: homeless employment	Skills development; food production
Gino Organic Gardens. Chicago, IL (1998)	Volunteer-based and entrepreneurial	Local food nonprofits	Raised beds, donation model. Subsistence and donation-oriented UA	Mixed vegetables; raised beds; 670 m² vacant lot	Direct: homeless employment; Indirect: produce to homeless-serving orgs	454 kg produce donated in 1998

Seattle Youth Garden Works. Seattle, WA (1998)	University-affiliated programme	Universities; community partners	Market gardening; skills training. Workforce development UA	Market garden vegetables; soil-based plots	Direct: training homeless	Workforce readiness
Urban Oasis / Community Harvest. Washington, D.C. (Late 1990s)	Community-based project	Public housing authorities; schools	Urban farm. Employment-oriented UA in underserved areas	Vegetables, herbs, flowers; 0.2 ha farm	Direct: homeless employment	Food access in underserved area
Justiceville.Chicago, IL (Late 1990s)	Transitional housing initiative	Restaurants; housing providers	Herb cultivation for restaurants. Micro-enterprise UA	Herbs; 93 m² plot; soil-based	Direct: homeless residents farm	Income, skills
City Growers. Boston, MA (2010)	For-profit social enterprise / cooperative	City of Boston; institutions; volunteers	Sales-based; co-operative governance. Commercial UA with a social objective	Intensive vegetable production; 0.4 ha over four vacant lots; soil-based	Indirect: jobs, food to nonprofits	Employment, food access
Higher Ground Farm. Boston, MA (2013)	For-profit commercial UA	Private founders; volunteers	Rooftop commercial farming. Commercial, market-driven UA	Leafy greens, vegetables, flowers; 1,300 m² rooftop; open-air beds	Indirect: unpaid/volunteer labour	Proof of rooftop UA viability
St. Vincent de Paul Urban Farm. Dayton, OH (2013)	Shelter-based participatory research	Univ. of Dayton; Ohio State Univ.; shelters	On-site shelter farms. Therapeutic and participatory UA	Vegetables; 2,500–3,000 m² on-site shelter gardens; soil-based	Direct: shelter residents participate	Improved nutrition, mental health, lower recidivism
Growing Hope Gardens. Los Angeles, CA (2010s)	Nonprofit	Shelters; housing providers	Gardens in shelters and housing. Regenerative, empowerment-based UA	Organic regenerative gardens; shelter and housing sites; soil-based	Direct: stewardship and participation	Belonging, empowerment

Table 2: Synthesis of international examples of AU interventions in homelessness. Source: Constructed from Kaufman and Bailkey (2000); Biewener (2016); Gibbens (2019); Brothers et al. (2020); Mjema et al. (2023)

Findings captured in Table 2 are further detailed in Section 9 but is pertinent to acknowledge that all instances encountered are North American, calling the nature of similar approaches in the rest of the world, but especially in the global South, into question. If and how such approaches manifest in one of the global South's most developed and unequal countries, South Africa, and one of its most developed and unequal Cities, Cape Town, is particularly intriguing.

6 HOMELESSNESS AND URBAN AGRICULTURE IN CAPE TOWN, SOUTH AFRICA

South Africa is wracked by severe housing shortages resulting from colonial and apartheid rule, structural unemployment and a contemporary neoliberal approach that has reduced output in the state's low-income housing projects. Some 3.4 million prospective beneficiaries were captured on the national needs register by 2024 (RSA, 2024), most of whom are accommodated in informal settlements and informal backyard rental accommodation. Access to the informal sector, especially the backyard component, reflects resilience and agency amongst the otherwise destitute (Lategan and Cilliers, 2017) and the capacity for resource mobilisation and/or supportive kinship networks that assist in accommodation access (Lategan and Cilliers, 2019). These informal settlers are not considered homeless, but survive in precarity close to the verge of destitution should their circumstances change.

The housing backlog is concentrated in the country's metropolitan areas, particularly in eThekwini (Durban), the City of Johannesburg and City of Cape Town, mirroring instances of absolute homelessness. Cape Town is highlighted for a lack of literature on the phenomenon and a large comparative homeless population (Viljoen, 2025). Hopkins et al. (2024) report that only five dedicated studies have emerged on homelessness in Cape Town since 2013 and that the exact extent of the homeless population is unknown. A 2020 estimate projected a population of14357 homeless (ibid). Studies show that up to 71% are classified as chronically homeless, having experienced constant homelessness for a minimum of one year, or repeatedly over certain periods (Viljoen, 2025).

Life on Cape Town's streets is particularly inhospitable in gentrified business nodes managed under low tolerance private improvement cooperatives and crackdowns on vagrancy and squatting in the central business district (CBD) (Michaels (2022). Punitive responses call on law enforcement and private security to fine or remove the homeless based on bylaws of 'antisocial behaviour' (Pitt, 2022; Viljoen, 2025). Cape

Town's homeless further face harsh summers, wet winters and gale force winds in what is known as the Cape of Storms. Some respite from authorities, the weather and hunger may be found in shelters provided by the state and non-governmental (NGOs) and non-profit organisations (NPOs). However, offerings generally deliver maintenance services and temporary accommodation, mostly failing to facilitate more permanent transitions from homelessness supported by long-term developmental assistance in social services, substance abuse treatment, skills development and economic empowerment toward permanent independence (Hopkins et al., 2024). The basic accommodation offered is also scarce and institutions under capacitated, with only 3246 shelter beds available (Table 3). Many homeless further actively avoid shelters due to strict operating hours and rules, including curfews, a ban on drug and alcohol use or non-admission of couples (Viljoen, 2025). Even when such detriments are inconsequential and more developmental interventions offered, Cape Town's homeless are reticent to commit to longer-term stays given loss of income from begging or casual employment (Hopkins et al., 2024). The need for proven intervention strategies providing multiple longer-term developmental benefits, like UA (Table 2), is thus imperative.

There is significant potential to draw on existing support for and implementation of UA in the city. Cape Town is regarded as a front runner in UA (Jagganath, 2022) as the first South African city to deliver an UA Policy in 2007. This policy, along with the City of Cape Town Food Gardens Policy in Support of Poverty Alleviation and Reduction, support UA and food aid for indigent households and schools (Smit, 2016; Kroll, 2021). Food systems were also included in the city 2019 Resilience Strategy through targeted action plans. However, integration into broader urban governance and management has remained limited (Haysom, 2021). Furthermore, The OneCape 2040 Strategy proposes transitioning to an eco-friendly, inclusive, resilient and sustainable economy that supports UA and sources 80% of food locally. Yet, few political aspirations have been articulated (Kroll, 2021). Planning documents like the Municipal Spatial Development Framework (MSDF) (COCT, 2023) provides for protection and recognition of significant agricultural land like the Philippi Horticultural Area in the Cape Flats region that produces a large proportion of the city's vegetables. The Cape Flats accommodates approximately 6000 small-scale and micro-farmers who operate some 100 urban gardens. Most are located on school and municipal properties, whilst others occupy liminal spaces like road verges to constitute more informal practices (Kanosvamhira et al. 2023). UA practices closer to the CBD are also documented, including the Oranjezicht City Farm located in a prestigious suburb in the Cape Town City Bowl which has itself supported the establishment of at least twenty other local UA initiatives (Steenkamp et al., 2021). Despite a significant homeless population and advancements in the establishment of UA policies and practices along the informal to formal continuum, the literature is sparse and whether, and how, approaches to homelessness in Cape Town have incorporated UA, unknown.

Nr	Organisation	Capacity	Nr	Organisation	Capacity
1.	The Haven Night Shelter, Bellville	83	16.	Elim Night Shelter, Elsies River	70

Table 3: Homeless shelters registered on the City of Cape Town Open Data Portal. Source: CoCT (2025)

7 METHODOLOGY

This paper employs data sourced from the City of Cape Town's Open Data Portal (CoCT, 2025) that provides publicly accessible municipal datasets across a range of thematic categories, including social development. Within this category, a 2025 dataset titled 'Homeless Shelters' was identified that indicates places of accommodation for the homeless within the City of Cape Town. It is acknowledged that the list

may not capture informal, faith-based, or unregistered initiatives operating outside of the City's officially recognised programmes. The twenty-nine organisations captured in the database are presented in Table 3.

Each organisation was subjected to a semi-systematic desktop review (Lategan et al., 2025) of grey literature (websites, media articles and reports) using key words and Boolean Operators to configure the following search strings: Organisation AND Cape Town AND Urban Agriculture; Organisation AND Cape Town AND Urban Farming; Organisation AND Cape Town AND Garden; Organisation AND Cape Town AND Food Security. Corresponding folders were created for each organisation and subfolders for each search query created on Endnote as reference management platform. Both deductive and inductive coding were completed using Atlas.ti. Results are discussed in Section 8.

8 RESULTS

Results demonstrate that 48.3% (n=14) of organisations referenced general gardening practices, whilst 17.2% (n=5) referenced larger scale UA activities more specifically, though not always directly by name. The relatively high number of instances recorded for gardening activities is largely due to the Haven Night Shelter collective with eleven branches, but one general website. Thus, making it impossible to gauge where and how much gardening takes place. The Haven Night Shelter and the Salvation Army's Beth Rogelim men's home mention resident involvement in garden-related activities (Haven Night Shelter, 2025; Salvation Army, 2025), with the available information suggesting that these activities are restricted to general maintenance and domestic gardening duties rather than a structured developmental strategy based on UA. The Somerset West Garden Project transformed a derelict park into a thriving urban farm that utilises volunteers from the homeless community, sells produce locally through a market and to restaurants and supplies the Somerset West Night Shelter and Thomas House of Hope (Atlantic Fertilisers, 2023). A Community gardening approach was also identified in the Ubuntu Circle of Courage organisation, which demonstrates how UA can support the homeless in personal development. The organisation is supported by the Western Cape Department of Agriculture (WCDoA) and the Cape Agency for Sustainable Integrated Development in Rural Areas (Casidra), with a five-year lease from a local company ensuring medium-term stability (Casidra, 2025a). The Happy Valley Shelter reports the existence of a vegetable garden damaged by a local baboon troop, calling for support to reestablish the space in recognition of its role in providing fresh produce for residents and in fostering a connection with nature (Happy Valley, 2025). However, no data were available on the garden's size, production capacity, governance, or operational model in contrast with other cases identified.

At the Oasis Reach for Your Dreams organisation, the Garden of Grace project trains residents, with the help of the Local Cape Roots company (Maledo, 2021), in the cultivation of a subsistence garden. The project has received support from the WCDoA and Casidra to upgrade infrastructure and increase production capacity (Casidra, 2025). The Garden of Grace supports nutritional needs but also advances personal growth, dignity and vocational opportunities whilst produce is sold locally in aid of broader food security concerns (Oasis, 2025). A wider focus at Garden of Grace sprouted the Gardens for Growth initiative that supports local families to initiate and maintain domestic food gardens, ultimately envisioning community-run enterprises that generate fresh produce and local employment whilst promoting climate resilience and ecological restoration (Casidra, 2025b). A focus on ecological functions is also evident in U-Turn Homeless Ministries' Living Roots Nursery in Claremont. Living Roots offers a distinct form of UA focused on horticulture, environmental restoration and sheltered employment and not food production. The indigenous nursery is operated by the formerly homeless in the final stages of U-Turn's rehabilitation programme (Shoba, 2023), with therapeutic benefits noted (Lemonaid and ChariTea Foundation, 2025). Living Roots is a social enterprise that generates income through plant sales, landscaping services and workshops, with profits reinvested into U-Turn's programmes (Volkwyn, 2023; Living Roots, 2026). Participants receive accredited training in gardening, landscaping, composting, first aid and environmental management, contributing to both personal rehabilitation and urban ecological outcomes (Lemonaid and ChariTea Foundation, 2025). Structured horticultural training is combined with practical food production in the Bellville CBD Food Garden, a purpose-built urban food production system integrated into a Safe Space for the homeless and vulnerable in collaboration between the Greater Tygerberg Partnership and social development NGO, MES and related to the Tygerberg Association for Street People (TASP). Founded on a 300 m² site, the garden was conceived during the COVID-19 lockdown to improve food security, health and

income opportunities. The project supplies fresh produce to a soup kitchen and sells surpluses to generate modest income for participants. Stakeholders emphasise dignity, mentorship, skills development and employability as central outcomes. Expansion plans to approximately 600 m² indicate a transition from pilot-scale production towards an expanded UA model (Alexander, 2021). The largest scale, and most mature, UA intervention was identified in the Ark City of Refuge's farm where a small vegetable garden evolved into an organic urban farm supporting a kitchen that provides approximately 3000 meals daily (Masiwa, 2024). The farm includes open-field production, tunnels, fruit trees and designated plots for school learners to gain agricultural experience. The project benefits from long-term partnerships with food retailer Shoprite, the WCDoA and other donors, who have provided infrastructure, training, seedlings, irrigation equipment and surplus food (Shoprite, 2021; Shoprite, 2024). Thirty to forty residents are empowered by direct participation in food production and receive permaculture training, enhancing their capacity for self-sufficiency. The farm further supports external organisations, including soup kitchens, crèches and old-age homes to position the initiative as a critical node in local food relief networks (The Ark, 2026).

9 DISCUSSION

This paper highlights homelessness as a heterogeneous condition affected by structural, spatial and personal impacts. Interventions that consider the homeless as a singular group risk strengthening stigma and advancing a disconnect between need and response. Sensitive UA initiatives are required that acknowledge homelessness as a condition of exclusion from urban citizenship and the right to the city. As alluded to previously, one of the principal considerations in claiming this right resides in meeting the basic human right to access adequate food. In keeping, studies on UA in the global South generally highlight issues of food security and poverty alleviation, adopting a reciprocal advocacy approach (Kanosvamhira et al., 2023). Studies in the Global North initially focused on a productivist approach but later acknowledged multi-level social and cultural factors (Kanosvamhira et al., 2023; Saguin, 2024). Thereby also recognising that food insecurity exceeds mere hunger to include indignity of access, preparation and consumption. Appropriately targeted UA practices thus reposition food access from charitable dependence to a communal participatory practice of agency, citizenship and community. The Food Project emphasises social cohesion and civic engagement alongside food production, positioning UA as a developmental and relational practice (Kaufman and Bailkey, 2000). Growing Hope Gardens and St. Vincent de Paul Urban Farm demonstrate how cultivation and shared meals can restore stewardship and belonging (Gibbens, 2019; Mjema et al., 2023). These cases also illustrate the value of embedding UA within supportive institutional settings, like shelters, transitional housing and correctional or rehabilitative environments, to connect UA sites directly with complementary social services. Thus, also suggesting that some of UA's most significant contributions for homelessness may not be caloric or economic, but rather social, cultural and psychological, espoused via routine, purpose, contact with nature and social interaction, as cultural ES. All Capetonian cases, bar U-Turn Homeless Ministries' Living Roots Nursery, focus primarily on sustenance and nutrition, reconfirming tendencies in the global South. However, most also recognise AU's therapeutic contributions and the advancement of personal development as significant drivers, often informed by structured training, skills acquisition and pathways to employability (Oasis Reach for Your Dreams, the Bellville CBD Food Garden, U-Turn Homeless Ministries and the Ark City of Refuge). This mirrors international precedents (Seattle Youth Garden Works, Justiceville, Growing Home) where workforce readiness, accredited training and transitional employment are central objectives rather than ancillary benefits (Kaufman and Bailkey, 2000). Activities pursued for income generation often benefit the broader community through fresh produce delivered to restaurants and sold at dedicated markets (Seattle Youth Garden Works, the Food Project, Somerset West Garden Project, Bellville CBD Food Garden, Ark City Refuge), or donated surpluses (Gino Organic Gardens, City Growers, the Food Project, Bellville CBD Food Garden), furthering general food security. The deliberate identification of access points to market, whether through farmers' markets, restaurant supply chains, or institutional procurement is important. Thereby enhancing financial viability and reinforcing dignity through productive participation to support a sense of achievement, contribution and belonging in aid of community assimilation.

External ties are significant in support of UA interventions for the homeless. International case studies like Seattle Youth Garden Works, Growing Home and City Growers and Capetonian examples like Ubuntu Circle of Courage, Oasis, Bellville CBD Food Garden and Ark City of Refuge illustrate that successful

initiatives are habitually rooted in intergovernmental involvement, multidisciplinary collaboration and public private partnerships. International and local cases further demonstrate that embedding volunteerism and co-production through resident participation, community volunteers and institutional partners, enhances ownership, social capital and programme resilience. Partnerships, sponsorships, goodwill and sound management are paramount in operating sustainably with security of tenure to allow UA interventions to mature and expand.

However, land access and tenure insecurity are often detrimental constraints to UA, specifically in high-value urban centres like the Cape Town City Bowl where market led competition is significant and risk of displacement imminent without explicit policy recognition, institutional land access and use rights. International examples demonstrate adaptive spatial strategies in response to such constraints, including the use of liminal and non-traditional spaces like rooftops (Higher Ground Farm) and the remediation of contaminated or underutilised brownfields (Growing Home), to expand the spatial repertoire available for UA in dense urban environments (Kaufman and Bailkey, 2000; Biewener, 2016). Comparable opportunities exist in Cape Town, and are already practiced in areas like the Philippi Horticultural Area (Kanosvamhira et al. 2023), but remain underexplored within homelessness responses.

Urban planning is thus identified as a champion for UA for its role in land use regulation, strategic development oversight and as multi-disciplinary entity with potential intergovernmental and private sector linkages (Górna and Górny, 2021; Skinner and Haysom, 2021; Ngie and Sithole, 2023). In many cases the strategic instruments informing planning policy and practice already support food-based uses like UA and more sustainable and environmentally sensitive development options like GI. However, as with other GI elements (van Zyl et al., 2021), urban planning professionals generally remain ill-equipped to integrate UA which may be illegal in many urban areas in contravention of traditional bylaws based on permittances and restrictions rooted in colonial conventions or benefitting neoliberalism and capital interests (Lee-Smith, 2013; Kroll, 2021; Matamanda et al., 2022). The absence of a definitive, proactive, integrated and pro-poor strategy focusing explicitly on the informal UA sector in Cape Town serves in substantiation (Skinner and Haysom, 2016).

Emphasising multi-functional ES, both informally and formally, beyond food for the homeless may be required to motivate UA in Integrated Development Plans (IDPs) and Spatial Development Frameworks (SDFs) aligned to South Africa's 2013 Spatial Planning and Land Use Management Act (SPLUMA) (Haysom, 2021). SPLUMA's emphasis on principles of justice, resilience and sustainability are prudent, especially when planners proactively consider ESD commensurate with a normative professional responsibility to separate incompatible land uses and guard against detrimental activities (Górna and Górny, 2021). In emphasising ESD, the paper cautions against the idealisation of UA. Risks related to soil contamination, food safety, labour exploitation and exposure to unsafe environments may disproportionately affect homeless participants. This is particularly evident in cases such as Growing Home, which addresses soil contamination through phytoremediation, highlighting that environmental risk is not incidental but structural. The ethical implementation of UA strategies for the homeless demands that environmental or institutional risks are not externalised for an already vulnerable group. The following section concludes the paper with six recommendations based on the discussion presented.

10 CONCLUSION AND RECOMMENDATIONS

Findings confirm that while Cape Town has a comparatively strong policy environment supportive of UA, the integration of UA into homelessness responses remains fragmented and opportunistic rather than systematic. Drawing on the literature, empirical findings and discussion, the following recommendations are proposed emphasising the role of urban planning in enabling homelessness-responsive UA strategies in Cape Town:

1. Integrate UA explicitly into homelessness and urban planning frameworks: UA should be recognised formally as an effective instrument in homelessness interventions within municipal planning instruments, including IDPs and SDFs. Aligning UA initiatives with SPLUMA principles would further legitimise their inclusion as instruments of spatial redress and inclusive urban citizenship. Explicit articulation would reduce legal ambiguity, protect UA from displacement and enable proactive land allocation.

2. Identify and secure land for UA via proactive spatial planning: Urban planners should lead targeted spatial analyses to identify suitable land for UA linked to homelessness services. This may include municipal land, school properties, rooftops, underutilised public land, servitudes, buffer zones and other liminal spaces. Secure tenure arrangements, even if time-bound, are critical to enable UA initiatives to advance, attract investment and deliver long-term benefits.

3. Promote multi-functional UA models beyond food production: Planning frameworks should explicitly recognise and incentivise the multi-functionality of UA, particularly enhancing and integrating cultural ES. In support, shifting evaluation metrics beyond yield, income, or traditional cost-benefit analyses to include dignity, wellbeing, agency and community integration to better reflect the objectives and outcomes demonstrated in both international and local case studies. This includes recognising UA sites co-located with shelters, safe spaces, rehabilitation centres and training facilities as critical social infrastructure and not ancillary land uses.

4. Support long-term, cross-sectoral partnerships: Evidence from both international and Capetonian cases highlights that successful UA initiatives in service of the homeless are secured by long-term partnerships involving multiple tiers of government, NGOs, academic institutions and the private sector. Urban planners may act as conveners to facilitate interdepartmental coordination between social development, environmental management, economic development and health departments, whilst also facilitating partnerships with civil society and donors. Such partnerships are essential to subsidise infrastructure, promote volunteerism and co-production in addition to ensuring sustained skills transfer and programme continuity.

5. Address environmental and ethical risks: UA initiatives involving homeless participants must guard the vulnerable against environmental and institutional risks. Urban planners should operationalise measures to guarantee that sites are assessed for soil contamination, water quality, food safety and exposure to hazards and that mitigation measures, including raised beds, phytoremediation, or controlled inputs, are implemented as required. Ethical practice will require that participation is voluntary, safe and empowering and not conditional or exploitative.

6. Expand empirical research on local UA initiatives: There is a clear need for further research on UA and homelessness in Cape Town and the global South. In-depth qualitative studies of existing initiatives that investigate governance arrangements, funding mechanisms, participant experiences and long-term outcomes would address existing shortcomings and strengthen the evidence base to inform more contextually appropriate policy design. Improved documentation of local successes is essential to move UA from isolated practice to strategic intervention. This research serves as a first step in this regard.

A Spatiotemporal Analysis of Duhok's Urban Growth (2010–2025): A Narrative Review of the Duhok Master Plan

Haval Bankin Qasim Kittani

(Assistant Lecturer Haval Bankin Qasim Kittani, Nawroz Univercity, Duhok – Kurdistan Region of Iraq, kittanihaval@gmail.com)

1 ABSTRACT

Duhok in the Kurdistan Region of Iraq has seen an expansion rapidly. The growth is so rapid that we think it goes against the planned development of the area. The Vossing Report's urban master plan is to be a guide for development until 2023. This narrative review will assess the effectiveness of the urban growth of Duhok governorate in the Iraqi Kurdistan Region. The main goal of this study is to show the current state of Duhok urban development. This study focuses on the different land use areas that were planned for and compares those that were developed with the residential and commercial land uses. Urban boundaries were determined based on the Google Earth Engine to demonstrate the difference between 2010 and 2025 with high-resolution satellite images. We then recorded land use via satellite images from other studies that were conducted to show the state of growth. Land use was mapped using Google Earth Engine. From this the intensity of urban growth was then used to measure the state of growth.

Keywords: Urban Sprawl, Master Planning, Duhok, GIS, Smart Growth

2 THEORETICAL PART

2.1 Overview of Duhok City in Iraqi Kurdistan

Dohuk is one of the three main cities of the Kurdistan Region of Iraq. It has grown rapidly in recent decades. This city is becoming a strategic economic and urban center with some environmental and planning challenges. Duhok lies in a valley between Bekhair and Zawa mountains around 585 m above sea level and the temperate of its climate is moderate to high in four seasons with all four season greatly seen in this city (Hassan & Kotval-K, 2019; Mohammed, 2013). It is called a Iraq's northern gateway for trade with Turkey and Syria. This has given the city its high economic importance, because of all fours seasons prints (Hassan & Kotval-K, 2019; Mohammed, 2013). Socially in a brief, Duhok is multicultural and multi religious with a Kurdish majority, Assyrian, Chaldean, Arab, and Armenian minorities (Hassan & Kotval-K, 2019). Population estimates range around 300,000–400,000+ in addition to numbers of strong in migration from rural Kurdistan other Iraqi regions, and refugees/IDPs (, 2025; Hussein & Al-Jameel, 2025; Taha, 2024).

Aspect	Main points	Citations
Natural setting	Between two mountain ranges; Duhok River green corridor	(, 2025; Hussein & Al-Jameel, 2025; Mohammed, 2013)
Economy & role	Border trade hub; fast post-2003 growth	(Hassan & Kotval-K, 2019; Hussein & Al-Jameel, 2025; Mohammed, 2013; Othman, 2014)
Land & environment	Surrounded by agricultural lands; rapid loss to urbanization	(, 2025; Mohammed, 2013; Mohammed & Ali, 2014)
Urban structure	Old core plus "urbanized villages" now city quarters	(Hussein & Al-Jameel, 2025; Raswol, 2017)

Table 1: Key Urban Characteristics of Duhok. Source: Key physical and functional traits of Duhok City Made by author based on the references

2.2 Urban Growth and Environmental Change of Duhok City

Since the late 1990s, Duhok has experienced a rapid growth largely unplanned urban expansion development driven by security, economic opportunities, and population growth (Mohammed & Ali, 2014; Hussein & Al-Jameel, 2025; Raswol, 2017; Othman, 2014). Remote sensing shows strong conversion of agricultural and vegetated land to built up areas between 1998–2016 (Mohammed & Ali, 2014; Mohammed, 2013). This has increased land surface temperatures, with built up and barren land reaching up to ~56 °C in summer, compared with much cooler water and forest areas (Mohammed, 2013).

2.3 Sustainability and Planning Issues of Duhok City

Studies highlight shortages of housing in green and open space and quality sidewalks plus car dependent development and informal settlements (Raswol, 2020; Raswol, 2017; Mohammed, 2013; Abdulsamad et al., 2019; Ali, 2016). Sustainability assessments has shown a weak progress in the 1990s with some improvement after 2005 in compact mixed use and walkable neighborhoods and protection of agriculture and

urban agriculture areas such as Shindokha (, 2025; Raswol, 2020; Hassan & Kotval-K, 2019; Raswol, 2019). Duhok is a strategically located for trade and is one of the rapidly growing Kurdish cities shaped by mountains, trade routes, and migration. Its fast expansion has brought economic opportunities but also stretches and environmental stress plus infrastructure gaps for that reason it has made a sustainable urban planning which is also a central challenge for its future.

3 METHODOLOGY

3.1 Research Framework

The study follows an approach to analyze urban growth. The study checks the papers that were published in the same area. The author has devised a narrative review designed to trace the cognitive and historical development of Duhok's master plans based on what was set by the Vossing Report. The spatiotemporal analysis using Google Earth Engine (GEE) from 2010 to 2025 was generated to transform theoretical planning into empirical spatial data. This structure ensures that research results are translated from theoretical knowledge into practical application.

3.2 Search Strategy and Boolean Search

To identify relevant literature a systematic search was conducted in the Google Scholar database following the methodology of (Büttcher et al. 2010) to search via utilized Boolean operators (AND, OR) to refine results and ensure high relevance to the research objectives.

The search model was structured as follows ("Urban growth" OR "Urban expansion") AND ("Duhok" OR "Kurdistan") AND ("Master plan" OR "Vossing Report" OR "Land use") (Büttcher, Clarke, & Cormack, 2010)

3.3 Inclusion and Exclusion Criteria (PRISMA)

This review adheres to the PRISMA 2020 guidelines to ensure transparency in study selection. The following criteria were applied:

- Study Type: Only peer-reviewed journals and published thesis and technical reports that are directly addressing urban growth or the Duhok master plan were included.
- Language: Only studies published in English were selected. The behind this is because majority of global research on strategic urban planning is documented in this language.
- Temporal Scale: While the narrative review covers the history of planning since before 2010 but to provide a comprehensive view the spatiotemporal analysis specifically the author focuses on the 2010–2025 window. (University of North Carolina at Chapel Hill, n.d).

3.4 Spatiotemporal Analysis and Google Earth Engine

The paper objective was supported by utilizing Google Earth Engine (GEE) to analyze high-resolution satellite imagery. In that process we first did a data extraction by Identifying urban boundaries and land-use. Secondly, we did a growth intensity mapping by comparing images from 2010 and 2025 to measure the intensity of urban sprawl against the planned growth trajectories of the planned master plan of the city.

Metric	2010 Value	2025 Value	Absolute Change	Percentage Increase
Total Area	34.78 km²	51.14 km²	+16.36 km²	47.04%
Perimeter	27.85 km	42.82 km	+14.97 km	53.75%
Min. Elevation	474.10 m	471.14 m	-2.96 m	-0.62%
Median Elevation	553.68 m	570.79 m	+17.11 m	3.09%
Max. Elevation	717.98 m	838.88 m	+120.90 m	16.84%

Table 2: Comparative Spatial and Elevation Metrics for Duhok (2010–2025). Source: Created by the author through GEE.

3.5 Data Synthesis and Filtering

As illustrated in the PRISMA Flow Diagram below studies were filtered through three distinct phases initial identification, secondly screening for accessibility (open-access journals only), and final eligibility based on the presence of key terms in the title, abstract, or core paragraphs. This rigorous process ensures that only the most pertinent data points are used to evaluate Duhok's urban evolution. (University of North Carolina at Chapel Hill, n.d)

3.6 Objectives

The primary aim of this study is to evaluate the urban evolution of Duhok City from 2010 to 2025. And answering how external geopolitical pressures influenced the execution of the official master plan.

Phase	*Step*	*Details / Numbers*
Identification	Records identified from:	Databases (n = 1) Registers (n = 265)
	Records removed before screening:	Duplicate records removed (n = 0) Records marked as ineligible by automation tools (n = 0) Records removed for other reasons (n = 0)
Screening	Records screened	(n = 265)
	Records excluded	(n = 65)
	Reports sought for retrieval	(n = 200)
	Reports not retrieved	(n = 0)
	Reports assessed for eligibility	(n = 200)
	Reports excluded	Total: 191 • Reason 1: Not related directly to Duhok • Reason 2: Not related to objective of review • Reason 3: Not English / missing data
Included	Studies included in review	Total items (n = 9) • Primary studies (n = 6) • Reports of included studies (n = 1) • Theses of included studies (n = 2)

Table 3: PRISMA 2020 flow diagram for new systematic reviews which included searches of databases and registers only. Source: University of North Carolina at Chapel Hill. (n.d.). Creating a PRISMA flow diagram PRISMA 2020. LibGuides

4 RESULTS

The Author has used a time series like approach to categorize the urban growth into three-time related category. The first category of growth is pre 2010 followed by intermediate phase which is between 2012 to 2019 and the modern category of urban growth between 2020 and 2025.

4.1 Historical Phase: Pre–2011 (Baseline and Initial Growth)

The city of Duhok has its roots from the very first settlement of the town in the year 1887, in the time of the Ottoman Empire (Hajani 2019). In 1923, Duhok City had transformed into a natural center of 18.6 hectares (Hussein & Al, Jameel 2025; Hajani 2019). During these years, the town had already begun to rely on paper cadastral maps to indicate its development. These maps were produced from the plane table detailed surveys and field surveys were direct on the trace paper (Kattan & Abdulrahman, 2019). The local architecture of Duhok City received a significant incentive in 1969 when Duhok became the provincial capital or in local legal term governorate. The population of Duhok city surged from 5, 621 in 1947 to 212, 469 by 1998 (Hajani 2019). To curb the rapid increase in population the government instituted a practice of free land allocation to public servants of which roughly 23, 000 land parcels were allocated between 1998 and 2011 (Hajani 2019). The city underwent rapid extension to the west during the years 1998 to 2011, characterized by the dominance of the single.

4.2 Intermediate Phase: 2012–2019 (Intensification and Environmental Stress)

The city also suffered from some minor environmental degradation during this period. Furthermore, large gaps existed in the application of the institution framework. By the year 2014 the expansion of the urban area was 5, 763 hectares and dense forest cover had greatly reduced due to clearance of the area for the construction of the city (Khwarahm et al., 2021; Hajani, 2019). The residential areas built during this period such as Masike were good but did not apply the strict international standards of sustainability and the good thing about this was having feature of a low population density of 120 people per hectare, making the area car-dependent (Raswol, 2019a).

As a result of the economic crisis and the ISIS war less than 5% of the proposals of the Duhok City Center Masterplan in 2014 achieved implementation by 2019. The project experienced severe challenges (Saadulla, 2019). Later in 2016, the technical documentation was improved by creating an official land use master plan that was confirmed to be of a very high position accuracy of 1.5 cm (Kattan & Abdulrahman, 2019). The sustainable energy action plan, which was conducted through the 2018 Duhok SEAP, demonstrated that the residential and transport sectors are still the major current anthropogenic sources of greenhouse gas (Duhok Governorate, 2018).

4.3 Modern Phase: 2020–2025 (Governance and Heterogeneity)

Recent studies characterize Duhok as a diverse city that requires the abandonment of the concept of citywide uniformity (Hussein & Al-Jameel, 2025). Planners suggest the development of distinct urban codes for the diverse historic, organically developed core, and the separate, amenity rich modern development zones to foster and protect the local distinctiveness (Hussein & Al-Jameel, 2025). To substitute traditional zoning, Urban Transect Theory has been utilized as a potential regulatory framework to enhance urban and natural systems synergy by using a collection of regulatory frameworks to create and maintain urban areas that are high in density and facilitate walkability (Hussein & Al-Jameel, 2023).

The Duhok governance has been integrating E-management and smart services to minimize time and cost of administrative processes (Duhok Governorate, 2018). The goals for 2025 and beyond include:

- Emissions: Committed to a 40% reduction in emissions by 2030 by implementing energy saving "Green Codes" for building (Duhok Governorate, 2018).
- Urban Growth: Urban footprint is projected to grow by 271% by 2060 compared to 2017, with the majority of the loss of farmland (Khwarahm et al., 2021).
- Policy Innovation: Immediate integration of the Sustainable Development Goals (SDG 11) into the city's urban development framework is imperative to enhance the city's resilience and inclusiveness (Dohok Governorate 2018; Raswol, 2019b).

5 DISCUSSION

The assessment of the urban development of Duhok between the years 2010-2025 shows a city with adaptive capacity and the importance of its geostrategic position. While the spatiotemporal data shows a variation from the original master plan, a more detailed review informs us that Duhok is more likely to have had a master plan that is due to exceptional geopolitical circumstances, was delayed, and thus, why the framework was never completed. It lacked systemic failure.

5.1 Resilience and the Geopolitical Crisis

The 2014 regional crisis is pivotal to understanding Duhok's development trajectory. The 2014 Masterplan was a document of great merit with sophisticated technical features and the use of high precision GPS. However, as a consequence of the ISIS war the governorate's primary focus shifted from urban expansion to humanitarian and security imperative.

Duhok became a safe haven for over hundreds of thousands of internally displaced persons (IDPs) and refugees which meant that housing and land had to be allocated rapidly, and the traditional phased land development sequencing of the Vossing report had to be bypassed. Duhok's ability to maintain its primary urban functions and grow was nothing short of remarkable, and this was a reflection of Duhok's resilience as a city and the supportive governance structure, rather than a reflection of failure of the plan.

5.2 The "Safe Haven" Effect and Urban Vitality

The rapid development of Duhok is a testament to its livability and economic potential. Duhok has become a significant trading and safe haven center within the region's persistent instability. The increasing influx of people and consequent urban sprawl is a problem of success. The city developed because people wanted to live there. While the Masike area and others developed as low-density sprawl they were important to provide shelter during a time of extreme pressure at a national level. The period of modern phase Duhok (2020–2025) and the transition to E-management and Smart Services demonstrate that despite the external challenges of the preceding decade, local government is committed to modernization and efficiency.

5.3 Strategic Pivot Toward Sustainability

The modern phase encapsulates how Duhok is not just growing but changing. The city is changing for the better as shown by the 40 percent emissions reduction pledge by 2030 and the continued inclusion of the SDGs in city planning. City planners in Duhok are developing a world-class city, and they are doing so despite the conflicts that plague the region. The shift from firm zoning regulations to the Urban Transect Theory demonstrates Duhok City planners' appreciation and understanding of the city's physical context. By

designating the historic core as a protected area and designing a high-density walkable core the city is re-booting the Vossing report.

5.4 Synthesis of Potential

The evidence shows that a Smart Green Duhok is within reach. The Master Plan Gap was a product of a necessity that arose from the ISIS war whereby planners were forced to choose from a growing set of maps or the immediate protection of the people. Duhok is now in a unique position to integrate its high-resolution planning data with its innovative digital governance to align with the emerging stability in the region and correct the sprawl that so many cities in the region have experienced.

Factor	Planned Trajectory (Master Plan)	Observed Reality (2010–2025)
Land Use	Managed green belts & agricultural protection	High conversion of land to residential
Density	Sustainable, walkable neighborhoods	Low-density, car-dependent sprawl (e.g., Masike)
Governance	Strict adherence to Vossing plans	Flexibility due to economic/security crises
Environment	Emission reduction & temperature control	Urban Heat Island effects

Table 4: Summary of Discussion Points. Source: Created by the author.

Factor	Strength / Success Indicator	Resilience Context
Technological Base	High accuracy in land use mapping	Maintained despite economic crisis
Social Role	Multicultural trade and humanitarian hub	Absorbed massive migration without city collapse
Modernization	Shift to E-management & Green Codes	Preparing for post-2025 sustainability
Resilience	5% plan implementation with 100% functionality	Survival and growth during the ISIS war

Table 5: Key Strengths of Duhok's Urban Framework. Source: Created by the author.

6 CONCLUSION AND RECOMMENDATIONS

6.1 Conclusion: A City of Resilient Growth

The analysis of Duhok’s development over the years 2010 to 2025 depicts a highly remarkable development of urban fortitude. The analytical data suggests that a tiny portion of Duhok’s Vossing Report and 2014 Masterplan was actually materialized. However, this study interprets the implementation gap differently. It suggests that the gap was not a result of a loss of vision but rather a significant shift in focus that was needed to deal with the unforeseen external stresses. The period of 2014-2019 captures the essence of Duhok’s balancing act as it successfully played out the role of a safe sanctuary for the people during the ISIS crisis providing humanitarian assistance, while, paradoxically, assuming the position of a Regional Economic Element (REE) as a cross-border strategic trading facilitator. The rapid development and subsequent urbanization were a result of a choice by Duhok to be functional and open under difficulties. Duhok has now emerged as a multicultural urban center and is no longer in a state of emergency expansion. Immediate development of digital services, and long-term planning for sustainable development has placed Duhok in a reasonable position for planning additional steps. Current development is based on earlier planning. Technically, this planning is still sound and is now based on a highly precise geospatial foundation for the next generation of smart growth.

6.2 Recommendations

To integrate historical planning with modern realities, the following steps are proposed. Master Plan Update With the original Vossing timeline but extended. The governorate must establish a Duhok 2040 vision with incorporating the current sprawl into a unified urban framework. Enforcement of the green code on new developments with a recorded heat island effect. The city requires the immediate enforcement of building codes aimed at energy conservation. This will support the city’s aim for a 40% emission reduction by 2030. The city needs to shift from large homogeneous zoning to the transect theory in order to retain the gorgeous integrated structure of the old city core and the less of the smart zones with high density and walkable of the newer areas. Utilize Google Earth Engine (GEE) and similar technologies for real-time monitoring of the development of different land uses so that any further settlement on the agricultural land can be identified and managed. In response to the car dependency noted from 2012 to 2019 green corridors and crossable sidewalks that integrate with commercial areas from residential areas must be prioritized in order to facilitate walking.

To further visualize the “Resilience Context” you've established in the discussion, the following table summarizes the city's trajectory:

Feature	The Theoretical Plan	The Resilient Reality (2010–2025)
Land Use	Managed green belts & agricultural protection	Rapid conversion to residential to house growing populations
Urban Density	Compact, walkable neighborhoods	Low-density sprawl due to emergency housing needs
Governance	Strict adherence to Vossing/2014 maps	Adaptive/Flexible governance prioritizing safety and trade
Technology	Standard paper/digital cadastral maps	High-precision GIS (1.5cm accuracy) and E-management

Table 6: The end result of the review (Planning vs. Reality). Source: Created by the author

1 ABSTRACT

Cities and municipalities face major challenges in times of climate change. As key actors in the transition towards climate neutrality, they require analysis, planning, decision-making processes and services to help them prioritise and justify the necessary measures and activities.

One option for data-based decision-making is the use of satellite-based services. The Urban Sky research project is therefore collaborating with representatives from Austrian cities of various sizes and structures to identify challenges and needs. This information will be used to develop satellite-based services concepts for urban planning, neighbourhood development, natural hazards, and urban mobility, while taking into account the relevant legal and normative framework conditions.

The project focuses on using freely available data such as that from the Copernicus programme. The aim is to explore the potential of the satellite data, review its feasibility and combine it to create useful services. The project also assesses the added value for cities, the market potential and the research requirements, and categorises and prioritises the services, resulting in actionable recommendations. To achieve this, the following research questions are answered: (1) What challenges do Austrian cities face regarding urban and neighbourhood planning? (2) How can satellite data help to solve these challenges? (3) Taking into account spatial and temporal resolution, what additional data and information is required to use satellite data effectively to overcome these challenges?

Following a literature review, the topics were narrowed down to the following areas: buildings; green spaces and biodiversity; infrastructure; mobility; natural hazards; urban planning; and spatial planning. These areas were further discussed and specified during the first Stakeholderworkshop, which was attended by representatives of several Austrian cities varying in population and structure. Particularly urgent needs were identified focussing e.g. on buildings and potential renovation, solutions to reduce heat energy losses and the potential for redensification. In the field of natural hazards, key topics included small-scale air temperature monitoring and the development of early warning systems for floods or agriculture. In the context of infrastructure, the focus was on the detection of damage after extreme weather events and the analysis of photovoltaic (PV) potential in car parks. In addition, priorities were identified in the following areas: recording of traffic movements and parking space usage (mobility); calculating the degree of greening and tree canopy cover to comply with the EU Nature Restoration Regulation; and smart irrigation management (green spaces). Other priorities included urban heat island monitoring and climate risk analysis (urban planning).

The applications are primarily based on time-series data from optical satellite missions, such as Sentinel-2 and commercial very high-resolution satellites like Pléiades, Synthetic Aperture Radar (SAR) missions (such as Sentinel-1, NISAR, and future ROSE-L), and thermal missions, e.g. TRISHNA, ECOSTRESS, and the upcoming Land Surface Temperature Mission (LSTM) from the European Space Agency (ESA). A key outcome of the Urban Sky project is a structured study on the potential of satellite technology for urban and neighborhood planning. The study identifies and analyses existing satellite applications in cities (both nationally and internationally), and assesses their compatibility with current geodata sources. Based on the

stakeholders‘ requirements, the study proposes ten potential applications to serve as a foundation for further RTI (research, technology, and innovation) initiatives.

Keywords: satellite data, services, stakeholder-driven, urban planning, climate resilience

2 INTRODUCTION

Climate change poses multiple challenges for Austrian cities and municipalities. As the main contributors to greenhouse gas emissions, they are required to implement climate mitigation measures in order to meet both national and international climate goals. However, urgent action is not only required due to legislative requirements; cities are also the most severely affected by the consequences of climate change such as urban heat islands (UHI), heavy rainfall events and biodiversity loss. Therefore, they must develop comprehensive adaptation strategies. This pressure has been further intensified by the European policy framework. While the European Green Deal (European Commission, 2019) established the ambitious ecological targets, its successor, the Clean Industrial Deal, introduced in February 2025 (European Commission, 2024), has shifted the focus towards competitiveness and efficient implementation. Within this new framework, local authorities are not only required to prove ecological compliance (e.g., under the Nature Restoration Regulation (Regulation (EU) 2024/1991)) but are also urged to accelerate planning and permitting processes to foster economic resilience. Recent policy analyses emphasise this pivotal role, arguing that cities act as the 'central architects' of the Clean Industrial Deal, because they directly control critical levers such as land use, transport, and energy systems (C40 Cities, 2025). To fulfil this role and tackle these challenges of 'greening' and 'speeding up,' administrations urgently need scalable, evidence-based decision support systems.

To meet these requirements, urban planning authorities and decision-makers need accurate, up-to-date and comprehensive data. Traditional survey methods (terrestrial surveying, aerial surveys, local sensors) are often costly and updated at intervals that are too long to monitor dynamic changes. Satellite-based services (Earth observation – EO), in particular cost-free data, e.g. as provided by the European Copernicus programme, offer enormous potential in this regard. They provide continuous time series on parameters such as surface temperature, soil moisture and vegetation density. Nevertheless, practical experience shows that this potential has not yet been sufficiently exploited in municipal administration (Murgante et al 2024, Gulyás et al. 2025, Strand et al 2025).

A major obstacle to the integration of EO data is the discrepancy between large urban agglomerations and smaller municipalities. Large cities often have specialised GIS departments and budgets for commercial data, but face the challenge of complex inner-city structures and extreme pressure on land use. Small and medium-sized towns – the majority of Austrian municipalities – are often confronted with limited human resources and municipal finances, resulting in a lack of expertise to process raw data and budget for expensive software solutions. Therefore, the solution must not consist of providing even more raw data, but must lie in the development of tailor-made, cost-efficient services that can be directly integrated into existing administrative processes.

The Urban Sky research project addresses this topic. The aim is to identify the specific needs of stakeholders using a demand-driven approach in order to develop concepts for services supporting their urban challenges. The focus is on freely available data (open data) in order to lower the financial hurdle for local authorities.

This paper presents the results of the stakeholder process and the needs analysis. In order to derive recommendations relevant to action, this article addresses the following research questions:

(1) What challenges do Austrian cities face regarding urban and neighbourhood planning?

(2) How can satellite data help to solve these challenges?

(3) Taking into account spatial and temporal resolution, what additional data and information are required to effectively use satellite data to overcome these challenges?

3 METHODS

An initial literature research and review was conducted to gain an understanding of the field of satellite data and Earth observation for urban planning. The results were used to set up a first online Stakeholderworkshop, which aimed to gather information on the needs of cities´ representatives regarding their goal to become climate neutral cities. During the workshop, the participants were asked to consider

their daily challenges and what they would like to change. The impressive variety of anwers enabled us in various internal workshops to come up with over 15 service concepts which have been prepared with descriptive texts and graphical abstracts and are currently being evaluated by our stakeholders in a comprehensive online survey. Based on the results, the best ranked ideas will be detailed in a second Stakeholderworkshop. For the prioritised ten final results, a roadmap will be developed including an assessment of added value, market potential, future research needs, and feasibility.

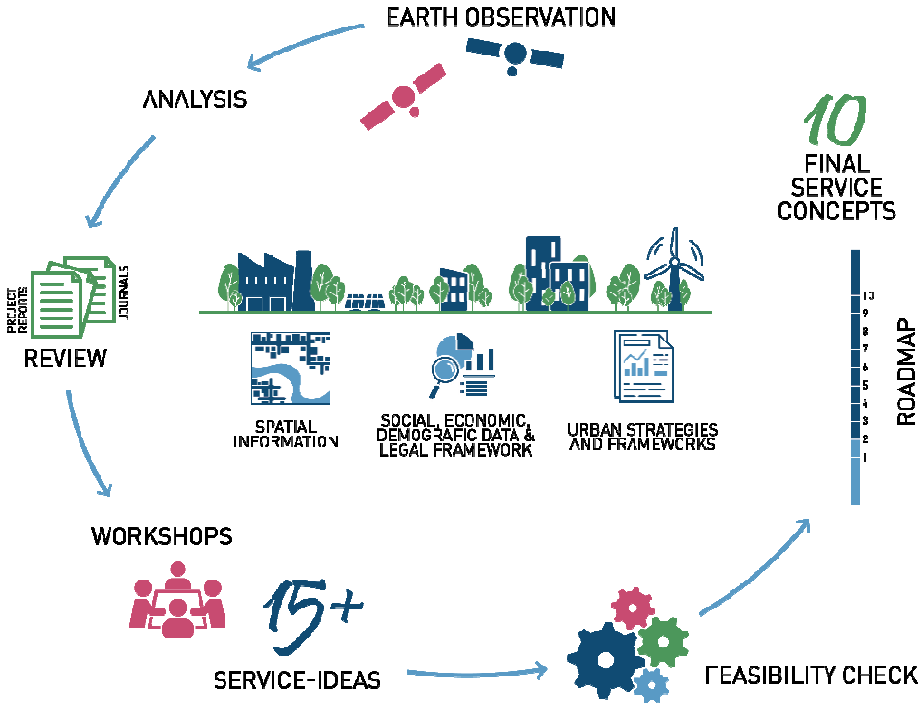

Figure 1: Urban Sky Project Plan © AIT

4 URBAN REQUIREMENTS AND PRIORITY FIELDS IN AUSTRIAN CITIES

Based on the literature review, the topics were clustered in priority fields that were used throughout the stakeholder process. Although there are overlapping areas, the priority fields help to classify and get an overview of most important topics for the cities: Urban Planning & Urban Climate, Buildings & Energy, Green Spaces & Biodiversity & Water management, Natural Hazards, Mobility & Infrastructure. The following section summarises the stakeholder inputs.

4.1 Results of the needs assessment

4.1.1 Priority Field: Urban Planning & Urban Climate

One of the main topics that were discussed during the stakeholder workshop was the field of "Urban Planning and Urban Climate". Throughout the conversations, climate-related risks emerged as a cross-cutting concern that should not be overlooked.

The following topics were highlighted in the discussions:

- The importance of systematic monitoring and assessment of urban heat islands and surface temperatures, with a particular focus on public spaces. Participants discussed the need for city-wide assessments considering perceived temperatures, shading conditions, cold air corridors and monitoring the quality of stay. This information is essential to identify priority areas for heat mitigation and support climate risk analyses at neighbourhood scale.
- The need to identify and reactivate brownfield sites and vacant urban areas including large, sealed surfaces such as parking lots and increasingly also privately-owned sealed green spaces. Sealed surfaces were highlighted as major heat traps and therefore high-priority targets for cooling-oriented reuse and redesign. For the participants it was important to prioritise adaptation, renovation, and climate-sensitive redevelopment over new greenfield construction, as well as monitoring changes in

land use, vacancy and unused spaces over time. Therefore, change detection was considered one interesting topic to be supported by using satellite time-series data.

- Additionally, monitoring of light pollution was discussed as an important topic as the view from above reveals unnecessary electricity use and shows where light can be reduced and energy saved.

4.1.2 Priority Field: Buildings & Energy

The field of Buildings & Energy was one of the central topics discussed during the stakeholder workshop as it is one of the main levers to reach the goal of climate neutrality and energy efficiency in cities. The following topics were discussed:

- Updating and improving existing building inventories, including the identification of conditioned and non-conditioned building areas was seen as essential to support reporting obligations under the revised Energy Efficiency Directive EED III (Directive (EU) 2023/1791), which requires member States to improve the availability and consistency of data on building energy performance.
- Closely linked to this, stakeholders highlighted the need for the detection of thermal energy losses through the building envelope to identify renovation priorities.
- The assessment of rooftop solar potential including shading was identified as crucial to assess seasonal yields to support the usage of renewable energy and strategic energy planning.
- In addition, the monitoring of green roofs was highlighted as an important climate adaptation measure. From an EO perspective, time-series analyses allow vegetation development and vitality to be monitored in a consistent and city-wide manner. This is relevant not only for building owners/tenants to assess, whether green roofs effectively contribute to heat mitigation, but also for city administrations to verify the performance of (potentially) subsidised measures, ensure the effective use of public funding, and support strategic planning and monitoring of urban climate targets.

4.1.3 Priority Field: Green Spaces & Biodiversity & Water management

The stakeholders ranked the priority field “Green spaces, Biodiversity and Water Management” as very important. This was particularly pertinent given the future tasks arising from the implementation and enforcement of the EU Nature Restoration Regulation (Regulation (EU) 2024/1991), a key element of the EU Biodiversity Strategy (European Commission, 2020). The discussions covered the following topics:

- Quantitative and qualitative mapping of tree populations (including tree species, crown diameter/tree canopy cover and height) and changes therein (such as tree health), with the aim of establishing a baseline in accordance with the EU Nature Restoration Regulation.
- Another closely related topic was efficient and sustainable irrigation management (smart irrigation), with a view to preserving tree health and adapting to changes of vegetation period. This included the question of automation.
- Green spaces, particularly trees, were regarded not only as a means of mitigating urban heat, but also as a steppingstone for establishing resilient biodiversity.

4.1.4 Priority Field: Natural Hazards

The topics discussed in the “Natural Hazards” priority field were diverse and naturally overlapped with those in other priority fields. There were overlaps, particularly in the “Green Spaces” priority field.

- The participants prioritised two topics regarding climate change: the small-scale monitoring of inner-city air temperatures, and the identification of areas where cold air forms.
- The monitoring and management of neophytes and invasive species (as a biological natural hazard) currently was mentioned as a contribution to biodiversity. However, the use of EO was questioned and deemed ineffective.
- Stakeholders also identified the assessment (and monitoring) of stormwater events or flooding in urban areas as essential (for assessing the risk situation, for designing danger zones, and for the

identification of gaps and lack of protective measures). However, it was noted that responsibility actually lies with higher levels of administration. The same applies to the topic of mass movements.

4.1.5 Priority Field: Mobility & Infrastructure

The focus area of "Mobility & Infrastructure" was a broadly discussed topic in the stakeholder workshop.

The main topics resulting from the exchange among workshop participants who came from various professional background regarding needs assessment for mobility can be narrowed down:

- Monitoring of commuting and traffic patterns, more specifically a request was to monitor long-term the change rate on the used traffic corridors and streets as well as the frequency of its use and the number and types of vehicles using which road when. This topic was also discussed from the perspective of congestion and traffic frequency, road utilization, peak times, and improvement of traffic flow.
- Monitoring the transit traffic in its amount and main routes used with the aim of developing seasonal deviation roads easing the main routes.
- Monitoring the intensity and frequency of utilization of parking lots by using multi-temporal satellite acquisitions (mornings, middays, evenings and nighttime) over a longer period to detect daily as well as weekly or seasonal patterns.
- Monitoring the traffic of cyclists to raise the share of modal split cyclists. E.g. systems for counting bicycles, traffic flow measurements with smart cameras have been discussed.
- CO_2 and energy accounting of traffic: Especially transport of goods and cargo, but also public transport and general transport of passengers. The assessment of this need focusses on measurement of plausible data instead of a model. The stakeholders mentioned punctual counts of passenger mobility and the use of telecommunication data as well as google analytics, the Google Mobility report or traffic models. The example Vorarlberg was mentioned, where a traffic behavior survey was conducted for the years 2008, 2013, 2017 and 2023 (Herry, 2024).

The focus area "Infrastructure" covered the following topics:

- Detection of infrastructure damages after extreme weather events, including the mapping of economic or monetary damage. Another perspective was the need to detect and prevent damage at an early stage, caused by excessive heat.
- There is a need to gather information on the thickness, density and persistence of snow cover for winter service and snow clearing units. This can be tied to weather and temperature scenarios including the local topography.
- Identification of parking lots which are not covered yet, as possible space for PV installation on roofs.
- Identification of gas leakages or damages along pipelines or power lines that could be caused by landslides, avalanches or storms.
- Mapping and regularly updating construction sites or road closures of each kind. This need includes regular updates on construction progress and compliance with regulations concerning deposit of sewage and construction waste.
- Monitoring the demolition of buildings for reusing its materials, to establish a proper recycling system, interim storage areas would be needed. This poses major difficulties within cities, but remote sensing can help identify brown field/fallow areas.

The following table summarises the five priority fields, and the key urban challenges identified for Austrian cities based on literature and stakeholder input.

Having established the main urban priorities and requirements from Austrian cities, the next step is to examine how current satellite-based applications can address these needs. Chapter 5 presents the key EO application domains identified in literature and international projects, providing a foundation for matching city priorities with usable Earth observation services.

Priority Field	Main Challenges	Typical EO-based use case[1]
Urban Planning & Climate	- Identification and monitoring of urban heat islands and heat stress in public spaces - Assessment of thermal comfort and quality of stay (perceived temperature) - Detection and constant monitoring of vacant areas	- Mapping of surface temperatures using EO data (Landsat, ECOSTRESS) - Identification of potential air corridors using 3D building models in combination with land cover and elevation data (Sentinel-2, LiDAR, DEMs) - Detection of vacant areas through land use classification and time-series analysis of satellite imagery (change detection) - Light pollution
Buildings & Energy	- Updating and improving building inventories - Detection of thermal energy losses to identify renovation needs - Assessment of rooftop solar potential, including shading and energy yield - Monitoring of green roofs	- EO-supported building inventory updates using Sentinel-2 and LiDAR data - Urban heat loss screening with thermal satellites (ECOSTRESS, Landsat) - Roof PV potential assessment combining optical imagery and LiDAR for shading analysis - Green roof monitoring using time-series NDVI (Normalised Difference Vegetation Index) from Sentinel-2
Green Spaces & Biodiversity	- Updating and improving green space/tree inventories - Efficient and sustainable irrigation management (smart irrigation)	- EO-supported green space/tree inventory updates using Sentinel-2 and LiDAR data - Using time-series NDVI for health monitoring of trees for maintenance and irrigation
Natural Hazards	- Small-scale monitoring of inner-city air temperatures - Identification of areas where cold air forms - Mass movement	- Validation with satellite data: ECOSTRESS (daily cycle), Landsat (long-term dynamics) or by future missions e.g. TRISHNA, LSTM - InSAR (Interferometric Synthetic Aperture Radar)
Mobility & Infrastructure	- Monitoring of commuting and traffic patterns (frequency, types of vehicles, peak times, congestion) - Detection of infrastructure damage after extreme weather events - Mapping and updating construction sites or road closures to support traffic management - Monitoring demolition of buildings and brownfield areas for potential material reuse and urban redevelopment	- Traffic pattern and congestion analysis using high-resolution optical imagery and Sentinel-2 time series - Post-event infrastructure damage assessment using Sentinel-1 SAR and optical data - Construction site and road closure monitoring through change detection on optical imagery and aerial photos - Identification of brownfield/fallow areas via high-resolution optical images and land-use data to support recycling and redevelopment initiatives

Table 1: Summary of Priority Fields, Key Urban Challenges and Relevant Earth Observation Data

5 EO-BASED APPLICATION DOMAINS IDENTIFIED IN LITERATURE AND PRACTICE

5.1 Overview of international EO-related urban projects and services

This section presents the main EO application domains identified in the scientific literature and international projects on using satellite data for urban decision-making in the context of climate-resilient cities. A literature analysis has been conducted, screening a total of almost 240 relevant projects and publications from various sources (publication databases, project databases, etc.). These were then clustered and the topics were visualised in a matrix (Figure 2). Among the sources were the FFG project database with a focus on the Austrian Space Application Programme (ASAP). The entire database was screened, and the Horizon Europe project databases were systematically reviewed. The ESA portfolio was also considered, particulary its demonstration projects and thematically relevant projects ("Infrastructure & Smart Cities") which were added to the list. Another source was a collection of ESA services which are continuously updated as a "living document". The "Urban EO Service Catalogue" (ESA, 2025a) lists a total of 17 services on urban heat (private access [11], public access [6]), 37 services on mapping urban areas (private access [29], public access [8]), and 15 services on air quality (private access [9], public access [6]). Recent activities originating from the Horizon project "Space4Cities" (Forum Virium Helsinki, 2025) were also reviewed. At the beginning of 2025, the project launched a €2.87 million call for proposals, and the winners have now been announced. Ten of the 20 selected consortia will now have the opportunity to further develop their solutions to common challenges in European cities, such as flood detection, identifying heat islands, reducing traffic emissions, preventing wildfire risks, protecting cultural heritage sites, locating underground pipe leaks, and monitoring the condition and changes of green spaces, bridges, and roads. The five best prototypes will then be tested in real-life situations in fifteen European cities from July 2026 to February 2027 (Space4cities, 2025).

5.2 Key thematic clusters identified in the literature

The urban planning theme covers projects that develop digital models (e.g. digital twins, 3D models) for analysing urban structures, vegetation areas and thermal properties, and for supporting planning decisions.

[1] Details on satellite technology see chapter 6.

They differ in their specific fields of application, which range from mapping green spaces, analysing the urban heat island effect and solar potential, improving urban resilience and adapt to climate change, optimising urban mobility and parking space utilisation, to automated mapping of land use and land cover (FFG 2026b; ESA, 2026), and supporting visually impaired people in urban areas. Projects in the field of heat islands deal with the combination of satellite data, meteorological information and climate models in order to obtain the most up-to-date or real-time picture possible of urban overheating areas (Cure-Copernicus, n.a; Geoville, 2025; LUP, n.a.; LAND, 2026). Surface temperature maps are created using satellite data or aerial survey data in order to provide cities with a basis for decision-making when planning green and blue infrastructure (Stadt Konstanz, 2025; UrbanFootprint, 2026). Covering the building domain, the creation of digital twins is common, both for individual buildings and for entire neighbourhoods (Buildspace Project, 2026). Projects adressing green spaces aim to monitor and optimise green spaces and their ecological functions (biodiversity, cooling potential, biotope areas, etc.) (BOKU, 2025; GrünStattGrau, 20, FFG 2026c). One project covering many of these aspects is the Green Transition Information Factory (GTIF), an ESA initiative designed to demonstrate the added value of EO. The Austrian GTIF currently covers various narratives tackling the named topics like Heat Risk Maps, High-Resolution Forecasts of Solar Potential and Extreme Temperature, Brownfield Recovery Potential, Wind Atlas, Urban Energy Performance Monitor (GTIF Austria, 2026).

In the field of natural hazards, projects focus on the early detection, monitoring, documentation and prediction of specific hazards such as forest fires or flooding, as well as on the creation of dynamic, comprehensive hazard maps. The projects differ in terms of the natural hazard they address, such as fire, water or mass movements, the level of detail in the analysis (from large-scale monitoring to specific hazard locations such as aquaplaning) and the focus of application (real-time warning, support for authorities, traffic safety, dynamic mapping) (FFG, 2026a; Joanneum, 2025; FFG, 2026d).

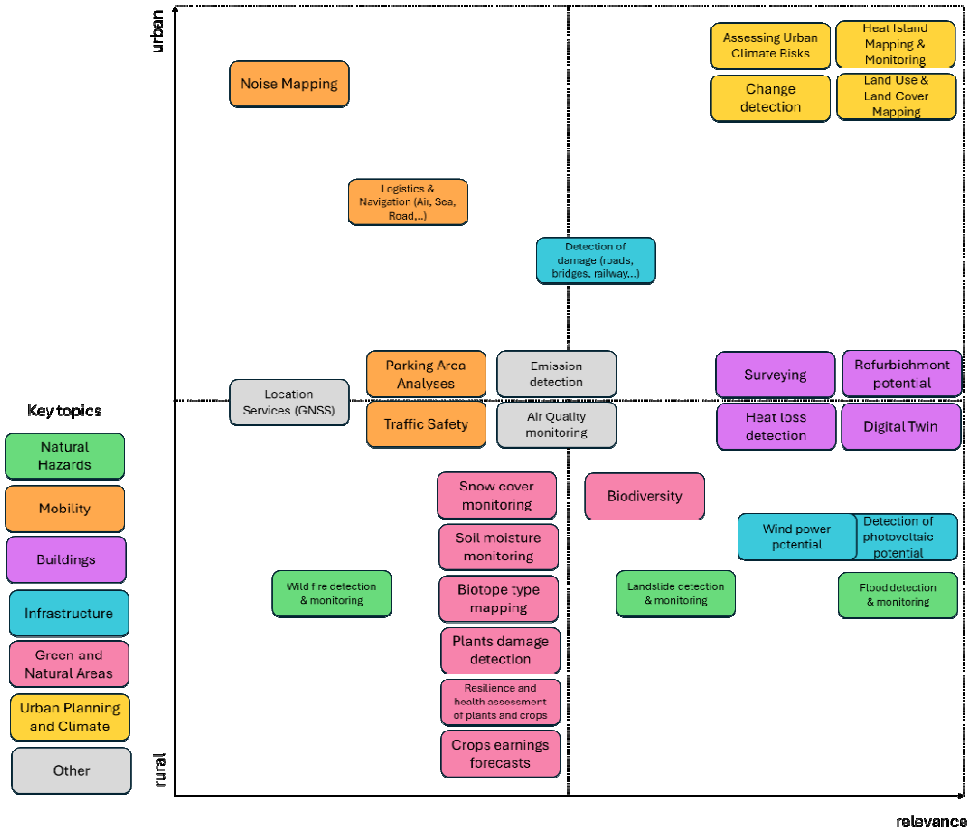

Figure 2: Illustration of the subject areas narrowed down into relevance, rural and urban focal points © AIT

Projects in the field of mobility and infrastructure aim to optimise and secure transport systems and monitor infrastructure. The applications range from high-precision positioning for accident prevention and route optimisation for cyclists to satellite-based detection of available parking spaces and road conditions. Due to space constraints only two of the 22 identified projects covering mobility are quickly mentioned. Firstly, SatPark is a completed FFG project from 2019 covering georeferencing, identification and classification of

vehicles based on satellite data to enable improved parking space analysis and navigation (FFG, 2026e). Secondly, ESERCOM-D is a project concerning the implementation of satellite-based data to support greener and smarter road usage, optimise road maintenance, and enhance traffic safety (EU-Project, 2026). In addition, solutions are being developed for the management of infrastructure assets such as power grids, street lighting and dams in order to improve their maintenance and resilience. In the literature analysis 17 projects and services have been identified that are within the field of infrastructure monitoring. For example, the FFG project RAVEN developed a radar-technology-based methodology for detecting structural and ground movement changes in urban buildings, enabling improved monitoring of infrastructure stability and early warning capabilities (FFG, 2026e).

The literature review confirms a strong alignment between international EO-based urban services and the needs expressed by Austrian cities, particularly in the domains of urban climate, buildings, and natural hazards. However, gaps remain regarding spatial resolution, operational integration into municipal workflows, and long-term sustainability of services.

6 SATELLITE DATA SUPPORTING URBAN DECISION-MAKING

6.1 Relevant satellite data types for urban applications

Optical, radar (SAR) and thermal satellite data each provide unique strengths and are suited for specific applications. To address the complexity of urban planning tasks, they are often combined to facilitate the complementary information content, which they provide.

Due to often limited resources in cities, they need to pay attention to costs. Therefore, for urban applications, it is crucial to distinguish between freely available satellite data and commercial datasets. Open-access Copernicus missions such as Sentinel-1 SAR and Sentinel-2 optical provide consistent, long-term time series with high temporal coverage, making them well suited for continuous monitoring and trend analysis for cities. Thermal open access data such as e.g. ECOSTRESS can be applied to assess urban heat dynamics such as e.g. UHI mapping and heat stress analysis. Commercial datasets such as Pléiades (Airbus, 2026) offer very high spatial resolution and are valuable for detailed analyses at building or object level. Due to higher costs and task-based acquisitions, they are typically used selectively, complementing freely available data where finer spatial detail is required.

6.2 Future satellite missions and their potential for urban applications

While these currently operational satellites already provide valuable data for urban applications, a new generation of satellite missions, both public and commercial, will significantly expand the availability of high-resolution, freely accessible, and near-real-time Earth observation data. These missions will provide a valuable addition to existing satellite missions, thereby offering Austrian cities enhanced capabilities for monitoring, analysis, and decision-making. The main new satellite missions are:

- TRISHNA (Thermal Infra-Red Imaging Satellite for High-Resolution Natural Resource Assessment): A French-Indian mission scheduled for launch in 2026, TRISHNA will provide thermal data at 57 m resolution, bridging the gap until Sentinel-8 LSTM becomes operational. Its focus on water resources and land surface temperature makes it highly relevant for heat stress monitoring (CNES/ISRO, 2025).
- Sentinel-8 LSTM (Land Surface Temperature Monitoring): Planned for launch in 2029, LSTM will deliver land surface temperature data at 30–50 m resolution with revisit times of 1–3 days. These EO data will be crucial for monitoring urban heat islands, energy efficiency, and climate adaptation strategies (ESA, 2025b).
- ROSE-L (Radar Observing System for Europe in L-band): Expected launch in 2028, ROSE-L will operate in the L-band, enabling penetration through vegetation and cloud cover. With 5–10 m resolution and revisit times of 3–6 days, it will support applications such as infrastructure monitoring, flood risk assessment, and land cover monitoring (ESA, 2025b).
- NISAR (NASA-ISRO Synthetic Aperture Radar): already launched in 2025, NISAR offers comparable L-band SAR capabilities as ROSE-L, providing early access to datasets relevant for European urban resilience planning (for details see: NASA, 2025).

- FireSat: Developed by the Earth Fire Alliance with partners including Google Research, FireSat aims to deliver near-real-time global fire detection with a 20-minute revisit cycle when the full constellation is operational. The first protoflight satellite launched in March 2025, and the system will expand in coming years (Earth Fire Alliance, 2025).
- HotSat Constellation (Satellite Vu): Following the HotSat-1 demonstrator (2023), HotSat-2 and HotSat-3 are planned for launch soon. These satellites allow monitoring of heat stress and detection of heat losses in buildings and industrial facilities, supporting energy efficiency measures in cities (SatVu, 2025).
- CO3D (Constellation Optique 3D): Jointly developed by Centre national d´études spatiales (CNES) and Airbus Defence and Space, CO3D was already launched in 2025, and the commercial phase is expected to begin in 2027. It will generate high-resolution 3D surface models, enabling systematic urban morphology analysis and supporting spatial planning. Global coverage is expected within 3–5 years, with annual updates for priority regions (CNES, 2025).

The integration of these missions into Austrian urban planning frameworks offers several opportunities for Urban Climate Resilience:

- Enhanced monitoring of heat islands, water resources, and vegetation.
- Improved early warning systems for floods and fires.
- Detailed 3D urban models for infrastructure resilience and redensification strategies.
- Support for compliance with EU regulations such as the Nature Restoration Regulation.

Together, these missions represent a paradigm shift in satellite-based services, enabling cities to access actionable, high-resolution data for climate-resilient developments. Combined with existing Copernicus datasets and local geodata, this information forms the backbone of future applications and can now be turned into practical services to address municipal priorities, as presented exemplarily in the next chapter.

7 SERVICE DEVELOPMENT

7.1 Translation of requirements into service concepts

Based on the first Stakeholderworkshop, the consortium developed over 15 initial service concepts that directly address the priority fields identified by Austrian cities. The concepts cover a range of urban challenges, including climate resilience, energy efficiency in buildings, mobility and infrastructure, and natural hazard monitoring. These concepts were briefly described with graphical abstracts and evaluated by stakeholders through an online survey providing feedback on relevance, feasibility, and potential impact. This participatory approach ensured that the concepts reflect real municipal needs and priorities. For example, some ideas already highlighted ways to monitor urban heat hotspots or assess rooftop solar potential – practical services that cities could implement. The most promising concepts will be refined in a second workshop and translated into a roadmap, including their potential value, feasibility, and research needs. This process ensures that the resulting services are actionable, relevant, and ready to support decision-making in Austrian cities.

7.2 Legal, regulatory and organizational considerations

Legal, regulatory and organisational aspects play a crucial role in determining whether EO-based services can be operationally adopted by cities. Rather than acting as barriers, these framework conditions define boundary conditions that must be systematically considered during service design, implementation and long-term operation.

Within the Urban Sky project, the legal framework is primarily shaped by European and national regulations governing data protection, data governance, environmental monitoring and the use of geospatial information. A central element is compliance with the General Data Protection Regulation (GDPR), particularly where EO-derived data is combined with auxiliary datasets that could enable the identification of individuals or sensitive urban patterns. Objects or locations captured in very high-resolution imagery that can be linked to specific individuals – such as homes, vehicles, or other personal property – constitute personal data under the GDPR. Although EO data are typically non-personal, downstream processing, data fusion and spatial

resolution must be carefully assessed to avoid indirect personal data inference. Consequently, privacy-by-design and data minimisation principles are integral to the development of Urban Sky services.

In addition, the regulatory environment for spatial data infrastructures plays a significant role. The INSPIRE Directive (Directive 2007/2/EC) establishes common standards for the harmonisation, interoperability and sharing of geospatial data across public authorities within the European Union.

From an environmental and urban governance perspective, EO-based services operate within a framework of sector-specific regulations related to climate adaptation, air quality, land use planning and disaster risk management. In this context, the EU Nature Restoration Regulation (Regulation (EU) 2024/1991), which entered into force in 2024, introduces legally binding targets for the restoration of degraded ecosystems, including those located in urban and peri-urban areas. Organisational considerations are closely intertwined with the legal framework. The adoption of EO-based services requires clear role definitions between data providers, service operators and municipal end users. Responsibilities related to data stewards, quality assurance, liability and long-term maintenance must be contractually defined to ensure sustainability.

In summary, the legal and organisational framework provides a structured environment that shapes service development and deployment. By addressing these conditions proactively, Urban Sky aims to ensure regulatory compliance, institutional acceptance and long-term usability of EO-based services for urban decision-making, thereby supporting their transition from pilot applications to operational tools within city administrations.

7.3 Example Services

While this paper focuses on cities needs and the development and evaluation of the services, an analysis of their potential economic benefits for cities and stakeholders will be addressed in follow-up work. Nevertheless, two example service concepts are briefly described here to provide an idea of the direction.

7.3.1 Heat Dynamics

The service aims at enabling automated recording and analysis of spatio-temporal heat dynamics in urban areas in Austria. It provides cities with detailed insights to assess urban thermal stress and serves as a decision-making aid for urban planning and climate adaptation. The service combines multiple freely available datasets to ensure accurate and actionable results. This includes thermal satellite time series from ECOSTRESS, TRISHNA, Landsat, and in the future ESA-LSTM, calibrated and validated with meteorological station data from GeoSphere Austria. Additionally, Sentinel-2 optical imagery, land use data from zoning plans or the Copernicus Urban Atlas, aerial imagery, and LiDAR-based terrain and vegetation models are integrated to capture the urban landscape in detail. By merging these sources, the service identifies heat hotspots, monitors changes over time, and provides practical guidance for urban planners aiming to reduce thermal stress.

7.3.2 Remote sensing for the implementation of the EU Nature Restoration Regulation in cities

The aim of the service is to assess and support the restoration of urban ecosystems in Austria based on satellite remote sensing. The focus is on implementing Article 8 of EU Nature Restoration Regulation, in particular ensuring "no net loss" of urban green spaces and tree canopy cover by 2030. It integrates multiple freely available datasets to provide accurate and actionable insights. These include Sentinel-2 optical time series, land use data from zoning plans, the Copernicus Urban Atlas, aerial imagery and LiDAR, and the LUCAS land cover inventory (Eurostat, 2026). By combining these sources, the service derives ecological indicators, monitors changes over time, and guides planning and management decisions for greener, healthier urban environments.

8 CONCLUSION AND OUTLOOK

Based on the current findings of this study, satellite-based EO has strong potential to support cities on their way to climate-neutrality by providing consistent and spatially accurate information for planning, monitoring and decision-making. Freely available EO data already enable cities to better assess their key challenges such as heat stress, maintaining green infrastructure, detecting natural hazards, identifying buildings and tracking land use changes over time in a transparent and comparable way.

A key advantage of satellite data lies in the nature of the data itself, which makes it usable by stakeholders from different sectors: Mostly freely available access, automated and frequent updates, a holistic view from top and the ability to visualise continuous areas. This enables satellite data to be applied and transferred to all fields of application that benefit from change detection and continuous monitoring, spatially and temporally. Due to changing legislations on monitoring and reporting obligations, satellite data technology is becoming increasingly relevant.

To maximise the user uptake of the ESA Programme (e.g. Copernicus and Galileo) and address gaps in spatio-temporal resolution, the project is moving towards a multi-modal data fusion strategy for the considered services. This strategy synthesises freely available Copernicus and Galileo data, as well as non-remotely sensed data (e.g. socio-economic and/or environmental data), and considers commercial satellite products. Integrating non-remotely sensed data is essential, because satellite sensors alone cannot provide the services needed to adress cities´ specific needs. Adding, combining and layering data from multiple sources enables the development of services which might allow to monitor rapid, localised events, that would otherwise remain undetectable by single-sensor platforms or single data sources, and to respond to them in a timely manner.

Using satellite data strengthens transdisciplinary collaboration both horizontally across municipal departments and vertically between different administrative units and economic actors. In this context, start-ups and specialised service providers play an important role as experts in providing satellite data understanding and following the fast changes in this rather young technology. Public administration can benefit from the fast advancements of the Earth observation sector in terms of data-based decision-making and completely new perspectives on data collection.

So far, there is still a lack of communication and common ground between data providers, researchers and end users such as in public administration. This means that offered services often do not align with the requirements of public administration and are therefore less likely to be implemented and a fix component of running systems. For this reason, the Urban Sky project plays a valuable role in ensuring the practical applicability of solutions developed using satellite data.

9 ACKNOWLEDGEMENT

This research is carried out under the Urban Sky project, on behalf of BMIMI and KLIEN by the Austrian Research Promotion Agency (FFG) together with Austria Wirtschaftsservice Gesellschaft mbH (AWS). The call “Technologien und Innovationen für die Klimaneutrale Stadt” (Technologies and Innovations for the Climate-Neutral City) is part of the R&I focus "Klimaneutrale Stadt" (Climate-Neutral City) of the Federal Ministry for Innovation, Mobility and Technology (BMIMI) and the Climate and Energy Fund (KLIEN).

1 ABSTRACT

Community engagement and feedback has often been pinpointed as the weakest link in sustainable neighbourhood transformations. The living lab approach has been known as a promising methodology for engaging with multi-stakeholder groups in real-life contexts, yet studies have shown that engagement is rarely achieved in practice in many living labs. In this paper, we suggest it is helpful to take a process orientation to cut through the clutter of living lab literature, focusing on the "how" of establishing "living labs". We posit that it is most imperative in this process to put people in focus, foregrounding their specific needs, interaction, and wellbeing and channelling their competences and experiences towards urban regeneration.

Drawing inspiration from the literature that focuses on innovation-oriented living labs and based on a case study of organising and leading six living labs for community engagement in social renovation and energy transition in six European cities from 2022-2025, this paper will advance a methodology for establishing a living lab approach towards community engagement for urban regeneration. We suggest focusing on five phases to get going on the ground with the living lab networking approach– Scope, Map, Implement, Learn and Enhance – the S.M.I.L.E. methodology, What stands out from prevailing living lab approaches is Scope and Map. Scope foregrounds the importance of users (in their various roles) and the community. In this first step, a deep understanding of the citizens and community demographics regards citizens as catalysts of innovation and that their inputs can lead to better informed and robust outcomes in various measures and solutions. Map envisions all the actors relevant for the development of the socio-technical solutions and facilitates the possibility to review the congruence of their interests. Adopting the living lab approach requires thorough understanding of important actors' objectives and drivers, the alignment of operational processes, and establishment of open and collaborative culture. The S.M.I.L.E. methodology provides a pragmatic point of departure for a living lab facilitator responsible for engagement activities, whether newly set up and as an extension of ongoing programmes.

Keywords: Community engagement, Sustainable neighbourhood transformation, Living Lab approach, Stakeholder engagement, Deep renovation

INTRODUCTION

Decarbonising the urban built environment requires integrated innovations and solutions across climate mitigation, large scale renovation and urban greening. To meet the EU's ambitious climate and energy efficiency goals, the rate of deep building renovations must increase. In this regard, the interest in accelerating deep renovations on a neighbourhood scale has arisen as the adequate scale to adopt for essential solutions such as inclusion of renewable energy resources and decentralisation of energy production. In other words, going beyond the limits of the single building has become the more efficient and effective unit to work with. However, it has also been increasingly recognised that working on the larger neighbourhood scale is challenging as it requires integrated innovations and solutions involving multiple actors across different sectors (Sassenou et al. 2024). Indeed, stakeholder involvement, community engagement and feedback has often been pinpointed as the weakest link in sustainable neighbourhood transformations. Concomitantly, living labs have been known as a means to structure stakeholder and user involvement in innovation processes (Leminen et al. 2012, Almirall & Wareham 2011, Rizzo et al. 2021). However, in the rather young living lab research domain, there is no consensus yet regarding supporting theories and frameworks. This has resulted in a proliferation of projects and approaches carried out under the 'living lab' umbrella in a very loose sense that is not reaping the benefits of a living lab approach (Schuurman et al. 2013; Veeckman et al. 2013). In this paper, we distill our experience from planning six living labs for community engagement in social renovation and energy transition in six European cities. We suggest it is helpful to take a process orientation to cut through the clutter of living lab literature, focusing on

the "how" of establishing "living labs" as a promising platform for engaging with multi-stakeholder groups in real-life contexts.

This paper is organised as follows. We start with a review of relevant literature to understand the different types of living labs and specifically foreground the type of living lab focused towards multi-stakeholder collaboration and knowledge sharing. We do so to apply the living lab concept to community engagement efforts within the EU Green Deal project "ARV"[1] (https://greendeal-arv.eu/) which aims to demonstrate and validate attractive, resilient, and affordable solutions for a sustainable neighbourhood concept known as Climate Positive Circular Communities (CPCCs). The paper asks: How can a living lab approach be established for varying ambition levels of community engagement, communication and education towards sustainable neighbourhood transformations? Based on empirical insights from six demonstration communities with the ARV project, we advance a five-phase methodology for establishing a living lab approach towards community engagement for urban regeneration. We then discuss the implications of adopting a process orientation to living labs for research and practice before concluding the paper.

2 THEORY

This sections grounds the understanding of the living lab approach within the living lab literature focused on types of living labs, characteristics and outcomes, highlighting the need to establish a better understanding of how to plan and set up living labs in the practical sense. Based on the literature, the first sub-section presents a living lab typology to help make sense of the many types of living labs out there. Next, we review relevant literature looking for key dimensions that must be clearly defined and planned for when establishing a living lab. The third sub-section highlights variations in ambition levels in terms of community engagement, where metaphors such as "wheel of participation" have been used to characterise them.

2.1 Types of living labs

The living lab has been conceptualized as an environment (Ballon et al., 2005), a methodology or innovation approach (Bergvall-Kåreborn et al., 2009), an organization or an innovation intermediary (Schuurman et al., 2013), a network (Leminen and Westerlund, 2012), and a system (ENoLL – https://enoll.org/living-labs/). This lack of common consensus makes it difficult to advance research focused on living labs. To better understand the different typologies of living labs, a useful starting point is to distinguish between the American vs. European notion of living labs.

The first use of living labs in its present connotation was in MIT. This American notion of Living Labs describes a laboratory environment with all facilities of a regular home, optimized for multi-day or multi-week observational studies of single individuals and constructed to resemble a 'real' home as closely as possible (Schuurman et al., 2025). This American notion of Living Labs sees the Living Lab concept merely as a physical research facility that tries to overcome the artificial lab-context.

In Europe, the living lab movement has been gaining momentum since 2006 with the founding of ENoLL and the number of living labs has been growing (Schuurman et al., 2025). The overall aim of the ENoLL as an international federation of Living Labs is to support the creation of a dynamic innovation system throughout Europe. Two types of living labs can be distinguished within this European notion: living labs supporting context research and co-creation vs. living labs as extensions to testbeds (Følstad 2008). On the one hand, living labs supporting context research and co-creation would be based on an identified problem and focused on developing a solution in close interaction with end-users, or on the iterative finetuning of innovative products or services, tapping into the innovative capacity of test-users. On the other hand, living labs as extensions to testbeds describe testbeds (controlled network environments for test and validation) for e.g. ICT services (see Ballon et al. 2007).

According to Schuurman et al. (2013), a fourth type of living labs can be further distinguished. This final type is more focused towards multi-stakeholder collaboration and knowledge sharing, with less emphasis on developing and testing of new technologies and on deep end-user involvement. This fourth type of living lab are long-term and are intended to involve prolonged engagement with communities.

[1] ARV's meaning in Norwegian: "heritage" or "legacy"

2.2 Key dimensions for establishing an urban living lab

The living lab methodology has become a prominent approach in sustainable neighbourhood planning and development, often referred to as urban living labs.

Juujarvi and Pesso (2013) distinguish three types of urban living labs. First, urban areas can serve as technology-assisted research environments such that the living lab facilitators can collect feedback on products and services through webpages or sensor-based methods. Second, users can co-create urban artifacts and local services, such as communal yards, garden allotments or daycare services. Citizens are viewed as co-creators who contribute to designing and developing local services such as renovation processes. Third, an urban living lab can develop new kinds of urban planning using new tools and processes with the engagement of citizens. The goal is to facilitate vision-making of the area and planning processes, and increase the access and mutual learning of stakeholders. In this manner, the urban living lab can serve as a platform for stakeholders to participate in a neighbourhood's renovation initiatives and decision making.

One strand of living lab research positions living labs as a way to address the complex challenges of sustainable urban transitions and neighbourhood development through citizen engagement. When collecting the varieties of living lab definitions, Steen & Van Bueren (2017) structured them by defining four dimensions that must be clearly defined and planned for when establishing an urban LL:

- aim (a. innovation, b. formal learning for replication, c. for urban Living Labs: increasing urban sustainability)
- activities (a. development, b. co-creation, c. iteration),
- participants (a. public actors, private actors, users, knowledge institutes, b. decision-making power), and
- context (a. real-life use context).

In another study, based on empirical research from four living labs in Belgium and Finland, Veeckman et al. 2013 has discussed the characteristics and outcomes of living labs as a collaborative innovation approach and introduced a living lab pyramid to provide practical guidelines for organising living labs to foster user-centred innovations. The living lab pyramid framework consists of three pillars: living lab environment, living lab approach, and the innovation outcome. While one base of the pyramid anchors the living lab environment, considering technical infrastructure, ecosystem approach, level of openness, community, lifespan, scale, and real-world context, the other base of the pyramid secures the attention to the living lab approach, emphasizing evaluation, context research and user roles. The pinnacle of the pyramid addresses innovation outcomes, linking them to strategic intention, knowledge, resources, and partnerships.

Van Geenhuizen (2018) suggest attention should be given to both intended outcomes and unintended outcomes of living lab processes and results.

- Outcomes in the sense of intended outcomes include a better knowledge of user wishes and speeding up and bringing more solutions to market (e.g. Veeckman et al., 2013).
- Unintended outcomes may also happen. These include the absence of desired outcomes as well as adverse effects, and both are to a certain extent connected with bad predictability of influences and processes.

2.3 Mix of ambition levels for community engagement

Leminen et al. (2012) emphasize that living labs are open-innovation networks. Based on which actor drives the activities, living labs differ from one another in terms of activities, structure, organization, and coordination (Westerlund & Leminen, 2011). For example, living lab activities can be provider-driven when the innovation activities of the living lab aim to develop a solution for participants or other stakeholders, or have an educational purpose. Living lab activities can also enabler-driven, taking a bottom-up approach, when the activities focus on fulfilling the needs of a local community or association like improving the local social development where the living lab is located.

Nowadays, the Living Lab approach can be understood as an attempt to bridge the gap between multiple actors through directly involving them into the process of developing or transforming an urban neighbourhood (Steen & Van Bueren, 2017). However, a key finding of Steen & Van Bueren (2017)'s

review is that half of the living labs did not directly involve users, while the other half organised participation processes. It is apparent that engagement is challenging to achieve in practice in many living labs. Steen & Van Bueren, (2017) point out that the lack of participation may be a result of discrepancies between the methods used in practice and the ambitions of urban living labs defined in an early phase.

Arnstein`s ladder (1969) conceptualizes public involvement in decision-making as a hierarchy ranging from nonparticipation to full citizen involvement. However, studies have also put forth alternative frameworks to Arnstein's (1969) ladder, such as the wheel of participation (Davidson, 1998) as a more appropriate metaphor to deal with different levels of citizen engagement. The wheel promotes the appropriate level of community involvement to achieve clear objectives, without suggesting that the aim is always to climb to the top of the ladder. This wheel metaphor thus beckons the importance of a mix of engagement levels in living lab approaches to effectively channel citizens' experiences and competences.

Summing up

Taken together, to reap the benefits of living labs for collaboration and knowledge support activities, a systematic process orientation to the living lab concept is required. Living Lab facilitators working on the ground are in need of a simple methodology that is practical and easy to apply. Furthermore, a high degree of engagement is not always required to deliver change processes and implement sustainable solutions. The transformative potential of an urban living lab can also be realised with a low level of user involvement. As the literature points out, the 'higher level of engagement, the better' is not the aim. Instead, it is more important to consider the right form of engagement at the right time. This paper asks: How can a living lab approach be established for varying ambition levels of community engagement, communication and education towards sustainable neighbourhood transformations?

3 RESEARCH APPROACH

This section outlines the research approach. It is based on six living labs for community engagement focused on deep renovation. We draw on ongoing results from the EU Green Deal project 'ARV' (https://greendeal-arv.eu/) which aims to demonstrate and validate attractive, resilient, and affordable solutions for a sustainable neighbourhood concept known as "Climate Positive Circular Communities" (CPCCs).

A CPCC in the ARV project is defined as an urban area which aims to achieve net zero greenhouse gas emissions, enables energy flexibility, and promotes a circular economy and social sustainability. This novel concept focuses strongly on the interaction and integration between new and regenerated buildings, users, and energy systems, facilitated by ICT to provide attractive, resilient, and affordable solutions for citizens.

3.1 Purposeful sampling

To better understand the task of establishing a living lab approach for community engagement, purposeful sampling was relied upon. Purposeful sampling, or specifically criterion sampling, is widely used in qualitative research for the identification and selection of information-rich cases related to the phenomenon of interest (Creswell, 2009). A range of diverse strategies that can be used in purposeful sampling in accordance with different objectives (Palinkas et al. 2015).

Two widely used strategies for purposeful sampling include the identification of unusual phenomena from extreme cases as well as the identification of patterns of variation from heterogeneous cases. A third strategy can also include the simplification of the analysis and the emphasis on similarity from homogeneous cases or convenience sampling that emphasise collecting information from willing participants. While the first two strategies focus on describing the variability or dispersion of values, the third is used primarily to reduce the range of variation and identify similarities.

In line with this study's objective of increasing our understanding of how to establish a living lab approach for community engagement, we relied on the third strategy of purposeful sampling. This choice reflects our aim to deepen insight into the complexities of developing a living lab approach across the pilot sites and to provide detailed accounts of their contexts, aims, actors, and activities. This purposeful sampling strategy is particularly interesting where relationships between actors extend both horizontally, between organizations at the same level in the network context, and vertically from state to local stakeholders.

Various activites were carried out to interact, engage and collaborate with the multiple actors in the six demonstration communities in the ARV project during 2022-2025. These activites include, among other

things, stakeholder mapping, one-to-one meetings, workshops and events. Actvities conducted in the six demonstration communities were systematically registered in respective living lab logbooks over the four years. Furthermore, the community engagement activites were described and analysed in reports as a part of the deliverables for the ARV project.

3.2 Overview of cases

For this study, six pilot sites in different climate zones of Europe were used as cases. Within the EU Horizon 2020 project ARV, Climate Positive Circular Communities were designed and implemented in Oslo (Norway), Palma de Mallorca (Spain), Karviná (Czechia), Utrecht (Netherlands), Trento (Italy), and Sønderborg (Denmark), offering diverse contexts for examining living lab approaches to community engagement.

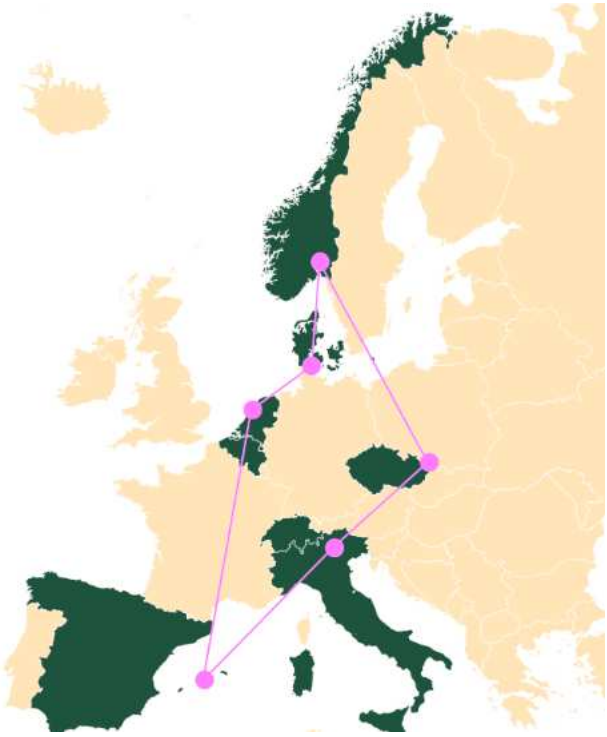

Fig. 1: Map of ARV demonstration sites in Oslo (Norway), Palma de Mallorca (Spain), Karviná (Czechia), Utrecht (Netherlands), Trento (Italy), and Sønderborg (Denmark)

4 FINDINGS

In a nutshell, the pilot sites encompass the development of a plus energy school and cultural area in a former industrial site in Oslo, Norway, energy upgrades of multi-family blocks with district heating in Sønderborg, Denmark, industrialized renovation of social housing in Utrecht, the Netherlands as well as in Trento, Italy, the transformation of an health care centre into a living lab for CPCC in Karvina, Czechia, and urban transformation of a city district in Palma de Mallorca, Spain.

Based on the place-based experiences of establishing a living lab approach for community engagement in the six pilot sites, we distill the most important aspects that stand out in its community engagement activities.

CPCC Demonstration Site (Neighbourhood)	**Understanding social contexts and embeddedness**	**Defining Goals and outcomes (the innovations)**	**Target groups to engage**	**What was learned**	**Enhance (what to do better next time wrt. Community Engagement)**
Oslo (Voldsløkka)	Location of the school bridging east and west Oslo; the need for a non-homogeneous façade appearance, and the highly ambitious energy goal for the building building-attached photovoltaic	Create awareness and understanding and hence acceptance and maintenance of these innovations/solutions BAPV and BIPV	Pupils of the secondary school (Voldsløkka school) and the culture school (Voldsløkka Culture Station) Building professionals	Long presentations on sustainability aspects did not attract the pupils.	Pupils liked contextualized and playful formats – such as climate bootcamps, board game co-creation, and prototyping – which helped translate abstract concepts into tangible understanding.

	(BAPV) and building-integrated photovoltaic (BIPV) panels on the East, West, and South façades, and on the roof. Outdoor stormwater solution.		Municipality planners		
Sonderborg	Cost-optimal design to reduce district heating return temperature[2] from substation systems in multi-flat buildings.	Tenants' usage of heating and radiator thermostats varied very much among apartments; activities were initiated to help the tenants to operate the radiators in an optimal way.	Tenants	Engaging representatives of residents (Green ambas-sadors) to help tenants using energy soluti-ons properly	Representatives of the housing organization visited each household to inform and engage the residents as a substitute for the green ambassador program.
Utrecht (Overvecht)	Social renovation process where the tenants are actively offered help before, during, and after renovation. Diffrent stake-holders were brought together.	These partners simultaneously implemented interventions to improve the tenants' conditions, such as work, mental support, healthcare, housing, social contacts, and finances. reduce renovation stress. Helps establish more trust in institutions and government in the neighbourhood.	Tenants Municipality actors	Multi-disciplinary coordination (housing, welfare and health workers) reduced tenant stress and prevented social issues. But, the colla-boraion needed time and effort, to create a common understanding.	To transfer the competence in the housing coorporation and the collaborative mechanisms among the social partners. In Overvecht, this alignment (multi-disciplinary coordination) has since become more efficient and has resulted in long-term collaboration that extends beyond the social renovation projects themselves.
Trento	End-users' perspectives have been addressed by a noise and dust perception campaign targeting the installation of the 'Renew Wall' kit vs. ETICS.	Cost optimization of the prefab kit vs. business-as-usual solutions	Tenants – elderly	Terminology "indoor comfort" By using existing communication channels and local dialect to communicate with and engage residents, the building manager made the residents to feel more comfortable and reassured and to build trust.	Using familiar means to communicate with tenants (especially when they are elderly people) will be a more effective way to engage them.
Karvina	Renovation of existing health care centre note context: region that has historically been built on coal mining) Health Centre –as an "educational building" (Note presence of vocal groups in the Czech Republic who are strongly opposed to the Green Deal and related sustainability topics)	Getting a building ready for PED development as an educational platform, and to stem outflow of young people	Centred on education and engagement of young citizens, particularly pupils aged 14 to 19. institutional stakeholders such as energy centres, schools, hospitals, and public service providers.	Spark interest in the topics of energy transition and sustainability and to foster a deeper connection between the youth and their region, with the broader ambition of motivating them to stay or return and contribute to local development Identified that long lectures to educate and encourage the youth to gain	To gather diverse perspectives on sustainability and identify potential roles for these institutions in future city projects. Youth: not overly technical tasks, importance of simplifying the content and incorporating more creative, hands-on elements for students to express their ideas. Institutional stakeholders: Projects must have specific, realistic goals,

[2] Reducing the district heating return temperatures from buildings allows the main district heating network to operate with a lower temperature level, which again allows the district heating company to utilize energy sources at a lower temperature level, enhancing the utilisation of energy produced by heat-pumps, excess heat from factories, cooling applications, data centres, etc. In Denmark, building users are economically rewarded if they can reduce the return temperature from their buildings back to the district heating network.

				knowledge on sustainability did not work well.	demonstrate cost-effectiveness, and offer a long-term vision. "The project format" (empowering pupils to shape their learning experience and to become co-creators of the solutions) has been chosen instead of long lectures.
Palma (64 homes initiative)	Attending to the buildings most in need of renovation which are often overlooked and not eligible for subsidy.	Affordability	Architect and engineer volunteers Residents – vulnerable segment	The construction company facilitated self-construction activities by the residents themselves. This has helped reduce costs, increase neighbourhood involvement and make viable a project that would otherwise have been economically unfeasible.	Focusing adequately on empowering residents / users can be beneficial.

Table 1: Components for establishing a living lab approach for community engagement

5 DISCUSSION

In this section, we discuss the type of living labs that best characterise the ARV living labs. We point out the most important components that living lab facilitators work with for establishing living lab activities. In our effort to channel the insights from the empirical material into a practical approach supporting community engagement, communication and education, we advance a five-phase methodology useful for getting community engagement activities up and running (whether new and as an extension of ongoing programmes). At the same time, we also point out the limitations of this methodology.

5.1 Living labs for multi-stakeholder collaboration and knowledge sharing

The ARV living lab activities have been focused on long-term collaboration and knowledge exchange. The activities in the Utrecht and Sonderborg demonstration sites are continuing existing programmes, while those of Oslo, Trento, Karvina and Palma are new programmes.However, long-term collaboration and knowledge exchange is hard to achieve if a living lab is project-based and unless there is a dedicated living lab facilitator.

In ARV, we observe that activities already embedded in stakeholders' established practices evolve quite differently from those introduced solely through the project. For example, Utrecht municipality had some headstart with working with the concept of social renovation and has collaborated with the housing associations prior to ARV. It also has the ambition to continue this work beyond the project period. Likewise, Sonderborg housing association has been working to deepen the trust with its tenants. In contrast, other demonstrations – such as Oslo – set up short term Living Lab activities that were created primarily to meet ARV's requirements. As a result, sustaining long term collaboration becomes challenging when enduring structures and organizational anchoring are not in place. We also observe that it is challenging to keep focus on the innovation outcomes once engagement activities take a life on its own.

Initial learnings point to the importance of identifying and prioritising the target groups to reach out to and establishing a deep understanding of the social context. Regarding target groups, at times, this can be planned such as the elderly residents in Trento. For Palma, the urgency and oppurtunity to reach out the a vulnerable segment of the neighbourhood presented itself when a building was no longer safe enough for pedestrians in its vicinity. As for social context, in Karvina, the understanding that a sizeable segmnet of the population in this region of Czech Republic are strongly opposed to the Green Deal and related sustainability topics is indispensable when planning and putting together the engagement activities.

The stakeholders that could make a difference also have to be systematically mapped out. In the case of Sonderborg, the district heating supplier is an important actor to enable the 'aftercooling concept', working in conjunction with the housing association.

The living lab facilitator is the instrumental actor for sustained interest and coordination of activities. A pragmatic approach to achieve a level of knowledge exchange commensurate with predefined goals makes the wheel metaphor appropriate for ARV living labs.

5.2 Five phase methodology: S.M.I.L.E.

Based on the insights from literature and the on-the-ground realities faced by ARV living labs, we propose a five-phase methodology to get community engagement activities up and running (whether new and as an extension of ongoing programmes). Community engagement is a difficult task, and some tools will be helpful to living lab facilitators and practitioners.

The diversity of the ARV demonstrations and the planned activities across the living labs demanded a coherent and structured approach for the living lab facilitators, practitioners and the researchers. As shown in Figure 2, a systematic process orientation to living labs can use five phases to get community engagement activities off the ground– Scope, Map, Implement, Learn and Enhance – the S.M.I.L.E. methodology. The idea of the SMILE methodology was developed to offer all project participants of ARV a common framework recipe for planning the activities, implementing them and reflecting on the results. Building on the key dimensions of living labs described by Steen and Van Bueren (2017), the S.M.I.L.E. methodology aims to operationalize these dimensions by providing a more concrete, step by step roadmap for designing, conducting, and following up living lab processes.

We outline each phase in more detail:

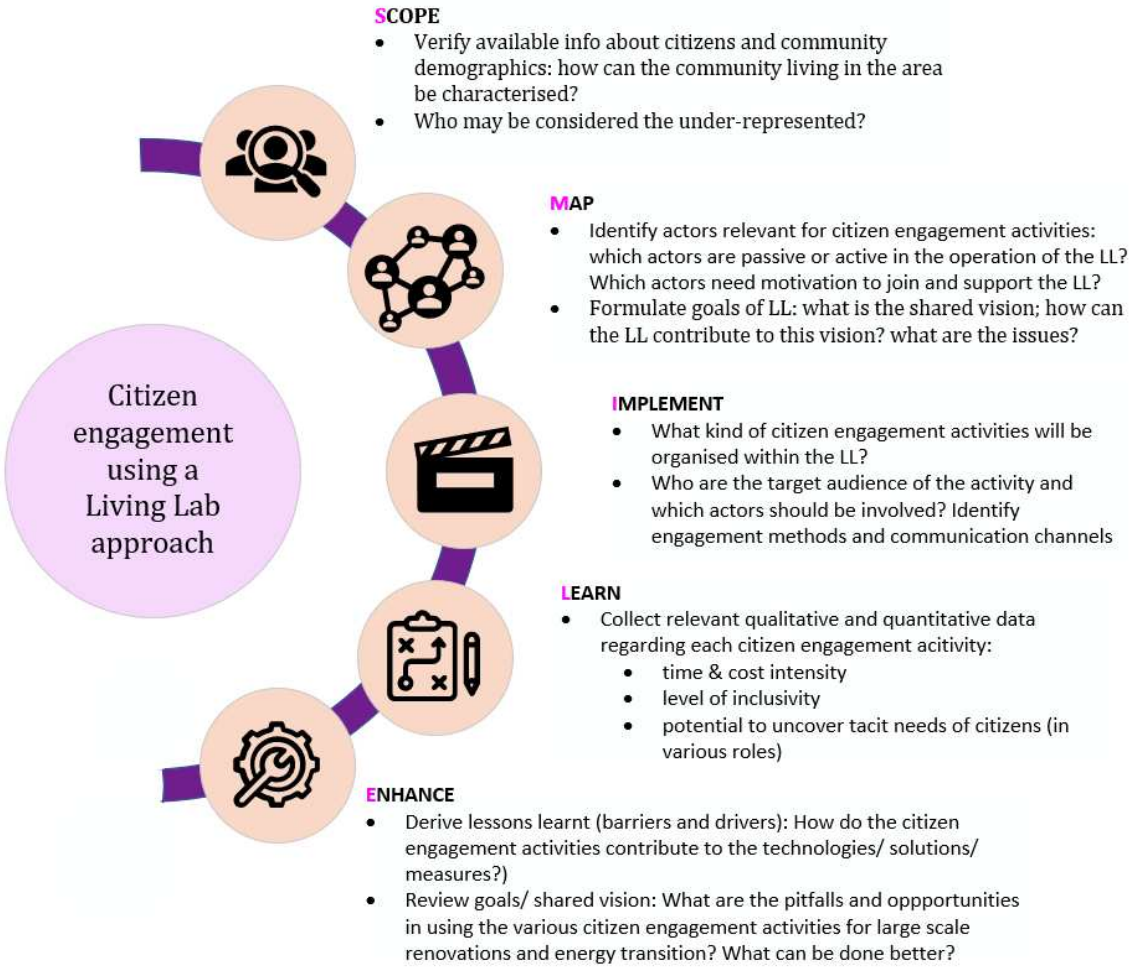

Fig. 2: The 5 phases of the S.M.I.L.E. methodology to reap the benefits of living labs for collaboration and knowledge support activities

Scope: In the first phase, Scope identifies the target groups. This foregrounds the users (in their various roles) and the community and focus the attention on the needs of the target groups within the community. In this first step, a deep understanding of the citizens and community demographics is essential to regard the selected target groups as catalysts of innovation and that their inputs can lead to better informed and robust outcomes in various measures and solutions. In addition, only when the citizens and the community living in the area has been characterized, the question of who may be considered as the under-represented or vulnerable can then be posed.

Map: In the second phase, Map tries to envision all the actors relevant for socio-technical innovation or solution in focus. This entails identifying and mapping out all the actors, their resources and goals. It should be noted that this is a dynamic picture that needs to be regularly reviewed. The Map phase then also involves formulating the goals of the living lab. Based on which actor drives the activities (living lab facilitator), the activities, structure, organization, and coordination can then be outlined. The living lab goals are also dependent on the main actor that drives the engagement activities.

Map allows the possibility to look at the dynamic picture of relevant actors and the goals of the living lab, reviewing their congruence. Afterall, adopting the living labs approach requires thorough understanding of important actors' objectives and drivers, the alignment of operational processes, and establishment of open and collaborative culture (Schaffers and Turkama, 2012).

Implement: In the Implement phase, citizen engagement activities (information-providing activities vs. co-creation activities) are being planned, organised, and rolled out. Various citizen engagement methods and digital tools as well as communication channels may be deployed associated with the activities. The important question to keep asking here is: Who are the target audience of the activity and which actors should be involved? How to gather their insights towards the innovation/solution?

Learn: The Learn phase will be evaluate the engagement activities, the use of various methods and tools (considering the innovation outcomes) and derive lessons.

Enhance: Building on the Learn phase, the Enhance phase will suggest enhancements on the effectiveness and efficiency of the engagement methods. The three important questions here are:

- How can the community engagement activities contribute to the awareness, undersrtanding and acceptance of social and technical solutions and measures related to sustainable transformation of urban communities?
- What are the opportunities (and pitfalls) in using the various citizen engagement tools for large scale renovations and energy transition?
- What can be done better in terms of community engagement, communication and education to increase the awareness and understanding and hence acceptance and maintenance of these solutions?

5.3 Community engagement for sustainable neighbourhood transformations – distinct contribution, limitations and unintended outcomes

Sustainable neighbourhood transformations are long-term initiatives. Working at this larger scale than the building level means involving multiple urban stakeholders such as landscape architects, the user community, making the task more complex and time-consuming. Map envisions all the actors relevant for the development of the socio-technical solutions and facilitates the possibility to review the congruence of their interests. Adopting the living lab approach requires thorough understanding of important actors' objectives and drivers, the alignment of operational processes, and establishment of open and collaborative culture. The S.M.I.L.E. methodology provides a pragmatic point of departure for a living lab facilitator responsible for engagement activities, whether new or an extension of ongoing programmes, towards development of innovations and solutions that support the decarbonisation of the urban built environment.

The S.M.I.L.E. methodology tries to establish a living lab approach that firmly anchors engagement activities in the local environment, considering technical infrastructure, ecosystem approach, level of openness, community, lifespan, scale, and real-world context. Sustainable neighbourhood transformations are local place-based initiatives that require ongoing formulation of challenges in its societal context. It tries to address concerns from researchers such as Roorda et al. (2014) that we should not bracket our research effort towards only focusing on the solutions and innovations while leaving out the context and underlying

systemic challenges and problems. The task of sustainable neighbourhood transformations is fraught with difficulty, and a practical tool like the SMILE methodology can be helpful to discourage working in silos but shape collaboration in a transdisciplinary fashion across topics, allowing for adaptability and reflection to find most effective ways of sharing knowledge, creating awareness and deepening the understanding of neighbourhood-scale interventions and developments.

The distinct contribution of the S.M.I.L.E. methodology is its simple, coherent and structured approach to get all CPCC living labs going in the 6 demo sites. With identifying target groups and their needs coupled with mapping relevant stakeholders at its core, the S.M.I.L.E. methodology can be considered a vital and fundamental preparatory measure for sustainable neighbourhood transformations. It is particularly suited for laying the groundwork for developing CPCCs – places where communities thrive, with low-carbon and energy-efficient building technologies, human-scale architecture, nature-based solutions and green-blue infrastructure, and inclusive public spaces.

However, a novel concept such as CPCCs is related to the notion that durable change has been achieved only when people's hearts and minds, their values and cultural practices, and the quality of relationships they have, are transformed. Engagement activites have both intended and unintended outcomes, and the S.M.I.L.E. methodology can be futher finetuned to address the absence of desired outcomes as well as adverse effects.

6 CONCLUDING REMARKS

This paper has advanced a practical five-phase methodology in order to reap the benefits of a living lab approach towards community engagement, communication and education for urban regeneration. The S.M.I.L.E. methodology puts people in focus, foregrounding their specific needs, interaction, and wellbeing, channelling their experiences to take positive steps towards acceptance of innovations and solutions that can support the decarbonisation of the urban built environment.

As living labs can be broadly interpreted as unique spaces where different types of innovators can interact and thus benefit from synergies, diversity and cross-pollination of ideas, a simple yet practical process-oriented approach can be useful for getting community engagement activities off the ground (whether new or an extension of ongoing place-based programmes). Offering a means to cut through the clutter of projects and approaches carried out under the 'living lab' umbrella, the S.M.I.L.E. methodology is particularly suited for living labs focused towards multi-stakeholder collaboration and knowledge sharing, and for initiatives pursuing the neighbourhood scale in deep renovations.

6.1 Research implications

Depending on the living lab facilitator who drives the activities, living labs differ from one another in terms of goals, activities, structure, organization, and coordination. Deploying engagement methods and tools will have to take this into consideration. Living lab facilitators and researchers contemplating innovation-oriented living labs need to consider the intended inputs and outcomes and reframe their engagement activities accordingly when relying on the S.M.I.L.E. methodology. Varying ambition levels of community engagement should be set to allocate resources accordingly.

6.2 Practical implications

A high degree of citizen engagement is not always required to deliver change processes and implement sustainable solutions. The transformative potential of an urban built environment can also be realised with a low level of user involvement, commensurate with the ambitions set for a particular target group. It is more useful to focus on target groups and their needs, consider their embeddedness, draw out their experiences and competences, and allow these to be channelled to the socio/ technical innovations that support sustainable neighbourhood transformations. Along this vein of thinking, the S.M.I.L.E. methodology can easily be understood and applied by living lab facilitators and practitioners. As the literature points out, the "higher level of engagement, the better" does not always hold true. Instead, it is more important to consider the right form of engagement at the right time for efficient allocation of resources.

7 ACKNOWLEDGEMENTS

The research conducted in this paper has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101036723, ARV Project.

A Systematic Review of Policy and Legislative Gaps in Advancing Sustainable Human Settlements in Small Rural Towns: A Case of South Africa

Lungile Mkhize, Trynos Gumbo

(Lungile Mkhize, University of Johannesburg, Department of Urban and Regional Planning, Cnr Siemert & Beit Streets, Doornfontein, 2094, Johannesburg, South Africa, mkhizelungile425@gmail.com)
(Trynos Gumbo, University of Johannesburg, Department of Urban and Regional Planning, Cnr Siemert & Beit Streets, Doornfontein, 2094, Johannesburg, South Africa tgumbo@uj.ac.za)

1 ABSTRACT

Despite South Africa's progressive policy and legislative frameworks aimed at transforming human settlements, the unique spatial, social, and economic dynamics of rural towns remain largely marginalised within mainstream planning discourses. As rural development gains prominence in national planning priorities, the question of whether existing policies and laws effectively support sustainable rural human settlements becomes critical. This paper contends that a disconnect exists between the legislative vision and the practical realities of rural settlement development. The study aims to systematically examine South Africa's policy and legislative environment to identify gaps, inconsistencies, and biases that hinder sustainable rural development. The study employs the PRISMA method, focusing on frameworks such as Breaking New Ground (BNG), the Integrated Urban Development Framework (IUDF), the Rural Development Framework, SPLUMA, and other sectoral policies and legislation. Findings indicate that most frameworks adopt an urban-centric approach, offering limited guidance for rural spatial forms, tenure arrangements, or informal settlement upgrading in small towns. Integrated planning is often cited but seldom achieved due to institutional fragmentation and inadequate coordination across governance levels. Moreover, rural development strategies lack enforceable rural-specific standards and actionable instruments. The paper proposes a multi-level governance framework anchored in spatial justice, legislative alignment, and capacity building at local levels. It calls for the localisation of planning tools, legal recognition of rural informality, and enhanced intergovernmental synergy to ensure that rural towns are not left behind in South Africa's human settlements agenda.

Keywords: South Africa, governance, human settlements, policy implementation, rural towns

2 INTRODUCTION

South Africa's post-apartheid policy and legislative architecture have evolved with a stated commitment to address spatial inequality and to enhance sustainable human settlements. Since 2004, the Breaking New Ground (BNG) policy has served as the government's comprehensive strategy for sustainable human settlement development, integrating subsidised, rental, and bonded housing with municipal engineering and mixed-use development principles. However, critiques argue that its implementation has been uneven, particularly in rural settings where small rural towns face entrenched socio-spatial disadvantages that typical urban-biased policies struggle to address effectively (South African Government, n.d.). Spatially, the Spatial Planning and Land Use Management Act (SPLUMA) 16 of 2013 provides a unified legislative framework for spatial planning and land use management across South Africa, aiming to redress past imbalances and promote social and economic inclusion through development principles such as spatial justice and sustainability. SPLUMA mandates wall-to-wall land use schemes and Spatial Development Frameworks (SDFs) at the municipal level, requiring integrated spatial planning that equally considers rural and urban localities (Republic of South Africa, 2013). At the same time, sectoral frameworks such as the Integrated Urban Development Framework (IUDF) stress spatial transformation and integration but are frequently interpreted through an urban lens, with limited tailored guidance for rural towns despite acknowledging rural-urban interdependencies (Department of Cooperative Governance and Traditional Affairs [CoGTA], 2022). Despite these progressive frameworks, significant limitations persist in how rural settlement realities are incorporated into legislative and policy instruments. The limited guidance on rural spatial forms, tenure systems under customary authority, and informal settlement upgrading in small towns reflects broader institutional challenges. Weak intergovernmental coordination, capacity constraints at local levels, and the dominance of urban-centred planning paradigms often undermine meaningful rural integration within national settlement agendas (IUDF, 2020). This review, therefore, situates South Africa's human settlements legislative frameworks within their historical and institutional aspects, intending to identify limitations that impede the advancement of sustainable human settlements in small rural towns.

3 SYSTEMATIC POLICY AND LEGISLATIVE ANALYSIS

The literature on sustainable rural human settlements in South Africa reveals persistent deficiencies in implementation that destabilize efforts to achieve equitable rural development. A significant theme in this body of work is that historical legacies of segregation, land dispossession, and dualistic spatial planning continue to shape rural settlement dynamics, resulting in structural barriers that current policies struggle to overcome. Early analyses of rural development in South Africa highlighted how apartheid land-use regimes produced marginalised rural economies and settlement patterns, reinforcing poverty and limited access to basic services and opportunities across rural localities. These structural factors have been seen not merely as residual "backlogs" but as deeply embedded socio-economic attributes of rural spaces that require setting-sensitive policy frameworks (Makgetla 2010). A growing body of scholarship stresses that government planning instruments tend to replicate urban-centric paradigms that are ill-suited to the complexities of rural areas. For example, traditional urban planning tools embedded in Integrated Development Plans (IDPs) and spatial frameworks often assume service delivery configurations appropriate to urban densities, leading to strained institutional and fiscal capacities when applied to dispersed rural populations. Linked to this is the argument that rural spatial forms are often ignored in dominant planning discourses, which prioritise densification and economic agglomeration as if rural settlements were scaled-down versions of urban centres (South African Local Government Association [SALGA], 2019).

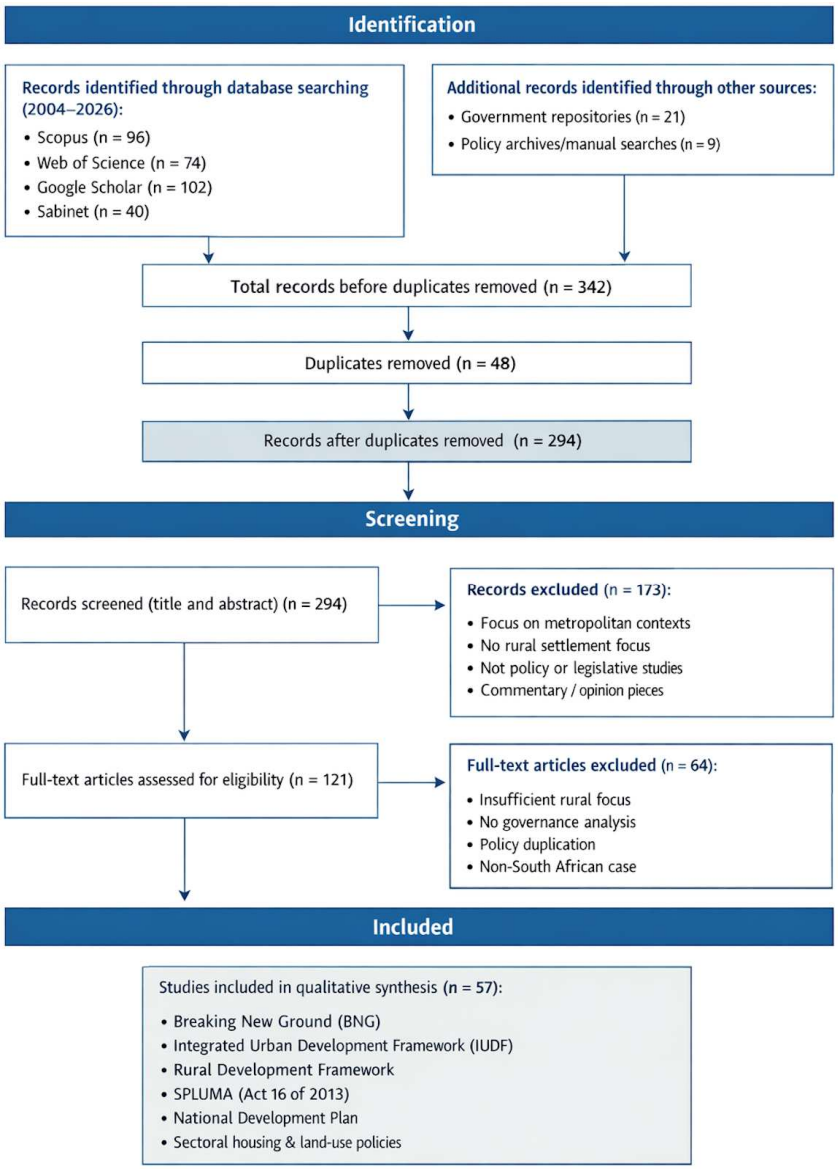

Figure 1: Review Approach

Several scholars also note the limitations of statutory planning instruments in navigating systemic constraints such as insecure land tenure and customary land governance. While SPLUMA provides a unified spatial

planning framework, its normative principles and reliance on formal land-use schemes have been critiqued for insufficiently accounting for rural land tenure heterogeneity, including communal land under traditional authorities. This tension has significant implications for sustainable settlement outcomes in rural towns where customary land rights remain central to social and economic life. In addition, recent research foregrounds the role of governance pluralism in shaping rural development trajectories. Studies advocating for frameworks such as the Rural Development and Governance Initiative (RDGI) argue that effective rural development requires mechanisms that bridge formal local government structures and traditional leadership systems, recognising that traditional authorities continue to wield considerable socio-political influence in rural areas. Such work also highlights capacity constraints and role ambiguities that currently limit the participation of traditional authorities in formal planning and governance processes (Sebola-Samanyanga, 2025). The literature highlights the need to reconceptualise rural development research and practice. Recent reviews argue for interdisciplinary frameworks that engage with rural heterogeneity, spatial justice, and governance dynamics rather than perpetuating simplistic urban–rural dichotomies. Such frameworks aim to better capture setting-specific definitions of 'rural' and integrate place-based development approaches that align policy instruments with lived realities in small rural towns. Overall, these strands of literature collectively point to an enduring policy–practice deficit in South Africa's rural settlement landscape, indicating the need for more adaptiveframeworks to advance sustainable human settlements in rural areas.

4 METHODOLOGY IMPERATIVES

This study employed a systematic qualitative review approach to investigate policy and legislative limitations influencing the development of sustainable human settlements in small rural towns in South Africa. The review was informed by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework, ensuring transparency, methodological rigour, and replicability in the identification, selection, and analysis of sources. A comprehensive and structured search strategy was implemented across academic databases, government repositories, and policy archives to capture relevant national legislation, policy instruments, and peer-reviewed literature relating to human settlements, spatial planning, and rural development, as shown in Figure 1. The inclusion criteria focused on sources that explicitly engaged with human settlements, spatial planning, land governance, or rural development within the South African setting, while exclusion criteria filtered out materials that did not address rural or small-town settlement dynamics. The selected documents were analysed using thematic content analysis, with attention given to policy objectives, underlying spatial assumptions, implementation mechanisms, and governance arrangements. Essential national frameworks, including Breaking New Ground, the Integrated Urban Development Framework, the Rural Development Framework, and the Spatial Planning and Land Use Management Act (SPLUMA), were examined comparatively to evaluate their coherence, alignment, and applicability to rural settings. This methodological approach was well-suited to interrogating a complex and fragmented policy landscape and enabled the synthesis of insights that underpin a practical, policy-oriented framework for advancing sustainable human settlement development in small rural towns.

5 ANALYSIS AND DISCUSSION

This section presents the results of the bibliometric analysis, highlighting publication trends, dominant themes, and patterns of collaboration related to sustainable human settlements. The analysis provides insight into the conceptual focus and knowledge limitations within the literature, particularly in relation to rural and small-town settuings.

Figure 2 demonstrates a marked and accelerating increase in scholarly output on sustainable human settlements from 2016–2026, with particularly strong growth after 2020. This rise coincides with renewed global and national attention to sustainability, spatial justice, and post-COVID development challenges, especially in the Global South (UN-Habitat, 2020). However, while the quantity of publications has increased, the findings of this review suggest that rural towns remain conceptually peripheral within much of this literature. Many studies framed under "sustainable development" or "human settlements" continue to privilege metropolitan, peri-urban, or informal urban settlements, often treating rural towns as transitional or residual spaces rather than as distinct settlement systems. This pattern mirrors South Africa's policy trajectory. Despite progressive post-apartheid reforms, such as Breaking New Ground (BNG) and the Integrated Urban Development Framework (IUDF), policy attention remains largely urban-centric, with rural towns frequently subsumed under broader rural development narratives or secondary cities, rather than addressed through tailored settlement frameworks.

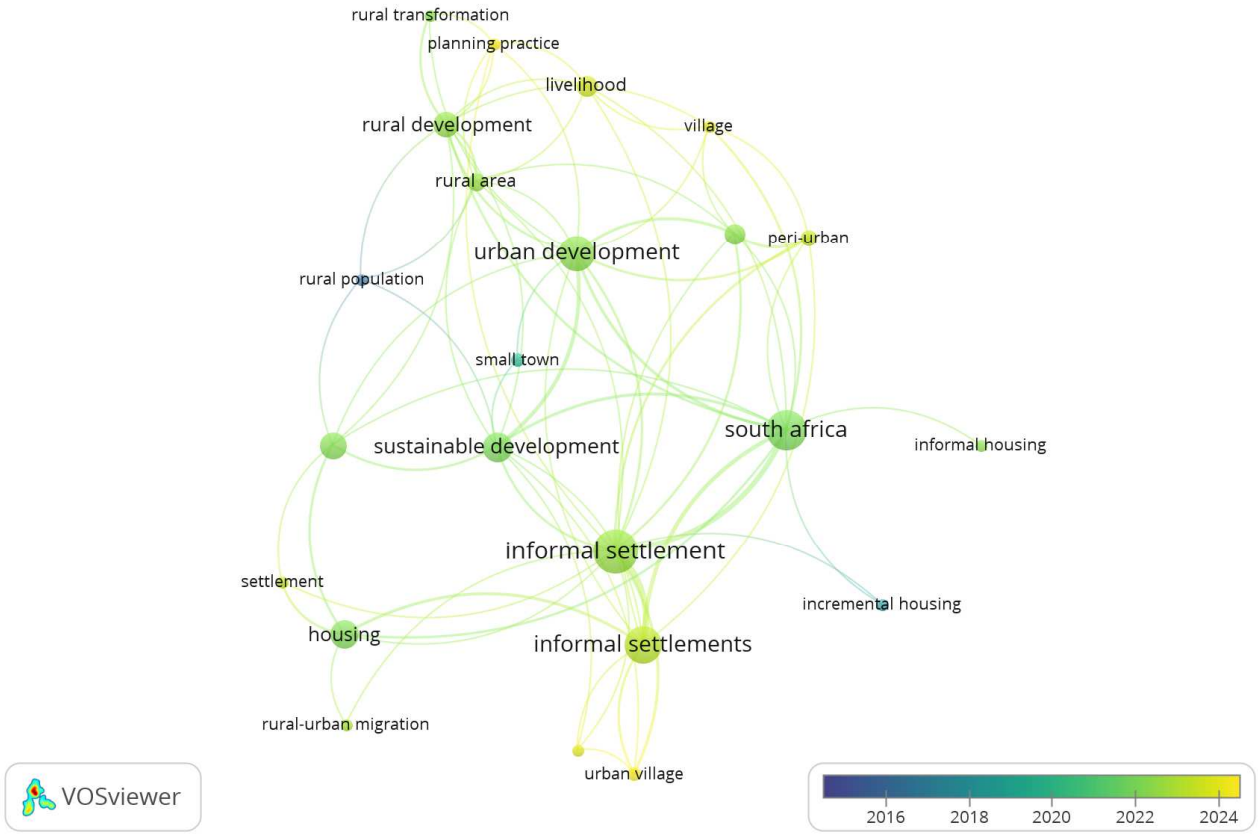

Figure 3: Keywords

Figure 3 provides a keyword co-occurrence network, offering important insights into the dominant thematic orientations shaping scholarly debates. The highly central keywords such as urban development, informal settlement(s), housing, and sustainable development suggest that the literature is primarily anchored in urban theory and practice, even when rural areas are nominally included. Informal settlements emerge as a critical concern, yet they are most often discussed within metropolitan upgrading paradigms, drawing on urban policy tools that are ill-suited to rural spatial forms. This aligns with the study's finding that informality in rural towns is poorly recognised in law and policy. Evidence from South African perspectives further indicates that effective settlement upgrading depends on legislative flexibility, strong community participation, and secure tenure arrangements, rather than solely on formal housing delivery models

(Mndzebele & Gumbo, 2023). Instruments such as SPLUMA (Republic of South Africa, 2013) provide procedural guidance for land-use management but fail to adequately address customary tenure, hybrid land-administration systems, or dispersed settlement patterns common in rural towns.

Keywords such as rural development, small town, livelihood, rural population, and rural transformation appear less central and more weakly connected within the network. This reflects a broader tendency in both scholarship and policy to treat rural towns as support spaces for urban economies, rather than as sites of autonomous development with distinct governance, infrastructure, and tenure challenges. Notably, planning practice appears weakly linked, suggesting a persistent deficit between policy rhetoric and implementation capacity. While integrated planning is repeatedly stressed in frameworks such as the National Development Plan (NDP) and IUDF, empirical studies show that rural municipalities often lack the institutional capacity, financial resources, and technical expertise to operationalise these ambitions.

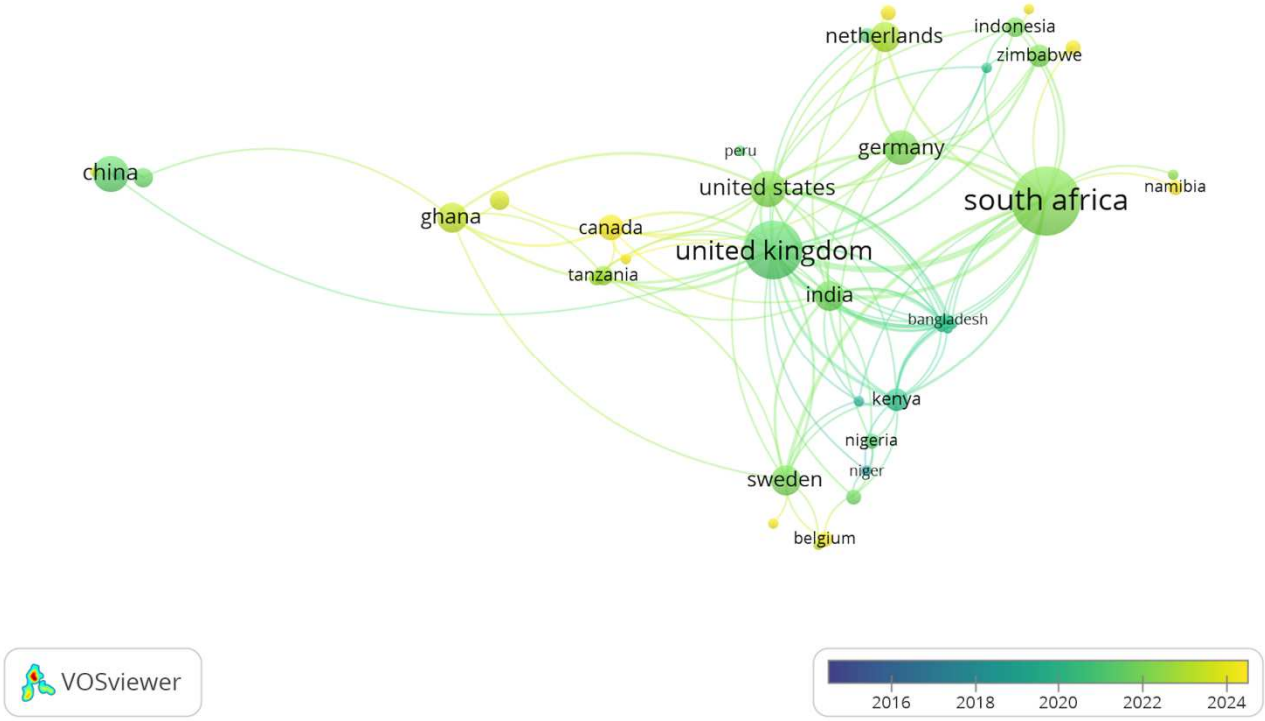

Figure 4: Countries

Figure 4 reveals the country co-authorship network in which South Africa occupies a dominant central position, strongly connected to the United Kingdom, the United States, Germany, and Sweden. This reflects South Africa's role as both a policy laboratory and a focal point for Global South urban and settlement research. While international collaboration has enriched the theoretical depth of South African planning scholarship, the findings suggest a continued reliance on Global North planning paradigms, particularly those rooted in urban sustainability, compact city models, and formalised land markets. This has important implications for rural towns. Planning approaches imported from urban or international contexts often fail to accommodate:

- communal and customary land tenure systems;
- seasonal and livelihood-based settlement patterns;
- incremental and self-built housing processes outside formal subsidy regimes.

As a result, rural towns remain legally and institutionally misaligned with the planning tools intended to guide their development.

6 TOWARDS THE INSTITUTIONAL FRAMEWORK FOR SUSTAINABLE RURAL SETTLEMENT DEVELOPMENT (IFSRSD)

This section converts the study's analytical findings into practical policy and planning recommendations intended to enhance sustainable human settlement development in small rural towns. The recommendations

are presented as an applied framework designed to promote legislative coherence, improve institutional coordination, and enable implementation across different levels of governance.

Framework Dimension	Strategic Recommendation	Primary Implementation Focus
Legislative Alignment	Introduce rural-specific provisions within existing human settlement and spatial planning legislation	Amend SPLUMA regulations, housing codes, and sectoral legislation to explicitly address small rural town contexts
Spatial Justice	Institutionalise spatial justice principles in rural settlement planning	Embed equity-based spatial criteria in SDFs and land-use schemes for rural towns
Planning Instruments	Develop context-sensitive planning tools tailored to rural settlement forms	Localised SDF templates, rural land-use schemes, and flexible zoning mechanisms
Informality Recognition	Formally recognise and regulate rural informal settlements	Legal recognition of incremental housing, customary tenure, and non-standard settlement patterns
Governance Integration	Strengthen intergovernmental coordination across rural development sectors	Clear role delineation between national, provincial, and local government spheres
Municipal Capacity	Enhance planning and implementation capacity in rural municipalities	Targeted technical support, training programmes, and resourced planning units
Policy Localisation	Enable adaptation of national policies to local rural realities	Municipal discretion to contextualise national frameworks without regulatory penalties
Monitoring & Accountability	Introduce enforceable rural development performance indicators	Rural-specific benchmarks, reporting requirements, and compliance mechanisms
Knowledge Production	Promote rural-focused research and planning innovation	Support locally grounded research, pilot projects, and practitioner-led learning
Funding Alignment	Align fiscal instruments with rural settlement priorities	Ring-fenced funding streams for rural town settlement upgrading and infrastructure

1 ABSTRACT

A major challenge in promoting sustainable mobility behavior in rural areas is the spatial structure. Mapping and modelling the causal interactions between land-use, mobility behavior, and local accessibility is associated with considerable methodolgical complexity. Accessibility analyses have to be linked with tangible applications in order to generate real added value for land-use planning. In the project move.mORe, an approach was developed, building on current research and practical findings, to use accessibility analyses effectively in advising rural municipalities on land-use planning..

Empirical evidence shows that structural parameters such as residential density, mixed land use, accessibility to public transport, and proximity to essential services strongly influence travel behavior. Areas with higher density, diverse land use, and efficient public transport connections exhibit lower car ownership rates and higher shares of walking, cycling, and public transport use. Longitudinal and quasi-experimental studies indicate that changes in the built environment can causally affect mobility behavior, although the extent of these effects is moderated by self-selection processes, whereby individuals choose residential locations aligned with their pre-existing mobility preferences. This poses challenges for researchers and planners seeking to disentangle causality from selection effects.

To address these challenges, the project move.mORe developed a multimethodological toolbox designed to support rural municipalities in evaluating and promoting sustainable mobility within the land-use planning process. The aim of the toolbox is to provide a scientifically grounded impact assessment. This enables municipalities to identify potential traffic-related effects of residential developments already in the early stages of the planning process and to develop evidence-based strategies to support the sustainable mobility of residents. On this basis, site-specific solutions can be developed to promote sustainable mobility. Policy interventions can support sustainable mobility through “pull measures” that enhance the attractiveness of environmentally friendly transport modes, as well as “push measures” that limit car dependency, such as parking management or restricted vehicle access.

The toolbox employs two primary indicators to evaluate the sustainability of the mobility in planned residential developments: traffic-related greenhouse gas emissions and the provided accessibility for residents. Greenhouse gas emissions quantify the ecological impact of transport demand generated by the development area, representing the environmental boundary of sustainability. Accessibility measures the ability of residents to reach essential destinations such as supermarkets, schools, healthcare providers, and public transport nodes within a defined travel time, reflecting the social needs dimension of sustainable mobility. Accessibility analyses within the regions and municipalities of the project area are conducted using weighted destination categories and isochrones based on the concept of “15-minute city” and transferring its ideas and applications to a “15-minute rural region”. The project’s core structure allows the analysis of these cities these “smaller” cities and municipalities in rural regions and explore different use-cases for accessibility analyses.

Keywords: toolbox, accessibility, sustainable mobility, rural areas, land-use planning

2 BUILT ENVIRONMENT AND MOBILITY BEHAVIOUR – THE INTERACTION BETWEEN CAUSALITY AND SELF-SELECTION

The development of mobility and built environment in rural areas can be described as a “vicious circle”. Since the mid-20th century, the increasing prevalence of the automobile and the expansion of car-oriented infrastructure have promoted an increasingly sprawling settlement structure. This leads to longer daily journeys and increased traffic volumes. In order to cover longer trip distances, many people rely on fast modes of transport, especially private cars, which reinforces car dependency. Increased travel speeds reduce

sensitivity to distances, leading to the acceptance of longer journeys and inducing additional car-oriented traffic flows. This in turn encourages people to choose more distant residential locations and exacerbates urban sprawl. In such structures, residents are heavily dependent on motorised individual transport and generate comparatively high greenhouse gas emissions (Holz-Rau and Scheiner 2019; Jarass 2018). This process has not only ecological but also social implications: public services are often only accessible by car, which places a financial burden particulary on low-income households and limits the social participation of people without access to a private car.

It is widely accepted in the literature that the settlement structure plays a significant role in shaping mobility behaviour of the residents and hence changes in the spatial structure can lead to changes in mobility behaviour and promote sustainable mobility (Planersocietät 2012; Holz-Rau and Scheiner 2019).Many authors assume that the mobility behaviour of residents differs depending on various built environment characteristics. Above all, constraints such as residential location, mixed land use, degree of integration into the existing road network, accessibility of daily trip destinations and developments in locations with good public transport connections can influence the mobility behaviour of residents. This is reflected in lower motorisation rates and a high proportion of enviromentally-friendly transport modes in settlement locations with good public transport infrastructure, sharing services and accessibility to daily destinations (see also Beckmann 2020). However, it should not be overlooked that individual parameters such as socio-demographic factors, lifestyles and mobility styles, as well as other structural parameters such as the transport system, also play an important role in shaping mobility behaviour and must therefore not be ignored (Beckmann 2020; Holz-Rau and Scheiner 2019; Jarass 2018).

A study by Christiansen et al. (2017) from Norway, which focuses on commuting, shows that parking availability at work and at home has a significant influence on the choice of transport. The longer the walking distance to parking at home, or if there is no fixed parking space at the workplace the less likely commuters choose the car as their mode of transport. This effect is even more pronounced when there are no parking facilities at the workplace. A combination of limited supply and additional parking fees proves to be particularly effective.

Næss (2011) examined the modal split of commutes in inner-city development projects ("new urbanism development") compared to conventional suburbs in Denver, USA. The results show that, in addition to non-spatial parameters such as transit pass ownership and socio-demographic factors, the availability of free parking at the destination is also correlated with the choice of transport mode.

Schwarze et al. (2025) demonstrate in their empirical study in Germany that walking distance to everyday trip destinations significantly increases the proportion of walking, cycling and public transport use, while reducing car use and the household motorisation levels. Multiple motorisation of households is also less common in residential areas which offer good local accessibility. Interestingly, households in such locations travel more frequently, but their journeys are shorter on average.

The longitudinal study by Bauer et al. (2005) examines the mobility behaviour of households before and after moving within the region of Dresden and shows that moving from the city centre to the surrounding area is often associated with an increase in motorisation level. This study also emphasises the role of car orientation in residential location preferences, so that moving from the city centre to a more peripheral location both requires and promotes car orientation.

Another study by Bauer et al. (2022) examines the influence of mobility concepts in car-reduced new neighbourhoods of Germany on the mobility behaviour of residents. The results show a decline in the degree of motorisation after moving, with less use of private cars in favour of public transport. In addition, the use of car sharing has increased after moving to new neighbourhoods.

A central question in the discussion on the interaction between settlement structure and mobility behaviour concerns, whether observed correlations are causal or whether they result primarily from processes of self-selection. This means that people consciously choose places to live that correspond to their existing mobility behaviour or mobility preferences (Scheiner and Holz-Rau 2007; Bruns 2014; Van de Coevering et al. 2018). Several studies therefore question the thesis that built environment characteristics alone shape mobility behaviour. Bagley and Mokhtarian (2002), for example, emphasise that the influence of built environment characteristics is often overestimated in comparison to socio-demographic variables and lifestyles.

Various methodological approaches have been developed to address the question of causality. Vance and Hedel (2007), for example, analyse variables that correlate with the urban form but are not directly correlated with mobility decisions.

Studies that use longitudinal approach to examine households before and after a move have been able to demonstrate a causal influence of settlement structure changes on mobility behaviour in some cases. A particularly illustrative example is provided by the study by Cao et al. (2019) from Norway, which uses a hybrid method combining a quasi-longitudinal approach and qualitative analysis in the form of interviews. One interviewee reported that after moving from a location close to the city centre to a peripheral location, she purchased a car, even though she had had no intention of buying a car before the move. The reason for this decision was that everyday trips were no longer feasible by public transport. This qualitative observation supports the assumption that the change in mobility behaviour was a consequence of the residential location and the built environment characteristics at the new place of residence and not an expression of pre-existing mobility preferences in the sense of self-selection when choosing a place to live.

Robert Cervero (2017) argues that sustainable mobility depends less on increasing the speed of travel and more on improving accessibility and the ability for people to reach jobs, services, and daily needs efficiently. This shift places land-use planning at the core of transportation policy. Rather than expanding road networks to ease congestion, Cervero advocates for compact, mixed-use, and transit-oriented development patterns that reduce travel distances and automobile dependence. By aligning urban form with high-quality public transit, walkability, and cycling infrastructure, cities can lower greenhouse gas emissions, improve public health, and advance social equity. Sustainable mobility is achieved not simply through cleaner vehicles, but through reshaping urban development to prioritize proximity, accessibility, and people-centered design.

3 LAND-USE PLANNING AS A LEVER FOR SUSTAINABLE MOBILITY IN RURAL AREAS

Despite the ongoing discussion on causality and self-selection there is a broad consensus that both transport mode choice and travel distances vary depending on the built environment characteristics and the spatial context (Jarass 2018; Scheiner 2009). Integrated land-use and transport planning is therefore an important planning approach, particularly with regard to ensuring that everyday destinations can be reached without a private car and creating a healthy and liveable environment (Holz-Rau and Scheiner 2019). Transport planning based on the principles of integrated land-use development forms the basis for promoting sustainable mobility behaviour. Only where suitable built environment structures and appropriate infrastructure conditions are in place do residents actually have the opportunity to adapt their mobility behaviour in favour of environmentally friendly modes of transport.

At the same time, implementing appropriate measures, such as increasing density and mixed land use, improving access to public transport stops or redesigning public spaces, often involves considerable time and financial expenditure once a settlement is developed. This makes it all the more important to consider these aspects at an early stage when planning new settlements. Nevertheless, existing areas also offer certain scope for action. The expansion of infrastructure for eco-friendly transport (e.g. through bicycle and pedestrian infrastructure, better public transport connections) and supplementary measures such as mobility hubs or parking management can provide behavioural incentives.

The spatial planning system in Germany shapes the built environment through a two-stage system of local spatial development planning comprising preparatory land-use plan (Flächennutzungsplan) and binding land-use plan (Bebauungsplan). Preparatory land-use plans define the intended types of land use for the entire municipal territory in accordance with proposed urban development strategies, aiming to address the anticipated needs of the municipality over often a ten- to fifteen-year period. These plans provide the overarching framework and serve as the foundation for binding land-use plans. Binding land-use plans constitute the principal instrument for implementing local government planning. They are developed based on the preparatory plans and contain legally binding provisions that guide and regulate urban development patterns, including the use of land for development and other purposes.

Both types of plans regulate a wide range of measeres that influence the mobility behaviour trough the built environment. For example, the preparatory land use plans affect future traffic volumes, in particular by specifying development sites and their integration into existing infrastructure. A compact, short-distance-oriented settlement structure and the concentration of new developments along high-capacity public transport

corridors can significantly enhance the attractiveness of sustainable modes of transport (SRL-FMV Working Group 2020).

Binding land-use plans adapt these objectives to local conditions and have a direct impact on accessibility and mobility behaviour through regulations on density, mixed land use and the design of public spaces. Requirements for transport facilities such as cycling and pedestrian infrastructures, bicycle parking facilities or car-parking regulations create the structural conditions for sustainable everyday mobility (SRL-FMV Working Group 2020). Once settlement structures have been established, they play a formative role in the mobility behaviour of residents for many years. Land-use planning therefore offers a fundamental opportunity to shape mobility behaviour in the long term and create the basis for sustainable mobility.

Mobility impact assessments for spatial development plans have become increasingly common in recent years, they are often limited to estimating car traffic volumes for the purpose of designing transport infrastructure. Assessing whether an urban development plan promotes or enables sustainable mobility behaviour in the long term is rarely the focus of consideration. The move.mORe project is an IHS-funded transfer project of the Karlsruhe university of applied science and Offenburg university of applied science. (IHS – Innovative Hochschule is a federal-state initiative designed to promote research-based ideas, knowledge and technology transfer).The work package “Region of Short Distances” focuses on the development of a practical toolbox that can be used to assess the extent to which specific measures at the urban land-use planning level will contribute to the development of sustainable mobility in the future. The toolbox builds on existing methodological approaches, which have been systematically combined as a multi-method approach in the project context, further developed and adapted to the specific conditions of rural areas. The adaptation to rural conditions includes the use of data from rural sites as well as the design of the toolbox for application in small not specialized adiminstrations. The aim of the toolbox is to provide a scientifically based impact assessment to support municipalities in rural areas in promoting sustainable mobility. This enables local authorities to identify the potential transport impacts of planned residential developments at an early stage of urban land-use planning and, if necessary, to take countermeasures at an early stage. On this basis, area-specific measures can be derived that promote sustainable development.

4 EXISTING APPROACHES FOR ASSESSING THE IMPACTS OF RESIDENTIAL DEVELOPMENTS ON SUSTAINABLE MOBILITY

A review of existing approaches to assessing the traffic impacts of residential developments is provided, which served as the basis for the development of the toolbox's multi-method approach. These approaches either enable an overall assessment of the plans in terms of their sustainability or focus on individual planning measures and estimate their specific traffic impacts.

4.1 Qualitative checklist: Options for establishing measures for greater climate protection in transport within the framework of binding land-use plan procedures

The Climate Mobility Competence Network (KKM) supports local authorities in promoting climate-friendly transport planning in state of Baden-Württemberg, Germany. It offers local authorities “guidance and advice on possible courses of action, contact persons and funding opportunities” (https://www.klimaschutz-bewegt.de/anlaufstelle/).

One of the KKM's tools is a checklist for the qualitative assessment of climate protection in transport within the framework of binding land-use plan procedures. The aim of this checklist is to support local authorities in avoiding traffic, expanding sustainable transport and strengthening climate-neutral modes of transport.

The checklist takes into account transport-related aspects that can be specified in a binding land-use plan. These include, for example, the location and density of development, the network of bicycle and pedestrian paths, public transport services, mobility hubs and parking management. In addition, supplementary measures that can positively influence mobility behaviour in terms of climate protection are also considered. These can be agreed upon in urban development contracts, e.g. car-sharing services, parking management or mobility consulting services.

The checklist can be applied to development area and analysed using a qualitative evaluation system. This makes it possible to assess the extent to which the planned measures of a development area contribute to

climate protection. The great advantage of this tool is its user-friendliness, which allows local authorities to easily obtain a comprehensive overview of possible specifications for promoting climate-friendly mobility.

4.2 Method for estimating the car ownership in neighbourhoods

The study "Parking space allocation and mobility concepts in residential development" by the Technical University of Hamburg, funded by the "Lebendige Stadt" foundation, uses a statistical method to estimate car ownership in residential areas and determine the necessary parking space requirements (Tahedl 2021). The investigations are based on approximately 900 neighbourhoods in the two major cities of Hamburg and Osnabrück in Germany and focus on the question of which spatial and socio-structural parameters influence car ownership. A small-scale neighbourhood-level analysis is applied.

The identified factors influencing car ownership at the neighbourhood level include: Population density and proportion of residential use in the area, walking distance to local amenities, level of mixed land use, walking distance to bus stops and their service frequency, walking distance to S-Bahn stations and their service frequency, public transport travel time to the city centre, household size or apartment size and houshold income.

Based on the assumption that the availability of parking spaces can influence mobility behaviour and, in particular, car use by residents, the underlying approach emphasises the importance of carefully determining the number of parking spaces required in the context of urban land-use planning. The aim is to contribute to the promotion of sustainable mobility behaviour through conscious control of parking space availability. In this context, it is emphasised that the decision on the number of parking spaces to be actually realised must always be made in the context of the conflicting interests of space availability, costs, requirements for public space and the goals of the mobility transition. The estimation of car ownership serves as a methodological basis. According to Tahedl (2021) it must be determined on a case-by-case basis how many of the forecasted vehicles should be allocated parking spaces and to what extent alternative mobility options can be considered as compensation.

Since the underlying factors are based on empirical data from large cities, the method is suitable for use in metropolitan areas as well as medium-sized and small cities (Tahedl 2021). For application in rural, small-sized municipalities, however, context-specific adjustments of the parameters are necessary.

4.3 Elasticity models for mode choice

Transport mode choice models based on elasticities analyse how much the demand for a particular mode of transport changes when travel time or travel costs change as a result of supply adjustments. They therefore enable an assessment of the extent to which measures that influence travel time or travel costs can change the probability of choosing a particular mode of transport. Examples of such models are the elasticity model for transport mode choice for regional routes in Switzerland developed by ETH Zurich (Vrtic and Axhausen 2000) and the standardised evaluation framework for transport infrastructure investments in local public transport, which is developed based on the empircial data in Germany (Intraplan 2016).

A disadvantage of these statistical models is that they can only take into account measures that can be quantified in terms of changes in time or cost. In addition, spatial conditions and socio-demographic characteristics have a considerable influence on elasticity. As a result, the elasticity values determined vary considerably between different studies. As Vrtic and Axhausen (2000) emphasise, the transfer of such model parameters only makes sense under clearly defined conditions and for comparable supply and demand conditions.

4.4 Estimating traffic volumes for modes of transport in development areas with Ver_Bau

The German tool for estimating traffic volume through urban land-use planning projects (Ver_Bau) serves to estimate the traffic impact of planned development projects within the framework of urban land-use planning. The tool enables a forecast of future traffic volume based on empirical values and data. It takes into account different types of areas such as residential, mixed land use, commercial and special areas, as well as large-scale retail facilities.(Bosserhoff and Vogt 2007).

The tool consists of two parts. In the first part, the structural variables and demand groups of the planned project are estimated on the basis of typical land use parameters (e.g. population density). Based on this, the expected traffic volume in the area is determined in a second step. Based on these values, other traffic-related

indicators such as modal split, travel frequency, domestic traffic shares, car occupancy rates and hourly shares in car traffic can be estimated (Bosserhoff and Vogt 2007).

While the tool can reliably predict the number of trips within an area, it has shortcomings in its assessment of the mode share and can only provide rough estimates. In order to account for the existing uncertainty in traffic generation forecasts, the results are given as ranges. A major advantage of the tool is the comparatively low time required, as the calculations are based on established parameters. Another limitation of the tool is the relatively rough estimate of traffic volume, as location-specific influencing factors are only taken into account to a limited extent. In particular, traffic-influencing factors such as the the mobility concept of the development area, measures to promote environmentally-friendly transport or connections to public transport are not taken into account.

4.5 Transfer of experience from case studies

As the above approaches are often based on studies in urban areas, their transferability to rural contexts is limited. In addition, many statistical approaches have difficulties in reflecting the complexity of real conditions in rural areas. Comparing the study area with relevant case studies can provide additional insights into the actual effects of planned measures.

However, analysing case studies presents several challenges. For example it is often difficult to identify comparable areas with similar conditions. This is particularly true in the case of new or innovative measures that have so far only been implemented in a few cases, especially in rural communities. In addition, the quantitative transferability of the observed effects is problematic, as they are highly context-dependent. Another methodological disadvantage is that, in real-world planning processes, individual measures are rarely implemented in isolation. Instead, bundles of measures are usually implemented, the effects of which influence and overlap with each other. It is therefore difficult to attribute the effects of individual measures within such a package to a specific cause. For these reasons, the uncertainty of assessments based on case studies is high.

5 TOOLBOX FOR LAND-USE PLANNING AND SUSTAINABLE MOBILITY

Despite the diverse approaches presented above, there are limitations to the evaluation of transport measures in spatial development processes. These weaknesses are particularly evident in the analysis of mobility in rural areas. Most existing approaches are primarily geared towards urban contexts and can only be applied to rural structures to a limited extent. In addition, they often focus on regional and community scales, while small-scale effects, for example at the neighbourhood level, have hardly been investigated to date. The developed toolbox addresses the limitations of previous assessment approaches. It aims to minimise the uncertainties existing in previous approaches while at the same time making targeted use of their potential. The toolbox integrates tried and tested elements from the existing approaches. So the multi-method structure of the Klima Mobil competence network checklist is used to structure the scope of the study, while the Ver_Bau tool is used as the data basis. Other approaches are used to assess the transport impacts of specific measures. The toolbox uses data from a comprehensive literature review on the transport impacts of urban land-use planning. In addition, data on mobility in rural areas from Mobility in Germany (nationwide survey of mobility behaviour: https://www.mobilitaet-in-deutschland.de) is used as a reference value.

5.1 Understanding and indicators Sustainable mobility

In order to assess the contribution of land-use planning to sustainable mobility, two indicators are used: accessibility and traffic-related greenhouse gas emissions. These indicators are based on the understanding of sustainability (Ott and Döring 2011) and the definition of sustainable mobility: enabling society to satisfy basic mobility needs while ensuring safety, health, the functioning of ecosystems and justice within and between generations (Gerlach et al. 2015; Eckart et al. 2020). In this context, “transport-related greenhouse gas emissions” (GHG emissions) represent the ecological upper limit of sustainable mobility (other possible ecological issues include air pollutants, noise, ecosystem protection, water and resource consumption), while the indicator “accessibility” marks the minimum social limit (other social issues include road safety, asset maintenance and fairness), thus reflecting the basic need for mobility. The scope for planning sustainable mobility is within these two limits. The following section describes the structure of the toolbox with its two

strands: determining transport-related GHG emissions and the accessibility of the development area (see Figure 1).

5.2 Input values for the assessment

The toolbox is based on a list of measures that influence traffic and can be influenced within the framework of German land-use planning. The toolbox is primarily based on the provisions of the German Building Code and the checklist of the Klima Mobil competence network. The measures considered were verified by an internal expert panel. The measures taken into account include: walking time to the car-parking space at home, walking travel time to the bus station from home, mixed land use, density, distance to the city center and to local amenities e.g.

The toolbox takes into account area-specific inputs, such as the planned number of residential units, the population of the municipality or the spatial typology according to the seven categories of RegioStaR (regional statistical spatial typology of the German federal ministery of transport for mobility and transport research). The input values required for the calculations are based either on data from the national survey Mobility in Germany (https://www.mobilitaet-in-deutschland.de), on the Ver_Bau tool or on user-defined specifications.

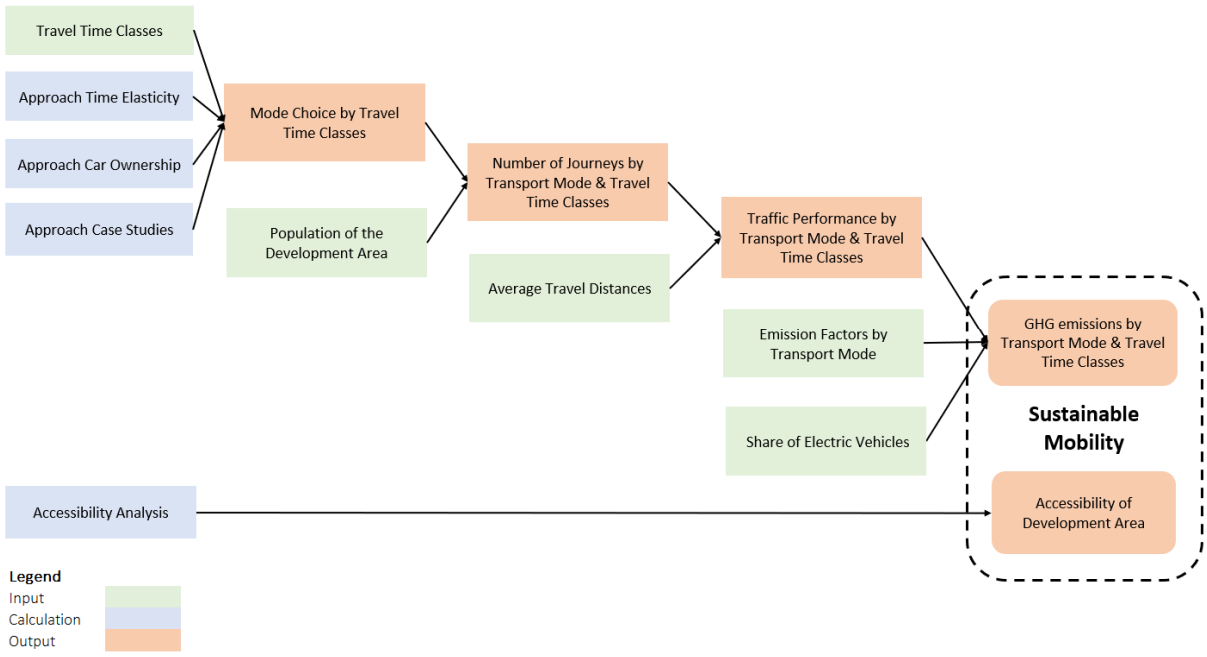

Figure 1: Flow chart of the toolbox

5.3 Determining the choice of transport mode

The modal split is a key factor in assessing the impact of planning on sustainability, as it has a significant influence on transport-related greenhouse gas emissions. Due to the inherent uncertainties of such assessments, the results are presented as ranges. The lower end of the range reflects the more conservative estimates, while the upper end represents the more optimistic effects. The impact of measures in the spatial development plan on the modal split is estimated on the basis of up to three different methodological approaches: car ownership models, time elasticity models or empirically based case studies. The approaches selected are those that are technically suitable for assessing the measure under consideration.

Within the framework of land-use planning, decisions about walking time to the car-parking space at home and walking travel time to the bus station from home are made. Measures such as the location of public transport stops, the location of parking spaces, the mixed land use and accessibility of everyday amenities have a significant influence on mobility behaviour, including the choice of transport mode. The time elasticity model is used to assess these consequences on the modal split. Region-specific boundary conditions that influence elasticity are taken into account when selecting elasticity values.

For measures that influence car ownership, the approach used to estimate the number of cars in neighbourhoods is applied. To ensure a more accurate representation of rural communities, the model was adjusted based on available published data. Due to limited data availability, additional surveys are planned.

The case study approach draws on a pool of empirical examples from the literature research and previous surveys. Suitable case studies are selected based on the measures and context. A forecast for the respective study area is created based on the relative change in the modal split in the selected case study. To calibrate the estimated modal split values, these are compared with empirical data from the project and from previous research in order to refine them and make the forecasts more realistic.

5.4 Greenhouse gas emissions

Based on the estimated range of the modal split, the number and length of trips for each mode of transport and mode-specific emission factors, the greenhouse gas emissions caused by traffic in the development area are calculated on an annual basis. A distinction is made between the emission factors for conventional and electric cars. The result is presented as an indicator of sustainable mobility in terms of the GHG emissions generated by the development area. In order to reflect the uncertainties of such a forecast, the results are presented as a range, with the lower end of the range representing the more conservative values (which will be achieved with a higher certainty), while the upper end represents the possible effects. In addition, qualitative information are provided on the conditions under which the upper or lower end of the range can be expected. It should be noted that the influence of residential self-selection is not taken into account in the toolbox assessments. This methodological limitation can lead to an overestimation of causal relationships between built environemnt and mobility behaviour. Accordingly, a reflective interpretation of the results in the planning context is required.

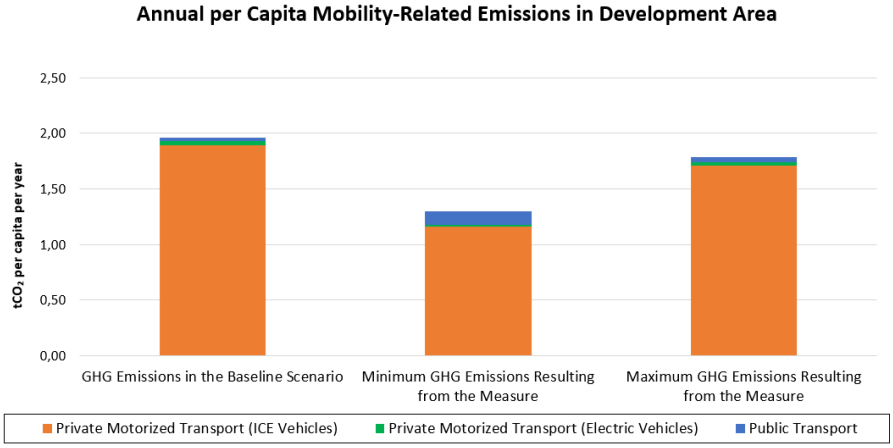

Figure 2: Calculated GHG emissions for a case study

5.5 Accessibility analysis

In parallel the accessibility in the vicinity of the development area is analysed. This is based on the concept of travel time budget indicators for accessibility, which describes how many activities can be reached by a means of transport within a certain travel time (Schwarze 2005). A comprehensive list, containing 24 different everyday activities, is used as a guideline for measuring accessibility (Schwarze 2025). These activities are categorized into four major dimensions: supply, healthcare, education and leisure. These dimensions split into detailed categories like level of schools, different services and types of markets. The toolbox focuses on six categories of everyday activities: supermarket/discount store, daycare centre, primary school, family doctor, pharmacy and local public transport stop. Accessibility of workplaces is not yet part of our categories. The analysis is carried out using a tool developed by the project team based on data from OpenStreetMap and isochrone and travel-time APIs. It determines the number of accessible facilities in each category within a 15-minute walk or bicycle-drive. So the focus are walking, driving by bicycle and in the future also public transport. As results two different indeces are calculated. The first index aims to provide a interpretation of the availability of local everyday destinations. We call it the 15-minute-index. The 15-minute-index describes how many of the twentyfour categories are accessible in 15 minutes by a predetermined mode which makes the most sense for the given category. Respecting the different weights (as

in: schools and supermarkets are heavier weighted than ATMs or repair shops) a percentage between 0 and 100 is the result of the calculation, with 100 meaning every category is reachable within 15 minutes. This index can then be compared with similar regions or residential developments. A second, much more descriptive index, called X-minute-index, describes the accessibility of an area based on the average travel time to destinations of the categories. To calculate this index, the travel time to the next destination and the the weight associated with that category are used. The result is an index that illustrates the average travel time in the context of the categories, meaning for example in a 7-minute-city, the average travel time to the important (highly weighted) categories is relatively short. It does not mean the average travel time to every category is 7 minutes, however the lower the value, the closer the important categories are. This index differs vastly dependent on area, population and destinations. Also different weights can alter the indeces. We plan to iterate on weights and categories depending on use cases.

Finally, the local accessibility values are compared with those of municipalities with comparable spatial typologies in Baden-Württemberg and throughout Germany. This is based on data from INKAR (indicators and maps for spatial and urban development) from the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR). Due to a lack of data in INKAR, daycare centres and family doctors are not included in these comparisons. An expansion of the accessibility analysis is planned. Based on first results with participating cities and urban planners, the details and weightings of certain categories and destinations will be made variable, to offer a more individual approach depending on the planned development.

Figure 3: Flow chart of accessibility analysis

5.6 Integrated assessment of sustainable mobility

For the purpose of advising local authorities and decision-makers, transport-related GHG emissions are presented as an indicator of the ecological limits of sustainability and accessibility as an indicator of the social limits of sustainability. The tool is delibarately limited on two indicators in order to facilitate the communication to decision makers and public. By comparing the two indicators for the development area, the contribution of various transport measures to sustainable mobility in rural areas is illustrated. In addition, the contribution of the measures taken in the development area to achieving German Climate Action Programme 2030 (reduction of 55% of greenhouse gases by 2030) is shown.

5.7 Application and need for further development

The current version of the toolbox is being tested as a tool for policy counceling in two pilot municipalities in order to check its functionality in real-life situations and to further develop the methodology on the basis of practical experience. As the testing is still in process, the results are pending. The current version only allows single measures to be evaluated. An extension for evaluating packages of measures in the form of a combination of qualitative and quantitative assessments is currently under development.

The methodology developed in the project has a high potential to be transferred to other countries, particularly where comparable planning frameworks and objectives exist in the field of sustainable

residential and transport development. Since the core principles of integrated planning such as promoting short distances, mixed land use, and multimodal accessibility are universally relevant for sustainable transport, the toolbox can serve as a conceptual approach in international contexts as well. However, the transfer requires adaptation to country-specific institutional structures (especially regarding approaches for estimating car ownership and the Ver_Bau tool), legal planning instruments, and available data sources (such as the Mobility in Germany dataset). Differences in spatial structure or public transport organization significantly influence the mechanisms through which planned measures have an effect. Therefore, contextualizing the indicators and evaluation criteria is necessary to provide valid assessments of transport-related impacts. Overall the methodology offers a transferable framework that, through appropriate localization of parameters, can provide a basis for sustainable land use and transport planning beyond Germany.

6 CONCLUSION

Due to the interactions between built environment and mobility behaviour, land-use planning influences framework conditions for sustainable mobility. The toolbox developed in the move.mORe project offers a practice-oriented, scientifically approach that supports local authorities in the early assessment of the transport impacts of settlement developments.

The toolbox can help to prioritise measures in urban land-use planning in a targeted manner and make their contribution to sustainable mobility transparent. This strengthens the capacity to act of small and medium-sized municipalities in rural areas, which often have limited technical resources.

Applying ideas from the “15-minute city” concept to rural areas offers a significant improvement in evaluating, comparing and quantifying accessibility, especially in terms of assisting municipalities in decision-making during stages of land-use planning.

To further develop the toolbox it is planned that the data basis for rural areas is to be expanded further and to facilitate the evaluation of packages of measures. Continuous validation in pilot municipalities can additionally increase feasibility and strengthen acceptance in municipal planning practice.

1 ABSTRACT

Building land registers have the task of providing potential areas for construction activities and developing them for the demand for residential, commercial and open space. They are therefore an essential basis for the ability of municipalities to plan strategically for future land use and to help implement development objectives. The emergence of artificial intelligence, open and free geodata and new technologies in data collection is creating new possibilities and business models for capturing potential areas. The data integration, evaluation and provision of the collected information, in turn, benefits from the development of Urban Digital Twins (UDT). Model projects show that UDTs potentially strengthen cooperation between authorities, the private sector and stakeholders. Existing software solutions already contain relevant data, which makes it easier to design the information model for a UDT.

This article focuses on the adaptation, scaling, and establishment of these solutions in the process management of land management. For this purpose, the current state of development for two common software solutions (ArcGIS Urban©, Urbanistic©) is compared for the requirements of land management. The focus is onthe design of land registers that conforms to the criteria of a new norm on digitals twins for cities and municipalities (DIN SPEC 91607). The results show that methodological approaches are mostly designed as GIS functions and challenging to implement. This learning from our test was further substantiated in discussions with experts, where the seamless integration of benchmarking functions and scenario indicators in UDTis seen as a main requirement for the technical progress and added value for planning. Artificial intelligence is of particular importance in the collection, processing and integration of auxiliary data.

The recommendations in the article conclude that new requirements for information management in urban planning have emerged. They require investments in the development of enhanced land management cadastres which benefit from UDT functions. Their introduction in local planning requires that organizations adapt new process management techniques. The accelerated activation of building land, which has recently been introduced through reforms of the building law in Germany (“Bauturbo”), requires a speedier and more comprehensive evaluation of urban development quality criteria if sustainability criteria are still to play a role. Over time, we expect that UDT technologies will help in this context.

Keywords: Digital Twins, Land management, Infill development, Climate adaptation, Process management

2 BACKGROUND

There is broad support in the literature on sustainable urban development for models and concepts of redensification and infill development (e. g. Heinig 2021; Barton 2016; WBGU 2016). The building land requirements of cities and municipalities should primarily be met within planned inner areas and harmonized with climate adaptation measures and the functional networking of sustainable infrastructures (Umweltbundesamt 2023, see Figure 1).

In planning practice, however, resolving conflicting goals is a challenge. In this context, one author describes the clash of narratives on sustainable urban development as follows:

“The guiding principles [of infill development] are well-founded in each case, and some measures can be implemented without conflict. However, they must enable sustainable socioeconomic development and measurable growth in prosperity. Private investors and project developers are concerned with market-driven utilization concepts, space efficiency, technical constructability, cost-benefit calculations, financial viability,

and marketability. Without a promising business case, no one will invest. Where this understanding cannot prevail, where radical, uncompromising demands from isolated individual interests clash, decisions cannot be made, plans cannot be drawn up, and construction cannot begin, resulting in valuable time being lost" (translated from the German original, see Achilles 2024). In order to bridge this gap, newer approaches focus on a digitally supported flow of information that is specifically practiced between urban development stakeholders (Brade 2025).

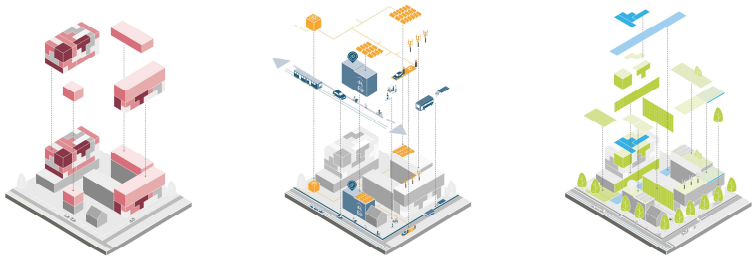

Figure 1: The three challenges of infill development (from left to right: building redensification, sustainable infrastructure, climate adaptation; source: courtesy of Must Städtebau https://must. eu/ [18. 01. 2026]).

UDTs provide new technologies for this purpose. They are currently being introduced in local government as a building block of smart city strategies (Etezadzadeh 2020). In this context, Figure 2 shows two frequent and legally requried tasks in local government for land management which can be supported by UDT technologies in the future:Issuing building permits (left) and setting building regulations through the development of local areaplans (right).

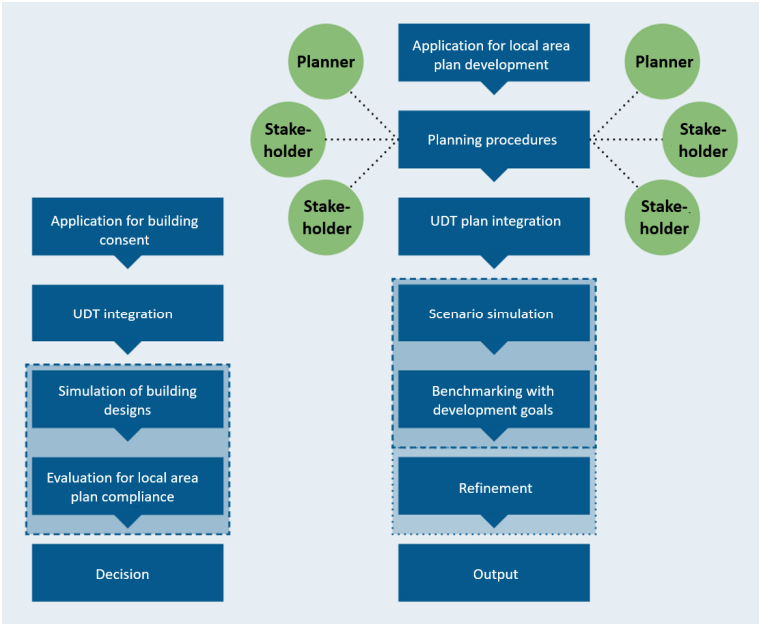

Figure 2: Schematic representation of the process for reviewing a building permit (left) and the process for drawing up a development plan (right) with the support of a digital twin (adapted from BBSR 2025, p. 22).

The workflows depicted in Figure 2 are taken from pilot projects where UDT technologies are currently being introduced (here: City of Kirchheim near Munich). In general, however, there is not much empirical knowledge about UDTusage in planning practice(Guckenbiehl et al. 2021). It is largely unclear what technologies or functionalities constitute a UDT and what makes it unique in comparison to other GIS applications. The term originally comes from industry and is used to create digital representations of products or machines. These serve as virtual replacements for physical prototypes, which can be used to create simulations and analyses (van der Horn and Mahadeva 2021). Applying this concept to the UDT gives cities and municipalities a comprehensive virtual representation of their structural elements and functional networks. This opens up new possibilities for projecting planning goals and building land development designs into the future (Schubbe et al. 2023). Accordingly, a smart city requires a dynamic, digital representation that not only integrates the physical building fabric, infrastructure, urban processes, and

citizen feedback. The intelligent digital image also knows about the business processes (e. g. , informal and formal urban land-use planning), responsibilities (role and user concept), and interfaces to systems at partners that map the state of the city for their needs (Brandt et al. 2023). This means that not only does the city provide the twin with up-to-date information, but the twin can also transmit data and insights from other systems back to the city (Guckenbiehl et al. 2021).

In summary, UDT technologies have the potential to improve land management procedures in planning practice. This comes at a time where remaining infill land potentials in German cities have become more difficult to activate, since many larger potentials have already been developed over the last decades. Interviews with experts in Northrhine-Westphalia explain that remaining potentials are more difficult to activate. Cities like Munster have been successful in the past to direct growth to derelict sites within the urban compound. Now, continued growth pressure forces city planners to develop new suburbs on the outskirts and expand the urban footprint (Fina et al. 2020). In this context, some authors argue that proactive land management needs to focus more on land potentials that are likely to become available in the future and plan for its reuse at an early stage. Newer methodological approaches from pilot studies show that continued urban transformation trends can lead to new obsolete land uses (e. g. petrol stations, car parks, retail and offices, Wenner und Thierstein 2024; Rettich und Tastel 2023). In the past, federal and state research and funding programs have provided valuable impetus to plan for the reuse of such potentials, which has led to improvements in the information base in recent years (BBSR 2022). In planning practice, however, dealing with conflicting planning law objectives in the activation of infill potentials remains a challenge (Preuß und Böhnke 2024).

In 2025, political targets to provide housing for residential use and economic development have led to policy reforms in the building code (“Bauturbo”, i. e. Construction Acceleration Act). Many planning requirements are not required anymore, local planning authorities can or even must provide building consents to applicants without environmental impact assessments or other forms of planning regulation compliance that are usually spelled out in local area plans. This leads to uncertainties about the legal status of building consents in conflicting situations. Many experts predict that such cases will be subject to subsequent legal conflicts that have to be decided in court, counteracting on the target to accelerate land activation. For instance, the tasks of climate protection and climate adaptation and the associated requirements for land use have increasingly being regulated over the last years (Mitschang 2021). It is unclear how the resulting conflicts in legislation can be resolved. Planning asscociations and planning pracitioners warn that the reform falls short from ensuring associated sustainable urban development requirements(SRL 2025). The main line of argument, on one hand, revolves around a large consensus that does support the debureaucratization of planning procedures for faster activation of land potentials. On the other hand, this should not come at the cost of giving up on planning controlsand risk new forms of land speculation(von Lojewski 2025).

Based on this background, we address the question whether (1) UDT technologies can contribute to accelerate the activation of land potentials for infill development and (2) still ensure sustainable development targets at the same time (“accelerating instead of waiving planning”). In the following sections we posit that the emergence of new norms and standards will help to innovate digital planning in urban land management.

3 METHODOLOGY

In the first step, we evaluate these questions based on a review of UDT norms and standards. In the second step, we evaluate two widely used software options (ArcGIS Urban©, Urbanistic©) against criteria taken from the DIN SPEC, focusing on aspects of data interoperability and integration, indicators and benchmarks as well as workflow requirements for planning practice. A special focus is on indicators for climate adaptation. The work was carried out in a third-party funded research project[1] at THA where this perspective is of particular importance.

Our initial findings lead to insights about the importance of digital innovation and process management in local government (Will und Winter 2024). We address this viewpoint in a separate chapter and in the discussion section.

[1] Digital Planning Support for carbon-neutral urban development (DiPukS), https://www. tha. de/Architektur-und-Bauwesen/DiPukS. html [18. 01. 2026].

4 NORMS AND STANDARDS

Since the end of 2024, DIN SPEC 91607 "Digital Twin for Cities and Municipalities" has specified a UDT standard that was developed by municipalities, associations, business, politics, and science in the Connected Urban Twins cooperation project (Munich, Leipzig, Hamburg). In addition to technical issues, the standard also incorporates ecological, economic, and social aspects, including topics such as building permits and sustainable neighborhood development. It defines usage scenarios and methods for accessing and displaying data (Schonowski et al. 2025; DIN SPEC 91607). Another standard, "Municipalities and Digital Transformation – Overview of Fields of Action," serves as a guide for the digital transformation of municipalities. Among other things, DIN identifies digital infrastructures, digital administration, mobility, construction and housing, as well as energy and the environment as areas for action (DIN SPEC 91387).

While developing DIN SPEC 91607, a similar methodology was established to systematically define concrete application cases for the Urban Digital Twin. The approach followed a four-step process to derive use cases addressing municipal needs:

(1) Structuring by establishing initial frameworks through the preliminary identification of application cases

(2) Capturing usage scenarios by collecting input from municipal stakeholders

(3) Grouping application cases according to thematic relevance and alignment with defined fields of action

(4) Developing case profiles to describe selected use cases in detail and to prepare subsequent implementation steps

The resulting set of use cases compiled within DIN SPEC 91607 demonstrates that the five most frequently mentioned municipal needs concerning usage scenarios are similar to DIN SPEC 91387: environment, building and housing, mobility, digital administration, and energy, are all directly linked to spatial and land management. Regardless of the specific use case, the geospatial base twin consistently constitutes the foundational layer and is likewise developed based on a municipal target vision. This process relies on municipally curated datasets in the domain of geospatial base data, including infrastructure and 3D building models, which are implemented using open source data models compliant with OGC standards (e. g. , CityGML, json, gml) as well as XÖV standards (e. g. , XBau, XPlanung). An XÖV standard is a German e-government data exchange standard for interoperable electronic communication between public administrations.

Building upon this foundation, municipal requirements are subsequently integrated in the form of application-oriented use cases as additional modular components of the UDT. Within the domain of digital land management, the digital building permit process plays a decisive role. The current building permitting process requires substantial effort to research, consolidate, and evaluate approval-relevant data from various municipal sources as well as from legal and regulatory frameworks. Delays often occur due to complex coordination among multiple stakeholders and the iterative, human-centred nature of decision-making. UDT technologies address these challenges by digitally supporting all phases of the permitting process. By integrating property and building-related information from public registries, GIS, and BIM data models, the UDT enables partially or fully automated, transparent, and accelerated decision-making. Through the digital representation of legal and regulatory evaluation criteria, formerly analogue workflows can be efficiently parallelized and simplified. Application scenarios include decision support based on indicator-driven data visualization, simulation-based assessment of planned projects, digital communication and collaboration among stakeholders, automated issuance of digital permits, and ongoing digital monitoring and documentation of construction progress. Furthermore, the UDT serves as a training platform for authorities and professionals to build competencies in managing digital permitting processes and assessing construction-related risks.

However, practical implementation examples remain scarce, with current developments largely limited to the application of XÖV standards and the solution DIPlanung that is currently being introduced by state authorities, amongst others in Bavaria (DIPlanung 2026). Following Kaushal (2022), initial international research on application of an UDT in urban planning can be observed. In his work, ArcGIS Urban© is employed in combination with a Spatial Urban Quality Framework that transfers urban quality indicators from first tier to second-tier cities, enabling spatial analyses to support data-driven urban planning. Our own tests with this and alternative software solutions shows that data integration of legally binding district and

local area plans are technically laborious. To date, there is no clear added value of UDT applications for the efficiency of building permitting processes. One main obstacle are the delays in the introduction of the subject-independent and interdisciplinary XÖV standard XPlanung, a data format for use in municipal GIS software solutions for urban land-use planning (Brade 2025). The corresponding legislation for XPlanung was already passed by the federal and state governments in 2017 and should have become the basis for a more direct and cross-system form of cooperation in digital planning by 2023. However, due to implementation problems, interim solutions are currently being pursued which define partial vector capture as a minimum standard in stage 1 of the introduction and only represent the georeferenced scope of a development plan with undefined essential information from a plan in accordance with XPlanung. Only in a later stage 2 will full vector-based recording of all spatial data (e. g. , areas, specifications) as digital objects become mandatory (STMBW 2025). The current data landscape therefore continues to be characterized by formats and tools that are subject to specific domain knowledge and system barriers and create barriers to communication between the actors involved. Land management planning processes will therefore only become fully machine-readable with the delayed introduction of the full range of features in development plans. Furthermore, this regulation only applies to plans that have been drawn up in development planning procedures since 2017. Important planning law indicators that provide decisive information about the permissible extent and scope of development (e. g. , floor area ratio and floor space index) in older plans must therefore continue to be interpreted manually.

In this context, the question arises wether XPlanung-compliant digitization should extent to cover legally binding older development plans. It is mostly in these plans where crucial building regulations for existing development based on the principle of infill developmentcan be found. Efforts to fully digitize these plans require the allocation of considerable time and financial resources within the administration or for the commissioning of service providers. In the process, technical standards with sample directories are being reinterpreted in order to achieve the best possible results for specific urban land-use planning applications, depending on feasibility (cf. NRW. Urban 2021 STMBW 2021). Pilot studies show that artificial intelligence (AI) can be a game changer in this context. A technological leap is being observed in this area, with the use of AI to transfer a new generation of digital building land and brownfield site registers to UDTs. In a pilot study Schwarz (2024) concludes that current AI tools are already capable to interpret text and images in local area plans in high quality. Prerequisites are that the resolution of the documents is high and location specific markers help to interpret map legends and other plan signatures. Additional domain-specific training material is likely to emerge over the coming years to further improve results.

5 EVALUATION OF UDT APPLICATIONS FOR LAND MANAGEMENT

Software tools to capture, store and administer infill potentials in cities have evolved signficantly over the last few years. Initial database and spreadsheet driven approaches have increasingly integrated GIS functionalities to visualize land potentials on maps. Advanced GIS functionalities help to better understand and analyze the geographic context for building land activation, e. g. to inform and provide conditions that enable future usage according to development plans(Fina et al. 2023). Figure 3 shows selected parts of the software interface of the government funded research project KFMplus© (“Kommunales Flächen- und Ressourcenmanagement”, i. e. local planning land and ressource management) for the data-driven assessment of development options for the city of Dachau, Germany. The establishment of such software developments does not necessarily include 3D visualized objects. More importantly, they require interfaces to digitally map infill potentials and auxiliary information on land activation prerequisites, and to supply algorithms for data-driven assessment and visualization technologies. The software design of pilot projects like KFMplus© provided the path for innovations that are currently being rolled out in parts of Germany. One example is the introduction of new land management software with a similar design in the State of Baden-Württemberg.[2]

Sample indicators in the frame on the right of Figure 3(enlarged and translated from the German original) are compiled from a range of geodata inputs and compared between the current situation and a range of development options that the user can select from (in this case “dense built-up”). The Figure focuses on indicators on the acccessiblity of amenities and aspects of climate change. The colour coding of the

[2] https://mlw. baden-wuerttemberg. de/de/landesentwicklung/flaechenmanagement/digitales-flaechenmanagement.

comparison can help to better understand negative and positive effects when implementing a certain development option (shades of red: indicator values show negative effects; yello: neutral; shades of green: indicator values show positive effects). There are also a range of other indicators available in modules on urban amenities ("Daseinsvorsorge") at the location of a selected infill potential, and other important informaton to activate the site for reuse ("Innenentwicklungspotenziale"). The integration of planning regulations is limited to data fields for users to store and manually interpret permissible land use types, the ground area index, the floor area ratio or the building volume ratio. Spatial delineations like construction lines and building delineations are usually only available in linked documents (PDF) and have to be interpreted manually.

More advanced UDTs provide the possibility to integrate such spatial information from standards like XPlanung. Having the corresponding information fully integrated in the application provides possibilities to automatically test designs for building code compliance, in some cases with rule-based tools that deliver compliant design. Indicator-based comparisons of urban development scenarios and public participation to tag and label design and environment features enhance these applications further. In this context, we have tested two software options (1) ESRI's ArcGIS Urban© (supported by ArcGIS Pro/Online and ArcGIS City Engine) and (2) Urbanistic©. Both were used to set up UDT applications for specific use cases in the City of Augsburg in Southern Germany (pop. approx. 300,000). The city has successfully activated former military sites for infill development over the last few years and uses urban planning and architectural competitions to ensure high quality and economically feasible planning.

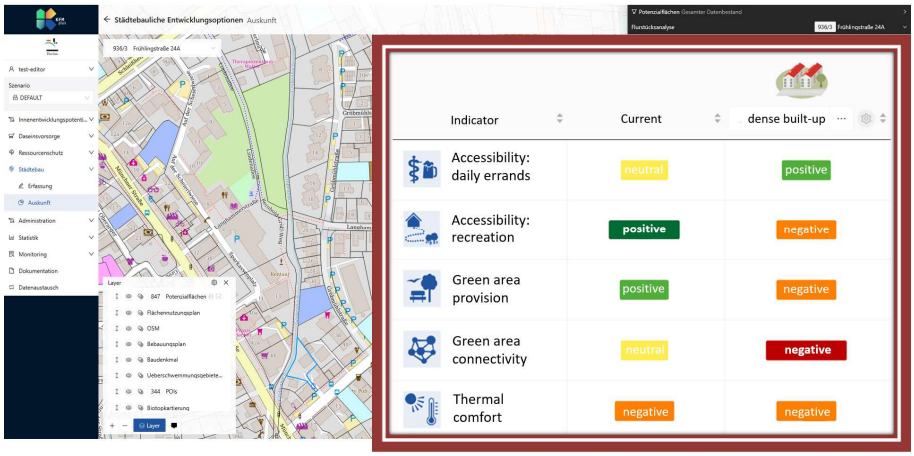

Figure 3: Data-driven assessment of development options in infill development (own design).

Figure 4 shows a UDT with a fully functional building design imported from Autodesk Revit©for the curent situation in an area known as the Prinz Karl area. The area is designated for a new campus for the Faculty of Architecture and Civil Engineering at the University of Applied Science. Results show that setting up the UDT in ArcGIS Urban© with relevant data is time consuming and requires expert knowledge at the interface of geoinformation science and urban planning. The bullet points in Figure 4 depict a summary of the steps in the workflow that need to be managed. After successful data acquisition and integration, the challenge is to harmonize and transform the data into required formats. This applies to context layers like digital elevation models and existing building representations (OpenStreetMap or LoD2 – Level of Detail 2 (LDBV 2026), vegetation and infrastructure. It also applies to the building code imported from XPlanung (if available) or digitized local area plans (Source: City of Augsburg). Architectural designs can currently only be imported as drawings that have to be located manually, with limited accuracy (Source: student projects at THA). Direct imports for object-oriented desing representations (e. g. BIM models in the IFC standard, see Figure 4) cannot be functionally connected to the context layers. In order to achieve this, BIM models have to be duplicated with ArcGIS Urban© modelling techniques.

In the same project, we have evaluated the software option of the Munich-based startup Urbanistic© (Urbanistic 2026). This cloud solution is pre-equipped with data from OpenData BY (LDBV 2026), using API calls for seamless data integration. It has a growing client base in planning practice which values the ease of use for data interoperability between GIS and CAD/BIM software. The graphics performance is higher compared to ArcGIS Urban© and many functionalities address the competencies of CAD/BIM users better than the GIS based software design of ArcGIS Urban©, including building code regulations based on

state legislation (“Landesbauordnung”) and specialized tools to model the land area requirements of fire brigades or emergency services. In contrast to ArcGIS Urban©, the business model of Urbanistic© requires subscriptions for additional data (e. g. local area plans, cadastral data) to be integrated by consultants rather than having a generic software that the user can equip with data from own GIS workflows.

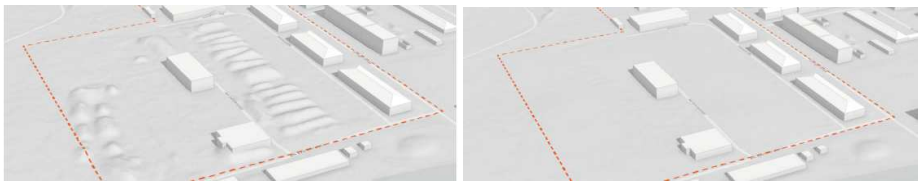
Figure 4: Current situation with a selected new redevelopment design in the Prince Karl area in Augsburg, Germany (own design).

Figure 5: Urbanistic© UDT Prinz Karl, Augsburg (own design, Urbanistic 2026).

Based on the software evaluations of the DiPukS project, one of the authors of this article proceeded to work on an another area development in Augsburg, namely at the former Reese baracks. The Reese development is divided into two separate developments. The southern part has already been subject to an urban design competetion with a winner, the northern part is set to go through the same process in the near future (Stadt Augsburg 2022). As is common in planning practice, the local area plan to regulate building and construction will only be developed once a design has been chosen. As already depicted in Figure 2, UDT applications can be used to inform this process. Figure 6 shows examples for the setup of a UDT for the design of the southern part.

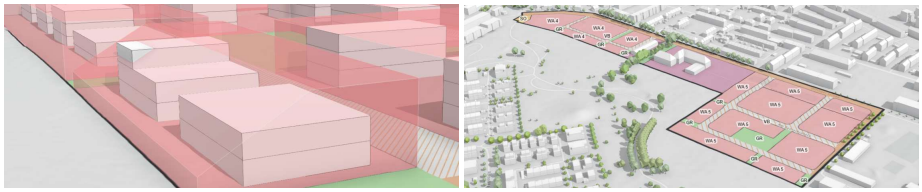
In summary of these learnings, both ArcGIS Urban© and Urbanistic© have the potential to set up UDTs specifically for urban planning. Data integration in ArcGIS Urban© is quite flexible, many datasets can be prepared and integrated. This process is laborious and requires expert knowledge, whereas Urbanistic© is already equipped with many relevant datasets, additional ones require consultant contracting. Both software options work with indicators that can inform planners on design scenarios. We will discuss further insights from this evaluation in the discussion section of this article.

6 INNOVATION AND PROCESS MANAGEMENT



As shown in the previous sections, the handling of new UDT technologies requires specific skillsets to set up, run and maintain the corresponding applications. Organizational structures are needed that support cooperation between administrators, geoinformation officers and urban planners in a range of tasks, including hardware and software provision, data integration and the domain-specific development and usage

of results. Figure 7 provides an overview of the correponding development stages depicted in DIN SPEC 91607.



Experience from model projects shows that the interdisciplinary coordination of the underlying digital business processes benefits from professional process management consulting expertise (Schubbe et al. 2023).

1: Building models derived from OpenStreetMap, 2: Level of detail 2 buildings from OpenData BY

2: Digital elevation model from OpenData BY, 3: Modificationsconducted in ArcGIS CityEngine

4: Building envelopes derived from local area plan digitization, 5: Zoning derived from local area plan digitization

6: Building types based on the winning design, 7: Combined tree canopy (existing + planned)

8: Indicators on size, cost, demography, mobility and emissions, 9: Selected shading and viewshed analyses.

Figure 6: Selected steps of a workflow to establish an UDT for the Reese barracks in Augsburg (Finger 2025, unpublished).

The successful adaptation of innovations requires new forms of "digital governance" which not only provides users with digital planning support tools and helps them learn how to use them (Przeybilovicz und Cunha 2024). It is also committed to the sustainable acquisition of knowledge infrastructures in the concrete accomplishment of tasks and establishes new, digitally supported forms of cooperation (Weber und Ziemer 2022).

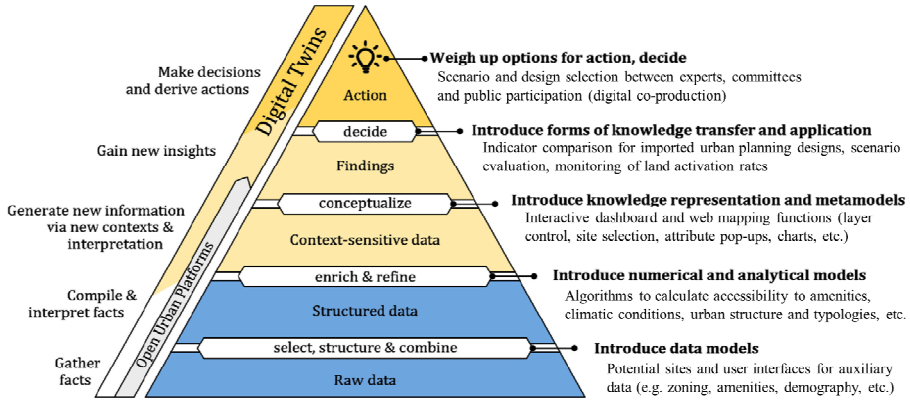


Figure 7: Development stages for UDTs, adapted for land management processes (modified from DIN SPEC 91607, p. 32).

The cooperation requirements are described as an innovation potential that still poses numerous challenges in the transfer and long-term establishment of pilot applications (cf. e. g. Prognos AG 2025). The institutional settings of public authorities with contractors and other stakeholders vary greatly in structure, for example between large, medium-sized, and small cities (Milbert und Fina 2021). Land management and location planning are also subject to urban-rural dynamics, which cause relocation effects to the urban periphery and peripheral locations (Zimmermann et al. 2025). The implementation of UDT technologies to activate infill potentials for sustainable urban development is thereoforealso a challenge for the cooperation between the different departments within one organisation and the cooperation beween neighbouring local governments and planning tiers like regional and state planning authorities. On the technical side, one main hurdle is the interoperability between the different land management systems and the applications of stakeholders, including government organizations, private industry and educational facilities. Data from one stakeholder often cannot be integrated into the platforms of others. This hinders the merging of data and information for joint use, such as analysis or planning. Another problem is the lack of clarity about what data and technical solutions are already available and what they can do. Because projects are often limited to a single sector, cross-sector effects are frequently neglected. The standardization of data structures and content is often inconsistent, which can lead to problems during integration (Donaubauer et al. 2023).

Geoinformation centers often make a cross-cutting contribution in administration to improve the interaction between geobasis data and specialist data from the departments. They are tasked with linking several application-specific UDTs into a “system of systems” during the development of UDTs. Independent data infrastructures and systems thus become a common information platform that supports application-specific scenarios. In addition to tools that allow practical access to available data, access to standardized and up-to-date planning and location data is required. To implement a UDT, data, tasks, and processes from various specialist departments and actors must be integrated. Effective project management organizes clear responsibilities and takes into account the requirements for communication, process planning, and financial resources. It establishes a common understanding of tasks to enable context-oriented communication and citizen participation across different organizational areas (Abt und Hohmann 2025).

The project of developing a UDT is therefore characterized by a high degree of uncertainty of a visionary nature. It can be expected that new requirements will continuously emerge from new usage scenarios that, at the present point in time, are very likely still unknown. Changes in requirements arise, among other factors, from political dynamics, changing climatic conditions, and newly explored technological possibilities in the construction sector. These aspects, together with the resulting complexity of such a project, argue strongly in favor of an agile approach to project execution.

Iterative development means that the development stages for UDT implementation are repeatedly carried out. At the end of each development cycle, a usable increment is produced that contains valuable enhancements compared to the previous version (Schwaber and Sutherland 2020).

Strictly speaking, projects are characterized as unique undertakings with a limited budget and a defined timeframe (“competence-based project managementPM4”,Deutsche Gesellschaft für Projektmanagement e. V. 2019). In view of the expected dynamics in this field, however, UDTs must be developed in such a way that, after project completion, they can be continuously further developed either within follow-up projects or within a permanently established organization.

In cases like land management, the highest stage ('action') of UDT implementation is interpreted as enabling the derivation of adaptive approaches for individual cases of land development activation based on the developed UDT. In industry, this is understood as a reference model from which context individual process models – in this case, checklists – can be derived. This includes the analysis described in Figure 10, but extends beyond it in the following manner. Figure 11 shows how the development stages of fig. 10 can be matched with the objectives of the proposed case. The boxes are placed below the related use symbol (current use, expected use, continuous improvement) they adress.

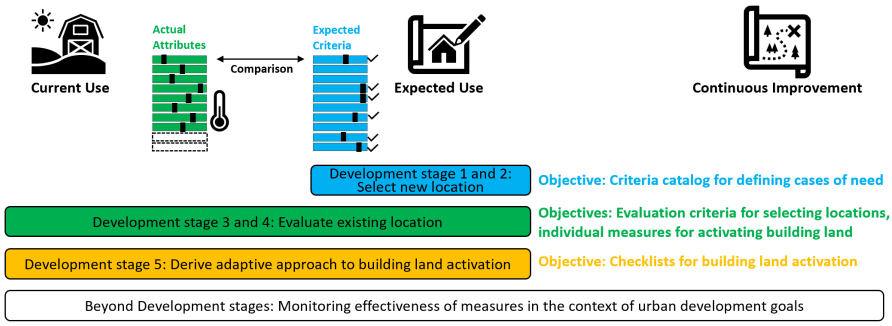

Figure 8: Matching of proposed project with development stages for UTD implementation after DIN SPEC 91607

Within stages 1 and 2 (raw and structured data), profiles consisting of several expected criteria for new development land are identified. These can then be compared to the attributes that describe current usage profiles. Existing UDTs already provide a substantial number of current attributes and their respective characteristics for existing areas (Figure10). However, the number of recorded attributes is not yet sufficiently comprehensive to assess whether the currently anticipated "expected criteria" – profiles are feasible. This goes well beyond a simple evaluation of a site based on predefined criteria (or, speaking in the UDT terminology, indicator values), as profiles made up of multiple criteria must be weighed against one another.

To enable this, in stage 3 (context-sensitive data) the systematic collection of criteria profiles as well as additional evaluation criteria must be consistently pursued. These profiles form the basis for the development of measures for land development activation (stage 4, findings). Building on this, a mechanism can be developed that adaptively derives sets of measures as context-individual approaches from the UDT. The UDT serves as a comprehensive reference model for deriving context-specific approaches(Königbauer 2021). Land development activation can be managed by orchestrating these approaches consisting of individual measures into a context-specific process, which can be understood as a checklist or a project plan(stage 5, action). This approach potentially accelerates planning,especially in more complex cases involving numerous stakeholders and many required individual steps. Such systematic measures have the additional benefit that the effectiveness of individual measures can be consistently recorded. Corresponding optimization measures can then be incorporated into subsequent land development activation projects.

Since neither project management nor UDTs are established practices within public administration, organizational structures must be introduced that support continuous improvement processes over extended periods of time. It cannot be expected that highly committed individuals will drive further development on their own or, in extreme cases, exhaust themselves in the course of implementation. Instead, the commitment of the involved organizations is required, expressed through leadership engagement in combination with subject-matter experts, to ensure that UDTs can evolve into practice-oriented and user-friendly instruments.

7 DISCUSSION AND CONCLUSION

This article discusses the potentials and challenges to implement UDT technologies for more efficient workflows in urban planning in general and sustainable urban land management in particular. Current political trends to waive planning requirements for speedier consenting procedures and critical comments from planning scholars on potential effects set the scene for this requirement: Can UDT technologies help to ensure high quality urban planning without placing new bureaucratic hurdles on the resources of urban planning departments,can they improve and accelerate planning processes in the long run? Are they transferable from piloting local government to a wider range of authorities with limited resources?

Our learnings from document and literature review and our own tests of software options show that norms and standards are urgently needed to provide user orientation. Difficulties to introduce the standards, especially for local area plans ("XPlanung") can potentially be overcome with new initiatives and AI support. The new DIN SPEC 91607 on UDTs is a good starting point to transfer learnings from pilot projects to the community. Available software options like KFMplus©, ArcGIS Urban© or Urbanistic©all run in cloud-based backends and browser-based frontends, but have been designed for different business models (e. g. KFMplus©: open source components, ESRIs ArcGIS© stack of software, Urbanistic©: native application). One main obstacle for easy-to-use UDTs are the requirements of data integration and the establishment of data-driven urban planning indicators. Where KFMplus© provides prefabricated indicator variants for a limited set of typical urban planning typologogies (e. g. densely built up, commercial, open space, etc.), ArcGIS Urban© and Urbanistic© work with variable designs based on building typologies that the user can select from (and, in the case of ArcGIS Urban©, enhance with custom typologies).

Apart from a few very generic indicators (e. g. volume, size, etc.), more advanced indicators require that the user sets up the calculation routines for inputs and outputs. Without going through this effort, the added value of UDT applications seems to be limited. Planning practice needs to know about the number of dwellings or floor area in a new building, derived number of required parking spaces, district heating demand, carbon dioxide emissions, etc. If this information is not available and/or the results are not credible for stakeholders, UDTs cannot reach their full potential for urban planning. We found in our tests that, at this stage, these tasks are laborious if standardized data is not available or supported. Users have to revert to digitizing PDF documents or scans, and subsequently deal with attribute generation, relationship modelling between object classes, and inaccuracies based on manually generated inputs. Interoperability between CAD/BIM on the one hand and GIS on the other needs to be further improved for seamless data exchange, including object-oriented attribution and relationship modelling.

A special focus of our evaluation was on indicators on climate change and climate adaptation, as shown for the software KFMplus©. ArcGIS Urban© can provide information about carbon dioxide emissions or soil sealing for urban planning designs if calculation routines are set up. More domain-specific information (thermal stress, air ventilation, stormwater runoff) is currently not available. New software options like the QGIS plugin Climate Scanner© (an AI trained software tool for climate effect assessments of urban designs) are being developed for UDT integration in emerging new research projects. Their evaluation is the next step in the currently running research project that we reported from in this article.

Affordable Housing in Emerging and Developing Economies: Exploring the Role of Urban Planning and Policy in African Countries

Parsa Arbab

(Ass. Prof. Parsa Arbab, School of Urban Planning, College of Fine Arts, University of Tehran, Tehran, Iran, parsaarbab@ut.ac.ir)

1 ABSTRACT

Housing deprivation remains a pressing global challenge in contemporary urban planning and development, particularly in metropolitan areas and large cities, where unaffordability arises when housing costs exceed a household's financial capacity. Affordable housing – along with related concepts such as low-income housing, public housing, social housing, and subsidized housing – serves as a key government-led solution to mitigate free-market inequalities, enabling low-income and vulnerable groups to access quality housing alongside essential services. Despite growing academic and professional interest in affordable housing, the issue still requires further attention, especially when considering local and contextual conditions. Hence, this study explores affordable housing in emerging and developing economies through the lens of urban planning and policy in African countries. The systematic literature review focuses on a comparative analysis of four distinct approaches in African cities: the state-led rental-sale model in Algiers, Algeria; the facilitated but unaffordable cooperative model in Bahir Dar, Ethiopia; the insurgent prefigurative movement-led model in Cape Town, South Africa; and the informal demand-side adaptation strategies in Lagos, Nigeria. The findings reveal a profound disconnect between top-down policies and on-the-ground realities. The analysis demonstrates that no single, ideologically pure approach is sufficient. Instead, effective strategies must forge a hybrid path that is: (1) empirically grounded in the lived reality and financial capacities of the urban poor; (2) built on an integrated system combining land access with enabling financial mechanisms; (3) reliant on a reimagined state role that moves from rigid provision to responsive partnership; and (4) focused on housing as an act of urbanism, integrating location, services, and liveability. The study concludes that achieving affordable housing in emerging and developing economies including African countries requires a pragmatic, context-sensitive urban planning framework that learns from informal systems, confronts unjust structures, and strategically combines the scale of the state with the agency of its citizens.

Keywords: Affordable housing, Social housing, Sustainable urban development, Urban planning, Urban policy

2 INTRODUCTION

Rapid urbanization and inadequate housing supply have led to increasing demand for affordable housing from low income households with limited financial resources especially in in developing countries (Adigeh & Abebe, 2024). Affordable housing – along with related concepts such as low-income housing, public housing, social housing, and subsidized housing – serves as a key government-led solution to mitigate free-market inequalities, enabling low-income and vulnerable groups to access quality housing alongside essential services. From an urban planning perspective, affordable housing entails habitable units with suitable facilities subsidized/provided by the government, where prices/costs bear a reasonable proportion to income, leaving sufficient funds for other necessities, such as food, clothing, transportation, healthcare, and education (Arbab & Shabani, 2023; Makhloufi, 2025).

Despite growing academic and professional interest in affordable housing, the issue still requires further attention, especially when considering local and contextual conditions. Hence, this study explores affordable housing in emerging and developing economies by a focus on the role of urban planning and policy in African countries. In African cities, rapid urbanization, colonial legacies, and ineffective policies have converged to exclude the majority from accessing decent shelter. As the studies on Ethiopia and Nigeria show, cities overwhelmed by a demand for housing that far outstrips the supply of serviced land, forcing low- and middle-income residents into informal settlements or unaffordable rental markets, despite government programs intended to help them (Adigeh & Abebe, 2024; Akinwande et al., 2024). The top-down interventions often fail, as seen in Nigeria where schemes are frequently unaffordable for their target demographic (Ale, 2025), ignoring the resourceful informal housing strategies – like incremental construction and community finance – that the urban poor already rely on to survive (Akinwande & Hui, 2024). This crisis is further exacerbated by the proliferation of informal settlements lacking basic services, which perpetuates poverty and inequality across the continent (Bhanye et al., 2024). It reveals the profound

disconnect between top-down policies and the on-the-ground realities. The research from Algeria and South Africa demonstrates that studying social housing exposes the multifaceted nature of the challenge, encompassing not just financial and land-access barriers, but also the political battles, the struggle for spatial justice in post-apartheid cities, and the need to critically assess the quality and appropriateness of the housing that is actually delivered (Makhloufi, 2025; Tattersall & Iveson, 2024). Furthermore, sustainable housing solutions must address environmental, social, and economic dimensions simultaneously to create truly inclusive and resilient communities (Bhanye et al., 2024).

3 METHODOLOGY

This study adopts a systematic literature review (SLR) approach to examine social housing in emerging and developing economies, with a particular focus on African cities. Emerging and developing economies encompass nations transitioning from low-income status to advanced industrialization, characterized by rapid GDP growth, increased global trade integration, and maturing financial systems, yet facing challenges such as income inequality and infrastructure deficits. A structured search was conducted using Google Scholar to identify peer-reviewed articles containing the terms “affordable housing” or “housing affordability” in their titles. The search was limited to publications indexed in Web of Science and released by reputable international publishers from 2024 onward. Review articles and studies emphasizing technical, architectural, or psychological dimensions were excluded. The initial screening process identified 40 articles. Following the application of inclusion and exclusion criteria – particularly the removal of studies conducted in advanced economies – the corpus was reduced to 21 articles. A further refinement was made to retain only those studies that included specific city-level case studies with an emphasis on contextual and local dimensions, resulting in a final set of nine articles.

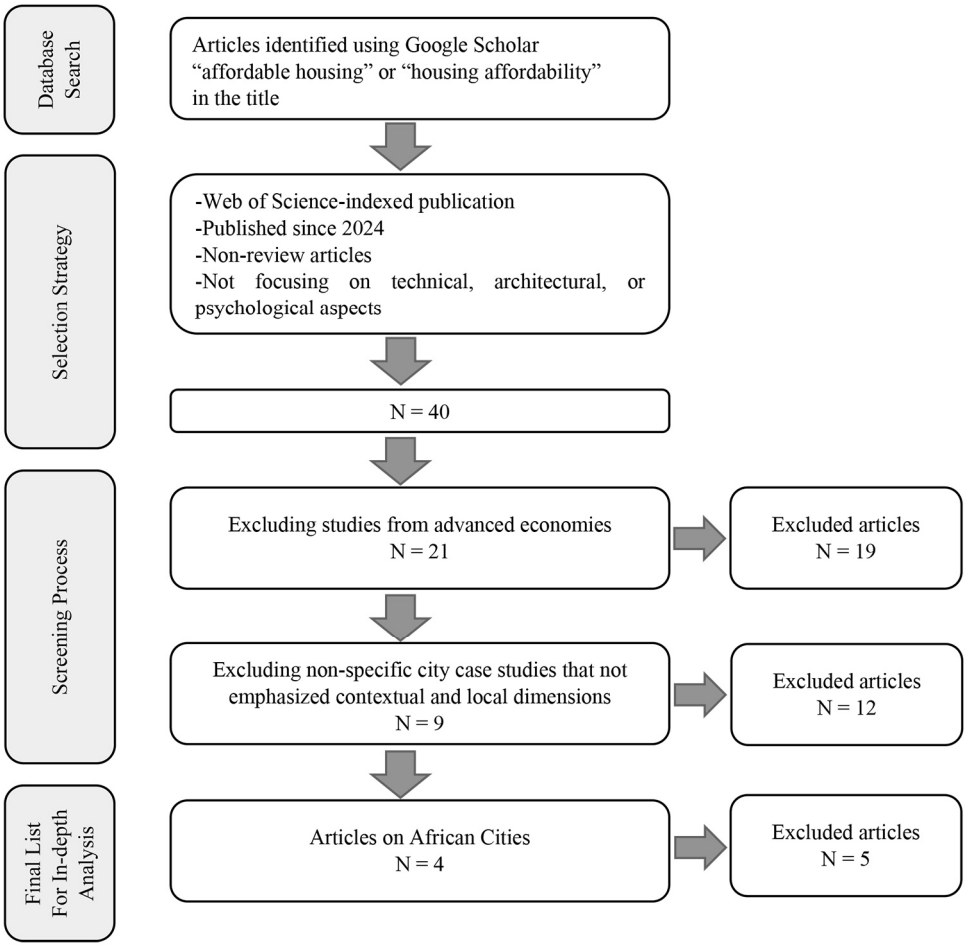

Fig. 1: Literature selection process for systematic literature review (SLR)

The literature selection process is illustrated in Figure 1, and the specifications of the included articles are summarized in Table 1. The selected articles cover a diverse range of cities across the Global South,

including Algiers (Algeria), Bahir Dar (Ethiopia), Cape Town (South Africa), Hangzhou and Shenzhen (China), Ho Chi Minh City (Vietnam), Istanbul (Turkey), Lucknow (India), and Lagos (Nigeria). Given the scope of this review and the need for focused analysis, particular attention was paid to four studies centered on African cities to enable a more in-depth exploration of social housing issues in that context.

4 RESULTS

4.1 Algiers, Algeria: The State-Led Rental-Sale Model

Algeria employs a top-down, state-driven model to address its housing shortage. The rental-sale program, managed by the Housing Improvement and Development Agency (AADL), targets middle-income households. It is a structured pathway to homeownership where beneficiaries pay 10% upfront, 15% upon completion, and the remainder in monthly installments over 20 years. This program is part of a broader strategy that includes slum eradication and caters to different income groups (low, middle, high) through various housing types. The new town of Sidi Abdallah, located on the near periphery of Algiers, built with the help of international contractors like China State Construction & Engineering Corporation (CSCEC), is a prime example of this large-scale, industrialized approach.

4.1.1 Strengths

The program's primary strength is its scale and state capacity. It has demonstrably delivered a vast number of housing units and contributed to the near-elimination of slums in major urban areas. The income-graduated system provides a clear, bureaucratic framework for targeting different socioeconomic groups. For middle-income families, it creates a viable, state-backed path to homeownership that the private market may not offer.

4.1.2 Weaknesses/Critique

Quality vs. Quantity: The model prioritizes quantitative output (units built) over qualitative outcomes. As the study's survey reveals, a significant majority of residents (61%) were unsatisfied with their units, citing poor workmanship and construction defects. This highlights a critical gap between housing as a product and a home.

Homogenized Urbanism: The mass production of identical blocks of flats has created monotonous environments lacking the vibrancy and amenities of older neighborhoods. This has led to a spatial mismatch, where residents (20% in the survey) still commute to the city center, 25 km away, for work, healthcare, and social life.

Financial and Data Gaps: The model relies heavily on state oil revenue, making it less replicable in fiscally constrained contexts. Furthermore, its eligibility criteria are based on outdated income data, raising questions about whether the housing remains truly affordable for the intended middle-income group.

4.2 Bahir Dar, Ethiopia: The Facilitated but Unaffordable Cooperative Model

In Ethiopia's state-owned land system, the government in Bahir Dar acts as a facilitator. It provides land at a subsidized benchmark price to self-help housing cooperatives, leveraging collective community action. The policy is detailed in regional regulation 9/2013 to promote affordable housing for low- and middle-income urban residents, outlining cooperative size, member eligibility (e.g., no prior home ownership), land plot sizes (100-150m²), and building standards (G+1 villa house: a building consisting of a ground floor and one additional floor). Between 2014 and 2022, this scheme allocated land to over 31,000 cooperative members.

4.2.1 Strengths

The scheme has been remarkably effective as a land distribution mechanism. It has formally allocated plots to a large number of people, demonstrating the potential of cooperatives to organize demand for housing.

4.2.2 Weaknesses/Critique

Fundamental Unaffordability: The core finding of the study is that the scheme fails the test of affordability. By shifting all financial risks (land compensation, full construction costs, infrastructure) onto the members, and coupling this with the high-cost mandate of a G+1 villa, the policy prices out the very low- and middle-income groups it was designed for. This is a classic case of a policy being designed for affordability but implemented in a way that makes it unaffordable.

Lack of Enabling Environment: The self-help model has become a cost-shifting exercise. Unlike historical Ethiopian models or contemporary examples in Kenya mentioned in the study, there is no government-backed housing finance. Members are left to rely on inadequate personal savings and high-interest informal loans.

Implementation Gaps & Corruption: Municipal delays in providing serviced land (up to 5 years) and corruption in member eligibility screening (using non-digital IDs that confirm the residency in the city for a minimum of 2 years) have severely undermined the program's equity and efficiency. The result is that less than 7,000 of the 31,000 who received land have been able to build homes, forcing many to sell their plots. This is a devastating indictment of the program's effectiveness.

4.3 Cape Town, South Africa: The Insurgent Prefigurative Movement-Led Model

In Cape Town, when formal strategies (through litigation and protest) failed to stop the sale of prime public land for affordable housing, Reclaim the City (RTC), a new social movement of Black working-class and poor communities fighting to reverse apartheid-era spatial segregation, shifted to prefigurative politics. In 2017, they occupied two vacant provincial buildings in the inner city, turning them into live-in models of the affordable housing they demanded. This action was part of a constellation of people power strategies, used alongside legal challenges and mass mobilization.

4.3.1 Strengths

Prefigurative action proved to be a uniquely powerful tactic. It provided immediate, direct relief to those in housing stress, demonstrated concretely that inner-city affordable housing was possible, and created organizing spaces that built community and sustained the movement. The combination of strategies proved effective, leading to the City identifying affordable housing sites and, crucially, a 2020 court ruling that set aside the land sale and affirmed the government's duty to address apartheid spatial planning.

4.3.2 Weaknesses/Critique

This strategy is highly demanding and precarious. Sustaining the occupations required immense effort from residents and institutional backing (from partner NGO Ndifuna Ukwazi which means 'dare to know' and called for the inner-city land to be converted to state-owned public housing rather than the sale). The participatory, non-hierarchical governance model was vulnerable to internal tensions and violent external pressures, including two murdered residents in 2017. The movement's gains are also vulnerable to political shifts, as progress stalled when supportive politicians resigned. While a powerful form of resistance and advocacy, it is not a scalable model for mass housing production on its own. It is most effective as a tactic to force state action, not as a substitute for it.

4.4 Lagos, Nigeria: The Informal Demand-Side Adaptation Strategies

The study of Logos experience takes a radically different approach by analyzing the demand side – the informal strategies of the urban poor themselves. Through interviews in five major Lagos slums, the researchers document how residents house themselves despite state neglect. Key findings include the prevalence of rental housing (82.5%) and shared apartments (7.5%), extremely low and irregular incomes (90% earn < US$30/month), strong economic ties to their settlement location, reliance on community savings groups (87.5% membership), and the use of incremental building.

4.4.1 Strengths

The primary strength of the case of Logos is its empirical grounding in lived reality. By quantifying the actual income and expenditure of the target population, it provides a stark reality check for formal policies. The findings and recommendations – prioritizing rental housing with daily/weekly payments which are more realistic for the urban poor, supporting livelihoods through existent savings group and microcredit institutions, and adopting alternative housing approaches such as incremental housing (by use of cheaper construction materials) and shared housing (as convertible homes and hostels) – are not abstract theories but are derived from proven, working strategies. This experience identifies the raw materials for a genuinely pro-poor housing policy.

4.4.2 Weaknesses/Critique

The study of the Lagos experience is diagnostic and prescriptive but does not deeply explore the complexities of implementation. How can a government institutionalize an informal savings group without destroying its trust-based, flexible nature? How can technical support for incremental building be provided without triggering gentrification? This case successfully identifies what needs to be done but is less detailed on the how – the intricate political and administrative work required to integrate informal systems with formal state structures without breaking them or enabling co-optation.

Aspects/Cases	Algiers, Algeria	Bahir Dar, Ethiopia	Cape Town, South Africa	Lagos, Nigeria
Main Approach	Top-down State-Provision: The state is the primary provider, financier, and developer. It aims at mass production and homeownership for the middle class through a structured formal market mechanism (rental-sale).	State-Enabled Collective Self-Help: Government creates a policy framework (land at benchmark price) for citizens to form cooperatives and help themselves. Places the financial burden and construction risk on the cooperative members.	Bottom-up Insurgent Making: A social movement confronts the state by creating a concrete micro-utopia (housing occupation) to directly challenge exclusionary land use and demand policy change. The approach is pragmatic, using direct action when formal channels fail.	Bottom-up Informal Adaptation: The urban poor are active agents who have developed their own solutions (incremental building, informal finance) outside the formal system. The study advocates for the state to learn from and build upon these strategies.
Role of the State	Primary Provider & Regulator: The central actor in funding, building, and managing the program. The state‘s role is dominant and essential to the model‘s functioning.	Facilitator & Enabler: Provides the policy and land, but shifts the financial burden entirely to members. The state is the gatekeeper of land but fails to provide essential financing or timely delivery.	Adversary & Target: The movement opposes the state‘s (including provincial governments) actions (selling public land) and demands it become a social housing provider. The state is the target of protests, occupations, and litigation.	Absent or Hindering: Formal policies are seen as ineffective or irrelevant. The study argues the state should shift from control/provider to partnership by learning from informal practices.
Target Population & Affordability Definition	Middle-Income: Strictly defined by monthly income bands (1.5 to 6 times the minimum wage). Affordability is about matching a fixed, subsidized price to a fixed income bracket.	Low- & Middle-Income: Targeted by policy, but the critical finding is the scheme is unaffordable for most. High costs of land compensation and construction, coupled with a total lack of accessible housing finance, exclude the intended beneficiaries.	Low-Income & Black Working-Class: Affordability is defined by the lived experience of housing stress, spatial exclusion (apartheid legacy), and the threat of displacement. The movement directly challenges the state and market‘s exclusionary logic.	The Urban Poor: The study reveals their actual affordable threshold is <$9/month, a figure far below any formal scheme. Affordability is defined by extreme income precarity (90% earn <$30/month).
Land Acquisition	State-Allocated: The state provides land for the Housing Improvement and Development Agency (AADL) projects. The cost is integrated into the final price paid by the beneficiary over	Government-Allocated at Benchmark Price: Land is the key state contribution, but members must pay for it indirectly through compensation fees for previous users. A critical	Contentious Occupation: Land is acquired by physically reclaiming vacant public property. This illegal but politically powerful tactic directly challenges the state‘s land use priorities and exposes	Informal & Market-Based: The poor access land in unserviced, hazardous peri-urban areas (swamps, peripheries) because it‘s all they can afford. They have strong economic ties to these locations, living and

Aspects/Cases	Algiers, Algeria	Bahir Dar, Ethiopia	Cape Town, South Africa	Lagos, Nigeria
	20 years. The user doesn't directly negotiate for land.	bottleneck is multi-year delays (up to 5 years) in getting serviced plots.	under-used public assets in the wealthy inner city.	working within them.
Financing & Construction	Structured Long-Term Payment: The state provides a 20-year payment plan. The household pays 25% upfront (10% pre-construction, 15% on completion) and the rest in monthly instalments. Construction is done by large contractors (e.g., China State Construction & Engineering Corporation: CSCEC).	Member-Financed & Built: This is the critical failure point. Members must save 50% of construction costs before getting land and then cover all costs. No state-backed mortgages or affordable finance options exist. This leads to very low construction rates (<7,000 out of 31,596 plot recipients built homes).	Sweat Equity & Community Governance: Residents maintain the building and govern the space themselves. The key output is not just the physical space but a new model of community-led housing governance, which they propose to the city as an alternative to top-down, bureaucratic management.	Incremental & Shared: The poor build in stages (incremental housing) as money allows. They use cheaper materials (wood), share housing with family, and prefer daily/weekly rent. Community savings groups (thrifts, cooperatives) are their primary and most effective financing tool.
Main Challenges	- Poor build quality and monotonous urban design in new towns like Sidi Abdallah. - Balancing the speed of mass production with quality of life for residents. - Financialization of housing potentially undermining broader social goals.	- Policy is fundamentally unaffordable for its target group due to hidden costs (land compensation). - Corruption in member selection. - Extreme delays in delivering serviced land (up to 5 years). - Complete lack of accessible housing finance for members.	- State repression and continuous legal challenges. - Internal conflicts and violence within occupied spaces. - The resource-intensity of sustaining long-term occupations. - Vulnerability to shifts in the political landscape (e.g., resignation of supportive mayor).	- Extreme poverty and income insecurity (90% earn <$30/month). - Mismatch between formal housing products (homeownership) and the needs/capacity of the poor (need rental <$9/month). - Lack of formal finance and secure land tenure.
Outcomes & Effectiveness	High Output, Mixed Satisfaction: Successfully delivered thousands of units, contributing to significant slum reduction. However, resident satisfaction is low (avg. 2.85 of 4) due to quality and design issues. The product is delivered, but is it a good place to live?	Quantitative Success, Qualitative Failure: The policy successfully transferred land to over 31,000 members. However, it failed in its core mission of creating affordable housing. Most plots lie empty, members cannot afford to build, and many are forced to sell.	Political & Policy Wins: The occupation forced the city to identify and zone specific sites for affordable housing. It stalled the sale of large piece of inner-city public land (Tafelberg) and won a court case affirming the state‘s duty to reverse apartheid spatial planning. It created a sustained political force.	Identifies a Viable Policy Alternative: The study provides a powerful demand-side critique. It identifies realistic affordability parameters (rent <$9/month) and highlights the potential of incremental housing and informal savings. It argues for formalizing, not replacing, these strategies.
Critical Analysis	The Commodification vs. Quality Tension: The program successfully financializes housing for the middle class but struggles with the quality of life and urbanism it produces. This shows the limits of a purely quantitative, state-driven production model.	The Policy-Reality Gap: The experience is a stark critique of a well-intentioned policy that is blind to the economic realities of its target group. The self-help model becomes a burden, not a benefit, without financial support. It highlights a profound failure of policy design.	The Inside/Outside Tension: The movement successfully uses "outside" tactics (illegal occupation) to win "inside" concessions (policy changes, court rulings). However, maintaining the internal participatory democracy of the occupation is fraught with conflict and requires significant NGO support, challenging romanticized notions of autonomous movements.	The Formal/Informal Tension: The study makes a powerful case for a paradigm shift from replacing informality to learning from and building upon it. This requires a fundamental reorientation of the state‘s relationship with the poor, from control to partnership.

Table 2: Comparative Analysis of planning and policy on affordable housing in African cities

5 CONCLUSION

The challenge of affordable housing in emerging and developing economies including African countries cannot be resolved by singular, ideologically pure approaches. The diverse experiences of Algiers, Bahir Dar, Cape Town, and Lagos collectively demonstrate that effective strategies must move beyond false dichotomies – state vs. market, formal vs. informal, ownership vs. rental – and instead forge a hybrid path that strategically combines the strengths of multiple actors and processes. This path rests on four following foundational pillars:

(1) Successful approach must be grounded in the lived reality of the urban poor. Policy must begin not with idealized housing standards or financial models, but with a deep, empirical understanding of what the target population can actually afford. As the Lagos study starkly reveals, when formal mechanisms ignore the

precarious, often daily, incomes of the poor (in this case, less than $9 per month for housing), they become fundamentally inaccessible. Policy must therefore recognize and enhance, rather than replace, the sophisticated informal strategies of incremental construction, shared housing, and community-based savings that the poor have already invented.

(2) Land is a necessary but insufficient condition for affordable housing; it must be integrated with enabling financial mechanisms. The Ethiopian experience serves as a tragic cautionary tale: providing land without a concurrent strategy for housing finance is not a policy, but a transfer of unbearable risk. It creates a class of plot-holders who cannot build. In contrast, the Algerian model demonstrates the power of the state to provide structured, long-term finance that aligns with household income, transforming tenants into owners. The critical lesson is that land and finance cannot be siloed; they must be designed as an integrated system.

(3) The state is an inescapable actor whose role must be reimagined, not retreated from. Across all cases, the state is central – as builder (Algiers), enabler (Bahir Dar), target (Cape Town), or absentee (Lagos). No amount of community self-help can substitute for its capacity to act at scale. However, the state must evolve. It must move from imposing rigid, top-down products to supporting housing as a dynamic social process. It must build the capacity for responsive listening, flexible implementation, and accountable partnership with social movements and community organizations. As Cape Town's pragmatic prefiguration shows, an adversarial state can be forced to change through a constellation of people power strategies – combining litigation, mobilization, and the physical demonstration of alternative possibilities.

(4) Housing is fundamentally an act of urbanism, not just shelter provision. The location, quality, and liveability of housing are as important as its existence. The dissatisfaction of residents in Algiers' new towns and the struggle of Cape Town's movement for inner-city land underscore that peripheral housing, no matter how cheap, imposes costs in time, dignity, and opportunity that undermine true affordability. Effective policy must integrate housing with transport, services, employment, and thoughtful urban design.

In conclusion, affordable housing in emerging and developing economies requires a new kind of urban planning – one that is humble enough to learn from the informal, courageous enough to confront unjust structures, and pragmatic enough to combine the scale of the state with the energy of its citizens. The goal is not a blueprint, but a framework: a hybrid approach that empowers the poor, enables the state, and ultimately, reimagines the city as a place of justice and belonging for all.

Future research must move beyond siloed analyses to investigate integrated land-finance policy models, comparing outcomes for households that receive land with and without accompanying financial mechanisms. Researchers should document and analyze informal systems as intelligence, conducting ethnographic studies of incremental building, community savings, and shared housing to understand how these strategies can be enhanced rather than replaced by formal policy. The concept of pragmatic prefiguration requires comparative investigation across housing movements to understand when and how occupations, community experiments, and constellations of people power successfully force state transformation. Multidimensional affordability frameworks must be developed and tested, integrating shelter costs with transportation, employment access, and residential satisfaction. The state's multiplicity of roles demands comparative institutional analysis to explain why some states enable, others obstruct, and still others are forced to change, identifying the conditions under which productive state-society synergy emerges. Finally, longitudinal studies tracking households over time through incremental construction, policy interventions, and movement participation are essential to understand the dynamic processes that determine whether housing strategies succeed or fail – moving beyond static snapshots to capture housing as a temporal process.

1 ABSTRACT

In developing countries, human settlements are increasingly becoming more vulnerable to high flood risks and damages, especially those who are situated near rivers, flood-prone areas, and at low elevations. Correspondingly, South Africa is one of the developing countries that often experience devastating impacts of climate-related disasters, such as significantly heavy rainfall-induced flooding. However, floods persist, repeatedly affecting the residents despite the existing mitigation measures such as spatial planning. In addressing these ongoing challenges, this paper aims to analyse the effectiveness of spatial planning in enhancing rural resilience to flooding in South African rural areas and identify opportunities for improvement. Using a mixed methods approach, the role of spatial planning in enhancing rural resilience to flooding is assessed in relation to spatial development and flood risk management of rural areas in South Africa. Findings highlight that spatial planning frameworks in rural areas often lack clear consideration of flood risks, resulting in increased vulnerability. Most rural areas are situated in areas that are vulnerable to flooding, highlighting the necessity for enhanced planning. Limited and poor infrastructure provision in rural areas also hinders rural resilience to flooding. This paper recommends the incorporation of flood risk management into spatial planning frameworks, enhancing green infrastructures, raising awareness among residents about flood risks, and promoting collaborative spatial planning. This paper emphasises the necessity for incorporating spatial planning and flood risk management in rural South Africa, contributing to more rural resilience and sustainable rural development.

Keywords: Flooding, Flood Risk Management, Rural Areas, Rural Resilience, Spatial Planning

2 INTRODUCTION

In developing countries, human settlements are more vulnerable to flood disasters due to the combined consequences of climate change, rapid land-use change, and socioeconomic vulnerabilities (Ananwa, 2023). In South Africa, rural communities located near rivers, low-lying areas, and flood-prone areas are particularly at risk, frequently sustaining repeated flood damage with limited ability to adapt and recover (Chakwizira et al., 2021). Worldwide, flood damages and risks are increasing as climate change increases the frequency and severity of heavy rainfall events, leaving pressure on both urban and rural communities (Raphela, 2025). In South Africa, rural human settlements are increasingly vulnerable to flooding due to inadequate infrastructure delivery, a lack of adaptability, and underfunded institutions (Ampofo et al., 2024). To address the increasing flood risks and damage, researchers and policymakers have devoted substantial focus to flood risk reduction and climate adaptation strategies, notably on governance arrangements and planning tools employed to manage development in areas vulnerable to flooding (Loschner, 2020). Among these planning tools, spatial planning is commonly known as a main mechanism for preparing for flood risk and shaping land use patterns in a way that minimises exposure and long-term vulnerability (Roosimagi, 2021). Spatial planning is a tool that can play a critical role in prevention and transformation in flood risk management through guiding settlements in areas that are feasible for residing, regulating land use, and incorporating environmental challenges into development decision-making (Kodag, 2022). Existing literature largely conceptualises spatial planning as a technical and physical intervention tool, mainly concentrating on spatial design measures such as buffer zones, flood-resistant building standards, and stormwater management systems (Meng, 2020). Although these approaches are essential for flood resilience, they tend to overlook the governance, political, and institutional aspects of planning that shape how such tools are enforced in practice. Consequently, limited focus has been given to how spatial planning systems, decision-making processes, and

institutional capacity influence flood resilience outcomes, especially in areas characterised by poor resources and weak governance. In addition, flood risk management research persistently focuses much on urban areas, with rural areas receiving limited scholarly attention despite facing persistent exposure to flooding, poor infrastructure investment, and poor planning and governance systems. This gap is particularly evident in South Africa, where flooding is the most frequent and damaging natural disaster. Between 2000 and 2016, floods accounted for nearly 42% of all natural disasters worldwide and 35% of those recorded in South Africa (EM-DAT, 2017). In South Africa, rural areas mostly operate under complex land tenure arrangements, poor technical capacity, and fragmented institutional responsibilities, conditions that cater to an urban-centred planning model that cannot address rural areas flood vulnerability.

South Africa exemplifies the aforementioned challenges. The country experiences recurring flood risks and damages due to the combination of climatic stressors, historical spatial planning inequalities, and continuing institutional and governance challenges (Raphela, 2025). Provinces in South Africa, such as Limpopo, KwaZulu-Natal, North West, and the Eastern Cape, are disproportionately affected by more extensive flood risks due to a combination of geographic and government-related weaknesses, and limited adaptation capacity (Munyai et al., 2021). Despite spatial planning being formally known as a vital mechanism for enhancing flood resilience, many rural municipalities struggle to translate planning regulations into efficient flood risk reduction practices due to weak inter-sectoral collaboration and poor incorporation of flood risk consideration into land use decision-making (Munyai et al., 2021). As a result, flooding continues to have impacts on rural settlements repeatedly, raising questions about the effectiveness of existing spatial planning techniques. Despite the growing recognition of spatial planning as the main mechanism for flood risk management, there is limited empirical knowledge about how spatial planning is being implemented in rural South African contexts, the institutional challenges that hinder its effectiveness, and the extent to which current spatial planning frameworks support rural flood resilience. This signifies a vital gap in the literature, especially considering the accelerating climate change impacts and the disproportionate vulnerability in rural human settlements. Addressing these challenges, this study aims to analyse the effectiveness of spatial planning in enhancing rural resilience to flooding in South Africa.

3 LITERATURE REVIEW

3.1 Climate change and flooding in developing countries

Worldwide, flooding is known to be one of the most frequent and catastrophic natural disasters, emerging when water temporarily overwhelms normally dry land due to heavy rainfall, river overflow, or inadequate drainage systems (Ran & Nedovic-Budic, 2016). This statement simply emphasises that globally, floods affect more residents than any other type of natural disaster. UNISDR (2018) reported that floods are the most frequently reported natural disasters, repeatedly affecting a large number of people. According to the United Nations (2015) and Abdrabo et al. (2020), between 1995 and 2015, floods were reported to be 43% of all natural disasters, impacting over half of the residents experiencing any other natural disasters and resulting in more than a quarter of all disaster-related deaths. As mentioned above, climate change continues to increase the flood risks by increasing the frequency and severity of heavy rainfall events, leaving pressure on both urban and rural communities (Raphela, 2025). Worldwide, between 2000 and 2022, floods resulted in inflation-adjusted economic loss equal to US$929 billion, illustrating 3852 floods (Centre for Research on the Epidemiology of Disasters (DRED, 2023). In South Africa, floods and storms are the most frequent natural disasters, resulting in 71.2% of the total disasters in the country (CRED, 2023). In the Global South, flood risks and damages are intensified by structural and socioeconomic aspects, encompassing inadequate infrastructures and weak governmental regulations, and unplanned rural settlements that usually encroach on natural floodplains (Nuissl, 2020). According to Liu (2024), globally from 1990 to 2022, 168 countries experienced 4,713 flood events, impacting more than 3.2 billion residents, resulting in over 218, 000 deaths, and economic losses exceeding $1.3 trillion. Africa continues to be vulnerable to flooding, experiencing the third-highest proportion of global flooding events and associated deaths (Hamidifar and Nones, 2021). In 2024 alone, floods impacted over 8.5 million residents and claimed more than 1,460 lives across 20 countries in West and Central Africa, emphasising the combined impacts of climate variability and inadequate infrastructures (Ramadane, 2024). These flooding statistics highlight that flooding is not only a repeated environmental disaster but also a pressing developmental and governance challenge, especially in areas with limited adaptive capacity.

3.2 Role of spatial planning in flood risk management

Spatial planning is known as a process in which public and private sectors influence the spatial allocation of activities, people, and land uses to guide long-term development outcomes (Roosimagi, 2021). In addition to oversight, spatial planning signifies a coordinated and strategic approach aimed at shaping spatial patterns of settlement growth to enhance resilience, efficiency, sustainability, and safety of human settlements (Thistlethwaite, 2019; Roosimagi, 2021). This has placed spatial planning as a possible vital tool in addressing complex environmental risks and damages, including flooding. Considering flood risk management, spatial planning is known as a preventive tool that can minimise exposure by directing human settlement developments away from areas vulnerable to flooding and incorporating environmental challenges into land use decision-making (Ran, 2016). Spatial planning operates proactively by directing where and how human settlement developments should occur, unlike structural flood control tools such as dams, levees, and drainage systems, which minimise flooding probability but cannot fully stop risks and damages (Sayers et al., 2013; Thistlethwaite, 2019). Therefore, it plays an enhancing role in engineering-based interventions by tackling the fundamental drivers of flood vulnerability. Notwithstanding the recognised capability, the literature repeatedly emphasises major challenges in translating spatial planning principles into successful flood risk management practice. One of the most commonly quoted challenges is the weak collaboration and communication among spatial planning officials and flood risk management institutions, which usually work within incoherent government systems (Ran & Nedovic-Budic, 2017). This institutional disconnect is worsened by varying professional viewpoints, with town planners and flood risk officials mostly holding contrasting perspectives on the role and scope of spatial planning in enhancing flood risk (Solin, 2023). These issues are overlooked and threaten the incorporation of flood risk consideration into spatial development processes and minimise the effectiveness of planning interventions. The mutual reliance between spatial planning and flood risk management highlights the necessity for more integrated mechanisms that correspond to spatial planning, environmental management, and governance processes (Ran, 2016). Effective spatial planning needs to balance environmental, social, and economic aspects while concurrently tackling the current vulnerabilities and hindering the creation of new risks and damages (Thistlethwaite, 2019). Incorporating flood risk management into spatial planning regulations is therefore vital for minimising long-term exposures and enhancing the rural resilience and sustainability of human settlements. These challenges are frequently seen in Africa, where flooding is the most common natural hazard and usually leads to notable loss of lives, property damage, and disturbance of livelihoods (Cilliers, 2019). Under these circumstances, spatial development planning has a vital role in hindering unsuitable settlement development in areas that are vulnerable to flooding and supporting disaster risk reduction efforts. When executed correctly, spatial planning can contribute not only to minimising flood risks and damages but also to addressing social vulnerabilities and reinforcing societal resilience to flooding (Priest et al., 2016; McEwena et al., 2018).

4 APPROACH AND METHODOLOGY

An exploratory research design was adopted in this study to allow for a flexible and in-depth examination of the role of spatial planning in enhancing rural resilience to flooding in South Africa. This design is particularly suitable for gaining new insights, clarifying concepts, and identifying patterns, relationships, or factors influencing complex phenomena (Saunders, Lewis, & Thornhill, 2019). The study employed a mixed-methods research approach, integrating both quantitative and qualitative techniques to provide a comprehensive understanding of the research problem. Mixed methods research is especially valuable for addressing complex issues that cannot be sufficiently explored through a single methodological approach (McLeod, 2024). The quantitative component focused on collecting data related to flood risks, infrastructure availability, and spatial planning indicators, while the qualitative component involved semi-structured interviews with town planners to explore perceptions of flood risk, the effectiveness of spatial planning interventions, and barriers to implementation. A random sampling technique was used to select South African residents for the quantitative survey to ensure representativeness, while purposive sampling was employed to select town planners with relevant expertise for the qualitative interviews. Data analysis involved the use of descriptive statistical tools, including SPSS and Microsoft Excel, for quantitative data, while qualitative data were analysed using thematic analysis to identify recurring themes and patterns. Ethical considerations were rigorously observed throughout the study. Participants were fully informed about the purpose of the research and assured that they would not be deceived in any way. Participation was

entirely voluntary, and respondents were informed of their right to withdraw from the study at any stage without any consequences. To avoid coercion or undue influence, participants were provided with adequate information to make informed decisions and were allowed to ask questions and seek clarification regarding any aspect of the study.

4.1 Data Collection Methods

Data collection refers to the systematic process of gathering, evaluating, and analysing accurate information using established and validated research methods (Mazhar, 2021). This study employed both primary and secondary data sources to ensure a comprehensive and well-rounded analysis of the role of spatial planning in enhancing rural resilience to flooding in South Africa. Primary data were collected through surveys, interviews, and field observations. Secondary data were obtained from policy documents, local government reports, and existing scholarly studies related to spatial planning, flooding and rural resilience.

4.2 Survey Questionnaires

A questionnaire is a research instrument used to collect data through a structured series of questions (Hussain, 2022). In this study, structured survey questionnaires comprising both closed-ended and open-ended questions were used to collect data from South African residents living in rural areas vulnerable to flooding. The mixed question format allowed for the collection of both quantifiable data and contextual insights. A total of 20 questionnaires were distributed to participants residing in flood-prone rural areas. Each questionnaire was designed to take approximately 5–10 minutes to complete.

4.3 Interviews

Interviews are a qualitative data collection method that utilises open-ended questions to obtain in-depth information from participants (George, 2022). Semi-structured interviews were conducted with five town planners, selected due to their role in spatial planning and flood resilience in both rural and urban contexts. The semi-structured format enabled flexibility, allowing participants to elaborate on their experiences, perceptions of flood risk, the effectiveness of spatial planning measures, and challenges in implementation. Each interview was expected to last between 10 and 15 minutes.

4.4 Literature Sources

A comprehensive review of existing literature was conducted to establish a strong theoretical and contextual foundation for the study. This review focused on spatial planning, rural resilience, flooding, land-use planning, and climate change at global, national, and local levels. Key policy documents, including the Spatial Planning and Land Use Management Act (SPLUMA, 2013), Spatial Development Frameworks (SDFs), and Integrated Development Plans (IDPs), were analysed to understand the role of spatial planning in enhancing rural resilience to flooding in South Africa. Additionally, the study was framed within the existing research on theoretical viewpoints in land-use planning, rural resilience, flooding and climate change found in academic literature.

5 RESEARCH FINDINGS

5.1 Flood experience among residents

The findings highlight that flooding is a common experience among most of the participants. The majority of respondents, 83%, stated that they have been exposed to flooding in their communities, while only 17% highlighted that they have not. The absence of “not sure” responses highlights that participants were confident about their responses, emphasising the tangible and memorable nature of flooding events within their communities in South Africa. The majority of affirmative responses emphasise the repeated occurrence of flooding in the study area and confirm that flooding is a common and lived challenge for residents who stay in rural communities. These results further highlight the need for effective flood risk management and spatial planning intervention, as flooding is not a hypothetical risk but a repeated reality impacting most of the residents in rural communities in South Africa, mostly those who reside in areas vulnerable to flooding or low-lying areas.

5.2 Frequency of flood occurrence

The following figure shows that flooding occurs with different regularity in the study area. Half of the participants (50%) reported that they experience flooding every year due to heavy rainfall, highlighting that flooding is a common and recurring event for a significant portion of rural South Africa. About one third of participants (33%) experience flooding occasionally throughout the year, highlighting irregular but still noteworthy exposure to flooding events. 17% reported that they experience flooding rarely, highlighting that a smaller portion of the rural South Africa population faces infrequent flood events. Overall, the data shows that flooding is the most frequent natural disaster in South Africa, with most of the rural communities' residents affected regularly, emphasising the necessity for robust flood risk management and resilience strategies.

5.3 Impacts of flood encountered

The figure below highlights that housing damage during flooding is the most major impact of flooding, affecting 50% of the participants. This emphasises that human settlements in rural areas are highly developed in areas that are vulnerable to flood events, possibly because of weak construction materials used or the location in flood-prone areas and poor infrastructure, such as drainage systems. The loss of crops and livestock is reported to be the second most common impact in rural South Africa, reported by 33.3% of participants. This shows that the negative impacts of flooding on agricultural livelihoods and food security are particularly significant for households that rely on farming and livestock rearing. Displacement of residents affected 16% of the participants, highlighting that fewer households had no choice but to relocate due to flooding, causing damage to living arrangements and community stability. Notably, no participants reported health problems or loss of income (0%). This may highlight effective coping mechanisms and timely evacuation. Overall, the results highlight that flood impacts were primarily physical and livelihood-related, with housing and agriculture being the most affected aspects.

5.4 Challenges of flooding in South Africa

5.4.1 Settlement Patterns in Flood-Prone Areas

The results highlight that settlements developed in areas vulnerable to flooding are strongly affected by land allocation, poor awareness, and weak governmental challenges. All surveyed participants (100%) stated that they were not informed about flood risks and had no idea that they were being placed in flood-prone areas before residing in their respective communities. This shows an urgent gap in risk communication and public awareness about the flood risks, highlighting that flood risk information is not effectively shared with residents before settlement decisions are made. The responses further highlight that the lack of knowledge is a main issue contributing to continued residential development in flood-prone areas. As highlighted by one resident, due to an absence of information pertaining to flood risks, it hinders residents' ability to make informed settlement choices (Resident 16, 2026). This result emphasises that the tribal authorities in rural communities continue to allocate land in areas that are vulnerable to flooding, leaving residents being the ones to experience the challenges. Viewpoints from town planners point to systemic and governmental challenges within spatial planning and human settlement delivery processes. Backlogs in the delivery of properly demarcated and serviced human settlements have resulted in residents settling in available land despite flood risk and damage exposures (Town Planner 1, 2026). This scenario is worsened by repeated housing delays, which drive communities to prioritize having shelters rather than considering their safety. Additionally, it emphasises that municipal planning priorities are more focused on urban areas, leaving rural communities with limited planning support and awareness initiatives. According to Town Planner 3 (2026), weak spatial planning practices in local municipalities, lack of land for development, and poor community awareness programme lead to the continued allocation of stands in flood-prone areas. This shows a broader spatial inequality between rural and urban areas in South Africa. The role of tribal authorities was also mentioned as one of the major aspects influencing settlement patterns in areas that are vulnerable to flooding. Town Planner 4 (2026) emphasised that tribal authorities often lack adequate knowledge of environmental buffers and disaster-prone areas when they allocate stands to residents under their jurisdiction. This emphasises the disconnect among formal spatial planning, disaster risk management regulations, and customary land allocation practices, further exacerbating settlement vulnerability. Overall, this analysis shows that human settlement in flood-prone areas is not solely a result of individual choice but rather a

combination of poor awareness, poor spatial planning, inadequate governmental collaboration, and land scarcity. These results highlight the necessity for improved flood risk communication, stronger coordination among municipalities and tribal authorities, and proactive spatial planning intervention to avoid further human settlement in areas vulnerable to flooding.

5.4.2 Inadequate Integration of Flood Risk into Spatial Planning Frameworks

This paper found that flood risk management is poorly incorporated into rural spatial planning regulations, significantly restricting their effectiveness in minimising flood vulnerability. Spatial Development Frameworks and Land Use Schemes in most rural communities lack comprehensive flood risk assessments, up to flood hazard mapping, and clearly elaborated settlement development guidelines for areas vulnerable to flooding. This absence of risk-informed planning mechanisms leads to human settlement development decisions that do not adequately account for current and potential flood risks and damages. Therefore, spatial planning tools fail to effectively guide human settlement development away from high-risk areas or encourage adaptive land use practices such as controlled development, buffer zones, or flood-resilient human settlement patterns. Instead of spatial planning operating as a proactive and preventive mechanism, spatial planning regulations mostly respond reactively after flood events have already happened. This responsive approach threatens the core objectives of spatial planning in enhancing safety, sustainability, and resilience. Additionally, the results show a disconnect between spatial planning and disaster risk management regulations. Although there is the existence of national and local disaster management frameworks, their principles are not enforced within spatial planning tools at the rural community level. This poor incorporation results in recurrent flood challenges in rural communities, as human settlements continue to be exposed to flood risks without adequate preventive planning mechanisms. Overall, the paper emphasises the immediate necessity for incorporated, risk-sensitive spatial planning approaches that coordinate land use planning with flood risk management and climate change adaptation measures.

5.4.3 Poor Infrastructure Provision and Maintenance

The results of this study confirm that poor infrastructure provision and maintenance significantly challenge rural resilience to flooding. Survey findings highlight that 66.7% of participants have drainage infrastructure to help during flooding, while only 33.3% show the presence of some form of drainage infrastructure. This imbalance emphasises the widespread absence of basic flood mitigation infrastructure in rural areas and underscores the vulnerability of these communities to heavy rainfall events.

Inadequate drainage infrastructures increased flood impacts by allowing stormwater to accumulate within human settlements, exacerbating surface runoff and prolonging inundation periods. These results align with broader observations that infrastructure developments in rural communities commonly lag behind urban areas in both delivery and maintenance. Furthermore, poor infrastructure hinders access to essential services during flooding events in rural communities. Poorly maintained roads and the absence of stormwater systems impede mobility, delay emergency response, and restrict access to healthcare and markets. As a result, flooding not only leaves physical consequences but also threatens socioeconomic status, further minimising the adaptive capacity of rural communities. From spatial planning viewpoints, these results highlight a disconnect between human settlement development and infrastructure planning in rural areas. The absence of incorporated infrastructure planning within SDF undermines long-term sustainability and resilience objectives. Overall, the findings highlight the necessity for enhanced investments in rural drainage and stormwater infrastructure, alongside regular maintenance, to enhance flood resistance in rural areas and support sustainable rural development.

5.4.4 Weak Stakeholder Coordination and Governance

The paper highlighted that poor collaboration between key stakeholders undermines the effectiveness of spatial planning and flood risk management in rural communities. Coordination among town planners, disaster management officials, environmental officials, and local government departments is often weak, leading to fragmented planning processes and poor enforcement of flood resilience mechanisms. The absence of incorporated government structures, formal communication channels, and shared data systems further heightens these impacts, resulting in duplicated efforts in some areas while leaving critical policy gaps in others. This lack of collaboration not only limits the effective execution of flood mitigation strategies but also minimises the capacity of rural communities to benefit from available resources and expertise. For

example, without collaborative planning, disaster management units may enforce emergency approaches that are not aligned with spatial development priorities, while environmental officials may fail to protect natural flood buffers critical for minimising flood challenges. The results emphasize the need for strengthened intergovernmental and cross-sectoral coordination, including the establishment of shared information platforms, joint planning committees, and regular stakeholder engagement forums. By encouraging incorporated governance and cooperative decision-making, rural flood-prone areas can achieve more coherent spatial planning outcomes, enhancing overall community resilience to flooding.

5.4.5 Limited Community Awareness and Participation

Limited community awareness and participation emerged as a significant challenge affecting rural flood resilience. The findings indicate that many residents have insufficient knowledge of flood risks, early warning systems, and appropriate preparedness measures, which reduces their ability to anticipate, respond to, and recover from flood events. The lack of accessible and targeted risk communication in rural areas contributes to this knowledge gap, leaving communities unprepared for recurring flooding. In addition, community involvement in spatial planning processes is often minimal. Residents are seldom actively engaged in decision-making related to land-use planning, settlement development, and disaster risk management. This limited participation restricts opportunities to incorporate local knowledge and lived experiences into planning processes, which are essential for identifying context-specific flood risks and feasible adaptation strategies. When residents are not involved in planning decisions, they are less likely to understand, support, or comply with planning regulations and risk reduction measures. As a result, spatial planning strategies aimed at enhancing flood resilience become less effective and more difficult to sustain over the long term. Overall, the findings highlight the need for participatory and inclusive planning approaches that prioritise community awareness, education, and involvement as central components of rural flood resilience.

6 IMPLICATIONS AND RECOMMENDATIONS

The results of this paper have several implications for spatial planning in rural communities in South Africa. The repeated flood impacts highlight that the existing spatial planning approaches insufficiently consider environmental risks and damages. The town planners and tribal authorities must therefore prioritise flood risk assessment when allocating land uses to residents under their jurisdictions and approving developments, especially in rural and low-lying areas. This paper suggests a necessity for stronger implementation of spatial planning regulation and frameworks. Despite spatial planning regulations, their limited consideration of flood risks and poor enforcement contribute to continued human settlement in areas vulnerable to flooding. Municipal town planners must enhance compliance monitoring and make sure that planning decisions align with disaster risk reduction principles. Exacerbated heavy rainfall variability and extreme weather events require spatial planning regulations and policies that are flexible and responsive to changing climatic conditions. Spatial planning tools such as the Spatial Development Framework and Land Use Schemes should be regularly reviewed and updated to reflect the evolving flood risk and damage. The results suggest that infrastructure planning must be treated as a priority tool for spatial planning, rather than as a split sectoral mechanism. Inadequate infrastructure in rural communities exacerbates vulnerability to flooding, highlighting the necessity for collaborative planning among town planners, engineers, and disaster management officials. Also, the paper emphasises the need for an inclusive and collaborative spatial planning process. Weak community awareness of flood risks and damages shows a gap in public engagement. Spatial planning should then actively collaborate with rural communities to incorporate local knowledge and enhance preparedness and resilience to flooding. The results show that nature-based and green infrastructure resolution should be widely adopted in spatial planning decisions. Protecting wetlands, river buffers, and natural drainage systems can minimise flood risks and damages while supporting sustainable land use and environmental protection. Overall, these implications highlight that spatial planning in rural South Africa must be integrated, proactive, and resilient to effectively minimise flood vulnerability and support rural developments in South Africa.

Flood risk management should be incorporated into rural spatial planning frameworks and policies. SDF and LUS must explicitly identify areas that are vulnerable to flooding and restrict settlement development in high-risk areas. In areas where relocating is unfeasible, spatial planning frameworks and policies must enhance flood-resilient settlement patterns and implement development control measures that minimise

exposure to flood risks and damages. There is a need to enhance infrastructure development in rural communities, especially drainage systems, roads, bridges, and stormwater management infrastructure. Enhanced infrastructure will minimise flood impacts and enhance accessibility during and after flood events, thereby heightening the adaptive capacity of rural communities. Green infrastructure and nature-based solutions should be enhanced as part of spatial planning strategies to minimise flooding in rural communities in South Africa. Tools such as wetland restoration, riparian buffer zones, reforestation, and sustainable land management practices can minimise surface runoff, promote water absorption, and minimise flood risks while supporting environmental sustainability. Rural community residents should be educated about flood risks, early warning systems, and appropriate response strategies, and also enhance community awareness and participation. Participatory spatial planning processes that actively include local communities can enhance local knowledge incorporation and ensure that spatial planning interventions are socially acceptable and contextually relevant. Effective flood resilience needs collaboration among town planners, disaster management authorities, environmental officials, and local governments. Enhanced data sharing and governmental capacity building will support informed decision-making and the enforcement of incorporated flood risk management strategies.

7 CONCLUSION

This paper analysed the role of spatial planning in enhancing rural resilience in South Africa, with particular emphasis on settlement patterns, spatial planning regulation and policies, infrastructure delivery, and community involvement. The results present that flooding continues to be a lived reality for many rural communities in South Africa, with repeated challenges to housing, agriculture, livelihoods, and human settlement stability. Although formal recognition of spatial planning as the main mechanism for flood risk management exist, its practical effectiveness in rural communities remains weak. This paper shows that many rural communities persist in areas that are vulnerable to flooding due to limited awareness of flood risks and damages, poor incorporation of flood risk management into spatial planning regulations and policies and weak governance systems. SDF and LUS in rural local municipalities commonly lack detailed flood risk assessments and hazard mapping, leading to reactive rather than preventative spatial planning approaches. This weakens the capacity of spatial planning to guide safe human settlement development and minimise long-term flood vulnerability. Poor infrastructure delivery and maintenance further increase rural flood risks. The absence of effective drainage systems, inadequate road networks, and poor stormwater management infrastructure exacerbate the frequency and intensity of flood impacts and limit emergency response and recovery. This infrastructural impact shows broader spatial inequality among urban and rural communities and emphasises the necessity for incorporated infrastructure and land use planning.

This paper also identifies the poor collaboration among key stakeholders, including tribal authorities, municipal officials, and environmental and disaster management officials. This poor collaboration weakens the implementation of spatial planning regulations and hinders the effectiveness of flood risk reduction measures. Furthermore, limited community awareness and involvement in the spatial planning process limit local preparedness and weaken the sustainability of planning involvement. Overall, the paper results highlight that spatial planning in rural South Africa has major potential to enhance flood resilience, but it is currently hindered by institutional, infrastructural and governance impacts. Enhancing the incorporation of flood risk management into spatial planning, investing in resilience and green infrastructure, enhancing intergovernmental collaboration, and promoting inclusive and participatory planning processes are important to minimising rural flood vulnerability. By integrating a more proactive, incorporated and risk-sensitive spatial planning approach, rural South Africa can move towards greater resilience, safety, and sustainable human settlement development.

1 ABSTRACT

In the City of Johannesburg (CoJ), the proposed Clean Air Zones (CAZs) initiative, aligned with the C40 framework, promises substantial public health gains through air pollution reduction. However, without equity-centered design, CAZs risk deepening entrenched socio-economic disparities inherited from apartheid-era spatial planning. This study analyzes CAZ implementation pathways and their differential impacts across Johannesburg's seven administrative regions using datasets from the Gauteng City Region Observatory (GCRO), South African Census, and municipal reports. Five regulatory mechanisms comprising vehicle restrictions, solid fuel prohibitions, waste management formalization, industrial emission controls, and charging zones are examined through the lens of income inequality, service access gaps, spatial poverty, and environmental justice indicators. Findings reveal acute vulnerability concentrations: 71% of residents defaulting on utility bills cite unaffordability; 41% of Region G households experience meal-skipping; and declining service coverage (water satisfaction dropped from 79% to 59% between 2020/21-2023/24) compounds policy compliance capacity. A composite regional vulnerability matrix identifies Regions D and G as requiring priority equity interventions, while Regions B, E, and F demonstrate greater adaptive capacity. The study concludes that Johannesburg's CAZs must operationalize through phased geographic implementation, targeted subsidies for clean energy transitions, formalized inclusion of informal waste reclaimers, and participatory policy co-design with marginalized communities. This approach harmonizes environmental sustainability with social justice, advancing SDG commitments while preventing policy-induced displacement.

Keywords: Clean Air Zone (CAZ), Social Equity, C40, Environmental Justice, Vulnerability Assessment.

2 INTRODUCTION

The imperative to combat urban air pollution has mobilized cities globally toward Clean Air Zones (CAZs). Designated areas where vehicle emissions, solid fuel combustion, and industrial pollutants face stringent regulations to protect public health (Altarrazi et al., 2025; Bloss et al., 2025; Mebrahtu et al., 2025). As a C40 Cities member, Johannesburg has committed to implementing CAZs to address deteriorating air quality exacerbated by vehicle congestion, informal solid fuel use, and waste accumulation that undermines its "world-class African city" aspiration. Yet environmental policies designed without socio-economic analysis risk reproducing the very inequalities they claim to transcend (Druckman & Jackson, 2008).

South Africa's persistent inequality, rooted in colonial and apartheid spatial engineering, creates differential vulnerability to environmental regulation (Mashabela et al., 2025). Where European and North American CAZs operate within relatively robust social safety nets, Johannesburg must navigate a context where 48% of households depend on social grants, 11% default on utility payments, and informal economies provide survival mechanisms for populations excluded from formal employment (Götz & Seedat, 2024). In this landscape, policies restricting polluting fuels, informal waste picking, or high-emission transport without viable alternatives do not merely regulate environmental behaviour; they eliminate livelihood pathways and deepen material deprivation.

Recent research by Nabilla et al. (2025) through the Seriti Institute surveyed Johannesburg residents' perceptions of air pollution causes and health impacts, establishing public awareness of the CAZ rationale. However, this polling did not systematically assess households' capacity to comply with anticipated regulations or map vulnerability differentials across the city's socio-economic geography. This gap is critical: effective CAZ implementation requires understanding not whether residents support cleaner air, a near-universal preference, but whether they possess the economic resources, service infrastructure, and social capital to adapt to regulatory changes without catastrophic livelihood disruption.

This paper addresses that gap through socio-economic vulnerability assessment, analyzing how five CAZ regulatory mechanisms, vehicle restrictions, solid fuel prohibitions, waste management formalization, industrial emission controls, and charging zones intersect with Johannesburg's inequality landscape. Drawing on GCRO Quality of Life Survey 7 data (Tshuma et al., 2024), we map spatial patterns of income precarity, service access deficits, transportation dependence, and environmental injustice across the city's seven administrative regions. Our analysis reveals that CAZ regulations, if uniformly imposed, would function as regressive taxation on the urban poor, extracting compliance costs from populations least able to bear them while delivering environmental benefits disproportionately consumed by affluent communities already insulated from pollution exposure (Metheny et al., 2025).

The contribution of this study is threefold. First, we theorize the causal pathways linking CAZ regulations to household-level economic shocks, moving beyond correlation to a mechanism explanation. Second, we develop a composite regional vulnerability matrix synthesizing multiple deprivation indicators to guide geographically differentiated policy rollout. Third, we translate empirical findings into actionable implementation guidelines that harmonize environmental sustainability with social equity, demonstrating that these objectives, often framed as trade-offs, can be mutually reinforced through deliberate institutional design.

The urgency of this analysis extends beyond Johannesburg. As developing-world cities increasingly adopt environmental frameworks designed in Global North contexts, understanding adaptation requirements for settings characterized by informality, service deficits, and entrenched poverty becomes essential. Johannesburg's CAZ implementation will either demonstrate equitable environmental governance or reproduce colonial patterns where regulation serves affluent interests while criminalizing survival strategies of the marginalized. The evidence and framework presented here aim to ensure the former outcome.

3 LITERATURE REVIEW

Investments in environmental policies hold life-supporting potential in contemporary times due to the rapid environmental degradation. Despite their utility, inadequate assessment of their social costs could limit their effectiveness or even lead to social destabilization in societies. As governments strive to ensure that cities support healthy living, they must maintain social justice while doing so.

Cities around the world are implementing Clean Air Zones (CAZs) initiative, an embodiment of the global C40 framework for reducing air pollution and enhancing public health (Altarrazi et al., 2025; Bloss et al., 2025; Mebrahtu et al., 2025). Although this initiative is essential for ensuring urban resilience and environmental sustainability, if it is not properly planned and implemented in conformity with the socio-economic realities of the people, it risks exacerbating existing social inequalities. This is particularly true among South African cities, particularly Joburg, where deep-rooted social disparities continue to shape access to opportunities and resources (Metheny et al., 2025).

In the City of Johannesburg (CoJ), South Africa, the municipal government is trying to enhance city life through the implementation of the CAZ initiative. This need arises from the increasing erosion of public spaces by informal recyclers, homeless people, and the increasing waste accumulation in the city. Clearly, these emerging features negate the aspiration of Johannesburg as “a world-class African city”. To address this trend, public policies, particularly environmental policies in the city, must regulate pollution, waste management, and related urban activities that contribute to the current environmental challenges. While intervening policies in this regard are urgently necessary, such policies must consider the differing socio-economic disparities among the people. As posited by Druckman and Jackson (2008), without this consideration, developing inclusive policies for environmental sustainability and social justice could be difficult.

While the city, through a company, Seriti Institute, conducted a polling survey to aggregate residents' perception of the CAZ initiative (Nabilla et al., 2025), the focus was more on the causes and impacts of air pollution in the city than on the socio-economic realities of the people with the potential to impact the success of the initiative. This study extracts data on socio-economic indicators of people in the city of Johannesburg, mainly from the GCRO datasets, to assess the socio-economic realities of Joburgers and frame the implications of these on CAZ initiative implementation in the city.

4 METHODOLOGY

In conducting a socio-economic assessment of residents in CoJ, this study relied on existing data collected and analyzed by various government bodies in South Africa. Conducting this assessment using primary data could be more comprehensive but also resource-intensive. However, in the absence of budget coverage for this, existing data in documents such as the Gauteng City Region Observatory (GCRO) report (2024), South African Census Report, CoJ reports, etc., were adopted in assessing the prevailing socio-economic status of people living in the city to understand and adequately accommodate their needs and peculiarities in the programs of the city, particularly the implementation of the CAZ inititive. Five indicators relevant to the successful implementation of CAZ, while ensuring social equity and justice, were adopted. These indicators were: income and employment status, access to basic public services, spatial inequity as regards poverty and transportation, waste management, and social inclusion.

5 FINDINGS

5.1 Socio-Economic Indicators

In understanding the socio-economic life patterns of the people of CoJ, the indicators of income & employment, public service access, spatial inequality spread, environmental justice, and digital & social inclusion were adopted. It is based on these indicators that the subsequent sections of the report were discussed.

5.1.1 Income and Employment

Income is strategic to the conditions of living of households as it funds their daily and seasonal needs. Furthermore, it dictates the extent to which paid basic public services can be accessed. In economics, three levels of income earners exist. While there are high- and middle-income earners, there are also low-income earners. In the CoJ, a GCRO QoL Survey 7 explored the percentage of residents with unpaid utility bills (water/electricity) and the reasons for defaulting. In the survey (see Figure 1), it was found that 11% of respondents have unpaid utility accounts, with 71% reporting that they cannot afford to pay. Additionally, 14% respondents reported not knowing whether their household owes money for water or electricity (not shown in the graphs). In addition, the highest percentage of respondents with unpaid bills (22%) was recorded in Region D, highlighting significant affordability challenges in this area. Region B has the lowest proportion, at 4%, indicating fewer payment issues in this region. On average, therefore, 11% of residents in the city have unpaid utility accounts, with 71% of them citing an inability to pay as the reason for the default. This indicated a growing financial incapacity among residents of the city.

This financial condition could be explained by the rate of unemployment in the city (see Figure 2). For instance, 505 of the respondents sampled in the GCRO QoL Survey 7 were unemployed or not working for various reasons. Approximately 2% reported being appointed to a new job they had not started yet. Among those not working, over half (53%) are looking for work, while a quarter (25%) never secured a paying job, with 54% of respondents are retired.

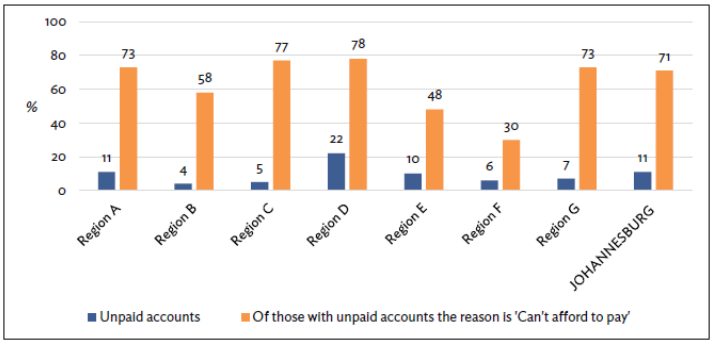

Figure 1: People with unpaid utility accounts (water/electricity) in the CoJ.

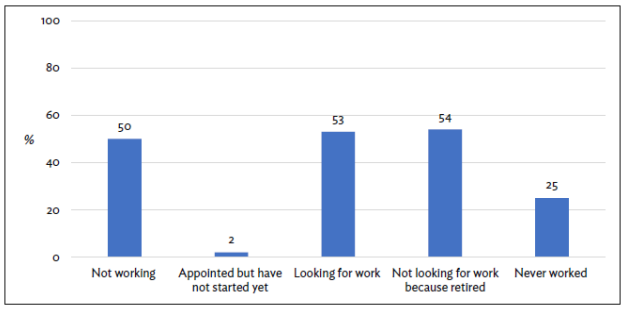

Figure 2: Employment status of GCRO's Survey respondents in CoJ. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

Invariably, the majority of Joburg residents are unemployed and lack a steady source of income, resulting in their inability to pay their utility bills. Furthermore, this limits the extent to which people have access to basic public services.

5.1.2 Access to Basic Services

Public service delivery in South Africa has been characterized by widespread dissatisfaction over the years (Götz & Seedat, 2024). Before focusing on the City of Johannesburg, this paper provides an overview of the public service delivery trend in Gauteng province, a broader context for CoJ, as presented in Figure 3.

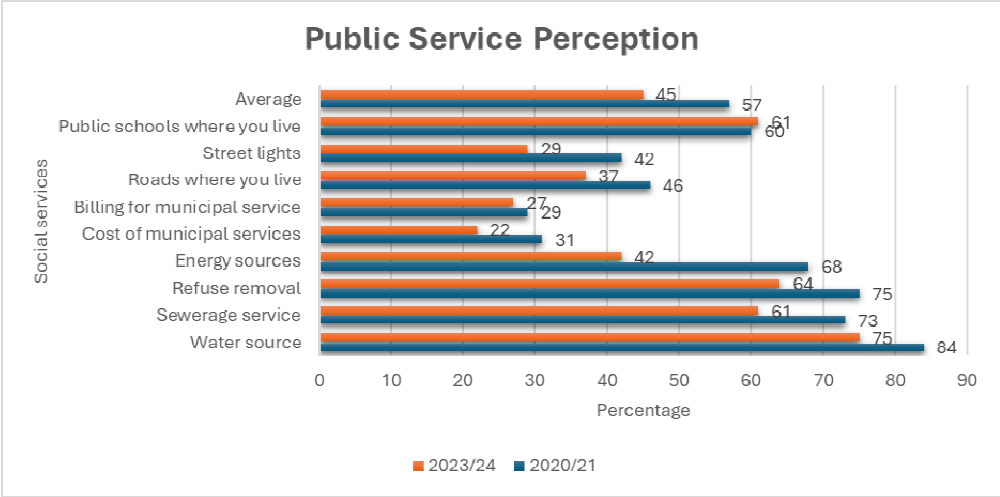

Figure 3: Public satisfaction with basic services in Gauteng. Source: GCRO QoL 7 Survey (Götz & Seedat, 2024).

Indications from Figure 3 suggest that access to public services in Gauteng province has steadily declined over time. In 2020/21, 57% of the population reported satisfaction with service performance; however, by 2023/24, this figure had dropped sharply to 45%, despite a modest increase in the number of public schools in the province. A closer examination of individual cities reveals a similar downward trend.

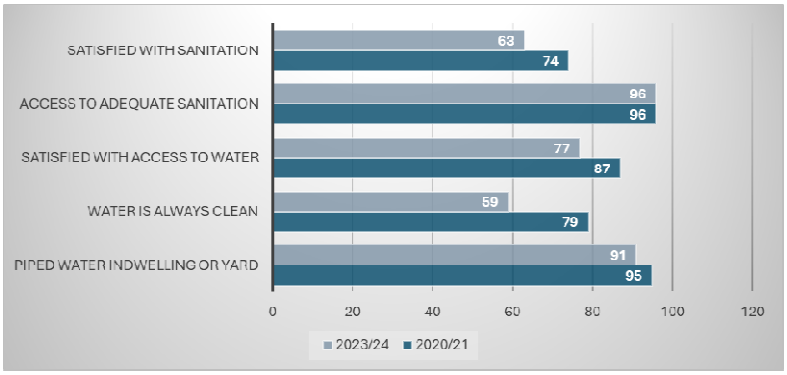

Figure 4: Perception of CoJ residents on water/sanitation service delivery. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

In the City of Johannesburg, Figure 4 highlights the situation regarding water and sanitation services. Satisfaction with these essential services has continued to deteriorate. For example, access to piped water within dwellings has declined: in 2020/21, 95% of residents reported access, but this fell by 4% in 2023/24. Likewise, satisfaction with water quality dropped significantly, from 79% in 2020/21 to 59% in 2023/24. Dissatisfaction with overall water service delivery also increased, with 77% of respondents expressing concern in 2023/24, 10% more than in 2020/21. The same pattern is evident in sanitation services, where confidence has continued to erode, even as the proportion of households with adequate sanitation remained unchanged between 2020/21 and 2023/24.

Another important social service that was investigated in the GCRO's QoL Survey 7 was the supply of electricity to the 7 regions in CoJ (see Figure 5). Basically, electricity functions as both a source of lighting and energy. For lighting, between 202/21 and 2023/24, the percentage of residents in the city that relied on it for lighting drops from 94% to 82%, indicating either an increase in loadshedding/interruption or a reduction in the capacity of residents to afford it, thereby switching to alternative light sources such as candles, solar, etc.

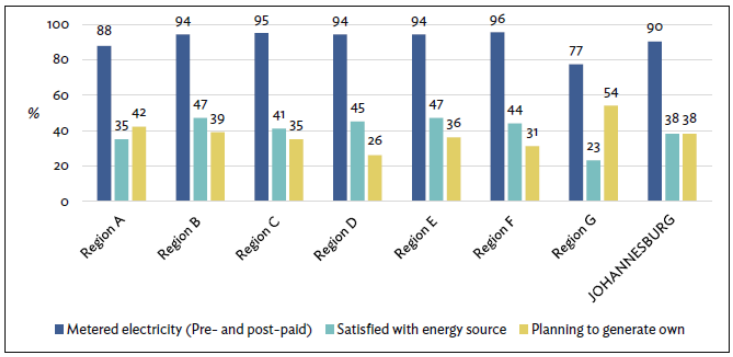

Figure 5: Perception and plans of CoJ residents on electricity supply and consumption. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

Access to metered electricity (both pre- and post-paid) is high across all regions, as depicted in Figure 5, with over 90% of households connected to the grid, on average, except in Region G, where the rate is 77%. In Region F, the highest proportion of households (96%) with metered electricity access was recorded, followed by Region C at 95%. Satisfaction with the energy sources varies widely: Regions B, D, E, and F report higher satisfaction levels (44% to 47%) compared to other regions. Region G has the lowest satisfaction at 23%. Notably, 54% of Region G residents plan to generate their own electricity, likely in response to lower access to metered electricity or general dissatisfaction with energy sources.

Healthcare is equally an important social service that governments, at all levels, commit to ensuring unhindered access to. This is given its connection to healthy living and its support for building an agile workforce necessary for achieving economic growth and development. In the City of Johannesburg, access to healthcare facilities is based on proximity, affordability, and belief system. This suggests the availability of three healthcare categories, consisting of public and private healthcare facilities, and traditional/spiritual healers that attract rural dwellers, mostly, given their belief in spirituality. Figure 6 below shows the spread of residents in the city across these healthcare options.

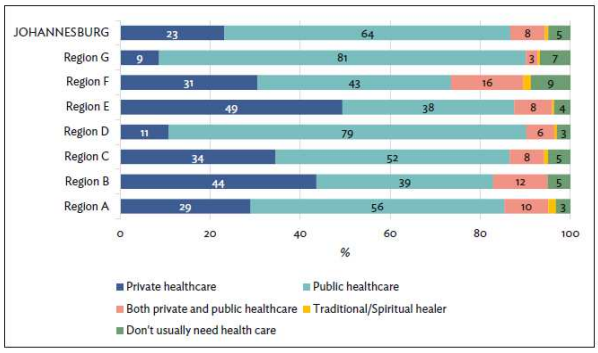

Figure 6: Healthcare service access in CoJ. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

In the figure above, while 5% of Johannesburg residents do not patronize any of the healthcare categories, nearly one in four residents access private healthcare facilities, whereas 64% use public healthcare facilities. An additional 8% use a combination of both. The use of private healthcare facilities is highest in Region E and lowest in Region G. Consequently, Region G has the highest reliance on public healthcare, at 81%. This trend suggests that Region E could be a suburb comprising educated and middle-income earners with the capacity to afford orthodox healthcare service, and with the direct opposite in Region G.

Furthermore, the survey provides data explaining the motivation for the growing acceptance of alternative healthcare providers in the city. Basically, the survey showed a decline in the level of satisfaction with the public healthcare services. As presented in Figure 7, a 38% dissatisfaction rate was reported with public healthcare services. This rate becomes significant when converted to the number of people involved. At the individual regional comparison in the city, 77% satisfaction rate, the highest in the city, was observed in Region B, while the lowest, 39%, was reported in Region G. This corroborates the earlier submission of the growth of patronage for alternative/native healthcare systems in Region G.

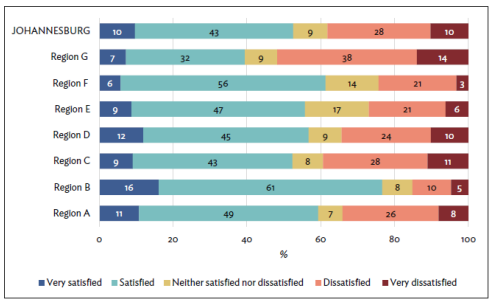

Figure 7: Perception of respondents on public healthcare service access in CoJ.

5.1.3 Spatial Inequity (Poverty & Transportation)

Characteristically, poverty has been explained to be the inability of an individual or group of people to have the wherewithal to provide themselves or their dependents with the necessities of life. These necessities include food, shelter, healthcare, education, transportation, and others. Given the centrality of food/hunger to categorizing poverty, this report, relying on the GCRO data on the prevalence of hunger among Johannesburg residents, presents the spatial poverty spread among regions in the city (see Figure 8).

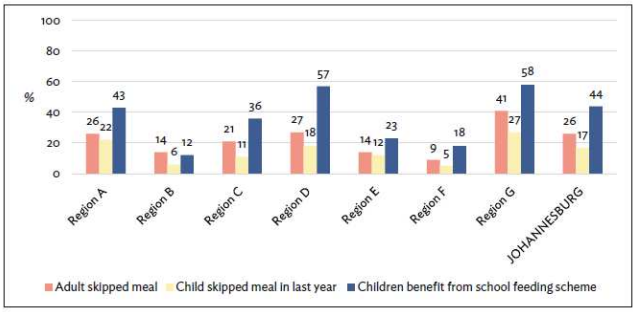

Figure 8: Hunger spread among residents in the CoJ.

In the figure above, the data were based on the criteria of "any member of the household who has skipped meals in the last 12 months owing to inability to afford food," and "the number of children within the household that benefit from a school feeding scheme."

Hunger remains a significant challenge in the CoJ, given the rate of adults (26%) and children (17%) who skipped meals in the last 12 months. Furthermore, Region G has the largest proportion of households where adults have had to skip meals (41%), followed by Regions D and A, at 27% and 26%, respectively. Region F reported the lowest proportion, at 9%. In total, 66% of Johannesburg households have one or more children, with 17% of these skipping at least a meal in the past year due to insufficient money for food. Regional variation is slightly less pronounced compared to households where adults skipped meals. In cushioning the effect of this trend, on average, 44% of Johannesburg households have children benefiting from a school feeding scheme. The highest levels of such support are in Regions D and G, where 57% and 58% of

households with children reported benefiting from these schemes. Region B has the lowest proportion, at 12%.

To further address the spreading hunger and poverty, a social grant scheme to support households facing difficulties was introduced. In Johannesburg, 48% of households have at least one member receiving a social grant (see Figure 9). Additionally, 41% of respondents live in households registered as indigent. In terms of monthly household income, around one in five Johannesburg respondents (22%) live in households with a total monthly income of less than R3,201. In some regions, the proportion of households receiving a social grant aligns closely with the proportion registered as indigent, while there are notable disparities in other regions. For example, in Region D, 67% of households receive a social grant, compared to 46% registered as indigent. In contrast, in Region F, only 26% receive a social grant, with 53% registered as indigent. This disparity may indicate that many households are unaware of how to register as indigent. Overall, these indicators highlight a particular concentration of poverty in Regions D and G.

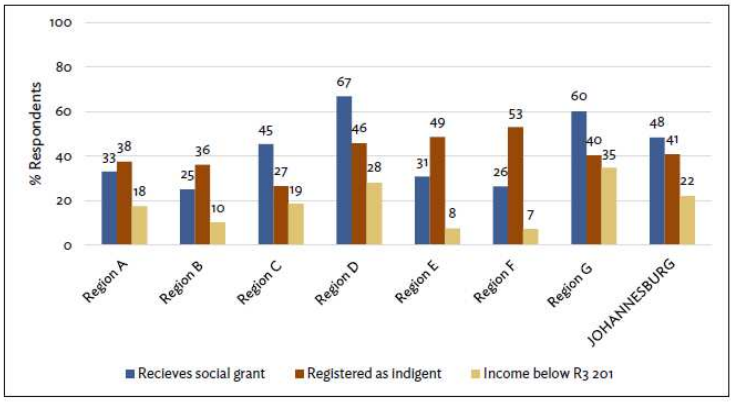

Figure 9: Social grant spread in the CoJ.

In the daily commuting of residents in Johannesburg, there exist many means of transportation, with each indicating the socio-economic status of the people concerned. This is not a clear-cut generalization; rather, it is an attempt to understand the living conditions of the people through their means of transportation on a regular basis. As found in the GCRO's QoL Survey 7 dataset, public transport was the most used mode of transport (47%), followed by cars (33%) and walking (18%) (Figure 10). Cars are more frequently used by respondents in Regions B, E, and F, with over 50% reliance. Public transport usage is highest in Region G, at 62%, while Region D has the highest proportion of respondents who walk, at 25%.

This mobility pattern could explain the socio-economic status of people in the various regions of the city. While residents of Regions B, E, and F with cars as their most frequent mode of transportation could be explained to be of the upper income class, given their ability to afford cars and fuel them, it could also be the absence or inadequacy of public transportation routes in their areas. Understanding this more deeply would require the examination of the public transportation route in the CoJ. Nevertheless, there appears to be a general low socio-economic status among residents of Regions D and G, given their reliance mostly on public transport and walking.

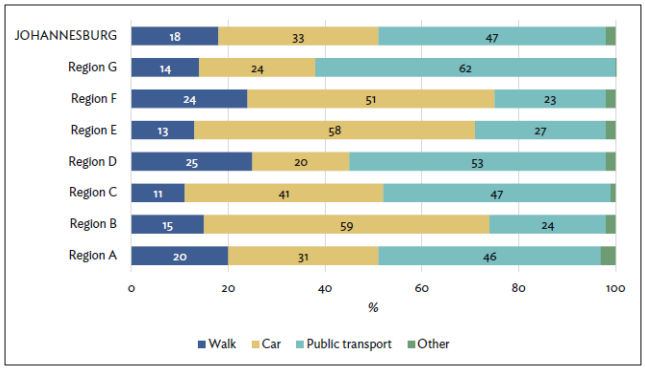

Figure 10: Transportation modes in the CoJ.

5.1.4 Environmental Justice

Regarding the CAZs initiative, waste management is central, given the impact of unsustainable waste management practices on environmental pollution. In the City of Johannesburg, there exists an organized waste collection scheme, and in gauging the frequency of weekly waste collection and the overall satisfaction with the service, GCRO's QoL Survey 2023/24 was conducted (see Table 1). Findings from the survey indicated that in 2020/21, 89% of the surveyed residents confirmed that their household waste was regularly removed on a weekly basis. This figure dropped to 84% in 2023/24, showing a contraction in the service coverage of the waste management body in the city. This service decline justified the reduction in the level of people's satisfaction in the service from 82% in 2020/21 to 80% in 2023/24.

Environmental justice indicators	2020/21	2023/24
Weekly refuse removal	89%	84%
Satisfaction with service	82%	80%

Table 1: Waste management scheme in CoJ. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

5.1.5 Digital & Social Inclusion

Access to information is assuming an important right of every individual, given its centrality to accessing opportunities and avoiding danger. In this mix, smartphones occupy a central position. With the increasing mobile applications for varied activities, the level of internet access can be measured using data on smartphone distribution in the City of Johannesburg. In Figure 11, the spatial variation in the proportion of households per ward in Johannesburg with access to a working smartphone is presented. Since most households have access to a smartphone, the spatial pattern does not vary much. Wards with low access (between 36% and 50%) are mostly in south Johannesburg, especially in wards around Soweto and some near the CBD. In the rest of Johannesburg, the proportion of households with access to a working smartphone is much higher (above 90%), with slight variations in and around townships such as Alexandra, and near Ennerdale in the far south.

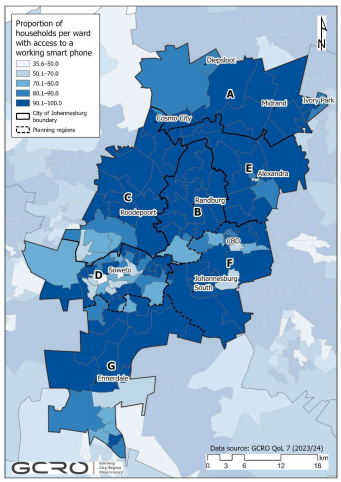

Figure 11: Smartphones spread in the CoJ. Source: GCRO's Quality of Life Survey 7 (2023/24) (Tshuma et al., 2024).

6 DISCUSSION AND POLICY IMPLICATIONS

There are many pathways for operationalizing the Clean Air Zones initiative, with each capable of deepening existing disparities when imposed without equity safeguards (Druckman & Jackson, 2008). Understanding these pathways is critical for Johannesburg, where prolonged inequality creates a differential policy burden (Mashabela et al., 2025).

First, CAZ implementation required restricting high-emission vehicles disproportionately, with possible impact on the travelling experience of low-income commuters and informal transport operators. With 62% of Region G residents relying on public transport and 25% of Region D residents walking (Figure 10), CAZ-induced fare increases from fleet upgrades would compound existing mobility poverty. The 22% of households earning below R3,201 monthly cannot absorb these costs, forcing further service exclusion. Second, restricting cheap energy sources, such as coal and firewood for heating/cooking, directly threatens the 71% of residents unable to pay utility bills (Figure 1). In Regions D and G, where 41% experience adult meal-skipping and electricity satisfaction is lowest (23% in Region G), households depend on polluting fuels

as survival mechanisms, not lifestyle choices. Prohibition without subsidized alternatives forces impossible trade-offs between compliance and basic needs (Götz & Seedat, 2024).

Thirdly, formalizing waste collection threatens informal reclaimers' livelihoods, a population already marginalized by declining municipal service (84% coverage in 2023/24 vs. 89% in 2020/21). With 48% of households receiving social grants and 41% registered as indigent, informal waste picking provides critical income. CAZ restrictions on informal recycling eliminate this safety net without creating formal employment alternatives, exacerbating the unemployment crisis where 53% actively seek work (Figure 2). Furthermore, while regulating industrial emissions is necessary, these regulations impose compliance costs that formal businesses pass to consumers through price increases. For the 67% of Region D households on social grants, even marginal cost increases in essential goods deepen food insecurity and utility payment defaults.

These pathways interact synergistically: a household forced to abandon polluting fuels without affordable alternatives may default on electricity payments, lose waste-picking income from CAZ enforcement, face higher food prices from industrial compliance costs, and experience reduced mobility from transport restrictions, a cascading vulnerability spiral that transforms environmental policy into socio-economic destabilization (Metheny et al., 2025).

To explore the spread of vulnerabilities across the seven regions in the city, Table 2 is presented. The table synthesizes vulnerability indicators across Johannesburg's seven regions, revealing differentiated CAZ impact exposure. Regions are scored on key indicators, with darker shading indicating higher vulnerability.

Indicators/Regions	A	B	C	D	E	F	G
Unpaid utility bills (%)	11	4	9	22	10	8	18
Unemployment rate (%)	Moderate	Low	Moderate	High	Low	Low	High
Adult meal skipping (%)	26	15	18	27	12	9	41
Social grant dependency (%)	45	22	38	67	35	26	65
Public transport reliance (%)	45	28	42	52	32	35	62
Healthcare satisfaction (%)	62	77	68	58	71	65	39
Satisfaction with electricity (%)	38	47	42	44	45	46	23
Access to metered electricity (%)	92	94	95	91	93	96	77
School feeding scheme (%)	38	12	32	57	28	18	58
Composite vulnerability	Medium	Low	Medium	High	Low	Low	Very high

Table 2: Composite Regional Vulnerability to CAZ Implementation. Source: Compiled by the Authors

Table 2 presents the vulnerability spread across regions in the CoJ. Region G exhibits extreme vulnerability across all dimensions, the highest meal-skipping (41%), lowest electricity satisfaction (23%), weakest healthcare access (39%), and greatest transport precarity (62% public reliance). Region D follows with concentrated poverty (67% social grant dependency, 22% utility defaults). Conversely, Regions B, E, and F demonstrate resilience through lower poverty indicators and higher service satisfaction, though no region is immune to CAZ disruption.

This spatial concentration of vulnerability demands geographically differentiated CAZ implementation. Uniform policy enforcement would constitute environmental injustice, imposing disproportionate burdens on communities least equipped to adapt (Druckman & Jackson, 2008). The matrix provides an empirical foundation for a phased, equity-centered rollout that addresses Johannesburg's persistent inequality patterns (Götz & Seedat, 2024) while advancing environmental sustainability.

7 CONCLUSION

Johannesburg stands at a governance crossroads. The Clean Air Zones initiative can either exemplify equitable environmental leadership or reproduce historical patterns where policy serves affluent interests while criminalizing the survival strategies of marginalized communities. This study's evidence compels the former path. Most fundamentally, this study demonstrates that environmental sustainability and social equity are not competing values requiring tragic trade-offs. They are mutually dependent: environmental policies that deepen inequality invite resistance, undermine legitimacy, and ultimately fail to achieve ecological objectives. Conversely, equity-centered environmental governance mobilizes broad coalitions, generates compliance through capacity-building rather than coercion, and produces resilient systems benefiting all residents.

The time for transformative action is now. Johannesburg's CAZ implementation will be observed across the African continent and the Global South as cities navigate the tension between environmental imperatives and development justice. Success requires rejecting the false premise that cities must choose between breathable

air and livable livelihoods. By centering equity, through subsidies, phased rollout, participatory design, and service infrastructure investment, Johannesburg can demonstrate that its "world-class African city" aspiration is achievable precisely by prioritizing those historically excluded from such visions. Environmental resilience and social justice, implemented together, engender the foundation of urban excellence.

8 ACKNOWLEDGEMENT

The authors gratefully acknowledge the South African Statistics South Africa (Stats SA), Gauteng City Region Observatory (GCRO), and the City of Johannesburg's Citizen Relationship and Urban Management (CRUM), whose published datasets and reports served as a key reference in this study. The availability of their documented analysis significantly enriched the research and contributed to the robustness of our findings.

1 ABSTRACT

European policy documents underline the vital contribution of small and medium-sized towns to the urban systems of EU member states. Across several countries, there is a growing intention to equip these towns with new policy instruments that would strategically strengthen their position as drivers of regional development. Common areas of intervention include the regeneration of public buildings, support for business growth and innovation, enhanced regional connectivity, housing improvements, and increased investment in culture, education, and social services.

In the education of urban planners within the course Urban Planning Workshop 1: Settlement Planning at the Graduate Study Program in Architecture and Urban Planning at the Faculty of Architecture, University of Zagreb, small and medium-sized towns hold particular importance. Due to their optimal scale and the complexity of their challenges, they serve as suitable case studies through which students learn the processes of strategic thinking and spatial planning for future urban development. For the purposes of this paper, the example of the small town of Čakovec in northern Croatia was selected. In the academic year 2025/2026, Čakovec served as the workshop assignment for which students were tasked with proposing potential spatial development visions for the town for the period up to 2050.

The aim of this article is to present the educational process in Urban Planning Workshop 1: Settlement Planning, which focuses on planning the long-term future development of a small town. The main objective of the workshop is to formulate a comprehensive vision for the town's spatial development, while also providing a more detailed elaboration of selected areas considered relevant for future transformation and growth.

Keywords: Spatial planning, Small town, Development vision, Education, Čakovec

2 INTRODUCTION

Education in the field of spatial planning is largely shaped by national contexts and the institutional frameworks of individual countries. Janin Rivolin et al. (2025) start from the assumption that the educational process involves the transmission and development of specialized technical knowledge that can be taught through theoretical and practical education, independently of the specific features of national planning systems. They further argue that, although institutional and legal frameworks significantly influence professional practice, they do not fully determine the content and structure of technical knowledge within educational programmes. The authors advocate a clear distinction between spatial planning and urban governance, with the former serving as an instrument for the achievement of the latter. Technical knowledge in spatial planning is most effectively acquired when spatial zoning is established as its foundation and when long-term spatial patterns are identified.

Teaching requires that knowledge be presented to future professionals in a systematic and consistent manner. Due to the specific nature of education in the fields of urbanism and spatial planning, this requirement is less pronounced, as these fields encompass a complex domain of knowledge and practice in which diversity poses increasing challenges (Millard-Ball et al., 2021; Diko et al., 2023).

Understanding complex spatial systems and processes requires specific practical skills as well as theoretical knowledge drawn from multiple scientific disciplines and fields, thereby making the education of spatial planners more comprehensive. AESOP (2024) highlights the need to place particular emphasis on the development of strategic thinking competencies and on strengthening capacities for long-term foresight and spatial planning, whether at the regional or local level.

Since the 1990s, particular attention has been given in Europe to strategic spatial planning as a means of addressing economic, social, and environmental challenges, with the aim of developing a coordinated vision to guide medium- and long-term development (Albrechts & Balducci, 2013; Balducci, Fedeli, & Pasqui, 2011; Albrechts, Healey, & Kunzmann, 2003). Hersperger et al. (2019) point out that strategic spatial plans focus on a combination of development strategies and strategic urban projects. Schmitt and van Well (2016) argue that attention is predominantly directed toward governance processes, while insufficient emphasis is placed on linking these processes to physical transformations in terms of land cover and land-use change. In the implementation of strategic plans, particular attention should be paid to local statutory plans (Mäntysalo, Kangasoja, & Kanninen, 2015; van den Broeck, 2013), as these enable the physical transformation of space.

Small towns represent a particularly suitable context for the education of future spatial planners within the field of spatial planning. European policy documents emphasize their key contribution to the urban systems of EU Member States, and in many countries there is a stated intention to equip them with new policy instruments aimed at strategically strengthening their role as drivers of regional development. ESPON (2024) point out that particular attention should be devoted to development through the renewal of public buildings, support for entrepreneurship and innovation, the enhancement of regional connectivity, improvements in housing, and investments in culture, education, and social services. Within urban systems, such towns constitute spatial systems in which relationships between governance processes and physical spatial transformation are more readily observable and, due to their scale, less complex, thereby facilitating a more comprehensive understanding of space compared to large metropolitan areas.

The aim of this paper is to present the educational process in Urban Planning Workshop 1: Settlement Planning, which focuses on planning the long-term future development of a small town. The main objective of the workshop is to formulate a comprehensive vision for the town's spatial development, while also providing a more detailed elaboration of selected areas considered relevant for future transformation and growth.

3 EDUCATION OF FUTURE SPATIAL PLANNERS ON THE FUTURE DEVELOPMENT OF SMALL TOWNS

3.1 Education of Spatial Planners in the Context of EU Documents

The most significant European documents related to the education of spatial planners are the result of the work of two organizations: the European Council of Spatial Planners (ECTP-CEU) and the Association of European Schools of Planning (AESOP).

During the ECTP-CEU meeting in Athens in 1995, national institutes and professional associations of planners within the European Economic Community signed the International Agreement and Declaration, thereby harmonizing professional standards, ethical principles, and shared objectives for the education and practice of spatial planning in Europe. In the supplement of Appendix B: Education and Training of the Charter, five common cores were highlighted as essential for the education of spatial planners, representing a fundamental part of the planning profession in Europe:

- Environmental Context – Perception and evaluation of the environment; local development; sustainable development; individual needs.
- Theory and Methodology of Planning – History and theory of planning; urban policies; spatial and temporal parameters; methods and research.
- Institutional Framework – Legislation and administration; local economy; interactions at national, regional, and local levels; statistics and resources.
- Professional Practice and Technique – Planning and design; strategies and simulations; interdisciplinary teams; governance and implementation; communication; design and aesthetics.
- Professional Matters – Professional knowledge and competence; responsibility and ethics; guidelines for practice; codes of conduct; promotion of standards.

In its 2013 document, Charter of European Planning, ECTP-CEU points out that research and analysis, advocacy and mediation, and the ability to envision, evaluate, and promote potential future options for urban, spatial, and territorial development constitute the core commitments of planners. In the Guidelines on

Professional Competences in Spatial Planning (2017), ECTP-CEU presented a framework defining the skills, knowledge, and responsibilities that spatial planners should possess in order to practice their profession competently and effectively. The document emphasizes three specific needs for the competences of spatial planners: critical thinking and understanding of the rationale of planning, including its theoretical and legal foundations; an understanding of spatial systems; and the technical and creative competences required to engage in planning practice. These are linked to eight core competences, which are presented in Table 1.

Specific needs for the competences	Core competences
Critical thinking and understanding of the rationale of planning and its theoretical and legal basis	The Rationale of Planning: Spatial planning plays a key role within a market-oriented environment, as it is grounded in the principles of sustainability, social justice, and ethical practice. It balances individual rights with public interest, enabling evidence-based decision-making and the resolution of spatial conflicts. Planners must be aware of the political and ethical dimensions of planning, particularly in relation to the public good, equity, and the fair representation of all stakeholders.
An understanding of the spatial systems	Socio-economic systems: Spatial planning requires an integrated understanding of social and economic systems and their spatial implications. Planners must possess fundamental knowledge of geographic analysis and operational contexts in order to assess political, social, and economic factors, with specialized expertise necessarily linked to local conditions.
	The Built Environment: Spatial planning requires an understanding of the built environment and its impact on quality of life and sustainable development. Particular attention is given to the principles and processes of creating high-quality spaces, the role of urban design, and the evaluation of design. Planners must consider the strategic potential of planning, climate change, challenges in historic contexts, and develop skills for place-making, alongside the ability to engage in interdisciplinary collaboration and mediation to foster inclusive and safe urban environments.
	Spatial planning requires an understanding of physical and biological systems and the effective management of resources, including health, quality of life, and the sustainable use of ecosystems, landscapes, and energy resources. Particular emphasis is placed on the conservation of natural resources and biodiversity, climate change adaptation, heritage protection, the development of renewable energy sources, and the application of planning in maritime areas.
Technical and creative competence needed to engage in planning practice	Planning Techniques: Spatial planning requires both quantitative and qualitative techniques to address spatial challenges and support policy implementation. Planners employ methods to define problems and collaborate within multidisciplinary teams. Planning involves the analysis, assessment, and monitoring of development alternatives and requires specialized knowledge and skills. This includes scenario development and evaluation, visualization of alternatives, land-use and social needs analysis, resource management, assessment of transport impacts, fieldwork, and the application of GIS and other analytical tools. Particular emphasis is placed on interdisciplinary collaboration, urban design, and the capacity for mediation, negotiation, and stakeholder participation.
	Independent Research: A key outcome of education in spatial planning is the development of competencies for independent research, including literature analysis, data collection, application of research methods, and the use of IT tools for analysis and evaluation. Research skills can also be assessed through alternative formats, without the necessity of producing a formal thesis or dissertation.
	Planning Instruments: Spatial planning requires knowledge of institutional and legal frameworks and the application of legal, administrative, and financial instruments. This includes understanding national, European, and international contexts, relevant directives and environmental protection instruments, legislation, and participation systems in planning processes.
	The Planning Product: The outputs of spatial planning include policies, instruments, programs, projects, strategies, and urban and landscape plans at different territorial levels. They encompass strategic frameworks and development visions, thematic strategies for water, energy, and food security, urban regeneration programs, and the integrated use of land, transport, and infrastructure. Planners must combine technical, creative, and personal knowledge and skills, including project management, problem-solving, collaboration, communication, and knowledge transfer, alongside competencies in negotiation, mediation, advocacy, and leadership.

Table 1: ECTP-CEU specific need and core competences defined in Guidelines on Professional Competences in Spatial Planning (2017). Source: Author according to ECTP-CEU, 2017.

The AESOP Core Curriculum (2024) represents an updated version of the Core Requirements for a high-quality European Planning Education (1995) issued as part of AESOP's statement odn European Planning Education. The document has two crucial roles for AESOP: identifying knowledge, competencies and values deemed vital for spatial planners at the beginning of the 21st century; and serving as a 'benchmark' for the evaluation of applications and admission of new member schools and their education programmes.

AESOP core curriculum (2024) of planning programs highlights three essential components – knowledge, practical skills, and values – that planners are expected to acquire or apply in order to carry out their responsibilities in a socially responsible and professionally ethical way. Graduates are expected to understand spatial dynamics across different scales, demonstrating the ability to produce, manage, analyse, interpret, and communicate knowledge relevant to spatial planning. They should also be able to translate this knowledge into practice by designing, evaluating, and implementing spatial interventions that consider multiple stakeholders. Finally, graduates are encouraged to develop a sustainable professional practice by assuming the societal responsibilities inherent to the role of a spatial planner.

In Chapter B, From Knowledge to Action, the development of knowledge is emphasized: regarding the nature, purpose, theory, and methods of planning; its historical evolution as an institution and profession; planning instruments and their adaptation to new challenges; the role of actors and citizens in democratic processes; the political, legal, and cultural context of planning; the application of transformational technologies; and transformative action in the context of sustainable development, climate crises, and spatial injustice.

In addition, the chapter highlights the need to develop practical competencies related to: the assessment and enhancement of the values of natural and built environments; the application of planning concepts, instruments, and measures in practice; the integration of different types of knowledge as well as aesthetic and design dimensions into planning proposals; the development of design and visual representation skills; the preparation of plans, programs, and measures, and participation in their implementation; active collaboration with civil society and stakeholders; and the management of complex governance and transformation processes.

Finally, it stresses the importance of cultivating an appropriate attitude and sense of responsibility, encompassing a conscientious and value-driven approach to planning that acknowledges its ethical implications, the cultural embeddedness of social and collective processes, democratic procedures, and rights such as the "right to the city," with particular attention to social justice, human and environmental rights, and respect for planetary boundaries.

3.2 Urban Planning Workshop 1: Settlement Planning: Case study Čakovec, Croatia

Urban Planning Workshop 1: Settlement Planning (UPW1) is one of the courses in the field of urbanism and spatial planning, offered in the first semester of the Graduate Studies in Architecture and Urbanism at the Faculty of Architecture, University of Zagreb. The main objective of the course is to develop a vision and concept for the spatial development of a small town based on the principles of sustainability. In the academic year 2025/2026, the assignment focused on the case study of the City of Čakovec.

The spatial development vision in UPW1 addresses the administrative area of the local government unit, the City of Čakovec, in the context of its surrounding settlements, with particular attention to the central settlement as well as Mihovljan, Savska Ves, and Ivanovec as potential areas for urban expansion. The task requires students to engage in strategic spatial thinking, assessing the potentials of the area and its acceptable capacities while taking into account spatial specificities and limitations arising from its unique values. Development guided by the principles of sustainability, as a paradigm of contemporary spatial planning, must be integrated into spatial visions and concepts to result in an environment suitable for living, working, and leisure, equipped with all necessary supporting facilities to meet societal standards.

Following analyses of the existing conditions, spatial planning documentation, and strategic development plans, the course assignment is developed on two levels of detail. At the first level, based on the objectives defined in the Spatial Plan of the City of Čakovec and the General Urban Plan of Čakovec, the town's development goals are established, and a vision for the spatial development of Čakovec is proposed and elaborated. At the second level, in accordance with the selected development concept, an optimal development program is proposed for individual areas of Čakovec, including concepts for land use, transportation, and spatial structures, as well as photomontages illustrating possible programmatic, design, and functional arrangements of the selected areas.

The course Urban Planning Workshop 1: Settlement Planning is thematically closely linked to Research Seminar 1: Settlement Planning and is primarily designed to complement and expand the knowledge and insights required to complete the assigned task. The aim of the course is to investigate spatial planning and urban design topics that contribute to the formulation of a spatial vision for the development of the studied small town and to propose a spatial development concept for the selected area. The course has a research-oriented character and culminates in the preparation of a seminar paper on the assigned topic.

At the beginning of the semester, in collaboration with the City of Čakovec and the Association of Architects of Međimurje, a joint site visit and invited lectures were organized for students to provide them with insights into the spatial specificities and local needs, as informed by professionals and residents.

In the summer semester, students will continue working on the Čakovec area within the framework of Urban Planning Workshop 2: Urban Transformation, where, in accordance with their previously developed concept

and development plan, they will create an urban-architectural design for the selected area. The most successful student projects from both courses will be exhibited in Čakovec at the end of the academic year, and a publication will be issued in collaboration with the local government.

3.2.1 City of Čakovec

The City of Čakovec is located in the northern part of the Republic of Croatia, in the central area of Međimurje County, serving as the administrative, governance, and transport center of the region. It covers an area of 73 km² and comprises 14 settlements, including the central urban settlement of Čakovec, which has a population of 15,078, out of a total of 27,122 inhabitants (2021 census). The central settlement of Čakovec is spatially and functionally connected with several surrounding municipalities, while the southern boundary of the City is defined by the Čakovec Hydroelectric Plant reservoir, which also forms the natural border between Međimurje and Varaždin Counties.

The town's favorable geostrategic and transport location has historically influenced its economic and social development. Čakovec is well-connected by international, national, regional, and local road and rail infrastructure. Moreover, the town demonstrates a strong functional link with the City of Varaždin, forming an increasingly integrated urban conurbation. Their shared development area significantly affects migration, transport, and economic patterns in northwestern Croatia. As the largest and most populous town in the county, Čakovec serves as the primary driver of economic, demographic, and infrastructural development in Međimurje and, within a broader spatial context, stands out as a potential contact, transit, and development center with substantial urban capacities. With its natural diversity, rich landscape base, and notable architectural heritage, Čakovec represents a valuable space within the Republic of Croatia, requiring the protection and enhancement of its fundamental spatial, cultural, and environmental values.

3.2.2 Spatial Planning Documents and Strategic Documents

The first document guiding the development of the City of Čakovec was the Directive Regulatory Basis of 1947, prepared by architect Prof. Josip Seissel at the Faculty of Architecture, University of Zagreb. The plan established a new network of major town roads beyond the then town center, introduced new residential neighborhoods for both individual and collective housing, and designated an industrial zone to the northwest of the railway station. The plan was preceded by the preparation of an early form of a regional plan, which examined the spatial and transport connections of settlements in Međimurje and demographic trends, influencing the foundational layout of Čakovec itself (City of Čakovec, 2005; Kranjčević & Pintar, 2017).

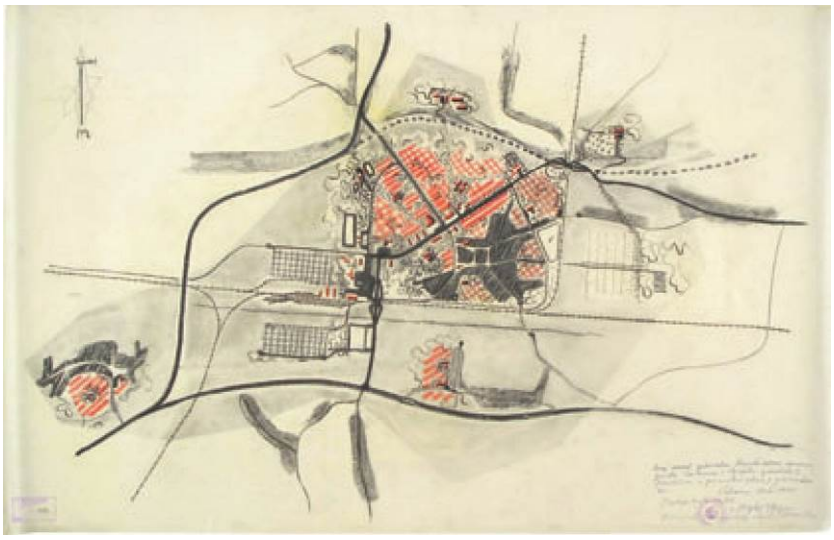

Fig. 1: Directive Regulatory Basis of 1947. Source: Archive of the Department.

The General Urban Plan (GUP) of 1964, prepared by the AR 59 project bureau under the leadership of architect Borisav Vasiljević, represents a revision of the 1947 Directive Regulatory Basis. The plan envisioned the southern expansion of the town beyond the railway line while integrating suburban settlements into the urban fabric. It disregarded the historic urban grid, permitting radical interventions that resulted in the interpolation of residential blocks and the construction of high-rise buildings (City of Čakovec, 2005; Kranjčević & Pintar, 2017).

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

In 1978, the General Urban Plan of the City of Čakovec "Čakovec 2000", led by architect Nada Golub-Piližota, established a long-term development concept for the town until the end of the century. The plan defined new residential, industrial, and sports-recreational zones, established a pedestrian zone in the town center, and set the southern boundary of the town with the southern bypass. New residential quarters with distinct identities were created. The plan also implemented the concept of the Eastern Industrial Zone and the Mladost Sports and Recreation Center. Subsequently, the plan was supplemented under the title “General Urban Plan of Čakovec” (led by architect Dragomir Sutlar), which included the construction of the southern bypass and introduced building development restrictions (City of Čakovec, 2005).

The Spatial Plan of the Čakovec Municipality (1978) was the first plan to consider the integrated territory of Međimurje, which at the time constituted the unified Čakovec Municipality (corresponding to the current area of Međimurje County, 729 km²). To ensure conditions for overall social and economic development and to create equitable living and working opportunities for the entire population of the municipality, while adhering to the principles of environmental protection and improvement and rational and efficient spatial management, the plan established the following key objectives: Enable polycentric, efficient, and functional spatial development; Ensure coordinated and purpose-driven land use that supports optimal, stable, and sustainable economic development; Provide a high-quality environment for healthy and humane living while preserving aesthetic and cultural values; Safeguard the territory against potential disasters, hazards, and destruction. The plan proposed a new spatial model of a polycentric settlement system, with Čakovec as the primary center. By connecting settlements with each other and with all parts of the territory, the plan aimed to ensure optimal mobility of the population, accessibility to workplaces, and connectivity of all areas to Čakovec within 30 minutes. This framework was intended to facilitate the gradual restructuring of the population and to free land for intensive agricultural use (Sutlar & Grgan-Makovec, 2017).

The Amendment and Supplement to the Spatial Plan of the Čakovec Municipality (1989) was primarily linked to finding a suitable solution for the alignment of the A4 Budapest–Zagreb highway. When defining the corridor, attention was given to minimizing the impact on valuable agricultural land, avoiding the Murščak protected landscape, and respecting the settlement orientation toward Prelog and Čakovec, so that the highway would not become a barrier within the territory.

The current legislative framework for spatial planning and strategic development at the local level for the town encompasses several types of spatial and strategic development plans, the most significant of which are outlined below.

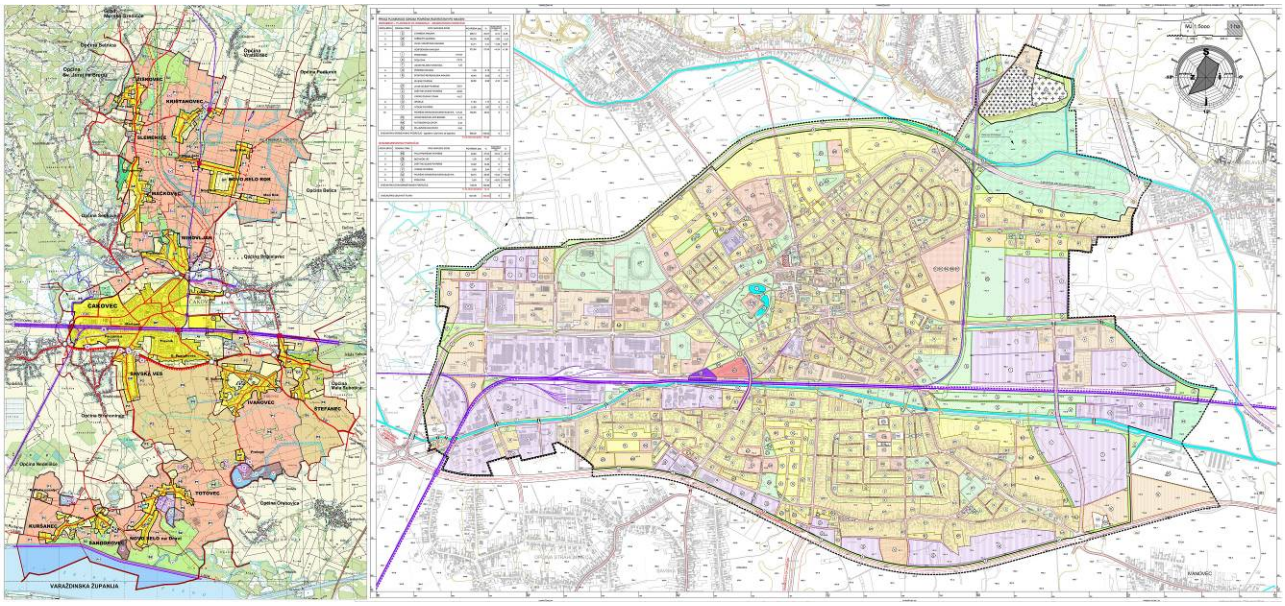

Fig. 2: The Spatial Plan of the City of Čakovec (left) and The General Urban Plan of Čakovec (right). Source: https://www.cakovec.hr/prostorni-planovi-grad-cakovec/

The Spatial Plan of the City of Čakovec (2003) defines the conditions for the development of the urban area, including its purposeful use, land use designation, spatial design, remediation of building and other land, environmental protection, and the protection of cultural heritage and particularly valuable natural areas

within the City's territory, which covers 72.97 km². The plan points out county-level spatial development objectives, including the development of the town and settlements with special functions and infrastructure systems, the rational use of natural resources, and the preservation of ecological stability and valuable environmental components. It also defines town-level spatial development objectives, which include demographic development aimed at promoting stable and sustainable population growth, settlement development, enhancement of social, transport, and utility infrastructure, and the protection of landscape, natural values, and cultural-historical units. Furthermore, the plan sets settlement-level spatial planning objectives within the town, which include the rational use and protection of space by directing land use to meet the town's needs, environmental protection, designation of building areas within settlements, and the improvement of settlement design and utility infrastructure to enhance the quality of life of residents.

The General Urban Plan of Čakovec (2005) establishes the fundamental spatial organization, the protection of natural, cultural, and historical values, and the use and designation of land for the central settlement area, covering 11.27 km². The plan emphasizes that Čakovec, as the county seat, should continue to function as the most important economic, administrative, cultural, educational, and healthcare center, as well as the largest transport hub of Međimurje County.

The plan defines the following key long-term objectives: Preserve the identity and specificity of the urban area; Protect natural and historical values, the environment, and promote sustainable development; Maintain undeveloped areas; Improve the quality of life and living standards of residents; Ensure space and corridors for all infrastructure to connect Čakovec with surrounding settlements, supporting its role as a regional center; Provide the spatial prerequisites for economic development and restructuring relevant to Čakovec and Međimurje County.

The primary goal of the plan is urban regeneration and consolidation of the town's structure. The plan emphasizes the need to: Enhance the spatial structure of the town at a human scale, ensuring good connectivity to all necessary urban functions; Spatially define the existing military zone (training grounds and barracks) and integrate it into the urban fabric with appropriate uses; Achieve urban quality through a system of urban-architectural projects; Use the town's space and environment in a way that prevents irreversible damage, enabling durable and sustainable development.

The plan specifies the following urban planning objectives: Ensure the development of all urban systems; Dimension spaces according to the scale of the town and moderate continuity of development; Promote construction that preserves cultural heritage and natural settings while highlighting urban aesthetics; Protect residents from adverse impacts while utilizing local environmental advantages; Align urban development with socio-economic programs; Ensure construction that supports economic efficiency of infrastructure systems and strengthens the town's economic capacity through functional distribution and overlap of urban functions.

The plan also identifies specific interventions: Expand areas for residential use (single-family and multi-family housing) in the northern parts of the town, Globetka, Sajmište, Martane, and Buzovec; Expand areas for economic, industrial, and business purposes east of Buzovec and on the former military training ground; Form and reconstruct the military barracks area for public and community buildings; Designate new multifunctional green spaces on undeveloped or abandoned agricultural land; Define zones to be regulated through detailed spatial plans; Provide space for the relocation of the bus and railway stations.

For the purposes of sustainable urban planning in line with European Union objectives and regional development criteria, the Čakovec Urban Area (covering 164.85 km²) has been defined, encompassing the City of Čakovec and the surrounding municipalities of Nedelišće, Strahoninec, Pribislavec, and Šenkovec. A Development Strategy for the Čakovec Urban Area has been prepared for the financial period 2021–2027. The medium-term vision for the Čakovec Urban Area emphasizes a resilient, innovative, and sustainable economy, as well as a healthy, educated, and inclusive society that promotes sustainable urban development to ensure a high-quality living environment. The strategy identifies three priority areas of public policy: Sustainable Economy; Healthy and Educated Society; and Pleasant Living Environment. Specific objectives have been established for each priority area: PP1 – Sustainable Economy: Development of entrepreneurship and supportive business infrastructure; strengthening of niche tourism; promotion of green solutions and smart innovations in the economy; PP2 – Healthy and Educated Society: Enhancement of lifelong learning; strengthening of sports infrastructure; improvement of quality of life through increased publicly accessible

amenities; and PP3 – Pleasant Living Environment: Development of cycling and pedestrian infrastructure; enhancement of green infrastructure; improvement and design of public spaces.

The Green Urban Renewal Strategy of the City of Čakovec 2022–2030 is aligned with the Development Strategy of the Čakovec Urban Area, and both documents contribute to achieving the strategic objectives of the National Recovery Strategy 2030 – Ecological and Energy Transition for Climate Neutrality. The strategy defines a vision for the development of green infrastructure in the City of Čakovec, including a development concept for both the wider and immediate urban area. Based on the identified developmental needs and potentials, as well as the established vision, three complementary and synergistic objectives for green infrastructure development have been defined. The strategy also establishes priorities for green urban renewal, specifying measures and proposed projects to be implemented within the town. The main strategic objectives of the strategy are: Increase the efficiency of planning and management of green infrastructure in the town; Improve, expand, and connect easily accessible green infrastructure within the town; and Create livable spaces and enhance the quality of life. By achieving these objectives, the strategy ensures the preservation and enhancement of the green character and identity of Čakovec and guarantees accessible green infrastructure of various types, sizes, and functions for all residents. Given the interconnected nature of the objectives, their implementation will foster a circular process, resulting in a continuous increase in interest and investment in green infrastructure development projects across the town.

3.2.3 Proposals for the Future Development Visions of the City of Čakovec

The following section offers a brief overview of two selected student projects, highlighting the distinct approaches and methodologies adopted by two different menor-led groups.

The project titled “Student Corridor Čakovec – Varaždin” (Figure 3) identifies, through the analysis of the broader spatial context, the need and potential for functional connectivity between the main cities of the neighboring counties, Čakovec and Varaždin. It proposes a joint campus in the eastern industrial zone of Čakovec and aims to enhance transport connectivity through pedestrian and cycling routes linking the two cities, as well as constructing an additional railway track for (inter)urban train services. Considering the concentration of existing higher education institutions and planned urban projects – including the Science Center, redevelopment of the former military barracks into a Creative-Inspirational Center, establishment of a business incubator, and the Međimurje Energy Center – the project proposes repurposing the industrial zone west of the railway into a new urban neighborhood with a student campus. The design envisions a new railway station along the eastern edge of a planned town park, which extends into a central east-west green axis. This axis is flanked by public service zones, such as the new campus with student dormitories, faculties, a primary school, kindergarten, library, and health center, and mixed residential and commercial zones. Peripheral roads in the northern and southern sections are planned for quiet residential areas with family houses, while the central axis culminates in a sports and recreational area forming a buffer zone toward the planned northern town bypass.

Fig. 3: “Student Corridor Čakovec – Varaždin” Vision for Čakovac (students: Petra Kujundžić & Ivan Kukuljević-Sakcinski; mentor: Damir Krajnik, PhD, Full Professor). Source: Archive of the Department.

The student vision entitled “En-park” (Figure 4) identifies multiple (E)layers that strategically aim to affirm Čakovec as a regional research and education center for biodiversity and nature protection, linked to the Mura-Drava Regional Park. The “En” acronym reflects adjectives describing the project’s values: ecological,

energy-resilient, educative, economic, efficient, eccentric, eclectic, experimental, expressive, and more. Students redesigned and integrated existing entrepreneurial zones, adding new educational, touristic, and business functions connected with urban green infrastructure (recreational areas, urban forests, and parks). At the regional level, Međimurje County was analyzed for three potential scenarios: depopulation, stagnation, and demographic growth. The study assessed the potential of built-up zones to become green infrastructure, agricultural land, or to expand. At the local level, the entrepreneurial zone in Čakovec East was planned in detail to integrate all aspects while considering existing and planned major road infrastructure. Integration changes were evaluated using the Space Syntax model, guiding students in selecting the most appropriate traffic solution between two proposed options.

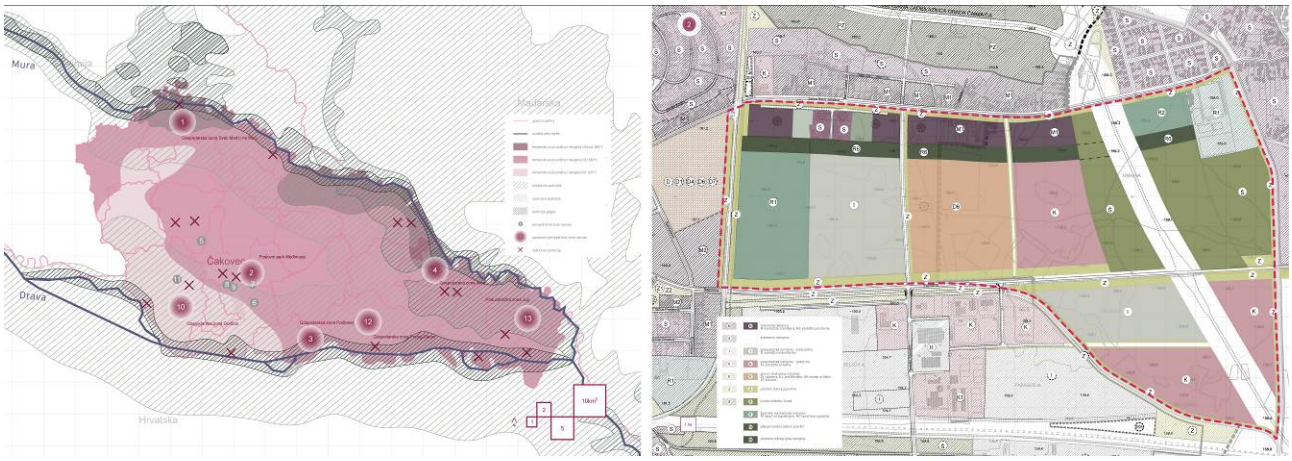

Fig. 4: "En-Park" Vision for Čakovac (students: Lara Prežgaj & Marija Pupovac; mentor: Tamara Zaninović, PhD, Assistant Professor). Source: Archive of the Department.

4 DISCUSSION

Based on the analysis of the most significant ECTP-CEU and AESOP documents related to spatial planning education, a set of comparison criteria was established. These criteria were derived through the synthesis of thematic categories presented in the documents, whereby competency domains and educational objectives were grouped into broader analytical units applicable to the analysis of Urban Planning Workshop 1: Settlement Planning focused on the topic of small towns' spatial vision.

Document analysis demonstrates a strong consensus in understanding the role, scope, and expected outcomes of spatial planning education, despite varying institutional frameworks. While ECTP-CEU approaches planning primarily through the lens of professional competencies and practice standards, AESOP offers an educational framework that integrates theoretical knowledge, practical skills, and the ethical values necessary for socially responsible planning. Within this context, UPW1 serves as a key platform for acquiring both theoretical and applied academic knowledge, simulating professional spatial planning practice.

A central objective of this education is the development of students' ability to integrate spatial, social, economic, and environmental systems, particularly across scales ranging from regional to local. UPW1 functions as a pedagogical instrument that allows students to explore complex spatial dynamics, synthesize knowledge across multiple domains, and translate these insights into foundational visions and concepts for the further development of the selected area.

Research competencies are similarly emphasized across educational frameworks, highlighting the capacity for independent inquiry, critical evaluation, and the translation of research into action and spatial transformation. In addition to the foundational investigations conducted in UPW1, Research Seminar 1 provides an opportunity for deeper, topic-specific research. Students independently explore themes relevant to their chosen area and communicate the entire research process through seminar papers grounded in scientific methodology.

Methodological and technical competencies are also central, with documents underscoring the importance of mastering analytical tools, planning techniques, and legal and institutional instruments, as well as applying them in practice from drafting plans to participating in implementation processes. UPW11 is particularly instrumental in this regard, enabling students to apply analytical methods, employ planning instruments, and

develop the capacity for spatially informed decision-making. Through exercises in strategic thinking, the formulation of development visions, and the proposal of their potential realization using planning tools, students acquire crucial skills for professional practice, making this a pivotal component in the education of future spatial planners.

Both documents recognize the importance of visualization, communication skills, and participation as integral components of planning competence. In this context, UPW1 plays a key role by enabling the integration of analytical work, spatial concepts, and visual presentation into a coherent planning product. Special attention is also given to the creation of a conceptual model to further develop students' abilities to visualize solutions at different scales. Engagement of experts and the local community in the planning process is integrated through organized site visits, guest lectures, presentations, and the curation of exhibitions and publications of selected student works.

Furthermore, both documents strongly emphasize professional ethics, social responsibility, and the value-based dimension of planning. UPW1 can be seen as a didactic space in which the ethical and value-oriented principles of planning are concretized through decisions on spatial priorities, stakeholder involvement, and the interpretation of the public interest in proposed spatial solutions.

While UPW1 primarily focuses on the formulation of spatial visions and planning concepts, real-world spatial planning extends beyond the development of plans to their concrete implementation. The success of planning proposals depends on institutional procedures, financial capacities, and the engagement of public and private development actors, which may significantly reshape initial concepts. Although the workshop setting cannot fully simulate these complex dynamics, students are introduced to existing statutory and strategic frameworks as instruments that shape spatial transformation. A more explicit reflection on implementation conditions and constraints could further strengthen the connection between planning education and professional practice.

The conducted research demonstrates that Čakovec, as a representative small town, possesses a long-standing history of spatial planning. Its further development was already considered in the first half of the 20th century within a broader regional context, underscoring its considerable spatial and economic significance for northern Croatia even at that time. Subsequent interventions in the urban fabric, which substantially transformed the town's character during the second half of the 20th century, were largely driven by modifications in the spatial planning framework. These interventions provide illustrative examples of specific planning practices that warrant critical reflection when envisaging future urban development. Furthermore, strategic planning documents at both the regional and local levels offer a structured basis for analyzing and evaluating previously established development objectives, thereby supporting the formulation and refinement of a coherent vision for the town's future growth.

Student reflections on the future development of Čakovec adopt a variety of approaches, ranging from regional-scale concepts that consider natural and socio-economic characteristics, to site-specific solutions, such as brownfield areas, which have contributed to shaping the broader spatial development framework of the town.

The analysis of student work shows that UPW1 fosters the development of key planning competencies, particularly in the area of integrated spatial and socio-economic processes understanding. The projects are notable for their analytical rigor and synthetic ability, effectively translating spatial analyses into strategic development concepts and urban plans as planning instruments. There is a clear capacity to work across different spatial scales and to integrate environmental considerations and principles of sustainable development into the proposed solutions.

5 CONCLUSIONS

Based on the conducted research, it can be concluded that small towns, such as Čakovec in this study, provide an appropriate context for education in spatial planning. They are large enough to encompass the complexity of spatial, social, and economic processes, yet small enough to remain comprehensible as a whole and analytically manageable.

Towns of this size and position within the hierarchy of spatial systems enable the development of a broad range of competencies as defined by relevant European documents on spatial planning education, while simultaneously providing space for experimentation and innovative planning approaches. The experiences

gained through working on small-town planning within the educational process can serve as a solid foundation for the later application of planning methods and concepts in more complex, larger urban contexts.

In this sense, Urban Planning Workshop 1: Settlement Planning can be interpreted as an integrative learning platform that effectively links theoretical knowledge, planning practice, and the value-based principles of spatial planning. At the same time, spatial planning education should acknowledge that the development of plans represents only one phase of the overall planning process. Their realization depends on implementation mechanisms, financial frameworks, governance structures, and the active engagement of development actors, all of which ultimately shape spatial outcomes. Strengthening students' understanding of these conditions and constraints would therefore further enhance the educational model, enabling a more critical and practice-oriented connection between planning concepts and their real-world implementation.

🏆 reviewed paper

Analysing the Logistics Space near Cape Town International Airport in Comparison to the Seaport and Dry Port Environments

Masilonyane Mokhele

(A. Prof Masilonyane Mokhele, Cape Peninsula University of Technology, PO Box 652, Cape Town 8000, mokhelem@cput.ac.za)

1 ABSTRACT

One focal point on the interconnections between transport and land-use patterns is the concentration of economic activities near airports. However, the literature typically analyses the environs of airports without drawing comparisons with other transhipment zones, such as seaports and inland ports. To contribute towards filling this literature gap, the paper analyses the monthly rental values of warehousing, industrial, retail, and office properties in the vicinity of Cape Town International Airport, compared with those around the Port of Cape Town and Belcon inland/ dry port, South Africa. Property rental data were scraped on 10 December 2025 from the website of Property 24, a leading South African property listing company. Following the cleaning process, the dataset comprised 240 data points: 105 industrial listings, 106 warehouse listings, 25 office listings, and four retail listings across the three transhipment precincts. However, only 186 street addresses were successfully geocoded in Python, forming the foundation for spatial analysis. Using QGIS, RStudio and SPSS for spatial and statistical analysis, the results showed that the mean rental values for industrial, warehouse, and office properties were highest in areas near the airport, followed by those near the port, and lowest around the inland port. The findings provide evidence that, relative to other transhipment precincts analysed, the airport environs may constitute a distinct industrial, warehouse and office property sub-market.

Keywords: Cape Town International Airport, Port of Cape Town, Belcon dry port, transhipment precincts, City of Cape Town

2 INTRODUCTION

One core area of the nexus between transportation technology advancements and land-use patterns is the concentration of economic activities near airports (Mokhele & Geyer, 2018), in line with the normative models of the so-called airport-led development. Proposing the idealised composition and spatial form of urban development near airports, these models are epitomised by the airport city and aerotropolis. Although the airport city conception encompasses various distinct categories (Conway, 1993), it is typically used to promote urban development in the immediate vicinity of airports (Kasarda, 2009). As the airport city evolves, intensifies and matures, urban development is expected to radiate outward, subsequently resulting in the spatial form of the aerotropolis, which could extend to a radius of about 20km from the airport (Kasarda & Lindsay, 2011). Policymakers, spatial planners, airport authorities, and developers across the world use these models to market and strategically guide the economic activity mix and spatial form of urban development, which is understood to be related to the airport's core aviation functions.

Despite its insights, the existing literature on the airport-urban development nexus analyses the environs of airports without comparing them with other transhipment zones within a given territory, particularly seaports and inland/ dry ports. The concept of transhipment points is akin to what Palander (1935) eloquently referred to in his seminal work as transport points connected to other transport points by transport lines. Intermediate transport points, therefore, have special transfer benefits when they are transhipment points or junctions (Hoover, 1948).

Various transhipment nodes are crucial for facilitating logistics processes and global trade amid intensifying globalisation (Chen et al., 2017), and therefore have the potential to shape development patterns and the spatial economy in their territories. Reflecting on the importance of ports, the UN Trade & Development (2025) argues that maritime transport is the backbone of global trade, accounting for over 80% of the volume of goods transported worldwide. Seaborne trade has evolved and gained traction over time, influenced by the increasing containerisation, the growth of developing economies and the shifting global patterns of production and consumption (UN Trade & Development, 2025). In this evolving economic milieu, the concept of an inland or dry port has been used to shift intermodal terminals inland and reduce traffic congestion at seaports (Bayene et al., 2023). While seaports undoubtedly dominate in terms of the volume of goods transported globally, the International Air Transport Association (n.d.) reports that air transport

accounts for approximately 35% of the value of global trade, reflecting the important role airports play in supply chains and logistics. Globally, cargo tonne kilometres increase year on year, reflecting the importance and growth of the air cargo market (International Air Transport Association, 2025).

To contribute towards extending the literature and filling the gap above (i.e., the lack of a comparative analysis of transhipment precincts), the paper analyses the rental value of properties in the vicinity of Cape Town International Airport, South Africa, in comparison to the values around the Port of Cape Town and Belcon inland port. The paper addresses the following research question: Do the environs of the airport represent a unique property sub-market compared to the Port of Cape Town and Belcon inland port? As detailed in the Methods section, the analysis focused on the monthly rental values of warehousing, industrial, retail, and office premises in and around the studied transhipment precincts.

3 LITERATURE REVIEW

As emphasised by Usman et al. (2021), the urban property market is characterised by price variation, which may be influenced by several spatial, social, and physical variables, arguably making it a composite of separate submarkets. Market analysis, therefore, requires segmentation to delineate the property market into distinct groups that are relatively homogenous within themselves, while heterogeneous with others. Sub-markets were introduced as an important analytical tool in the 1950s and 1960s, and the resultant research in property market segmentation has arguably improved the accuracy of property pricing. However, most segmentation studies have focused on the housing market with less attention on the commercial property market. Similar to the housing market, the commercial or non-housing property market is complex and heterogeneous and warrants attention on the market segmentation (Usman et al., 2021).

Aligned with the discussion above, Dunse, Leishman and Watkins (2002) argue that the spatial variation in urban property values is specifically due to the influence of the physical attributes of the property stock across different sections of the city. Two approaches dealing with this variation in property values have been developed. On the one hand, as noted earlier, markets can be interpreted as composed of interrelated sub-markets, each of which may exhibit different price or rental values. On the other hand, price and rental variations can be explained through trade-off theories of locational choice (Dunse, Leishman & Watkins, 2002).

In a study of the office real estate market in Tokyo, Japan, Matsuo et al. (2024) found that the presence or absence of amenities significantly impacted both rent and vacancy rates. Amenities have been perceived and interpreted differently in the literature, with numerous studies classifying them into neighbourhood, on-site, and worker amenities (Sivitanidou, 1995). Neighbourhood amenities include, for instance, the office's proximity to complementary facilities, such as restaurants and retail stores. Neighbourhood amenities are shared among various neighbouring office buildings and thus have a strong public element. By contrast, on-site amenities are private, as their benefits are restricted to tenants in the individual buildings and therefore serve as a differentiating factor from other premises. In this regard, neighbourhood amenities are exogenous, making it difficult for a property owner to directly influence them through capital investment. However, on-site amenities can be directly influenced by the individual property owners (Matsuo et al., 2024).

Sivitanidou (1995) argue that within multi-nodal metropolises, business rent variation across nodes should be attributed not only to differences in their amenity endowments but also to differences in their institutional frameworks. Coupled with a set of firm amenities reflecting traditional demand-side influences (such as access to the central business district, freeways, and airports) and various worker amenities (education quality, levels of crime, access to shopping opportunities, and the ocean), supply-side attributes, such as the availability of appropriately zoned land, and density restrictions, were found to play a crucial role in influencing price variations in office-commercial rents (Sivitanidou, 1995).

In another study, Franco and Cutter (2022) found that, on the one hand, open space, typically an amenity considered to be jointly valuable to firms and households, had either weak or non-robust effects on non-residential property values. On the other hand, the amenities of coastal access, air pollution, weather and crime levels appeared to have stable correlations with property values. In contrast, amenities that are likely valued only by firms, such as accessibility and proximity to concentrations of skilled labour, showed strong and significant correlations with non-residential properties (Franco & Cutter, 2022).

4 STUDY AREA

The study focused on the urban development precincts that are contiguous with the transhipment nodes of Cape Town International Airport, the Port of Cape Town, and the Belcon inland/ dry port in the City of Cape Town municipality, Western Cape province, South Africa. The subject development nodes are Airport Industria/ Airport City, Paarden Eiland, and Parow Industria, respectively (Fig. 1). The studied precincts are considered among the main industrial areas in the City of Cape Town municipality, with varying spatial economic attributes, backgrounds and histories, as highlighted below. It is important to note that the study did not examine areas within the seaport, the inland port, or the airport landholdings.

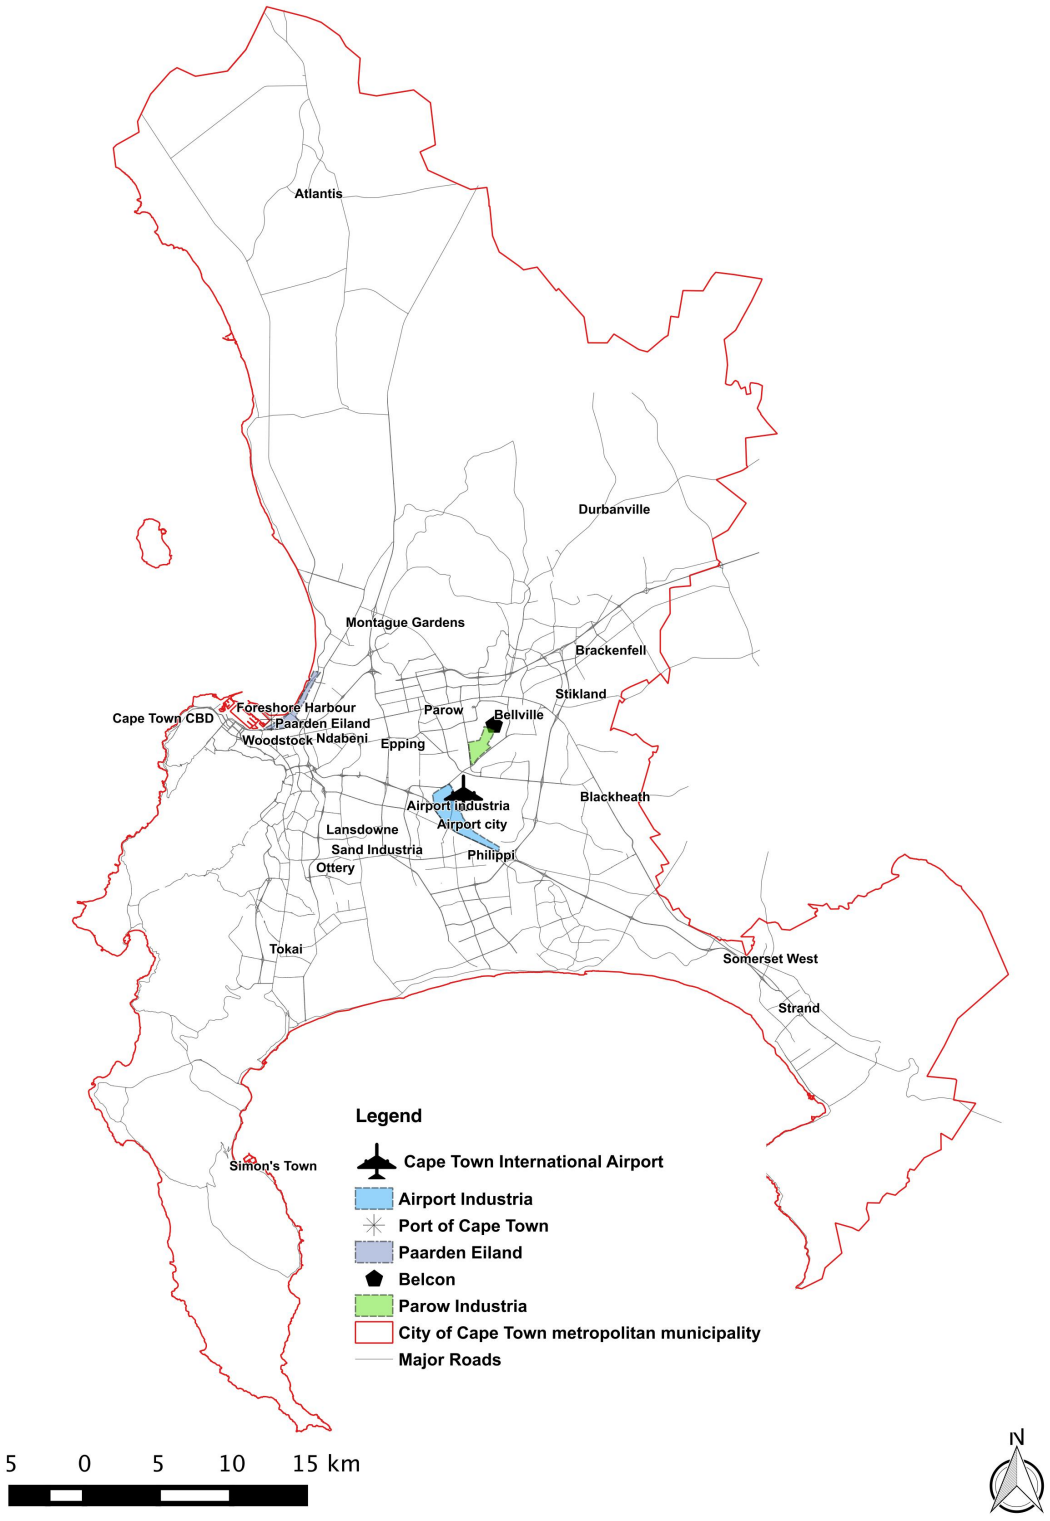

Fig. 1: Location of Cape Town International Airport relative to the surrounding municipalities.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

Established in 1954, Cape Town International Airport is the second-busiest airport in South Africa after OR Tambo International Airport in Gauteng province. It is also the only international airport and one of the two commercial passenger airports in the Western Cape province. Origins of urban development in the vicinity of the airport can be traced to the government's concerted efforts to promote industrial development, where in 1981, about 130 ha of land in this area was zoned for industrial purposes, albeit most of the landholdings were undeveloped at the time (Mokhele, 2017). A trend in the development of warehousing and storage facilities near the airport was particularly evident in the 1990s (City of Cape Town municipality, 2002).

The Port of Cape Town is also the second-largest seaport in South Africa, after the Port of Durban in KwaZulu-Natal province. Paarden Eiland, situated in the environs of the port, has a long spatial economic development history. The literature notes that, with the increasing scale and intensity of manufacturing in Cape Town in the mid-20th century, a search for more expansive and affordable land naturally led to the establishment of new industrial zones in, among other areas, Paarden Eiland. The area was developed mainly in the 1960s (Mokhele & Fisher-Holloway, 2024). In the mid 1990s, Paarden Eiland notably boasted a prime industrial rental rate that was about three percent higher than the municipal average (City of Cape Town municipality, 2002).

The third focus area, Belcon, is a dry port directly connected to the Port of Cape Town via rail. In 2010, Transnet Freight Rail officially opened the Belcon terminal, which serves as an inland port and an extension of the Port of Cape Town, focusing on rail-based container consolidation. Positioned about 30km from the port, this facility allows truckers to increase the number of loads per day by avoiding traffic congestion and delays in and out of the city, as well as congestion at the port itself.[1]

5 RESEARCH DESIGN AND METHODS

This section presents the overarching research design, the units of analysis, and the data collection and analysis methods employed in the study.

5.1 Research design

The study employed a quantitative comparative research design (Iranifard & Roudsari, 2022), using statistical and spatial analysis to compare the monthly rental values of warehousing, industrial, retail, and office properties in the environs of Cape Town International Airport, the Port of Cape Town, and the Belcon inland port.

5.2 Units of analysis

The study's units of analysis were the warehousing, industrial, retail, and office premises advertised for rent in the vicinity of Cape Town International Airport, the Port of Cape Town, and the Belcon inland port. This focus distinguishes the paper from previous related studies (for example, Mokhele, 2025), which used land parcels rather than individual establishments as units of analysis. A key limitation of land parcel-based studies is that they do not account for the potential influence of what Sivitanidou (1995) refers to as on-site amenities, as a single land parcel may accommodate multiple buildings or units with differing amenity provisions and value.

5.3 Data sources

Generally, data on land transactions are scarce in cities, whereas data on rental prices are relatively frequent (Fuss, Koller & Weigand, 2021). Property rental data were scraped on 10 December 2025 from the website of Property 24, a leading South African property listing company. Property 24 was selected because it is a platform widely used by both property agents and individual property owners to advertise properties for sale and rent. The data scraped from Property 24 comprised 361 data points: 218 industrial listings, 114 warehouse listings, 25 office listings, and four retail listings across the three transhipment precincts. To avoid distortions due to the typical conflation of and overlaps between the "industrial" and "warehouse" land-use/ economic activity categories, the industrial listings that did not mention warehouse were categorised under "industrial". In contrast, the industrial listings that mentioned "warehouse" were included under the warehouse category.

[1] https://www.freightnews.co.za/article/belcon-forever-a-white-elephant-or-the-port-of-cape-towns-saviour

The data scraped from the website were cleaned by removing duplicates and entries for which the average monthly rental price per square metre (m2) could not be determined, where, for instance, the monthly rental value or the extent of the property were missing. After discarding 121 entries, the cleaned data comprised 240 data points, as discussed in detail in the results section.

Furthermore, to prepare for the spatial analysis, the street addresses from the web-scraped data were geocoded in Python using the Google Maps application programming interface (API). The total number of geocoded data points was 186, after omitting the entries without accurately formatted street addresses. It is, however, important to note that the omitted data points were still valid and included in the statistical analysis.

5.3.1 Data analysis methods

Statistical and spatial analyses were performed to identify similarities and differences in property rental values across the three transhipment precincts, particularly to determine whether a unique property sub-market existed in the environs of the airport, or by implication, at the other two transhipment precincts.

5.3.2 Statistical analysis

The monthly rental information from the three transhipment precincts was combined into a single Excel spreadsheet and loaded into IBM statistical package for social sciences (SPSS) version 29 for analysis. Basic statistical analysis was then conducted on the 240 data points. The data were split in SPSS to disaggregate the analysis by the transhipment precincts and the four land-use categories analysed.

5.3.3 Spatial analysis

Spatial analysis of the 186 successfully geocoded points was conducted to compare the three transhipment precincts. Because of the relatively small population, the points were analysed at an aggregated level, without distinguishing between the warehouse, industrial, retail and office categories. After obtaining the coordinates through the geocoding process outlined in Section 5.3, the analysis and map visualisation were performed in QGIS and RStudio.

The first tool employed in QGIS, kernel density, estimates the density of features within an area and creates a smoothly tapered surface for each point (ESRI, 2019). In the study, the features whose densities were calculated were the geocoded warehousing, industrial, retail, and office premises advertised for rent across the three transhipment precincts.

Global and local Moran's I were also applied to measure spatial autocorrelation to examine the data's pattern and identify the similarities or discrepancies within the dataset (Yamada, 2024; Chen, 2023; Westerholt, 2022). Moran's I estimates typically range from -1 to +1 (Overmars et al., 2003), where negative values indicate that dissimilar values are closer together and positive values indicate that similar values are clustered. In contrast, a value of zero indicates that the data are randomly distributed. In Moran's I statistics, the p-value indicates statistical significance, where values below 0.05 are statistically significant, implying that the observed pattern is not due to random chance.

6 RESULTS

As noted in Section 5.3 above, the cleaned property rental data comprised 240 data points, including 106 warehouses, 105 industrial properties, 25 office properties and four retail properties across the three transhipment precincts. However, the successfully geocoded data used for spatial analysis comprised 186 points. Against this backdrop, this section presents the results of the statistical and spatial analyses comparing the monthly rental values of warehouse, industrial, retail, and office properties near Cape Town International Airport (Airport Industria/ Airport City), the Port of Cape Town (Paarden Eiland), and the Belcon inland port (Parow Industria).

6.1 Densities and land-use category mix

The kernel density estimations in Fig. 2 identify areas with a high concentration of warehouse, industrial, retail and office premises, where green indicates low-intensity areas and red marks high-intensity zones. Kernel density results show that the high density values were found in the vicinity of the Port of Cape Town, followed by the environs of the airport and Belcon inland port (Fig. 2). Notably, the data points in the environs of the airport were more spatially spread out compared to Parow Industria and Paarden Eiland.

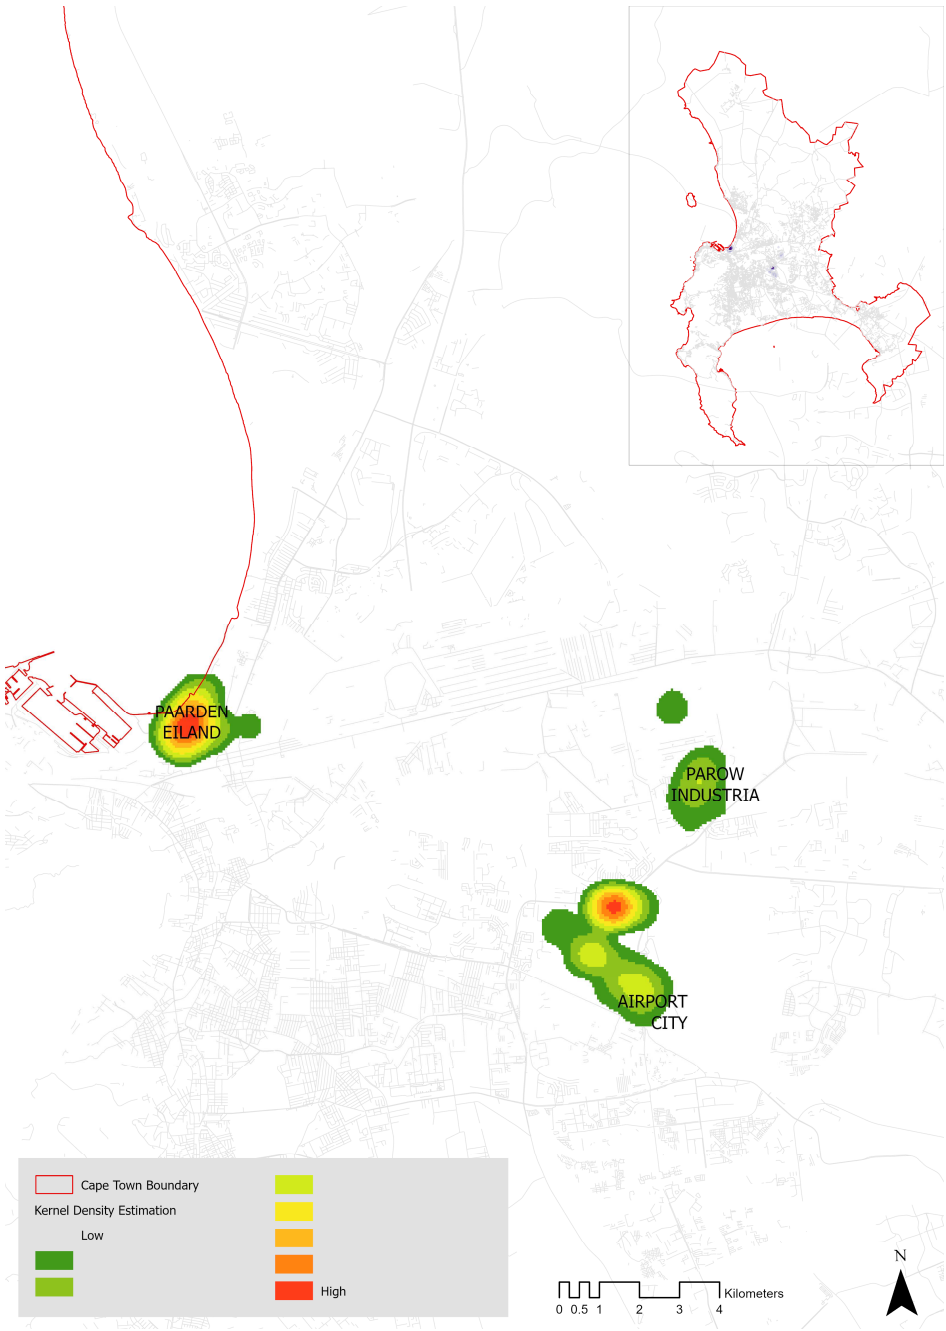

Fig. 2: Kernel density values

Building on the kernel density presentation above, it was also essential to investigate the economic activity or land-use composition across the three transhipment zones. As shown in Fig. 3, in Airport Industria, the majority of the advertised properties were warehouses, followed by industrial and office premises. Notably, no retail properties were advertised for rent near the airport. In Paarden Eiland, the majority were industrial properties, followed by warehousing, office and retail properties. In Parow Industria, most entries were industrial properties, followed by warehousing, office and retail properties. Overall, the number of retail properties was relatively low across the study areas, cementing the transhipment precincts' primary roles as industrial and logistics zones. Only Paarden Eiland reflected a fair number of office properties, albeit still lower than the other land-use categories within the precinct (Fig. 3).

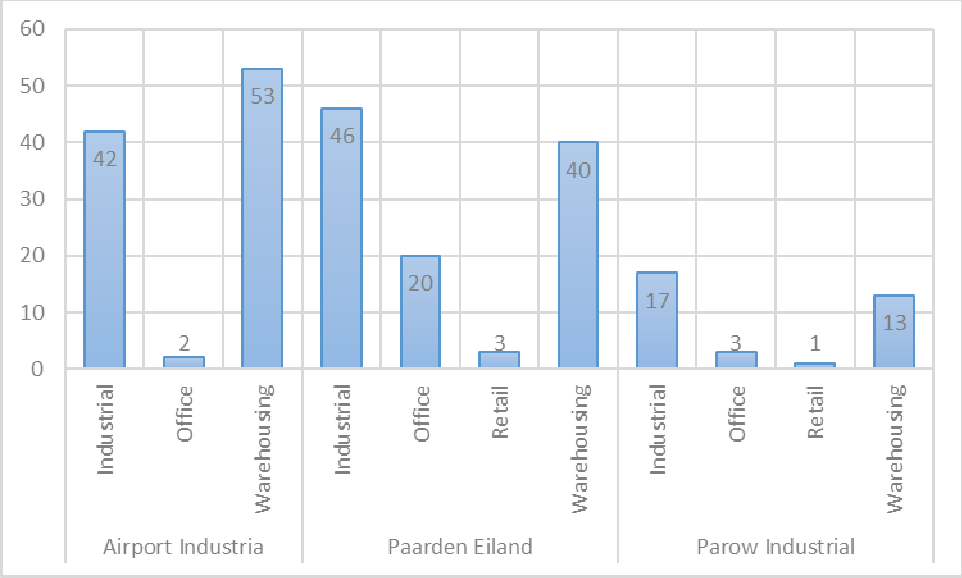

Fig. 3: Number of advertised properties at Airport Industria, Paarden Eiland, and Parow Industria.

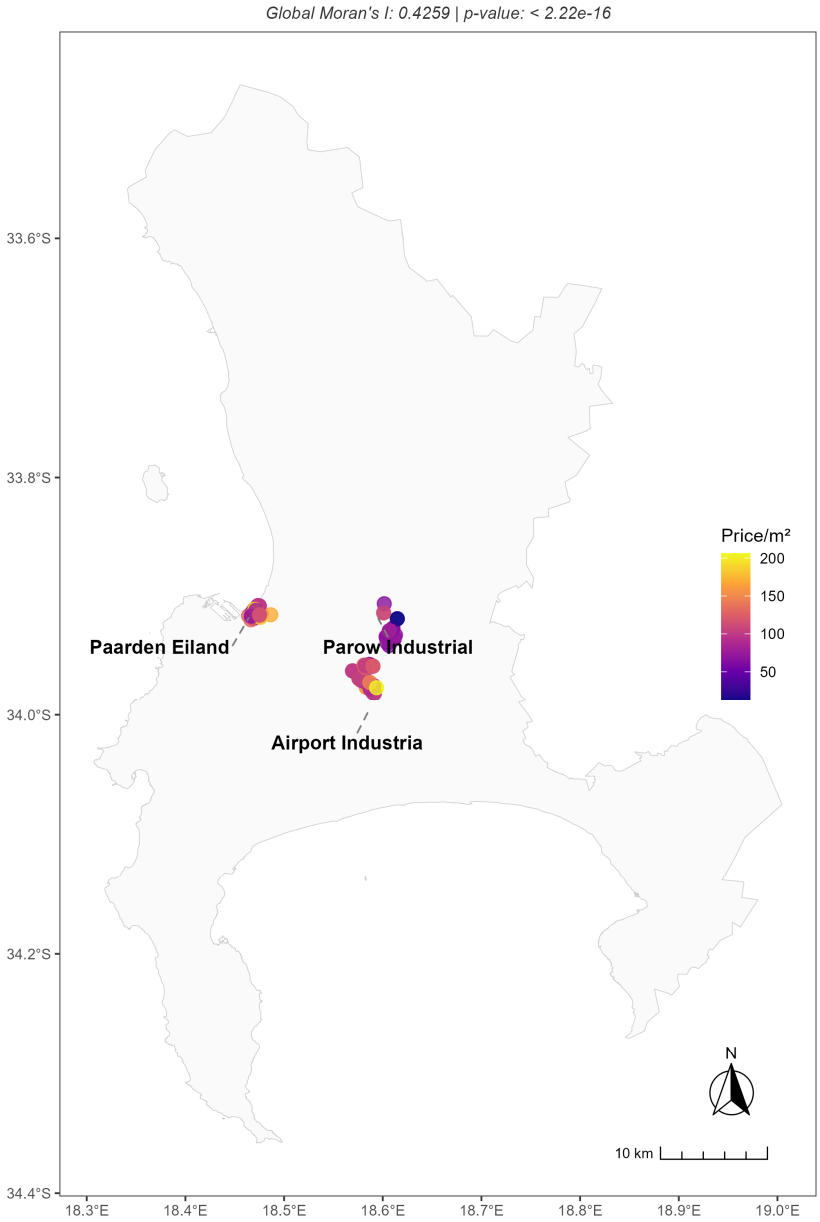

Fig. 4: Geographical distribution of the rental price variation (Global Moran's I)

6.2 Aggregated rental value variations between the transhipment precincts

The Global Moran's *I* yielded a value of 0.4322, indicating spatial clustering within the dataset. This suggests that premises with high rental prices tended to be located close to one another, and that lower-priced properties were similarly clustered. The *p*-value of < 2.22e-16 confirms that the observed pattern is statistically significant and unlikely to have occurred by chance. Fig. 4 shows that properties in Airport Industria near the airport and Paarden Eiland near the port had higher rental prices per m^2. In contrast, Parow Industrial was characterised by medium to low rental prices per m^2.

The Local Moran's *I* statistics are presented in Table 1 below. For Paarden Eiland, Moran's *I* statistic of 0.2158 implies that properties with similar price per m^2 were located near one another. This result is statistically significant, indicating spatial clustering in the area. In Airport Industria, clustering was slightly higher with a value of 0.3774, reflecting the tendency for properties with similar prices to be spatially concentrated. The *p*-value is significant for this location as well. In contrast, Parow Industria recorded a value of -0.0125, which is close to zero, with a *p*-value of 0.39768. This result is not statistically significant, suggesting that the distribution of monthly rental prices per m^2 in Parow Industria was spatially random.

Metric	Location	Moran's *I* Estimate	P-value	Observation Count
Moran's *I* statistic	Paarden Eiland	0.2158	>0.001	79
Moran's *I* statistic 1	Airport Industria	0.3774	>0.001	78
Moran's *I* statistic 2	Parow Industria	-0.0125	0.39768	29

Table 1: Moran's I statistics.

6.3 Disaggregated rental value variations between the transhipment precincts

The descriptive statistics results, disaggregated by transhipment precincts and the four land-use categories, are displayed in Table 2 and discussed in the subsections hereunder. Monthly rental variations within and between the precincts could potentially be influenced by differences in neighbourhood and on-site amenities (Dunse, Leishman & Watkins, 2002). Overall, the highest mean was ZAR177.5/m^2 for two office properties at Airport Industria, followed by ZAR139/m^2 for office premises at Paarden Eiland. The findings show that office properties have a higher rental value than warehousing, industrial, and retail properties across the three transhipment precincts.

Precinct	Category	N	Min	Max	Range	Mean	Std. Dev
Airport Industria	Industrial	42	69.6	204.6	135.0	104.6	24.9
	Office	2	150.0	205.0	55.0	177.5	38.9
	Warehousing	53	67.5	157.1	89.6	109.3	27.7
Paarden Eiland	Industrial	46	66.0	175.7	110.0	98.6	24.4
	Office	20	71.1	206.3	135.1	139.0	40.1
	Retail	3	114.8	116.7	1.9	116.0	1.1
	Warehousing	40	75.0	120.0	45.0	91.9	13.2
Parow Industrial	Industrial	17	12.0	115.0	103.0	65.1	24.6
	Office	3	65.0	80.0	15.0	70.0	8.7
	Retail	1	110.0	110.0	-	110.0	-
	Warehousing	13	60.0	110.0	50.0	74.3	12.3

Table 2: Disaggregated descriptive statistics.

6.3.1 Warehouse rental values

The mean monthly warehouse rental value was highest at Airport Industria (ZAR109.3/m2), near the airport, followed closely by Paarden Eiland at ZAR91.9/m2. The mean value of advertised warehouses was lowest at Parow Industria, at ZAR74.3/m2.

6.3.2 Industrial rental values

The mean industrial monthly rental value was highest at Airport Industria at ZAR104.6/m2, with the widest range at ZAR135/m2, followed by Paarden Eiland at ZAR98.6/m2. The mean industrial value was lowest at Parow Industria at ZAR65.1/m2. The findings indicate that, unlike in the mid 1990s when the industrial rental rate in Paarden Eiland was three percent higher than the municipal average (City of Cape Town municipality, 2002), the November 2025 rental rates were slightly higher in the vicinity of the airport.

6.3.3 Office rental values

The mean office rental value was highest at Airport Industria at ZAR177.5/m2, albeit only two properties were recorded. Paarden Eiland followed with an office rental value of ZAR139/m2. The office mean value was lowest at Parow Industria at ZAR70/m2, with only three properties recorded.

6.3.4 Retail rental values

The mean advertised retail rental value was highest at Paarden Eiland at ZAR116.7/m2, followed closely by Parow Industria at ZAR110/m2. As observed earlier in the paper, no retail property was advertised for rent in the vicinity of the airport.

7 CONCLUSION

The aim of the paper was to analyse the rental value of warehouse, industrial, office and retail properties in the vicinity of Cape Town International Airport, in comparison with values around the Port of Cape Town, and the Belcon inland/ dry port. The specific objective was to ascertain if the airport environs, in contradistinction to the other two transhipment precincts, represented a unique property market. Using QGIS, SPSS and RStudio to analyse the monthly rental data scraped from a prominent property-listing company, the results show that the mean rental values for industrial, warehouse, and office properties were highest near the airport, followed by those in the vicinity of the port, and lowest around the inland port. Global Moran's I showed a stronger clustering of similar rental values in the environs of the airport, followed by Paarden Eiland, while estimates in Parow Industria were not statistically significant.

Despite the densities that are higher in the vicinity of the Port of Cape Town and the absence of retail properties advertised for rent near the airport, the study's findings show that, from the perspective of rental values, it can be argued that airport environs may potentially constitute a distinct warehousing, industrial, and office property sub-market. Spatial planning efforts could leverage this unique position to, among other objectives, appropriately guide the municipality's spatial economy and maximise the agglomeration economies in the vicinity of the airport.

Despite the paper's insights, it has two main limitations. Firstly, the cross-sectional study's main limitation is that rental information was collected at a single point in time (i.e., November 2025) and may not provide a comprehensive picture of the dynamics of property rental value near the airport, relative to the seaport and the inland port environs. Secondly, the study relied on the scraping of a single website.

To address these limitations, it is recommended that future research consider different property listing websites, include sale prices, and scrape data at different times to identify trends and patterns in the warehouse, industrial, office and retail property values in the vicinity of transhipment zones.

1 ABSTRACT

Rapid urbanisation trends in Southeast Asia are primarily influenced by mass transit systems, however the influence of railways on land use dynamics in India remains unique from global patterns. Unlike contemporary Light Rail Transit (LRT) or Metro systems where Transit-Oriented Development (TOD) is often a planned and post-construction intervention, Indian railway nodes typically predate the very concept of TOD, implying urban areas have integrated organically following railway infrastructure rather than being retrofitted. The study investigates this Railway-induced spatial restructuring in the Indian context, specifically the Southern West Bengal region, a rapidly densifying polycentric system, with the primary objective of determining whether railway proximity naturally fosters efficient development or induces chaotic ribbon sprawl. The methodology incorporates a multi-scalar geospatial framework by employing a 25-year temporal gradient (2000-2025) to analyse the relationship between horizontal densification and vertical building density. Data from remote sensing (Landsat 7/8) was utilised to compute fragmentation metrics using FRAGSTATS to quantify horizontal sprawl, while Google Earth Engine (Open Buildings 2.5D) was utilised to derive the average building height. These morphological outputs were further correlated with Space Syntax Integration values to assess functional connectivity. The analysis established four distinct station typologies regarding the urban form efficiency, namely saturated node, stagnant core, benchmark model and developing node. Moving beyond standard computer simulations, the study predicts future growth by analysing these distinct evolutionary categories and utilising passenger footfall data to forecast passenger and train load transfer. The research concludes that without policy intervention, rapid expansion of these urban areas will overburden infrastructure, highlighting the need for specific policy formulation to mitigate these externalities before they become irreversible.

Keywords: Railway-induced Urban Growth, Transit-oriented Development, Spatial Metrics, Urban Sprawl, Urban Morphology

2 INTRODUCTION

2.1 Background and Research Motivation

The relationship between transport infrastructure and urban form is one of the defining characteristics of the 21st century Asian metropolis (Navalkar et al. 2023). A new global paradigm has emerged focusing on smart, sustainable, and inclusive development, yet the practical application of these concepts in Southeast Asia often faces unique challenges. In India, rapid urbanisation is not merely a function of population growth but is intrinsically linked to mass transit availability (Sekar and Gangopadhyay 2017). Southern West Bengal serves as a paradigmatic case of this phenomenon. As a major rail corridor and economic gateway for Eastern India, the region is witnessing a rapid emergence of peri-urban growth clusters centred around the railway stations. Unlike the planned Transit-Oriented Development (TOD) seen in other cities like Singapore or Hong Kong where density is not organic, the urban growth around Southern West Bengal is organic, historical and mostly chaotic (Mandal et al. 2020).

The motivation for this research arises from a critical observation of the surroundings where the Government of India (through the Ministry of Railways) has allocated significant capital of approximately INR 14,000 crores to upgrade railway infrastructure in West Bengal to support micro-enterprises and regional movement. But investment alone does not guarantee urban transformation. With the absence of evidence-based urban planning, capital investment runs the risk of accelerating “ribbon sprawl” rather than fostering efficient and compact transit nodes. This has led to discussions that investment numbers alone are insufficient, and closer

attention must be paid to the tangible morphological changes they trigger in cities (Ramachandra et al., 2014).

2.2 Problem Statement

The central planning challenge facing the Kolkata Metropolitan Area (KMA) and its hinterlands is the balancing act between infrastructure expansion and sustainable land management. Current frameworks of urban planning often lack the granular data required to understand how railway stations specifically influence the vertical and horizontal dimensions of growth. There is a clear methodological gap, as most existing studies focus only on 2D land-use patterns and overlook the vertical intensity of development (such as building heights), which is essential for understanding densification (Karmarkar, Jana, and Velaga 2024). Along with this, a significant contextual gap persists because international TOD frameworks are seldom tailored to the complex realities of Indian railway towns, where informal settlements and historically evolved urban layouts resist easy incorporation into conventional planning models (Mehra and Vardhan 2025). In these regions, the presence of informal settlements and historical urban forms resists the 'clean' geometry of conventional planning models. While this study establishes a vital baseline for these towns, it also understands that it lacks the socio-economic depth needed to fully capture these physical changes that involve the lives of the people inhabiting them. Consequently, the primary research inquiry stands at "How is railway expansion reshaping patterns of urban development in this dynamic region?" and "Do railway nodes encourage compact, efficient agglomerations, or do they contribute to more fragmented and dispersed urban growth?"

2.3 Aim and Objectives

The primary aim of this study is to investigate the phenomenon of transit-induced spatial restructuring along the Southern West Bengal rail corridor, specifically determining whether railway proximity fosters efficient densification or induces chaotic sprawl. To achieve this, the research examines the spatio-temporal evolution of urban forms around four distinct railway station contexts – Howrah, Shalimar, Santragachi and Uluberia – over a 25-year period (2000 to 2025). This involves a multi-scalar analysis that correlates horizontal fragmentation metrics with vertical building density to establish distinct evolutionary typologies of railway-induced growth. Building upon this morphological classification, the study further seeks to forecast future development trajectories for the active growth nodes by synthesising historical urbanisation trends with passenger ridership shifts.

3 LITERATURE REVIEW

The relationship between rail corridors and urban form has been extensively documented, establishing the fact that mass transit systems are acting as an active agent for densification and spatial restructuring. One of the studies monitored urban growth in Howrah (Mandal et al. 2020). The study used spatial metrics to reveal a distinct pattern of "clumping" in the core city, which is contrasted against rapid outlying growth and high fragmentation at the periphery. This also aligns with the findings of Sekar and Gangopadhyay (Sekar and Gangopadhyay 2017), who analysed land use changes around suburban rail in Chennai using a "concentration index". This index confirms densification has shifted decisively towards railway corridors, thereby altering the city's macro-spatial form. All these studies underscore that while rail proximity acts as a catalyst for growth, the resulting urban morphology varies significantly between compact and fragmented based on local constraints.

However, a significant methodological limitation in current research is the heavy reliance on two-dimensional Land Use Land Cover (LULC) analysis, ignoring the vertical intensity that defines the principle of modern urbanisation. While LULC effectively maps the horizontal expansion, it fails to capture the volumetric capacity of transit nodes. Recent work by Karmarkar (Karmarkar et al. 2024) attempts to bridge this gap by modelling "Volumetric Growth" (2D+3D) around new transit stations. Their work demonstrated that high-rise development correlates strongly with station proximity, yet such studies majorly rely on coarse building height classes or limited field data. There remains a gap of more precise and continuous building height assessments to accurately correlate horizontal with vertical densification, which is addressed by this study by using open-source 2.5D datasets.

While Transit-Oriented Development (TOD) frameworks are well established globally, they are rarely adapted to the specific spatial conditions of historical Indian towns. The assessments often utilise the index-based approaches involving density, diversity and accessibility, as demonstrated in a study by Uddin (Uddin et al. 2023) for the Dhaka MRT and Lin (Lin et al. 2023) for Taipei. However, these frameworks are applied to planned systems where the "railway station area" is a designed zone. The study by Mehra and Vardhan (Mehra and Vardhan 2025) emphasises the necessity of defining TOD typologies specific to the corridor context rather than applying generic metrics, arguing that design and density are the most influential factors in Indian suburban rail corridors. In the absence of such contextualisation, standard TOD principles may fail to address the organic, informal and historical nature of urban growth in the context.

Finally, the approach to forecasting future urban growth around these railway nodes requires re-evaluation. Current predictive models, such as those employing Cellular Automata (CA) and Markov chains by Fu (Fu et al. 2024) or SLEUTH models, have successfully predicted land use changes with high accuracy. However, these mathematical simulations often consider very limited variables, which mostly fail to capture the "messy" socio-economic complexities and historical contexts of Indian railway towns. Consequently, this study proposes shifting from purely mathematical simulations to identifying evolutionary typologies based on historical data and passenger footfall, which is a critical demand variable that is often absent in other research, to forecast future development scenarios more accurately.

4 STUDY AREA

The research focuses on the Southern West Bengal Rail corridor, specifically the South Eastern Railway corridor, which acts as the critical economic and trade gateway for Eastern India. This corridor was also selected for its strategic alignment with the urbanisation priorities and economic policies that were established by the Kolkata Metropolitan Development Authority (KMDA), which functions as a polycentric urban system where the selected railway stations act as anchor points for metropolitan area development. The spatial structure of this region is unique, urban growth is heavily constrained by the Hooghly River and existing infrastructure, forcing a linear north-south expansion pattern along the railway network. This geography of the region makes it an ideal laboratory for analysing "transit-induced spatial restructuring", as the railway line effectively dictates the spine of urban densification. To capture the diverse evolutionary stages of transit nodes, four specific railway stations were selected to represent a gradient of urban development maturity (Fig. 1).

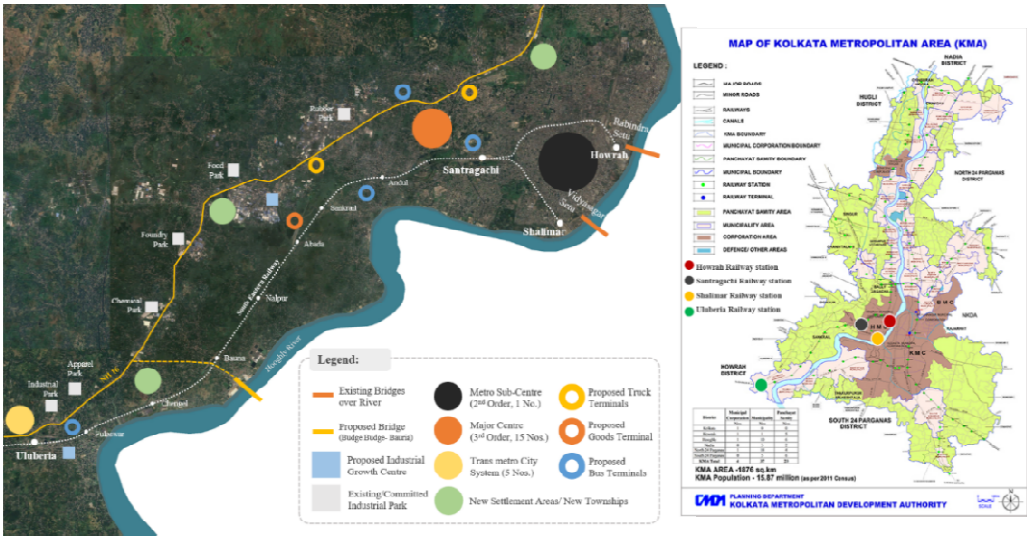

Fig. 1: Map of the Kolkata Metropolitan Area showing the strategic location of Howrah, Santragachi, Shalimar, and Uluberia Railway Stations along the South Eastern Railway Corridor (Source: Adapted from KMDA Comprehensive Mobility Plan, 2008)

- Howrah (The Historic Anchor): Howrah is selected as the primary baseline. It functions as the region's historic terminal and a designated "Metro Sub-Centre", which is providing a fully urbanised and spatially controlled case against which developing nodes can be compared. Currently it serves millions of commuters and also acts as the primary gateway to the Kolkata region .

- Shalimar (The Logistics Hub): Shalimar has a unique spatial dynamic of a specialised logistics and freight-orientated terminal located within the urban core, serving as the case for how heavy freight infrastructure and truck terminals influence immediate neighbourhood development which is distinct from purely passenger-centric hubs.
- Santragachi (The Dual-purpose Node): Santragachi has the strategic role of being a dual-purpose node i.e., functioning simultaneously as a high-volume suburban halt and a major express train terminal with Kona Expressway in close proximity with the railway stations, making it a prime location for analysing the integration of rail infrastructure with the National Highway (NH 16) and its potential as an emerging metropolitan sub-centre.
- Uluberia (The Peri-Urban Periphery): Uluberia represents the metropolitan as well as the corridor's developing edge. This station is designated as a "Trans Metro City" node that acts as a vital intermodal link to the Haldia industrial belt and is also the starting point of the upcoming Varanasi-Ranchi-Kolkata greenfield expressway project, providing a crucial case study for analysing early-stage urbanisation and land-use transformation at the metropolitan fringe.

5 METHODOLOGY

This study adopts an integrated urban development framework that synthesises multi-scalar geospatial analysis with morphological metrics to assess the impact of rail infrastructure on urban form. The methodological approach is subdivided into three distinct phases: urban development analysis, comparative analysis and categorisation, and policy recommendations (Fig. 2).

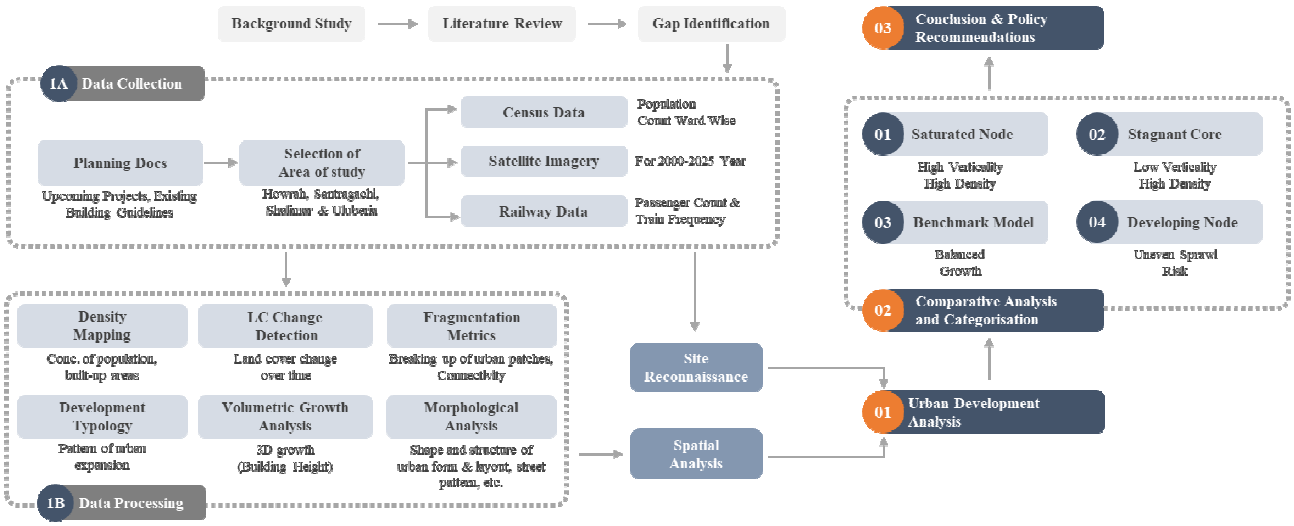

Fig. 2: Methodological Framework Flowchart. (Source: Author)

5.1 Data Collection

For a long-term analysis on transit-induced spatial restructuring, the study integrates diverse secondary sources to create a harmonised dataset spanning 25 years. Land cover changes were monitored using Landsat 7 and 8 satellite imagery (30M resolution) through Google Earth Engine (GEE) for the years 2000 to 2025. To address the critical gap in vertical densification analysis, which is often missed in traditional sprawl studies, building height data was extracted using the "Open Buildings 2.5D" dataset , helping in the calculation of volumetric metrics within the station catchment area. These morphological datasets were complemented by socio-economic layers. These include ward-wise population counts from the Census of India (2001 & 2011) and, crucially, the station-specific passenger footfall and train frequency data sourced from the South Eastern Railway division under Indian Railways. This integration allows for a direct correlation between physical urban form and transit demand.

5.2 Spatial and Morphological Analysis

To quantify the transit-induced spatial restructuring, the study employed a multi-scale buffer analysis. Using the geographic coordinates of each railway station as the geometric centroid, three concentric zones (with radii of 1 km, 3 km and 5 km) were established to capture the influence of railway nodes. The 1 km buffer

represents the immediate pedestrian core (TOD Zone), which assesses the walkability of a typical 10–15-minute walking radius. The 3 km buffer captures the intermediate catchment, which is served by non-motorised transport or para-transit feeds. The 5 km buffer shows the peri-urban interface, which analyses the extent to which the station's urbanisation pressure bleeds into the regional rural hinterland. Within these zones, three primary metrics were calculated.

5.2.1 Fragmentation Analysis (Horizontal Growth)

It measures the urban sprawl of the area. Patch Density (PD) was calculated using FRAGSTATS software as used in previous research by (Mandal et al. 2020; Ramachandra et al. 2014). Patch density is defined as the number of separate built-up patches per unit area. It serves as a robust method for classifying fragmentation versus consolidation. As observed in previous studies, high fragmentation at the periphery contrasts with "clumping" in the core. A greater patch density value signifies that the development is spread out, while a lower value indicates successful urbanisation and horizontal consolidation.

5.2.2 Volumetric Analysis

It fills the gap in traditional studies of urban sprawl. The research correlated Average Building Height (Havg) with the Building Density Index (BDI). This volumetric approach draws on methodologies for predicting the growth around the studied stations, which solidifies the fact that building height is a critical indicator of intensity. The Havg was derived using the Google Earth Engine's (GEE) Open Building 2.5D dataset. Comparing the Havg against the percentage of land cover by buildings (BDI), the analysis distinguishes between various categories of development pattern, thus determining the true 3D capacity of the urban core.

5.2.3 Space Syntax (Network Connectivity):

To evaluate the functional efficiency of the road network, Space Syntax Integration values were calculated. These metrics measure how accessible the street in the various buffer regions is, which serves as the unit for measuring walkability and spatial quality. High integration values indicate a movement economy that supports commercial vitality, while low values suggest isolation. This variable helps to identify whether the station node is effectively integrated or functionally disconnected from its regional hinterland.

5.3 Typology Identification and Predictive Scenarios

The final phase of the framework synthesises the quantitative metrics from section 5.2 to establish a qualitative classification of the railway nodes. These classifications form the basis for forecasting future urban growth (Fig. 2).

5.3.1 Station Typology Framework

A comparative typology matrix was established to measure the urban efficiency of each node. The various metrics used were fragmentation, verticality and connectivity. The first category was the "Saturated" node, which is defined by extreme vertical intensity (high Havg) combined with high spatial congestion, this also represents that a node has reached its physical capacity limits. In contrast, the "Stagnant" node is characterised by high horizontal density (high BDI) but has remarkably low vertical growth (low Havg). This indicates a failure to utilise its central location due to poor connectivity or infrastructure bottlenecks. The third category, the "Benchmark Model", represents the ideal Transit-Oriented Development (TOD) outcome. It is also defined by high horizontal consolidation (low PD) paired with sustained vertical growth, highlighting efficiently managed density. Lastly, low vertical density and moderate horizontal saturation indicate the "Emerging node". This designation represents an early-stage node containing large areas of undeveloped land and significant untapped potential for future densification.

6 RESULTS AND DISCUSSION

6.1 Spatio-Temporal Dynamics: Horizontal Fragmentation vs. Consolidation

The temporal analysis of Patch Density (PD) from 2000 to 2025 reveals two divergent urban growth trajectories along the corridor (Fig. 3). In the mature nodes of Howrah and Santragachi, the PD metric demonstrates a distinct consolidation effect. For Howrah, the PD has remained relatively stable over the last

decade, implying that the urban fabric is saturated and there are no significant spaces left to fill. This results in a contiguous and congested built-up area. Similarly, Santragachi exhibits a decreasing PD trend despite rapid development. This morphological behaviour, where the number of patches decreases while the total built-up area increases, confirms the successful consolidation of the catchment area. It also suggests that new developments are merging with existing clusters rather than isolated development, proving Santragachi's status as a potentially efficient transit node. In contrast to the previous observations, Shalimar exhibits a volatile spike in PD within the 3 km and 5 km buffers. The analysis shows high fragmentation, though the urban footprint is expanding. The quick growth of isolated industrial and residential areas at the periphery shows "ribbon sprawl" caused by speculative land conversion instead of planned transit-oriented densification. This unusual difference in spatial metrics highlights that while rail corridors drive growth, they don't guarantee morphological efficiency without careful planning interventions. Uluberia, on the other hand shows consolidation with PD decreasing gradually with minor spikes in between.

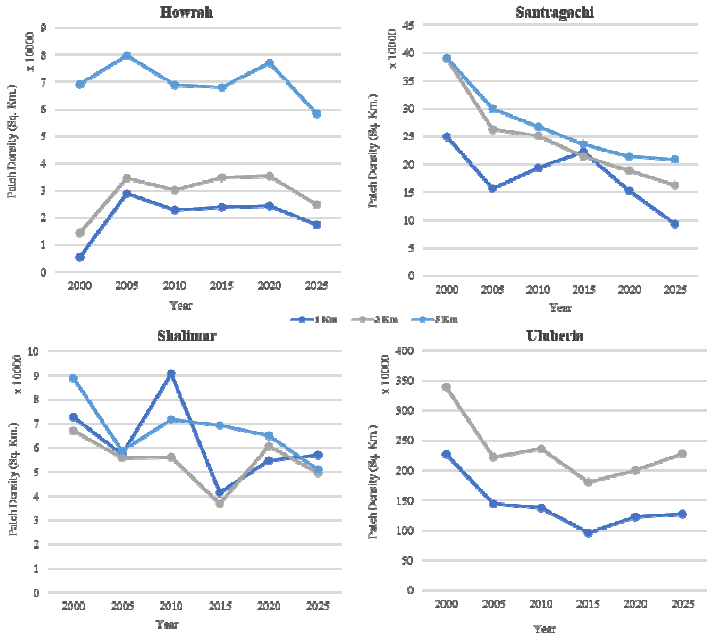

Fig. 3: Temporal variation of Patch Density (Sq.Km.) for Howrah, Santragachi, Shalimar and Uluberia across 1 km, 3 km and 5 km buffers (2000-2025) illustrating the contrast between consolidation (Howrah & Santragachi) and fragmentation (Uluberia). (Source: Author)

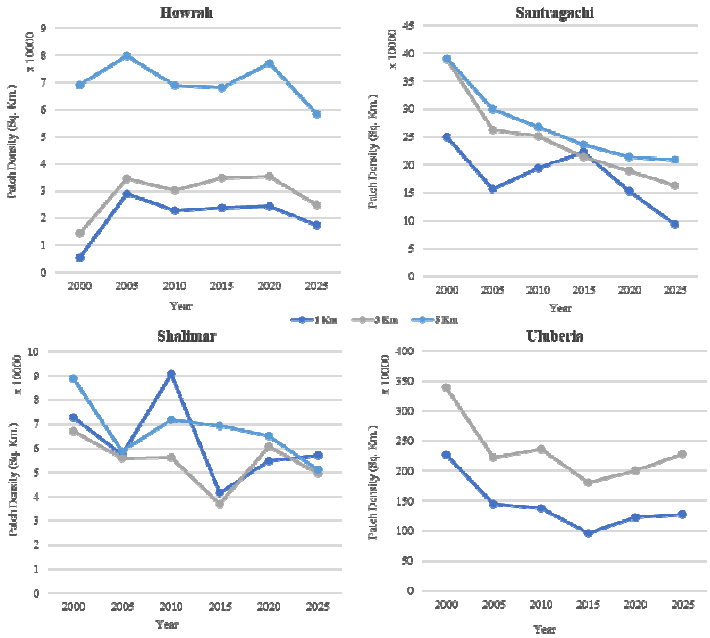

Fig. 4: Spatio-temporal map showing the population density variations for Howrah, Santragachi, Shalimar and Uluberia (2001 & 2011 years), highlighting the demographic shift from the core to the periphery. (Source: Census of India, 2001 & 2011)

6.2 Population Density Gradient and Demographic Shift

The morphological trend is replicated by the demographic pressure on the station areas (Fig. 4). Analysis of ward-wise population density (2001-2011) reveals a clear core-periphery gradient. Howrah exhibits a hyper-dense demographic profile that has stabilised over the last decade, implying that the area has reached its "Carrying capacity", where further population growth is physically constrained by the lack of developable land.

Santragachi and Uluberia demonstrate a sharp growth in population density, signifying a demographic shift where the functional load is moving away from the saturated core into these peri-urban pockets. This rising density perfectly relates to the Patch Density spike observed in section 6.1, confirming that these nodes are the new active fronts of urbanisation and require immediate infrastructure augmentation to prevent the formation of high-density slums.

6.3 Volumetric Analysis

By relating average building height (Havg) with horizontal saturation (BDI), the study identifies the physical efficiency of each station area (Fig. 5). Combined with saturated horizontal density, Howrah records the highest Havg in the studied area. This reinforces the fact that the node has shifted from horizontal expansion to vertical densification. However, the extreme BDI value suggests that this vertical growth is a reaction to land scarcity rather than a planned outcome. A critical finding is the performance of Shalimar. Despite being located within the high-value urban core and comparable in location to Howrah, it exhibits a (low Havg, high BDI) relation. The data shows that while the ground plane is saturated with logistics and low-rise structures, vertical growth is significantly suppressed compared to its neighbour Howrah. This gap defines the "Stagnant Core" typology i.e., a node where conflicting land uses (freight vs. passenger) have artificially capped development potential. The steady rise in Havg parallels its horizontal consolidation, implying that infrastructure upgrades are successfully inducing real estate investment. In contrast, Santragachi shows a balanced morphology where moderate vertical growth goes with horizontal consolidation. This confirms its status as a sustainable benchmark. Meanwhile, Uluberia records the lowest average vertical height, confirming that its rapid expansion is strictly low-rise and sprawling in nature.

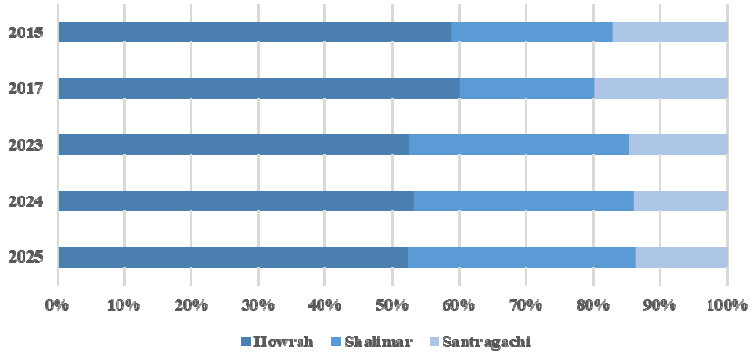

Fig. 6: Year-wise Number of Long-Distance Passenger Trains Originating from Howrah, Shalimar and Santragachi (2015-2025). (Source: South Eastern Railway Division)

6.4 Passenger Ridership Analysis

To support the evidence of urban sprawl, the study analysed station-level passenger footfall data along with express train frequency data for the 2015-2025 period. The data reveal a structural transformation in regional mobility plans, confirming the presence of an active functional load shift from the core to the periphery. In the fiscal year 2017-18, Howrah dominated the corridor with handling 75% of the total passenger volume, while Santragachi and Uluberia accounted for only 10% and 12%, respectively (Fig. 7). However, a sharp break is observed in 2018-19, where Howrah's share dropped to 50%, while Santragachi and Uluberia surged to 21% and 24% respectively. This drastic redistribution shows that satellite nodes are absorbing the exploding suburban demand that the saturated Howrah terminal can no longer accommodate. This supports the fact that the ridership shift is a distinct operational decentralisation of express train services. Analysis of train frequency data highlights functional roles for each terminal (Fig. 6). Howrah remains the primary hub for Western routes (e.g., Mumbai, Tatanagar) handling a total of 68 long-distance trains. In contrast, Shalimar and Santragachi have been tagged as specialised terminals for southern routes (e.g., Chennai, Hyderabad). This strategic diversion of specific long-distance corridors to satellite terminals is a key driver of the patch density spike observed in their hinterlands. These stations evolve from simple halts to major origins/destinations, they trigger immediate and unplanned residential conversion in the surrounding areas to support the new transit economy.

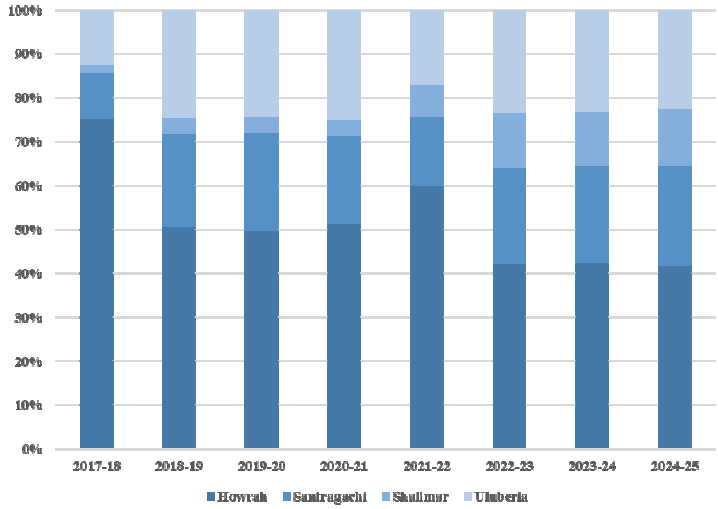

Fig. 7: Year-wise Distribution of Passenger Ridership Share across the Southern West Bengal Rail Corridor (2017-2025), illustrating the functional load shift from Howrah to satellite nodes. (Source: South Eastern Railway Division)

6.5 Operational Efficiency: Traffic Congestion Analysis

To validate the findings from earlier results, the study analysed real-time traffic congestion indices derived from peak-hour movement data (Fig. 8). This analysis serves as a proxy for the functional performance of the street network surrounding the stations. The traffic heatmap reveals that Howrah operates at a severe congestion level, with high indices during peak hours. This confirms the "Saturated Node" typology, where the street network has failed to cope with the vertical densification, resulting in a gridlock pattern that nullifies the benefit of transit proximity. In contrast to this, Santragachi records significantly low congestion indices even during peak windows. This validates its classification as the Benchmark Model. Despite its rising building density, the station area maintains operational fluidity, proving that its urban form (consolidated yet accessible) effectively manages the intermodal transfer of passengers without choking the local road network. This difference provides empirical evidence for the "load shift" strategy i.e., shifting terminal functions to Santragachi is not just a railway capacity decision, but it is an urban relief necessity. Shalimar exhibits a distinct restricted flow pattern. Being a freight terminal, the heavy logistics traffic clashes with passenger movement, effectively cutting the station off from its immediate neighbourhood. Meanwhile, in Uluberia, the outer peripheral roads remain free-flowing. The roads leading directly to the station record a high level of congestion. This specific bottleneck confirms that the unconnected local street network is struggling to cope with the sudden surge in daily commuters.

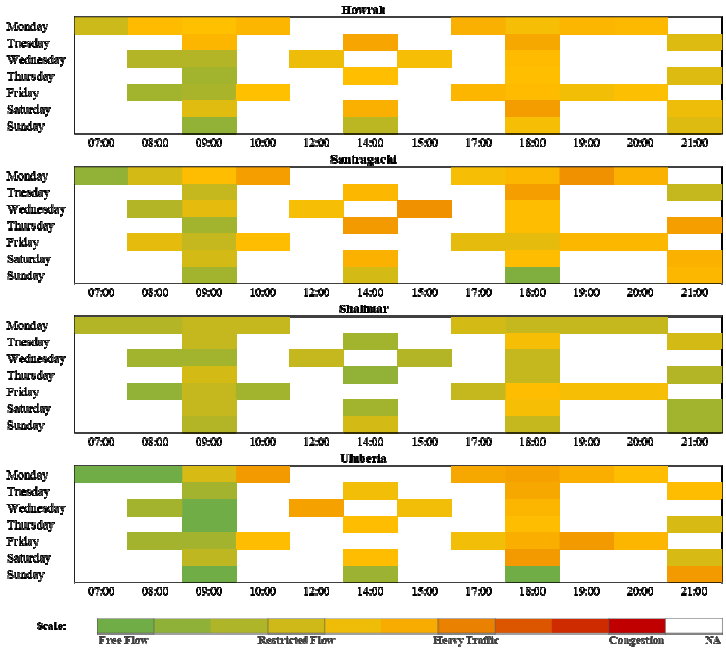

Fig. 8: Comparative Spatio-Temporal Traffic Heatmap (2025) showing congestion indices for peak and off-peak hours across all stations. (Source: Author)

6.6 Morphological Transitional Analysis

The temporal analysis of the spatial footprint across varying building height categories provides a critical indicator for the building transition potential of the station catchment areas (Fig. 9). By correlating the change in low-rise (G+1) versus low-mid-rise (G+4/G+5) built-up shares, the study deduces the probability of organic vertical conversion. In the core area, Howrah demonstrates a "saturation constraint" where the spatial share of the high-rise categories has effectively saturated over the last decade. This suggests the node has reached its morphological limit, and further densification is no longer a function of plot-level upgrading but requires a complex district level development. Conversely, Shalimar shows a stalled conversion trajectory. Despite recording a total built-up coverage comparable to the urban core, the dominance of the low-rise footprint paired with negligible growth in the mid-rise category confirms a deadlock. The functional dominance of freight logistics in this zone appears to suppress the land value aggregation required for residential verticality, effectively trapping the node in a low-rise equilibrium.

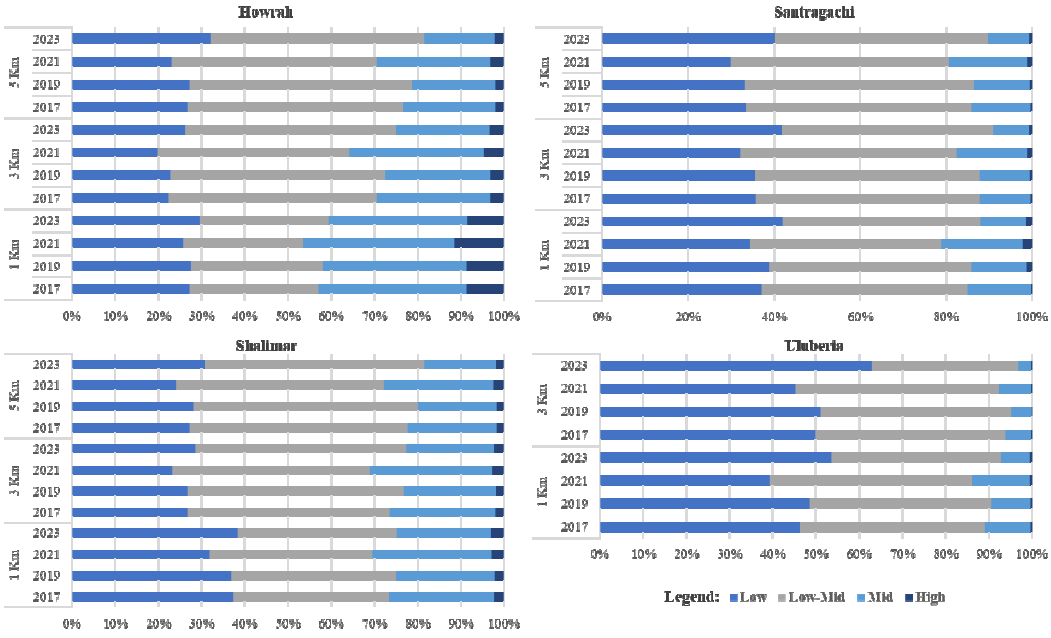

Fig. 9: Temporal Evolution of Building Height Composition (2017-2023) showing the share of low, low-mid, mid, and high-rise structures, indicating the probability of vertical transition. (Source: Google Open Buildings 2.5D Dataset)

Moving towards the periphery, Santragachi emerges as the corridor's active transition zone. The area records a steady increase in the spatial share of low-mid-rise structures relative to the low-rise baseline, which also confirms the high probability of conversion. This indicates that the market is actively responding to the "load shift" by using smaller and fragmented plots to accommodate higher-density housing. In direct contrast, Uluberia displays a probability of diluted conversion. The explosive expansion of the low-rise footprint in this zone far outpaces any transition to mid-rise structures. The data confirms that the market preference here remains skewed toward lateral "ribbon" expansion into the agricultural hinterland rather than vertical densification. As long as the volume of the low-rise construction continues to spike at the periphery, the economic pressure to vertically upgrade the town centre remains minimal. This diverts the growth outwards rather than upwards.

6.7 Comparative Analysis and Categorisation of Station Typologies

Integrating the horizontal, vertical, and other metrics allows for a categorisation of the corridor's urban evolution into four distinct typologies (Fig. 10). Howrah functions as the definitive "Type 1 – Saturated Node", where transit utility is maximised but liveability is compromised by the physical limits of the land. The convergence of peak building height, stabilised patch density and severe traffic congestion metrics indicates that the node has reached a saturation point. The future growth in this area can no longer be accommodated through expansion but is only possible through complex vertical redevelopment. In direct contrast, Shalimar is identified as a "Type 2 – Stagnant Core". Despite its proximity to the urban centre, the low verticality v/s high coverage correlation identifies it as an underperforming asset. The dominance of freight infrastructure and conflicting road networks has created a logistic trap which prevents the station area from transitioning into a modern and mixed-use passenger precinct despite its high land value. Santragachi is confirmed as the "Type 3 – Benchmark Model". The station area demonstrates a rare equilibrium. It absorbs increasing passenger loads and express train traffic while maintaining morphological consolidation (decreasing fragmentation) and low traffic congestion. This balance validates that transit-oriented growth can be sustainable if supported by adequate rail-road integration. Finally, Uluberia is identified as a "Type 4 – Developing Node", which is currently in a critical transition phase. The volatile spike in patch density combined with the massive surge in unreserved ridership indicates that it is rapidly evolving into a town. However, without immediate intervention, its current trajectory of ribbon sprawl suggests it will bypass the efficient "benchmark" stage and degrade directly into a chaotic and low-density agglomeration which mirrors the congestion issues of the core but without its infrastructure capacity.

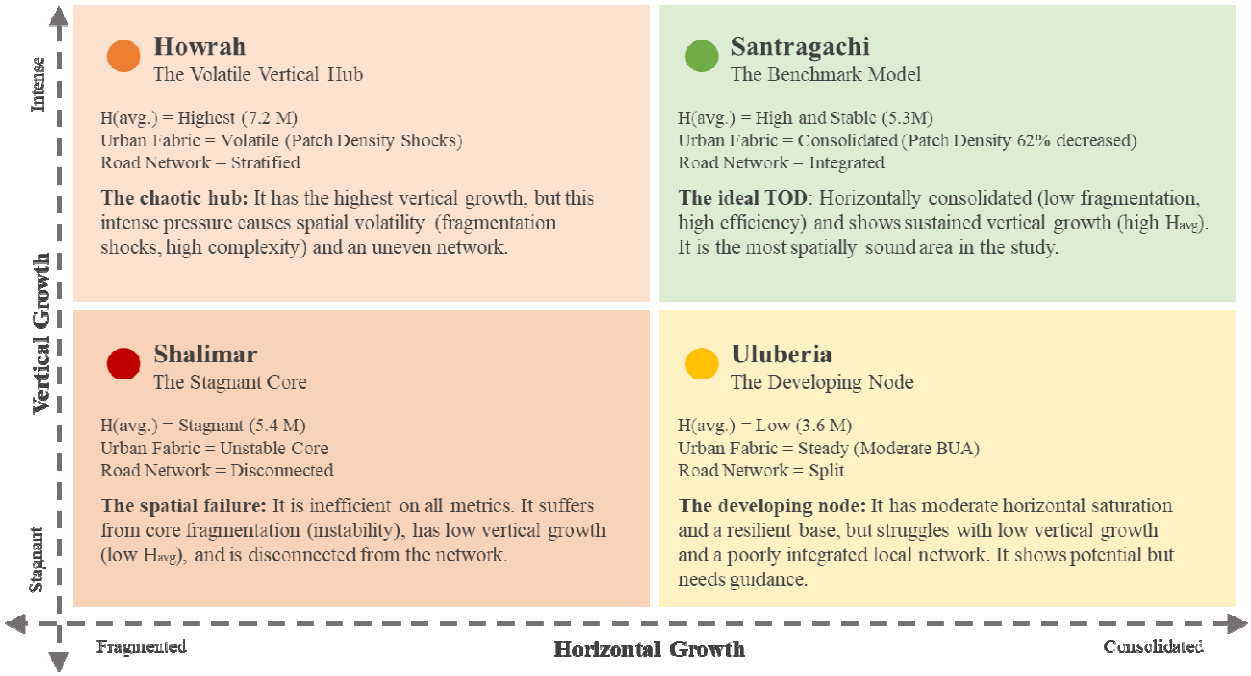

Fig. 10: Comparative Station Typology Matrix illustrating the classification of Howrah, Shalimar, Santragachi and Uluberia based on vertical growth and horizontal saturation. (Source: Author)

7 CONCLUSION AND WAY FORWARD

The study confirms that while railway proximity acts as the primary driver of spatial development, the resulting urban forms are strictly non-uniform. The study identified four distinct evolutionary typologies by considering demographic, operational and morphological data. The saturated node of Howrah has breached the carrying capacity, which is evidenced by a stabilised hyper-dense population and severe traffic congestion indices that nullify its transit advantage. The stagnant core of Shalimar remains paralysed by a "logistics trap" where conflicting land uses suppress vertical conversion despite having high land value. The Benchmark model of Santragachi demonstrates a rare equilibrium which absorbs the surging number of riders while maintaining its low traffic congestion and morphological consolidation. Conversely, the developing node of Uluberia exhibits a hazardous trajectory where an explosive rise in unreserved ridership is fuelling the fragmented "ribbon sprawl" rather than efficient densification.

7.1 Future Scenarios

Excluding the static baselines of Howrah and Shalimar, the study projects divergent trajectories for the two active nodes based on their current capacity to handle the "load shift". Santragachi is projected to follow an optimised densification path.[1] The node's ability to accommodate a 21% share of corridor ridership while maintaining free flow traffic conditions suggests a robust infrastructural baseline. By 2050, it is predicted to evolve into a fully integrated polycentric anchor, which naturally absorbs the demographic spillover from the core through vertical upgrading without suffering the gridlock associated with rapid growth. In contrast, the "business-as-usual" scenario for Uluberia predicts a systemic functional failure. The convergence of three negative trends, such as a massive surge in unreserved commuters, a volatile spike in horizontal patch density and a disconnected local street network, warns of an impending collapse of accessibility. Without proper intervention, the node is projected to bypass the efficient benchmark stage and degrade directly into a "Congested Sprawl Zone". By 2050, the fragmented settlement pattern will render the limited road network incapable of supporting the high-density commuter flow which replicates the worst aspects of Howrah's congestion.

7.2 Policy Recommendations

To align the future trajectory of the corridor with sustainable principles, the study proposes station-specific micro-plans. For Santragachi, where the road network and urban form are currently efficient, policy must focus on developing and retaining this form i.e., implementing transit-supportive mixed-use zoning (500m radius) to formalise commercial density and prioritising "grade separated pedestrianisation" to separate the growing footfall from vehicular traffic, preserving the node's high operational fluidity. For Uluberia, where natural forces favour chaotic expansion, the strategy must focus on restrictive spatial form. This requires a dual approach: establishing a strict urban growth boundary at the 3 km mark to halt ribbon sprawl while simultaneously executing a grid plan in the immediate vicinity to upgrade the local road network. Furthermore, introducing a differential FAR policy i.e., high FAR strictly within 1 km is essential to economically incentivise vertical redevelopment over horizontal expansion, which will prevent the formation of inaccessible settlements. Looking ahead, the next phase of research will focus on layering this morphological data with deeper socio-economic insights to better understand its impact on transit-induced growth. Additionally, future works must find ways to fully ensure that policies like the proposed micro-plans and FAR adjustments serve the entire community rather than just the formal urban fabric. Bridging these physical and human gaps is essential for creating transit nodes that are not just efficient but truly sustainable.

Architectural Rehabilitation of Charasteen Cave in Duhok: A Locally-Led Accessibility and Heritage Intervention within the UNESCO–EU MADAD Framework with Support from the Kurdistan Regional Government

Mahmood Albrifkany

(Dr. Mahmood Albrifkany, Nawroz University/ Faculty of Engineering/ Architectural Engineering Department, Duhok, KRI, Iraq, mahmoud.muhammed@nawroz.edu.krd)

1 ABSTRACT

This paper is the result of a successful architectural and heritage intervention at Charsteen (Charasteen) Cave in Kurdistan Region of Iraq, which is a very important cultural and spiritual place for Zoroastrians. In accordance with the framework of the UNESCO-EU MADAD "Support to Livelihoods through Cultural Heritage Development" program and with support from the KRG, the project was implemented using a low impact design approach that made safe access available while protecting the sanctity of the environment and the cultural significance of the cave. As the Head Architect Engineer and Project Coordinator of WADI (a German international organization) the author was responsible for leading the total redesign and implementation of the site's Master Plan; UNESCO experts, as well as the Duhok Directorate of Antiquities and Heritage, the Tourism Department, the Local Workers Union, and the International Labour Organization (ILO) provided the author with the necessary supervisory, coordinating, and technical assistance. The project consisted of a minimal amount of physical intervention with a focus on adaptive reuse, environmental protection, and the use of natural materials. Water supply line additions, a water-recycling system, sewage systems, improved lighting, and the stabilization of circulation pathways were among the infrastructure upgrade actions taken. A workforce consisting of women, persons with disabilities, Syrian refugees, IDPs, and local community members who were employed under ILO-Cash for Work schemes were involved in all aspects of the project. Capacity building activities involving training in heritage conservation, site management, safety, and construction techniques were also conducted to promote increased community involvement in the site's future stewardship. Utilizing an analytical-applied methodology, this paper will detail the entire process of the intervention from analysis/design phase to demolition/re-construction/evaluation phase, and assess the extent to which it achieved a balance of accessibility, heritage protection and community inclusion. Ultimately, the results of this study clearly show that when implemented under international frameworks locally-led, low-impact architectural interventions can be carried out successfully and maintain the highest levels of preservation and sustainability. The project has established a viable model for sustainable and inclusive restoration of vulnerable heritage landscapes in disaster-affected areas.

Keywords: architecture, accessibility, heritage, UNESCO, Kurdistan

2 INTRODUCTION

Cultural Heritage in conflict areas are at risk from Social Displacement, Environmental Deterioration and Economic Instability. In the Kurdistan region of Iraq (KRI) the pressures were increased as a result of the Syrian Crisis that displaced over 227,000 people to Iraq – 96 % of them settled in KRI. This resulted in an increase in population that placed pressure on the infrastructure, depressed wages and also limited employment opportunities especially for Vulnerable Community Groups.

In this sense, the EU-UNESCO MADAD initiative "Supporting Livelihoods through Cultural Heritage Development" is an example of how cultural heritage sites are being protected by creating job opportunities for Syrians and vulnerable people in Iraq using Cash for Work programs in the form of Employment Intensive Schemes. As part of this initiative, Charsteen (Charasteen) Cave a Zoroastrian religious site located near the old Dohuk Pass has been chosen for rehabilitation.

Prior to the intervention, the site presented many problems such as; dangerous walkways, inadequate infrastructure, uncontrolled flow of visitors, poor lighting and environmental damage. On the other hand, because of the sacred nature of the site, and the natural beauty surrounding it, a very particular approach was needed to create a project that would respect the spiritual dimension of the place and the natural environment surrounding it.

In order to carry out this project, the author performed all the architectural analyses, redesigned the master plan, produced the technical details and implemented the works at the site from May 2023 until May 2025. The other actors involved in this project were mainly UNESCO, ILO, Directorate of Antiquities of Duhok, Department of Tourism, and Workers Union that acted in a coordinating role and/or supervising one.

The present document describes the whole process of rehabilitation of the site and shows that with a minimum amount of resources, with an adaptive and inclusive towards the local communities' design, we can protect the heritage sites while providing jobs, training and social values. This study is guided by the following research questions:

- How can minimal-impact architectural interventions enhance accessibility while preserving the spiritual, cultural, and environmental integrity of sacred heritage sites?
- How does a locally led design and implementation approach influence heritage preservation outcomes within internationally supervised frameworks?
- What are the social impacts of employment-intensive heritage rehabilitation?

3 METHODOLOGY

The Charsteen Cave rehabilitation project employed a hybrid analytical applied methodology, integrating architectural assessment, heritage conservation, environmental management, and community development. The approach encompassed several complementary components:

3.1 Broader Urban Context and Long-Term Considerations

The rehabilitation process of Charstein Cave needs to be considered within the context of the broader urban and demographic trends that are impacting Duhok City, as shown in Figure 1. Illustrate the map of Iraq, showing the Kurdistan Region, including the map of Kurdistan Region showing Duhok, and including the map of Duhok showing the Charsteen site location.. For the past decade, the city has been absorbing large numbers of refugee and internally displaced persons, which has exerted considerable strain on the city's infrastructure, housing, and land reserves. While the demographic trend is a positive indicator of the city's capacity to adapt to crises, the urban sprawl that has ensued has led to the city expanding beyond the initially planned urban boundaries, thus leading to the increasing consumption of land reserves, which may otherwise be used for agricultural and forestry activities.

In this context, the heritage site that is Garstein Cave not only provides a sense of urban identity but also becomes a focal point that can be used to inform the urban planning strategies that will be adopted in the future to ensure that Duhok City does not become overly sprawled, thus leading to the degradation of the natural environments that surround the city.

Fig. 1: Location of the charsteen site in Duhok, Kurdistan Region, Iraq.

3.2 Site Analysis and Documentation

The purpose of a thorough site analysis of Charsteen (Charasteen) Cave was to provide an understanding of its historic, environmental, and physical aspects. A comprehensive site analysis was performed through conducting a topographic survey of the site that would include mapping of site features and terrain, a structural assessment to determine the level of hazard or risk involved with the site and to assess the current condition of the site, photography for use as a visual record and/or for comparison in the future, mapping of the site's circulation paths and potential hazards to enable safe passage of visitors to the site, and extensive observations of the site's environment to assess both the climate of the site and the natural characteristics of the site. All of the data collected from this analysis were used as a basis for making decisions regarding the final design of the cave and any interventions made on the site.

3.3 Stakeholder and Institutional Coordination

Coordination was needed at the daily and weekly level to work with the WADI team, UNESCO, the International Labor Organization (ILO), the Duhok Department of Antiquities and Heritage (DHAH), the Duhok Department of Tourism, the Duhok Workers Union, and local community leaders (Department of Media and Information, 2025).

3.4 Minimal-Impact Design Principles

This restoration used a “minimal impact” or reversible design approach that utilized non-invasive methods and natural materials (Lin et al, 2024). The principles for this were used as a guide for placement, construction, and detailing for all new components to match the sites' cultural, archaeological, and environmental attributes according to UNESCO and ICOMOS preservation guidelines (International Committee for the Management of Archaeological Heritage (ICAHM), 1990) (UNESCO, 1972).

3.5 Applied Materials Testing

All construction materials, as well as the technical components planned for installation on-site have been subjected to an extensive evaluation process in order to assure their appropriateness for a highly sensitive cultural-historical heritage environment. Materials used in civil and structural construction (i.e., limestone blocks and dust, steel products, reinforcing steel bars, concrete, sand, soil, wood) were assessed with respect to strength, durability, compatibility with the natural and built environments, and potential long term performance of each material type under the specific climate and geology of the region in which they would be installed. Likewise, the electrical and water supply systems were evaluated to confirm their safe functioning, compatibility with the existing heritage environment, and low-impact design into the heritage environment. Engineers from WADI worked closely with experts from UNESCO and the DoAH to evaluate all materials in accordance with the applicable national building codes, and in compliance with UNESCO/ICOMOS standards for the conservation and restoration of cultural heritage. Through this multi-faceted assessment, it was assured that only those materials meeting structural requirements, environmental considerations, and those most suitable for the heritage environment, were selected for inclusion in the proposed site rehabilitation project.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

3.6 Employment-Intensive Approach

The use of an Employment-Intensive approach (in accordance with ILO guidelines) allowed for the involvement of women, refugees, internally displaced persons (IDPs), persons with disabilities and members of the local community through the provision of Cash-for-Work programs (as shown in Figure 2). Manual building techniques enabled social inclusion while allowing for detailed, heritage-specific rehabilitation.

3.7 Continuous Monitoring

The use of a multi-level monitoring system (daily, weekly, monthly, and quarterly inspections) provided oversight of the project through Progress Reports; Site Visits; and Coordination Meetings. Oversight from UNESCO; Department of Antiquities and Heritage (DoAH); International Labour Organization (ILO); Tourism Authorities; and Workers' Unions ensured that all participants were compliant with safety, cultural and labor standards. This methodology brought together high levels of analytical detail; participation from stakeholders; low impact on the cultural resource; validation of materials used; inclusive job creation and systematic monitoring to enable a sustainable and culturally relevant rehabilitation process.

4 SITE CONTEXT AND HERITAGE SIGNIFICANCE

The Charsteen (cave Char-Steen) archaeological site is located in the city of Duhok, in the Kurdistan Region of Iraq. It is near the Duhok dam and is situated where the Dohuk river meets the White Mountain range. Historically, this location served as a sacred Zoroastrian worship place. The site represents a symbolic representation of water, earth, air and fire. “Charsteen” is the Kurdish word for four pillars. Remains found at the archaeological site show evidence that it was used as a fortification during ancient military campaigns. Due to the natural environment and the flow of water, the site requires careful treatment to prevent environmental damage. The site is known as one of the most significant cultural historic sites in the area of Duhok and has been restored through a collaborative effort from UNESCO, the WADI organization, the Directorate of Antiquities and Heritage of Duhok (Government of Kurdistan), and the European Union. The site includes an ancient temple carved out of rock, known as the Charsteen temple (see Figure 3). This temple has been dated thousands of years old and contains four natural rock pillars and a recently restored temple (known to be Zoroastrian) and is thus a major historic and tourism destination. In addition to the cave (temple) the site also includes an Anahita canal, open fire temple, rock fire, fire altar, fire temple, Anahita temple, tomb, cave, tunnel, simiting place, juicer, and is encircled by a fence (Nhili, 2022).

Fig. 3: Entrance of Charsteen cave (4 pillars).

5 NEEDS ASSESSMENT AND PROBLEM DEFINITION

Prior to intervention, a full site assessment was conducted at Charsteen (Charsteen) Cave, and it revealed several challenges related to function, environment, and safety that impacted the site. One key issue was poor condition of pedestrian walkways and handrails which were broken or did not meet compliance requirements. Lighting within the cave was limited and improperly positioned, as shown in Figure 4. Drainage systems failed to address water stagnation which led to rapid erosion of the cave's surface.

Furthermore, there was no control over stormwater run-off, no proper disposal of waste, and no formalized system to manage visitor traffic which posed threats to visitors and to the site's archaeological integrity.

Fig. 4: Pre-existing situation. Unsafe stairs, no stairs, deteriorated handrails, and bins on the west side of the Charsteen Cave.

The assessment found significant quantities of dense vegetative growth throughout circulation paths and on the outside of the cave, as shown in Figure 5. Using characteristics of leaves; growth patterns; and local environmental factors, the primary climbing and groundcover species was identified as Hedera helix (English ivy). While Hedera helix provided positive effects such as improved erosion resistance and microclimate stabilization, it also created negative impacts by obscuring the cave's entrance, signage, and interpretive features thereby limiting visibility and way-finding. This information directly influenced the need to provide for specific clearing and controlled vegetation management efforts and not total removal.

Fig. 5: Hedera helix (English ivy) covers symbolic representation of water, earth, air and fire, and the exterior surfaces of the Charsteen Cave.

6 DESIGN PHILOSOPHY AND MINIMAL INTERVENTION APPROACH

The overall design strategy for the rehabilitation of Charsteen Cave was based on a “minimalist” design philosophy that protected the cave's sacred/cultural/environmental aspects as much as possible. Three main principles were used in developing the architectural decisions of this project: a conservation-first approach to preserve the integrity of all archaeologically-sensitive layers and the spiritual essence of the cave; an environmentally sensitive approach to ensure that the site would be compatible with its natural surroundings; and reversible design elements to allow for the possibility of future modifications or removals without permanently damaging the heritage of the site. Additionally, the design solution incorporated the use of local/natural materials throughout to maintain the site's historic ambiance and create a seamless visual experience. In lieu of introducing new architecture into the cave system, the rehabilitation focused on improving existing circulation paths, consolidating unstable surface areas, and incorporating subtle safety features. This design strategy provided for both enhanced visitor access and safety while maintaining the cave's original authenticity and sanctity.

ISBN 978-3-9504945-5-6

7 MASTER PLAN REDESIGN

The redesign of the Master Plan was designed to improve circulation, increase the level of safety, protect the Heritage, and ensure that the new infrastructure integrates with the existing infrastructure while maintaining a “minimal impact” philosophy. The redesign of circulation has been addressed by creating stabilized stone walkways, standardized limestone steps, connecting the limestone steps with steel stairs and timber cladding of the existing iron paths to stabilize the rock. Amenities to support the visitors have also been improved, including the inclusion of rest points, an open stage for cultural activities, timber kiosks, seating areas and signs providing interpretation in Kurdish, Arabic and English. Infrastructure components (water supply networks, water recycling systems, sewage pipes, electric wires and lighting) are located away from sensitive archaeological zones as shown in Figure 6. In addition, the deteriorated existing structures have been repurposed via adaptive reuse as maintenance facilities, visitor resting areas and interpretive nodes to extend the useful life of the site. Rehabilitation of the environment has been accomplished through the controlled management of vegetation, the planting of trees, irrigation networks and relocating waterfalls to reduce their impact on the archaeological zones. Overall, the redesign of the master plan has effectively integrated improvements to accessibility, enhancements to the visitor experience and improvements to the existing infrastructure while preserving the site's Heritage, environmental integrity and cultural values.

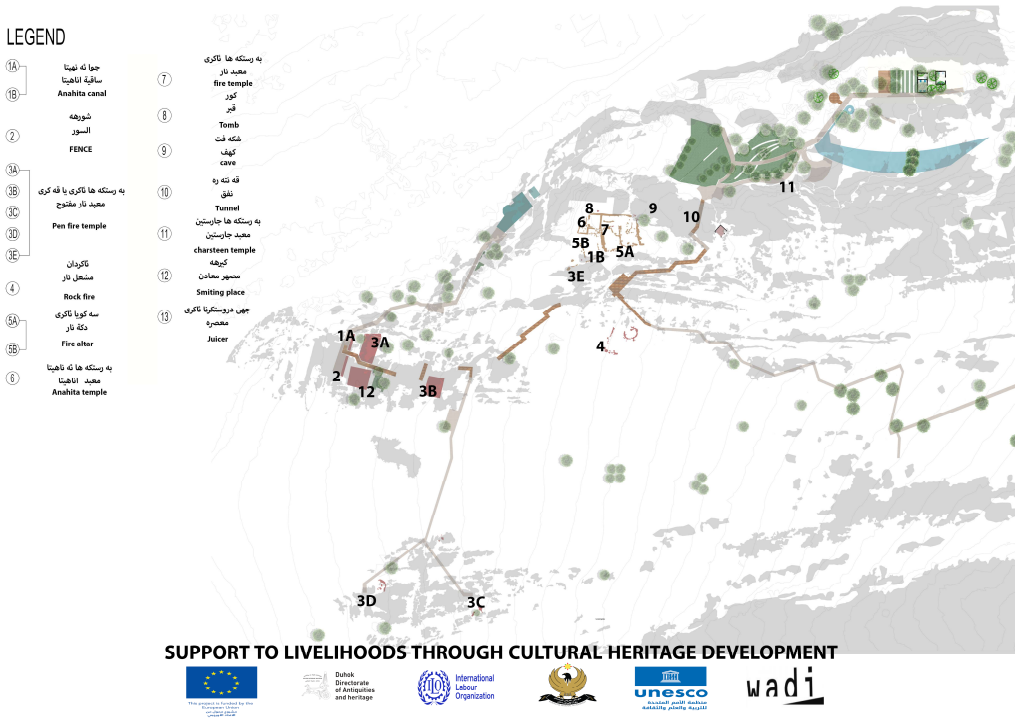

Fig. 6: The designed master plan.

8 IMPLEMENTATION AND CONSTRUCTION PROCESS

The implementation process for the construction of Charsteen Cave involved a series of planned and carefully controlled phases. The phases began with selective demolition and removal of unsafe or deteriorated infrastructure at Charsteen Cave; this was followed by the installation of natural stone staircases, timber-metal handrails, drainage channels and upgraded lighting systems. All the works were designed to provide enhanced accessibility and safety for visitors to the cave while providing the least possible disturbance to its heritage fabric.

The implementation was structured into six primary areas of work: Site Clearance Works; Pavement Works; Steel & Wood Works; Landscaping and Water Systems Works; Electrical and Lighting Installations Works.

Phase One of the project involved clearing the entire site of vegetation, removing grass, roots and all other forms of organic debris from the site, and safely disposing of all biological waste that had been removed from the site. The existing lighting system was carefully disassembled and then stored under close supervision. All deteriorated asphalt, concrete pavement, timber stairs, stone tile finish and parts of the reception building including floor tiles, cladding, ceiling tiles, windows, doors, electrical fittings and air

conditioning units were demolished and removed from the site. Associated services including entrance blocks, toilet facilities and pipe systems, and redundant seating, stairs and handrails were removed to ensure compliance with both heritage protection and safety standards.

The pavement and tiling works were coordinated closely with the Duhok Directorate of Antiquities. A detailed review of the Bills of Quantities (BoQs) against site conditions was undertaken to resolve technical issues and to modify designs where necessary, as can be seen in Figure 7. The excavation, sub-structure construction and installation of durable, safe, and compatible to the heritage fabric pavement systems were completed to provide improved access for visitors to the cave, while preserving the visual and cultural integrity of the cave.

Fig. 7: Stone stairs. The before and after intervention.

Steel works involved the design, manufacture and construction of handrail components, staircase and floor structural framing, benches, waste recycling containers, shade structures, stainless steel safety chain systems and signage systems (Fig. 8), that were constructed in compliance with regulatory requirements regarding both functional performance and safety, while visually being non-obtrusive. The wood works provided functionality and compatibility by installing stair treads, flooring, roofing and gabion-timber elements treated to ensure longevity under various environmental conditions and maintaining their natural appearance.

Fig. 8: Tunnel. The before and after intervention (iron and timber).

Coordinating landscaping, irrigation, and water systems was completed with the help of the Duhok Directorate of Water Resources and the Duhok Directorate of Antiquities. The revised drawings and trenching plans were developed to include galvanized storage tanks, booster pumps and polyethylene piping for drip irrigation for pipeline systems. Planting trees contributed to landscape stabilization, improved microclimate conditions and long term site sustainability, as shown in Figure 9.

The electrical and lighting works were performed together with both Duhok Directorate of Electricity and Duhok Directorate of Antiquities. The Electrical BOQ was reviewed and site visits conducted for optimal routing of trenches and cable path. Where required, design changes were made; all new installations were completed as part of a low-impact, heritage-sensitive approach to enhance both safety, visibility and the overall visitor experience.

Fig. 9: waterfall, ground cover, and shrubs 6. The before and after intervention.

9 INFRASTRUCTURE UPGRADING

Infrastructure improvements for this project included careful planning to protect sensitive areas by creating a new water supply system, sewage, water recycling, and electrical systems. Local and small-scale trenching with materials that are suitable and compatible with the environment/heritage area was done to minimize environmental and heritage impacts, increase durability and enhance visitor comfort and site resilience (Syriacpress, 2025). Materials such as plumbing fixtures, electrical components and construction materials were brought up to the top of the mountain, and a pump booster was utilized in order to cast concrete to build the water tank, as shown in Figure 10.

Fig. 10: Transporting materials and fittings and casting concrete for the water tank using a crane and a pump poster.

10 ADAPTIVE REUSE STRATEGY

The adaptive reuse strategy is about the rehabilitation or repurposing of previously used structures for new uses, with the goal of conserving structural elements while protecting historic architectural characteristics and extending the useful life of the location (Albrifkany et al, 2021). The rehabilitated areas at Charsteen Cave now house rest points for visitors, storage for tools, maintenance facilities, and educational stations. The overall purpose of the project was to have a reduced ecological footprint while increasing usability of the site. This involved creating both covered and uncovered rest places, as shown in Figure 11, as well as an open-platform stage for cultural events utilizing a stone masonry seating platform, timber kiosks and rest areas adjacent to the tunnel, and a complete water distribution system that would provide irrigation to all landscaping elements (shrubs, grasses, etc.). Restrooms are located in the reception area and in proximity to the open-stage. The irregularly shaped natural rock stepways were replaced by a series of regular local limestone stairways and two sets of steel stairways were installed to allow visitors to transition between the archaeological stairway and the limestone stairway. Minimal amounts of steel were utilized in order to minimize intervention to the site and protect it. Several pathways were created utilizing iron and clad with wood to protect the rocky surfaces.

Fig. 11: Creating covered rest places which situates on the west side of the cave (Before and After interventation).

A water collection tank was developed to allow recycled water to be used from artificial waterfalls that had been relocated approximately 100-200 meters away from the cave to further minimize the effects of this aspect of the project, as shown in Figure 12. Ground cover, shrubs, and trees were planted as part of the landscaping aspects of the project. Signs in three languages (Kurdish, Arabic, and English) were also designed and installed as part of the project. All water, sewage, and electric systems were carefully routed away from archaeological areas with approval from Duhok DoAH Supervisors, and documentation was maintained to assist with future maintenance needs. Overall, the adaptive reuse projects at Charsteen Cave have extended the functional life span of the site while preserving its environmental and heritage attributes.

Fig. 12: artificial waterfalls that had been relocated approximately 100-200 meters away from the cave to further minimize the effects of this aspect on the entran cave's surfaces (Before and After interventation).

11 CAPACITY BUILDING AND WORKFORCE INCLUSION

The Charsteen Cave project focused on developing the capacity of and promoting inclusion for workers within the framework of UNESCO and ILO goals that combine heritage preservation with long-term sustainable livelihoods. The project provided training opportunities at all levels of society (community, technical/professional) as well as providing vulnerable populations (women, refugees/IDPs, and members of the host community) direct training through labor-intensive heritage preservation construction/masonry/carpentry/safety and maintenance of infrastructure and environmental practices. At a professional level, the project staff/engineers received specialized training from the EU-MADAD, UNESCO, ICOMOS and ILO that included cultural resource management, conservation techniques, monitoring, site maintenance/tourism planning and additional technical training on the application of B.R.C. Gabion Systems for structural and landscape stabilization of sites. Evaluation and Impact Analysis

The data in the impact evaluation tables confirms that Charsteen Cave has achieved tangible advances in terms of: accessibility; safety; and the preservation of its heritage values by using a low-impact, reversible approach to intervention. In addition to stabilizing key archaeological features at the cave, the project was able to improve environmental conditions in the surrounding area by installing erosion controls and implementing a sustainable irrigation system. Furthermore, the project used local and natural materials which provided an additional layer of compatibility with the heritage characteristics of the site. The project also provided significant social economic returns on investment, providing in excess of 1200 days of employment

opportunities for vulnerable groups; enhancing the technical capacity of local communities; and significantly improving the site's readiness for sustainable cultural tourism; as demonstrated by the information contained within Tables 1 and 2.

	Impact Area	Indicator/ Measure	Baseline	Target/ Goal	Post-Intervention	Measurement Method
1	Accessibility & Safety	Number of stabilized pathways	Informal, uneven paths, erosion, and slip hazards	Safe, continuous pathways	Stone pathways	Site survey, visual inspection
		Number of stairs repaired/constructed	Irregular, unsafe stone steps	Regularized stairs compatible with the heritage	New Limestone stairs constructed	Construction logs, photographs
		Lighting coverage	Limited/ non-functional lighting	Adequate low-impact lighting for safety	Energy-efficient lighting installed along main routes	Site inspection, visitor survey
2	Heritage Conservation	Archaeological structures stabilized	Deterioration and exposure to environmental risks	Stabilized structures with minimal intervention	Key archaeological elements have protected	Expert assessment, site documentation
		Minimal intervention compliance	Risk of intrusive repairs	Compliance with UNESCO / ICOMOS principles	Interventions reversible, non-invasive, and site-sensitive	Project design review
		Adaptive reuse success	Abandoned/ deteriorated structures	Functional reuse without loss of heritage value	Structures reused as rest points, stages, kiosks	Site inspection, photographic record
		Condition of heritage fabric	Weathering and structural decay	Improved structural and visual condition	Heritage fabric preserved and enhanced	Measurement Method

Table 1: Charsteen Cave: Impact Evaluation Table, Accessibility and Safety, and Heritage Conservation.

	Impact Area	Indicator/ Measure	Baseline	Target/ Goal	Post-Intervention	Measurement Method
1	Environmental Resilience	Vegetation coverage managed	Uncontrolled growth affecting structures	Controlled, protective vegetation cover	Vegetation managed and replanted strategically	Site survey, GIS mapping
		Irrigation/water systems functional	Inefficient or absent systems	Sustainable irrigation and water reuse	Irrigation and recycled water systems operational	Functional testing logs
		Erosion/soil stability	Soil erosion near paths and slopes	Reduced erosion and stabilized soil	Gabions, and landscaping reduced erosion	Field measurement, photo monitoring
		Sustainable material use	Use of incompatible or modern materials	Local, natural, sustainable materials	Limestone, timber used	Project materials report
2	Community & Economic Impact	Jobs created	Limited local employment	Inclusive job creation	1200 workdays (women, refugees, IDPs, locals)	HR/project records
		Workforce diversity	Low inclusion of vulnerable groups	Gender and diversity inclusive workforce	Inclusive workforce	Employment records
		Capacity building/training	Limited heritage-related skills	Strengthened technical and conservation skills	On-site and formal training completed	Training reports, attendance
		Community engagement	Limited community involvement	Active local participation	Community leaders and workers engaged	Meeting records, interviews
		Tourism readiness	Site not prepared for visitors	Improved visitor experience	Site ready for cultural and eco-tourism	Visitor surveys, tourism data

Table 2: Charsteen Cave: Impact Evaluation Table, Environmental Resilience, Community and Economic Impact.

The intervention was carried out in accordance with UNESCO and ICOMOS conservation principles, which emphasize minimal intervention, reversibility, respect for authenticity, and sensitivity to the environment. The project also adopted UNESCO's integrated approach to heritage conservation and sustainable development, which emphasizes community involvement in conservation and development work.

12 CONCLUSION

The rehabilitation of Charsteen Cave is a successful example of how to conduct an inclusive, sustainable, and sensitive approach to preserving heritage sites.By using minimum impact design, reusing structures already on-site, protecting the environment through good stewardship practices, and working with the local community, this project was able to preserve the cave's spiritual, cultural and historical importance by making it more accessible and safer for visitors, all without reducing the site's authenticity. This project also contributed to creating jobs and developing the capabilities of the local communities through the use of inclusive and skill based approaches, and produced environmentally friendly infrastructure projects consistent with international preservation standards. Overall, this project demonstrates that if heritage sites are carefully planned, and low-impact design strategies are implemented, the preservation of these sites can be achieved in conjunction with the support of social and economic development, especially in crisis affected areas.

1 ABSTRACT

As climate change intensifies, European cities must adapt to increasingly frequent and severe heatwaves. Urban heat is not only an environmental concern but a key challenge for spatial justice, public health, and long-term resilience. For sensible adaptation strategies, planners require spatially detailed and comparable information to understand where heat accumulates, where cooling potential exists, and how equitably these cool spaces are accessible to different population groups. Recent advances in Earth observation and the availability of the German Census data at a spatial gridding of 100-m offer opportunities to integrate high-resolution environmental and demographic data into planning processes in a way that is consistent across cities of very different sizes and spatial configurations.

This study presents a scalable framework that combines satellite-derived Land Surface Temperature (LST) with population data to analyse urban heat patterns and the accessibility of naturally cool areas (cold spots) across all cities in Bavaria, ranging from small historic towns and medium-sized regional centres to large urban municipalities. Multi-year Landsat composites are processed to the harmonised 100-m grid aligned with the national census grid, enabling consistent and methodologically comparable cross-city analyses. Local Getis–Ord Gi* statistics are used to identify spatial clusters of unusually warm and cool surfaces within each city, creating a coherent thermal surface vulnerability indicator which can be compared across different urban systems.

To contextualize the spatial distribution of cold spots, we link them to sociodemographic data from the census grid and to walking-time accessibility. For each city, we derive population-weighted indicators that quantify how well different social groups (such as elderly people, children, and immigrants) can reach cold spots. These indicators reveal how accessibility inequalities vary not only between socio-demographic groups but also between various city sizes. This allows us to identify where targeted planning interventions are needed.

By applying this workflow to the full set of Bavarian cities, the study offers a state-wide, high-resolution comparison of urban heat structures and socially differentiated access to cooling. The results demonstrate how remote sensing, geospatial analyses, and census microdata can strengthen evidence-based planning, support climate-resilient urban design, and contribute to more equitable access to cooling in cities of all sizes.

Keywords: walking accessibility, land surface temperature, climate change, cold spots, Bavaria

2 INTRODUCTION

Climate change represents one of the most pressing societal challenges of the 21st century and its impacts are becoming increasingly evident in urban areas (IPCC, 2022). According to the European State of the Climate Report of the Copernicus Climate Change Service, 2024 was the warmest year on record since the beginning of systematic meteorological observations and the year with the second highest number of heat-stress days in Europe (C3S, 2025).

Currently, approximately 56% of the world's population lives in urban areas (United Nations, 2018), where exposure to extreme weather events such as floods, storms, wildfires, and heatwaves is particularly high (C3S, 2025). Compared to rural regions, the high degree of soil sealing, dense built environments, and limited vegetation in cities significantly reduces the capacity to mitigate the impacts of such events (Stewart & Oke, 2012). Among these hazards, heatwaves affect urban populations more severely than those in surrounding rural areas, as cooling locations are often scarcer and less accessible (Lan, 2022).

Heat has been identified as the most significant and urgent climate-related risk to human health in Europe by the European Climate Risk Assessment of the European Environment Agency (EEA, 2024). A lack of centrally located, easily accessible cool places poses substantial challenges for everyday activities, particularly for vulnerable population groups such as older adults, people with disabilities, and families with young children. Increased thermal stress, adverse health outcomes, and rising heat-related mortality rates are among the major risks associated with increasing temperatures and extreme heat events in Europe (IPCC, 2023). Recent studies suggest that these trends will persist in the future (Taubenböck et al., 2024), with climate change progressing particularly rapidly in European cities (Friesen & Taubenböck, 2025). Projections indicate that under the SSP5-8.5 scenario, average temperatures in European cities could in avaerage increase by 4 °K by the end of the century.

A prerequisite for effective climate adaptation in cities is the availability of up-to-date, spatially detailed temperature data. Satellite observations offer considerable advantages in this regard due to their regular temporal coverage and their retrospective availability dating back to the late 1970s. A widely used indicator for identifying thermally warm and cool urban areas is Land Surface Temperature (LST). LST derived from satellite data allows surface temperatures to be captured at spatial resolutions of up to 30 meters across the entire Earth's surface. It provides valuable insights into where cities tend to heat up most intensely during summer – and, crucially, where comparatively cool areas persist.

Land Surface Temperature (LST) is one of the currently 55 Essential Climate Variables (ECVs) defined by the Global Climate Observing System (GCOS). It describes the thermal radiation emitted by the Earth's surface and constitutes a key indicator for identifying thermal hot and cold spots across both sealed (impervious) and natural surfaces (GCOS, 2025). It is important to note, that LST captures radiative emissions; i.e. it does not capture the near-surface factors that contribute to the heat that is actually experienced by people such as air temperature, humidity, radiation or wind (Oke et al., 2017). However, it has been shown that correlations exist and that under the conditions that one is aware of what LST data shows and what not, it is valuable as a proxy with consistent and area-wide data (e.g. Leichtle et al., 2022). LST is widely applied in studies of the hydrological cycle (Wang, 2009), drought assessment (Karnieli, 2010), and even research on vector-borne diseases (Anyamba, 2014), but it is particularly relevant for analyzing heat-induced stress on urban populations (Malakar et al., 2018; Massaro et al., 2023).

LST can be measured either by in situ meteorological stations, which allow for detailed temporal analyses at fixed locations, or by satellite-based remote sensing. Due to their global coverage, regular revisit times, and high spatial resolution, satellites are the primary data source for LST measurements at regional (Friesen, Leichtle & Taubenböck, 2025) to global scales (Good et al., 2022; Massaro et al., 2023). Using thermal infrared (TIR) sensors, satellite-derived LST captures spatial patterns of urban surface heat and cooling phenomena (Bechtel et al., 2019) and is frequently employed in the literature to characterize the Surface Urban Heat Island (SUHI) effect (e.g., Choi et al., 2012; Isufi et al., 2021; Lemus-Cánovas et al., 2020; Xue et al., 2022).

In recent years, an increasing number of studies have focused on LST cold spots, which represent the thermal counterpart to SUHI hot spots. These areas play a crucial role in enhancing urban climate resilience and supporting climate adaptation strategies due to their cooling effects (Mavrakou et al., 2018; Xue et al., 2022; Choi et al., 2012). Although definitions of cold spots vary across studies, they are consistently characterized by lower surface temperatures relative to their surroundings. Cold spots in cities are most commonly associated with green spaces and water bodies, as well as with areas of low imperviousness, low building density, and good ventilation conditions (Bechtel et al., 2019; Xue et al., 2022; Weng, 2009).

Against this background, this study investigates LST cold spots in Bavarian cities as critical yet underexplored elements of surface urban heat adaptation. While previous research on Bavaria has primarily focused on identifying thermal hot spots and the Surface Urban Heat Island effect (e.g. Heldens et al., 2013;

Leichtle et al., 2023; Friesen, Leichtle & Taubenböck, 2025), comparatively little attention has been paid to the spatial distribution, accessibility, and social context of urban cooling areas. By integrating satellite-derived LST with high-resolution socio-demographic data and pedestrian network information (Weigand et al., 2023; Droin et al., 2024), this study aims to assess not only where LST cold spots are located, but also who can access them. Focusing on all 317 municipalities classified as cities in Bavaria, the central research question is: Which socio-geographical patterns can be identified in the spatial distribution and pedestrian accessibility of land surface temperature cold spots across Bavarian cities? In doing so, the study contributes to a more socially informed understanding of urban cooling potential.

3 CONCEPTUAL FRAMEWORK

This study follows a conceptual framework that links the urban surface thermal environment with pedestrian accessibility and socio-demographic characteristics.

Land surface temperature (LST) patterns within cities give rise to spatially distinct cold spots, which represent areas of comparatively lower surface temperatures and potential cooling benefits. However, the contribution of these cold spots to surface urban heat adaptation depends not only on their presence but also on their spatial distribution and accessibility by foot, i.e. by spatial proximity.

At the same time, socio-demographic characteristics influence heat exposure and vulnerability, shaping who benefits from available cooling opportunities. By jointly considering LST cold spots, pedestrian accessibility, and socio-demographic patterns across Bavarian cities, the framework enables an assessment of spatial inequalities in access to urban cooling and their implications for climate adaptation.

4 STUDY AREA & DATA

This study covers the entire federal state of Bavaria (Germany) and includes all 317 municipalities that are classified as cities according to the official census definition (Fig. 1, left). The spatial extent of each city is defined by its administrative municipal boundary, which serves as the analytical frame for all subsequent processing steps. By considering the complete set of census-defined cities rather than a limited number of case studies, the analysis enables a systematic and comparable assessment of thermal patterns and accessibility conditions across a wide range of urban contexts, including small, medium-sized, and large cities.

To support intra-urban analyses and ensure consistency with population data, each city is represented using a regular grid with a spatial gridding of 100 m × 100 m, clipped to the corresponding administrative boundary. This resolution was chosen to match the spatial structure of the available census grid (Destatis, 2024). All thermal, spatial-statistical, and accessibility indicators are derived and evaluated at this grid-cell level, allowing population-weighted aggregation and cross-city comparisons.

Land Surface Temperature (LST) was derived from Landsat 8 and Landsat 9 thermal infrared observations and processed as a spatially continuous raster dataset covering the entirety of Bavaria at 30 m spatial resolution. Only scenes with a nominal cloud cover below 50% were included in the analysis. Due to frequent cloud contamination over large parts of the study area, shorter time periods were insufficient to obtain robust spatial coverage of all cities. For this reason, the temporal extent of the dataset was expanded to a four-year period from 1 November 2020 to 31 October 2024. This ensures adequate data availability across all municipalities and avoids short-term anomalies by focusing on a long-term trend.

For all eligible scenes within the study period, LST values were aggregated on a per-pixel basis to compute a multi-year temporal mean at 30 m spatial resolution. This aggregation captures long-term average thermal conditions and highlights spatially persistent temperature patterns at the land surface. The temporal mean LST, expressed in degree Celsius, was selected as a robust indicator of urban surface thermal characteristics, as maximum LST values showed strong heterogeneity within cities due to differing acquisition dates of individual satellite scenes. Using the mean reduces artificial temperature discontinuities caused by short-term meteorological variability while preserving meaningful spatial contrasts between warmer and cooler urban areas. The resulting raster thus provides a harmonized representation of urban surface temperatures suitable for comparative analysis across cities.

5 METHODS

5.1 Grid-based aggregation and identification of thermal hot and cold spots

To enable city-scale and intra-urban analyses, the 30 m land surface temperature (LST) raster was spatially aggregated to the 100 m analysis grid defined for each city (Fig. 2, upper row). Zonal statistics were computed by intersecting the LST raster with the grid-cell polygons and calculating the mean LST value per cell. The resulting grid-based LST values were stored as attributes of the city-specific analysis grids.

Based on the aggregated grid-level LST values, spatial clustering of relatively high and low surface temperatures within each city was assessed using the local Getis–Ord Gi* statistic. This local indicator of spatial association identifies areas where grid cells with similar surface temperature values cluster more strongly than would be expected under spatial randomness. The analysis was conducted separately for each city to account for differences in urban extent, morphology, and thermal variability.

Spatial relationships between grid cells were modeled using a Queen contiguity spatial weights matrix, in which neighboring cells share either an edge or a corner. Only grid cells with valid LST values were included in the analysis.

Rather than applying fixed significance thresholds, a relative, quantile-based classification was used to define thermal hot and cold spots. Grid cells with Gi* z-scores in the lowest 20% of the city-specific distribution were classified as cold spots, while those in the highest 20% were classified as hot spots. This approach facilitates comparison across cities with differing sample sizes and thermal contrasts and ensures a consistent identification of relative thermal surface extremes within each urban system. The resulting binary cold-spot classification forms the primary input for the subsequent pedestrian accessibility analysis.

5.2 Pedestrian accessibility to cold spots

Pedestrian accessibility to thermal cold spots was assessed using a network-based routing approach grounded in OpenStreetMap (OSM) data (Fig. 2, lower row). For each city, a walkable street and path network was extracted using OSMnx. The network was projected to a metric coordinate system, and each edge was assigned a travel time based on its geometric length and an assumed constant walking speed of 4.5 km/h.

Cold spots were represented by the centroids of all grid cells classified as cold spots, which were spatially matched to the nearest nodes in the OSM network. Similarly, centroids of all census grid cells were mapped to their nearest network nodes. To efficiently compute walking times from all populated locations to the nearest cold spot, a multi-source Dijkstra algorithm was applied, treating all cold-spot nodes as simultaneous

sources. This yields the minimum travel time along the pedestrian network from each network node to the closest cold spot.

For each census grid cell, the travel time associated with its nearest network node was extracted and stored in both seconds and minutes. This procedure results in a spatially explicit representation of pedestrian access to cool locations across the entire urban fabric of each city.

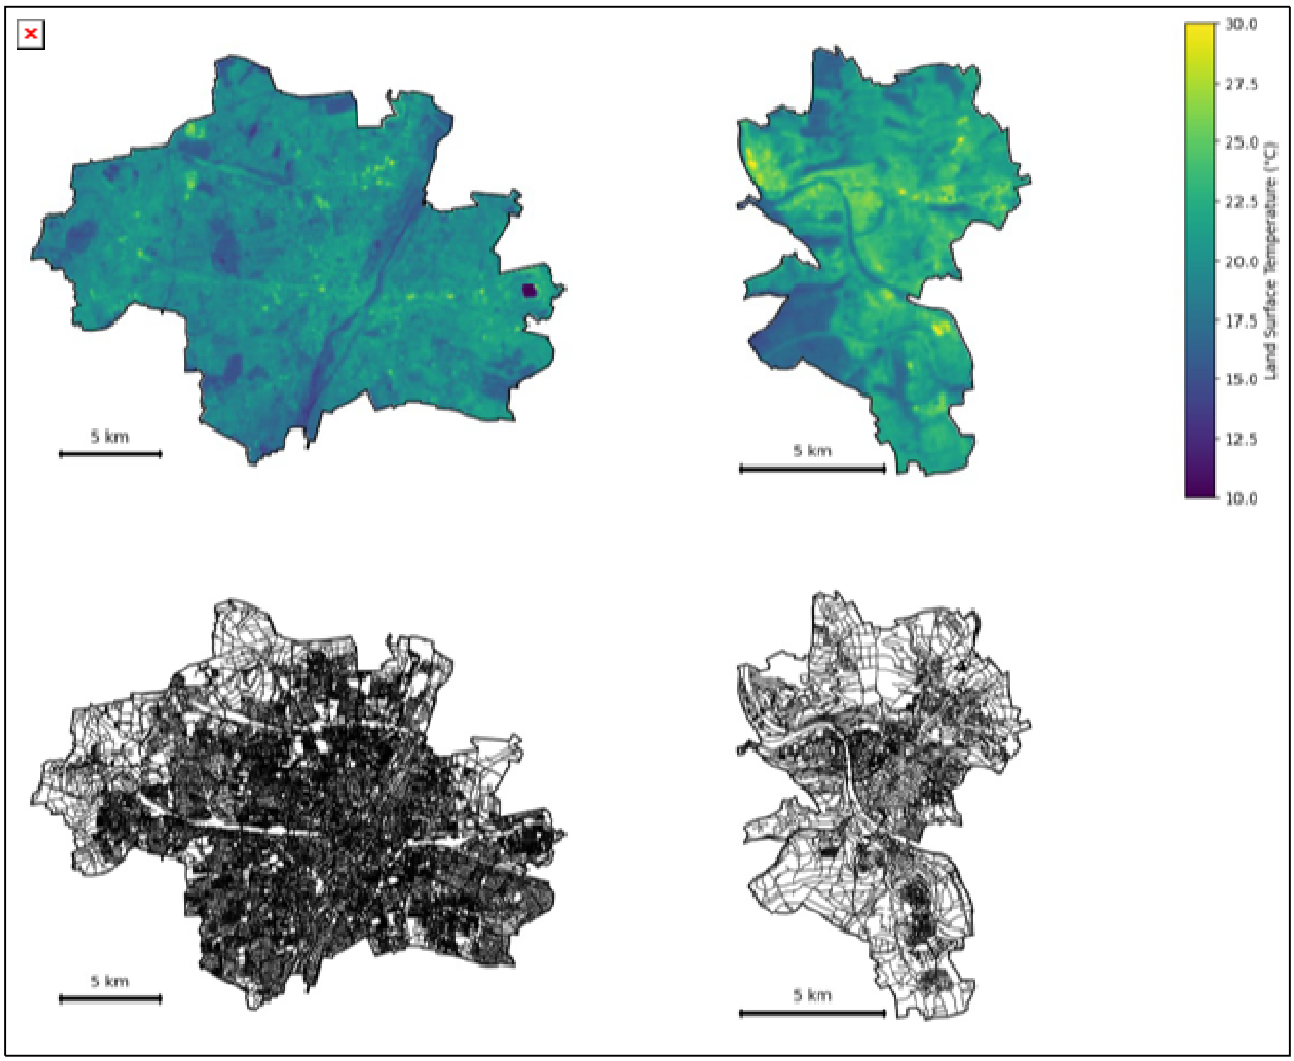

Fig. 2: Upper row: Land surface Temperature for the cities of Munich (left) and Würzburg (right). Lower row: Pedestrian network for the cities of Munich (left) and Würzburg (right)

5.3 Population-weighted exposure and relative risk analysis

Population exposure to limited cold-spot accessibility was evaluated using the 100 m census grid. For each cell, total population counts as well as subgroup attributes (population under 18 years, population aged 65 years and older, and the share of foreign residents) were considered. These groups are considered to suffer most during extreme heat events (Depietri et al., 2013).

Accessibility outcomes were summarized at the city level by calculating the population-weighted share of residents whose walking time to the nearest cold spot exceeds 10, 20, and 30 minutes. These thresholds were selected to reflect increasingly constrained pedestrian access in a particular urban context.

To assess social disparities in access to cooling opportunities, a relative risk (RR) metric was computed for a long-walking-time condition defined as more than 20 minutes to the nearest cold spot. For each population group g, relative risk was calculated as $RR_g = P(t>20|g) / P(t>20|all)$ where $P(t>20|g)$ denotes the proportion of group g living in census cells with walking times exceeding 20 minutes, and $P(t>20|all)$ represents the corresponding proportion for the total population (Friesen, Georganos and Haas, 2025). Values $RR_g > 1$ indicate that a group is disproportionately affected by limited pedestrian access to thermal cold spots compared to the city population as a whole.

6 RESULTS

6.1 Intra-urban thermal structure: hotspots and coldspots

Across the 317 cities included in the analysis, mean land surface temperatures (LST) show relatively limited variation, with a median of 18.9 °C (Inter quantile range IQR: 18.1–19.9 °C). In contrast, substantial differences emerge when comparing thermally extreme surface areas within cities. Hotspots exhibit a median LST of 21.7 °C (IQR: 21.1–22.6 °C), while coldspots are markedly cooler, with a median of 15.7 °C (IQR: 14.9–16.5 °C).

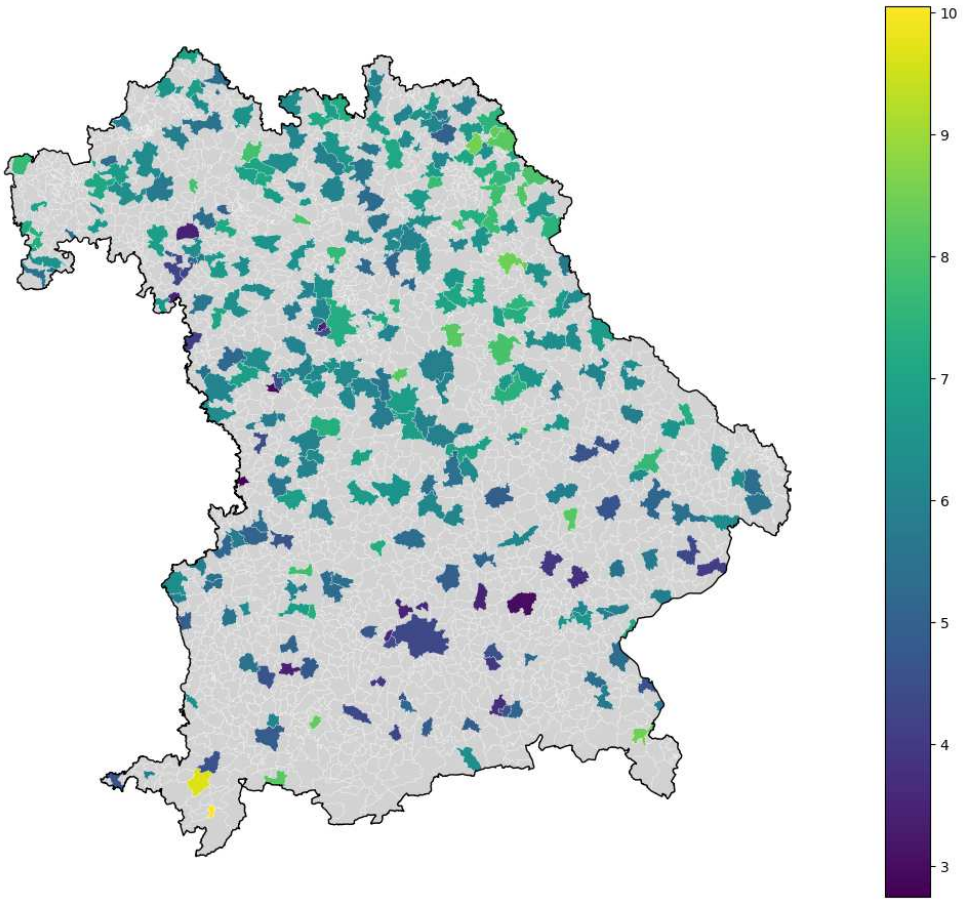

Fig. 3: Temperature differences in °K between hot- and coldspots in Bavarian cities.

The resulting hotspot–coldspot temperature contrast varies considerably across cities and across the state. Cities in the notheastern part show higher temperature differences than cities in the south and west. The median difference amounts to 6.1 °K, with an interquartile range from 5.4 °C to 6.8 °K. At the lower end, some cities show contrasts below 3 °K, indicating relatively homogeneous thermal conditions, whereas others exceed 10 °K, reflecting pronounced thermal segregation.

6.2 Accessibility of cooling areas

Accessibility to coldspots differs strongly both within and across cities. The median walking time to the nearest coldspot is 14.6 minutes (IQR: 11.7–18.9 minutes). It can therefore be stated that at the aggregated city level in Bavaria, the planning idea of the 15-minute city (Allam et al., 2022), i.e. being able to reach central functions for everyday needs on foot in less than 15 minutes, is just about fulfilled for cold spots. But of course there are many places at the intra-urban level that have much better or worse accessibility.

A median of 79.0 % of residents live more than 10 minutes away from the nearest coldspot. For stricter thresholds, the median share of the population living more than 20 minutes away is 32.8 %, while 2.2 % live more than 30 minutes away. However, the upper quartiles reveal much higher exposure levels: in 25 % of cities, more than 55.7 % of the population is located beyond the 20-minute threshold, and in some cities the entire population exceeds this distance.

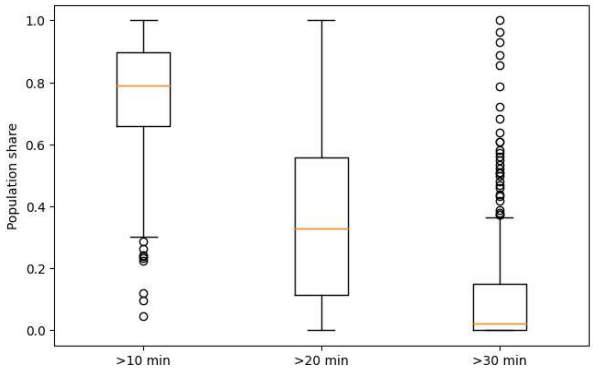

Fig. 4: Boxplots representing the accessibility to coldspots above 10, 20 and 30 minutes for Bavarian cities.

Large cities such as Augsburg illustrate the upper end of this distribution, with 84 % of the population with more than 20 minutes walking time to the next coldspot, whereas more compact cities like Abenberg or Altdorf show substantially shorter travel times for most residents. Nevertheless, similarly high accessibility deficits are also observed in smaller cities with dispersed settlement patterns.

6.3 Coupling of thermal contrast and cooling accessibility

Cities with stronger intra-urban thermal contrasts (Fig. 3) tend to exhibit poorer access to cooling areas. Fig. 5,a highlights, that the hotspot–coldspot LST difference correlates moderately with the share of the population living more than 20 minutes from a coldspot ($\rho = 0.51$).

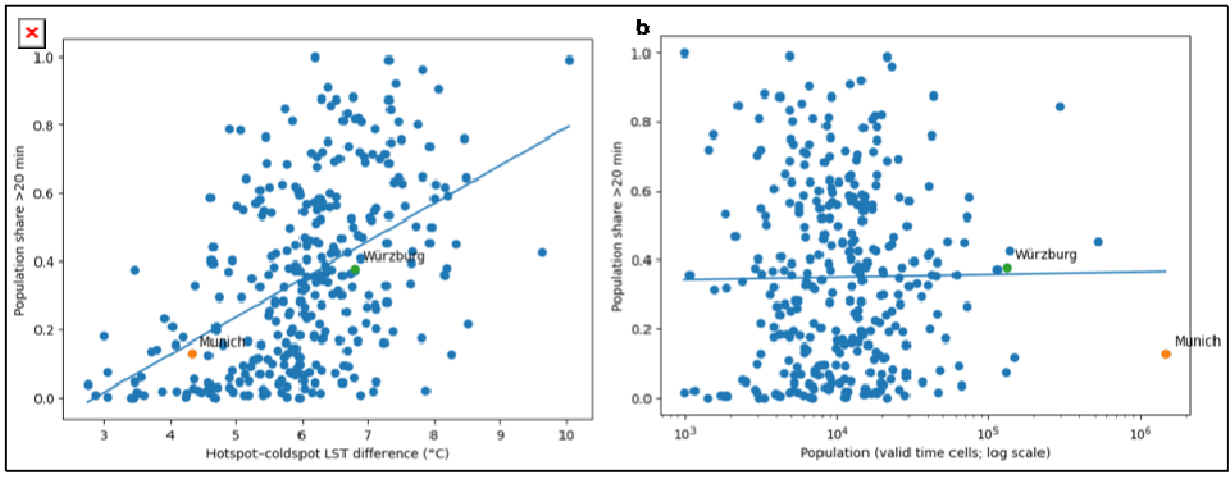

Fig. 5: a: Relationship between population share with more than 20 minutes walking time to cold spots for the analyzed cities. b: Relationship between population share with more than 20 minutes and population within the analyzed city.

While these relationships are intuitively plausible, their consistency across more than 300 cities suggests that they reflect structural characteristics of urban form and land-use configuration rather than isolated local conditions.

In contrast, total city population shows no meaningful correlation (Fig. 5, b) with either thermal contrast or accessibility indicators ($|\rho| < 0.1$). This finding indicates that cooling accessibility challenges are not primarily driven by city size but occur across the full urban hierarchy, from small towns to large regional centers.

6.4 City-level exemples: Munich and Würzburg

The detailed maps of Munich and Würzburg (Fig. 2 and Fig. 6) show how the aggregated patterns illustrated above occur on a city-wide scale. In both cities, coldspots are spatially coherent and closely linked to vegetated areas or bodies of water, while hotspots correspond to densely built-up zones. However, their accessibility patterns differ.

Munich, with moderate hotspot–coldspot thermal contrasts (see Fig. 5, left), exhibits relatively moderate median walking times to coldspots, with a more dispersed pattern of cold and hotspots.

By contrast, Würzburg exhibits a more compact spatial structure, with hotspots in the highly dense structures of the old town and the surrounding highly dense block developments and coldspots on the periphery, near local forests. This, in combination with a less dense network for walking due to topography, leads to localised accessibility deficits. It is important to mention, that some of the city's local parks (e.g. Ringpark in the center of Würzburg) that are supposed to be cold spots do due to our data and threshold approach not appear as cold spots.

6.5 Distributional impacts and relative risks

Relative risk (RR) analysis reveals systematic disparities in cooling accessibility across population groups (Fig. 7) and thus spatial inequality.

For residents with a foreign nationality background, the median RR is 1.07 (IQR: 0.80–1.26). In 59.3 % of cities, RR values exceed 1, indicating that this group is more likely than the general population to live more than 20 minutes from the nearest coldspot. In 25.2 % of cities, RR exceeds 1.25, and in 10.1 % it exceeds 1.5, pointing to substantial overrepresentation in a non-negligible subset of cities. In extreme cases, RR values approach 8, reflecting highly uneven spatial distributions.

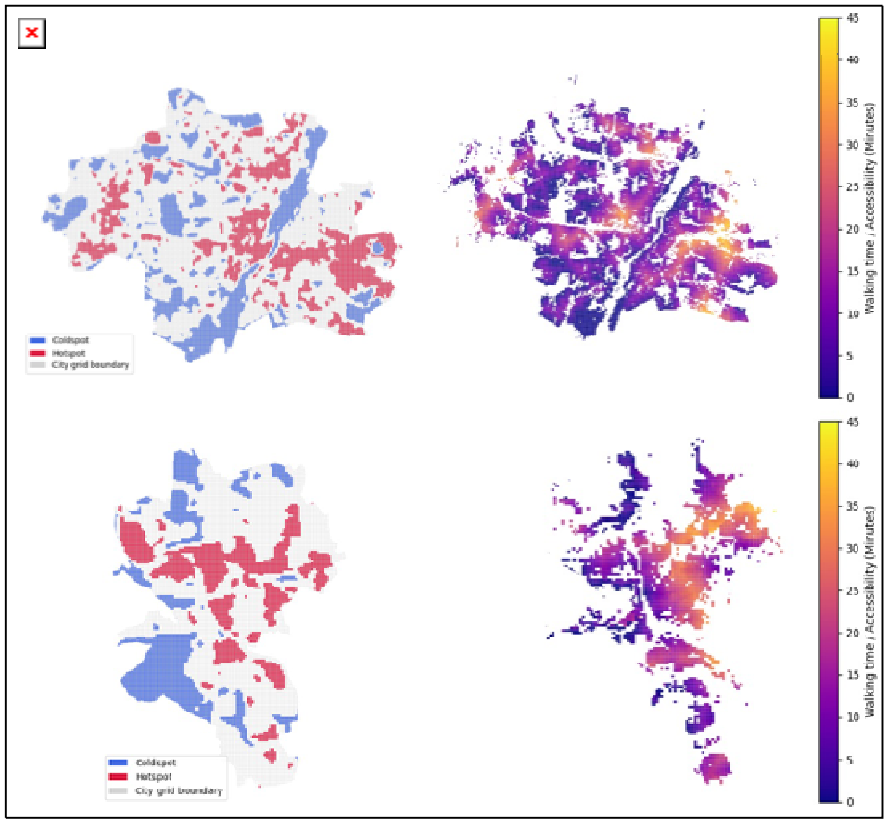

Fig. 6: Spatial distribution of cold- and hotspots (left column) and accessibility (right column) for Munich (upper row) and Würzburg (lower row).

For children and adolescents under 18 years, the median RR is close to parity (1.00, IQR: 0.95–1.06). Although RR values exceed 1 in 52.1 % of cities, stronger disadvantages are uncommon: only 5.7 % of cities exceed an RR of 1.25, and 1.6 % exceed 1.5.

A similar pattern is observed for residents aged 65 years and older. The median RR is 1.00 (IQR: 0.92–1.06), with RR > 1 in 50.2 % of cities. However, elevated values above 1.25 occur in fewer than 5 % of cases, and values above 1.5 are rare.

Comparing across groups, residents with a foreign nationality background consistently exhibit both the highest frequency and the highest magnitude of disadvantage. While slight deviations from parity are common across all groups, pronounced inequities are largely concentrated in this population group.

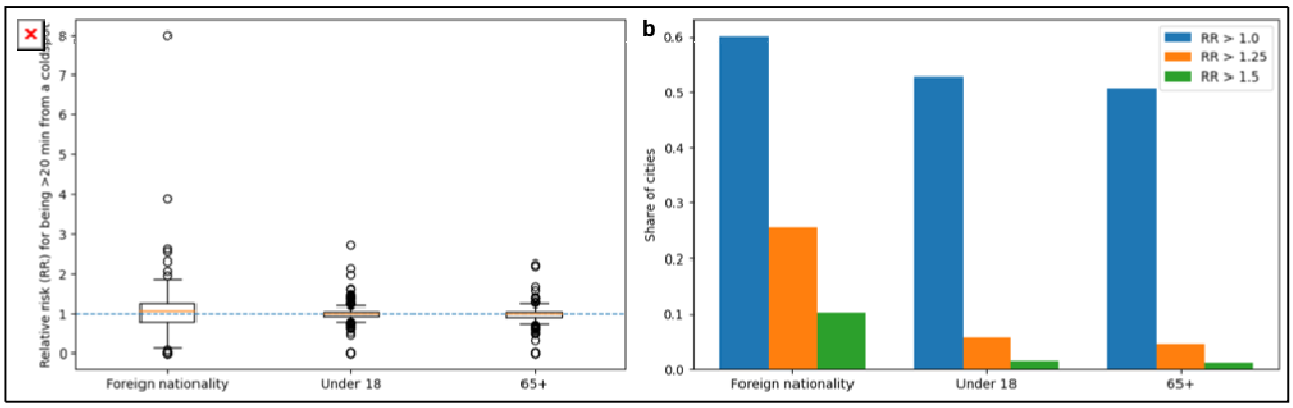

Fig. 7: (a) Relative risk (RR) for different social groups to have worse access to cooling space than the rest of the population and (b) share of cities exceeding a specific threshold of RR. The time threshold used for this analysis is 20 minutes.

7 DISCUSSION

This study demonstrates that pronounced thermal surface heterogeneity is a common feature of cities across Bavaria, extending well beyond large metropolitan areas. Across municipalities, the median difference in land surface temperature (LST) between hotspots and coldspots clusters around approximately 6 °K, with interquartile ranges between roughly 5.4 and 6.8 °K. These magnitudes confirm that even small and medium-sized cities exhibit strongly differentiated internal thermal surface structures rather than spatially uniform surface heat exposure.

The observed intra-urban contrasts are consistent with previous urban heat island research highlighting the role of land cover, vegetation, and impervious surfaces in shaping local thermal environments. Importantly, the lack of association between hotspot–coldspot contrast and total population size suggests that thermal differentiation is driven more by urban form and land-use configuration than by city size per se.

The Bavaria-wide comparison reveals that high thermal surface contrasts are not restricted to large urban centers. Several small and medium-sized municipalities exhibit hotspot–coldspot surface differences comparable to, or even exceeding, those of larger cities. This finding underscores that challenges related to urban surface heat exposure and cooling provision are regionally pervasive and should not be framed solely as metropolitan issues. From a planning perspective, it reinforces the need to consider heat adaptation and cooling infrastructure across the full spectrum of city sizes.

While thermal surface contrasts provide insight into the existence and intensity of coldspots, accessibility metrics reveal how unevenly these cooling resources are distributed relative to residential urban populations. Across cities, a substantial share of residents – around one third at the median – lives more than 20 minutes walking distance from the nearest coldspot, with upper quartiles exceeding 50%. At a more conservative 30-minute threshold, accessibility is given in most cities, indicating that coldspots are generally present but often spatially distant from everyday residential environments.

Another finding of this study is the positive association between hotspot–coldspot thermal surface contrast and poor cooling accessibility. Cities with larger thermal surface differences tend to have a higher proportion of residents living far from coldspots. While this relationship is moderate and not deterministic, it suggests that strong thermal surface heterogeneity may coincide with spatial concentration of cooling resources rather than their integration into the urban fabric. In other words, cities may exhibit substantial cooling potential without providing widespread, walkable access to it.

City-specific patterns illustrate how analytical choices and urban morphology jointly shape these outcomes. In cities such as Augsburg and Würzburg, large forested areas located within administrative boundaries dominate the coldspot classification due to the high temperature differences between the urban forests and the urban fabric. These specifics by the adminsitrative units influence the coldspot classification. For Würzburg this leads to comparatively low accessibility for large parts of the population in our analysis (Fig. 6). These cases highlight that coldspots are not purely physical entities but analytically defined spatial units whose extent and location influence observed accessibility patterns.

Importantly, not all cities with large thermal contrasts exhibit poor accessibility. This variation indicates that urban layout, connectivity, and the spatial distribution of green infrastructure mediate the relationship

between thermal patterns and effective cooling access. Walking networks, permeability (c.f. r.g. Droin et al., 2024), and the placement of small-scale green spaces appear to play a critical role in translating cooling potential into practical heat mitigation benefits.

Beyond average accessibility, the relative risk (RR) analysis reveals systematic but heterogeneous inequities in access to cooling. In approximately 60% of cities, residents with foreign nationality are overrepresented among populations living more than 20 minutes from a coldspot. For children and older adults, the proportion of cities with RR values greater than 1 is slightly above 50%, indicating weaker but still widespread inequities. While median RR values across cities remain close to 1 for all groups, the distribution for residents with foreign nationality shows a pronounced upper tail, with RR values exceeding 1.25 and, in some cases, substantially higher.

These patterns suggest that cooling accessibility inequities are highly context-dependent and shaped by local residential segregation and urban structure. The relative measures (relative risk) mentioned in the study are robust measures for capturing inequality in access to cold spots, as are the absolute values, since, as already indicated above, these are sensitive to the definition of cold spots. As a result, while absolute accessibility measures reflect conditional exposure patterns influenced by analytical choices, the observed relative inequities point to more robust social gradients in access to cooling resources.

Taken together, the findings suggest that surface urban heat adaptation strategies should not focus solely on increasing the total amount of green space or cooling capacity. Cities characterized by large, spatially concentrated coldspots but poor accessibility may benefit more from distributed, small-scale interventions (such as street trees, pocket parks, and shaded pedestrian corridors) than from further expansion of already extensive green areas. Integrating accessibility considerations into urban climate adaptation planning is therefore critical for translating cooling potential into thermal relief.

The observed equity patterns further highlight the importance of evaluating cooling interventions not only in terms of average benefits but also in terms of who gains access. Place-specific diagnostics that combine thermal (surface) patterns, accessibility, and socio-demographic characteristics can help ensure that cooling infrastructure contributes to reducing, rather than reinforcing, existing social inequalities.

Overall, this study should be interpreted as identifying indicative patterns of relative thermal surface exposure and cooling accessibility rather than providing precise estimates of individual-level heat risk. The sensitivity of results to coldspot definitions and boundary choices highlights the need for future work to systematically test the robustness of accessibility and equity patterns across alternative conceptualizations of urban cooling, including absolute temperature thresholds, usability-based criteria, and alternative delineations of urban areas such as functional urban areas. Despite these challenges, the consistent spatial and social patterns observed across cities demonstrate the value of the proposed approach as a comparative framework for understanding how thermal environments, accessibility, and equity intersect in urban heat adaptation.

7.1 Limitations

The following limitations should be considered when interpreting the results of this study, particularly with respect to data sources and modeling assumptions.

First, land surface temperature (LST) estimates were derived from multi-scene Landsat composites using median values. While this approach increases robustness against cloud contamination and scene-specific artifacts, it may underestimate thermal extremes that are most relevant for acute heat-related health impacts. Peak temperatures during extreme heat events are likely higher than the reported values, and their spatial patterns may differ. Although this limitation affects absolute temperature levels, it is less likely to substantially alter relative hotspot–coldspot contrasts within cities, which form the basis of the comparative analysis. It has also to be taken into account, that LST is just a proxy for thermal comfort and further studies on ambient air temperature, humidity radiation or wind (Oke et al., 2027) are needed to better understand to what extent the findings of this study relate to heat stress.

Second, pedestrian accessibility was modeled using OpenStreetMap (OSM) street networks. Despite generally high coverage in urban areas, OSM data quality varies with respect to pedestrian connectivity, access restrictions, and the representation of informal or recently developed pathways. Such inconsistencies may introduce spatial biases in estimated walking times, particularly in areas with complex access

conditions. However, as accessibility calculations were performed consistently across cities, these uncertainties primarily affect absolute values rather than relative comparisons between population groups within the same city.

Third, accessibility modeling assumed a uniform walking speed across all population groups and spatial contexts. This simplification does not account for differences related to age, health status, terrain, or environmental conditions, which may disproportionately affect vulnerable populations such as older adults or individuals with mobility impairments. Consequently, estimated walking times should be interpreted as generalized indicators of spatial proximity rather than precise measures of experienced accessibility.

Fourth, the analysis focused on spatial proximity to coldspots without explicitly accounting for their functional characteristics or usability. Coldspots differ substantially in size, public accessibility, amenities, and their capacity to provide effective thermal relief (e.g., tree canopy density, shaded seating, or water features). The presence of a coldspot within walking distance therefore does not guarantee that it functions as an accessible or effective cooling resource for all residents.

Finally, population characteristics were analyzed at the 100 m grid-cell level using aggregated census attributes. This spatial aggregation may mask intra-cell heterogeneity and does not capture temporal dynamics such as daily mobility, diurnal population shifts, or differences between daytime and nighttime exposure. As a result, the analysis reflects residential accessibility patterns rather than dynamic individual exposure.

Taken together, these limitations suggest that the results should be interpreted as indicative patterns of relative thermal exposure and cooling accessibility rather than precise estimates of individual-level heat risk. Nevertheless, the consistent application of methods across cities and the robustness of relative risk patterns support the validity of the comparative insights and provide a foundation for future studies using more detailed, temporally resolved, or context-specific data.

8 CONCLUSION

This study shows that strong intra-urban thermal surface heterogeneity is a widespread feature of cities across Bavaria, extending well beyond large metropolitan areas. Substantial hotspot–coldspot contrasts are common even in small and medium-sized municipalities. In many cities, a significant share of the population lives at considerable walking distances from coldspots, and stronger thermal contrasts tend to coincide with poorer accessibility. These patterns indicate that urban surface heat risk is shaped not only by the intensity of heating but also by how cooling opportunities are distributed within the urban fabric.

The analysis further reveals context-dependent but systematic social inequities in cooling accessibility, particularly affecting residents with foreign nationality. While absolute accessibility measures are sensitive to analytical choices and urban morphology, relative risk patterns are more robust, highlighting persistent social gradients in who benefits from urban cooling. Together, these findings underscore that effective urban surface heat adaptation requires attention to spatial distribution and walkable access, not only the amount of green space availability. The proposed framework demonstrates the value of integrating thermal data, accessibility analysis, and equity metrics to support more targeted and socially just climate adaptation planning, while also providing a basis for future robustness and sensitivity analyses.

1 ABSTRACT

Africa's rapidly expanding peri-urban zones have become critical sites of urban transformation, yet dominant narratives continue to frame these spaces through poverty-centred understandings of informality. This paper challenges these framings by systematically examining the emerging role of the African Middle class in driving self-help housing developments on customary land. It draws on a systematic literature review of 32 peer reviewed studies published between 1994 and 2025, and interrogates the intersection of middle-class investment practices, neo-customary land tenure, hybrid governance arrangements, and the implications of these dynamics for urban resilience. The review reveals four core patterns reshaping the African periphery: the commercialisation and reconfiguration of traditional authority; the emergence of institutional multiplicity and fragmented planning legitimacy; the strategic but spatially fragmented logic of middle-class self-help; and the production of ecological and infrastrucutural vulnerabilities that undermine collective urban resilience. The paper argues for a reconceptualisation of informality that recognizes class-mediated urbanisation as a structurally significant mode of African city-making. It concludes by proposing a resilience-oriented planning paradigm grounded in engaged tenure pluralism, metagovernance, ecological protection and differentiated housing policy responses.

Keywords: Peri-urbanisation, Middle-class self-help housing, hybrid governance, neo-customary land tenure, urban resilience

2 INTRODUCTION

The 21st century is projected to be the African century of urban transformation (UNECA, 2024). Yet, the patterns and processes of this urbanisation defy conventional models, unfolding not just within city cores but explosively across their peripheries. These peri-urban zones, the contested interfaces between the urban and the rural, have become the primary theatres for Africa's urban future, characterised by dynamic complexity, institutional hybridity, and profound socio-ecological change (Sihlongonyane & Sithagu, 2025; El Kahlaoui, 2024). Prevailing policy and research paradigms, often inherited from the Global North, have historically framed urban expansion through a lens of dichotomies: formal versus informal, legal versus illegal, planned versus unplanned. Within this framework, informality is frequently conflated with poverty, marginality, and a state of exception to be remedied through formalisation (De Soto, 2000).However, a significant and growing body of scholarship on African cities reveals a far more nuanced reality. A pivotal and under-acknowledged driver of this peripheral urbanisation is the formally employed, asset-accumulating middle class (Andreasen & Agergaard, 2022; Mercer, 2024). Faced with prohibitively expensive formal housing markets and inadequate state-provided housing schemes, these households are increasingly bypassing traditional governmental and market structures. Instead, they are engaging in self-help housing on customary land, leveraging their economic capital to secure plots and incrementally build homes in peri-urban areas (Ubink & Quan, 2008; Abdulai, 2024). This phenomenon represents a critical intersection of class, tenure, and urbanisation that fundamentally challenges existing narratives.This paper seeks to synthesise and analyse the emerging evidence on this phenomenon. It poses the following central question: How is the growth of middle-class self-help housing on customary land tenure systems reconfiguring governance, spatial forms, and socio-ecological resilience in Africa's peri-urban peripheries?

3 LITERATURE REVIEW

This review synthesises existing scholarship across three intertwined domains: the definition and role of the African middle class, the complexity of the peri-urban condition, and the evolving nature of customary land tenure and informality.

3.1 The African Middle Class: Beyond Income, Towards Asset-Building and Spatial Practice

Lentz (2015) argues that the African middle class is not a monolithic entity, but a social category defined by its "struggle for belonging" and distinction, often achieved through consumption patterns, educational attainment, and investment in housing and property. For these groups, formal employment, often in the public sector or services, provides a degree of economic security, which is then channelled into asset accumulation, primarily through real estate, as a strategy to mitigate pervasive economic precarity (Andreasen & Agergaard, 2022).This asset-building imperative is a key driver of spatial practice. It transcends mere shelter; it is an entrepreneurial act of investment and a claim to social status and urban citizenship. As Mercer (2024) illustrates in Dar es Salaam, the suburban frontier is being constructed by a middle class for whom self-built housing represents a primary strategy for securing economic futures. Their practices represent a form of "upwardly mobile informality" or "informalised modernity," where formal economic resources are deployed within informal institutional and spatial frameworks to achieve security and upward mobility, a phenomenon that reflects the "anxious, insecure and ambiguous" nature of this social stratum that Melber (2016) describes.

3.2 The Peri-Urban as a Zone of Institutional and Ecological Complexity

The peri-urban interface is a dynamic, multi-faceted space characterised by intense social, economic, and environmental interactions. Academically, it is understood as a zone of "fragmented governance" (Sihlongonyane & Sithagu, 2025), "ecological risk" (Mwonzora & Hamunakwadi, 2025), and "institutional multiplicity" (Nchanji & Bellwood-Howard, 2018). Ecologically, peri-urban zones are critical yet vulnerable. They often contain essential ecosystems like wetlands, watersheds, and green corridors that provide vital services for the entire urban region. However, they are also the prime target for urban expansion. The work of Mwonzora and Hamunakwadi (2025) in Harare illustrates the tragic trade-off between "securing a roof" and "securing ecosystems," as middle-class housing encroaches on wetlands, increasing flood vulnerability. Wijesinghe and Thorn (2021) further highlight the governance challenges in managing urban green infrastructure within informal settlements of Windhoek, underscoring the disconnect between ecological value and urban land pressure.

3.3 Customary Land Tenure and the Re-invention of Informality

Customary land tenure, once considered a rural and anachronistic system, has become central to peri-urban transformation. It is not a static relic but a highly adaptive and commoditised system. Due to rising land prices, traditional leaders have been allocating land more in a market-driven manner, creating what scholars refer to as "neo-customary" land tenure (Ubink & Quan, 2008; Abdulai, 2024).This neo-customary system is characterised by the commercialisation of land transactions, often to the detriment of the original communal principles. Sumbo (2022) provides an analysis of this shift in peri-urban Kumasi, showing how the transformation of usufruct rights into marketable commodities leads to the exclusion of indigenous community members. This process creates new social hierarchies and tensions within peri-urban communities. This commodification directly challenges simplistic formal/informal dichotomies. The housing that emerges on this land is "informal" from the perspective of the state (lacking planning permission, title deeds, and compliance with building codes) but is often developed with significant formal economic capital. It represents a "formal-informal hybrid" were salaried incomes fund incremental construction on extra-legal tenure. This is evident in the work of Andreasen and Agergaard (2022), who frame urban property explicitly as a form of security for Africa's growing middle classes, a safe haven for capital investment.

3.4 Synthesising the gaps

While many studies analyse customary tenure, middle-class housing, governance, and environmental risk separately, few systematically integrate all four to investigate their interconnection and cumulative impact on urban resilience.This paper seeks to fill this gap. It argues that understanding the resilience of African cities requires a holistic analysis of how class-driven investment, mediated through hybrid tenure and governance

systems, produces specific spatial forms that either enhance or undermine the capacity of urban peripheries to adapt to social, economic, and environmental shocks. The following sections will undertake this synthesis through a systematic analysis of the literature.

4 METHODOLOGY

This paper employs a systematic literature review methodology to synthesize existing scholarly knowledge on the intersection of customary land tenure, middle-class self-help housing, and urban resilience in Africa's peri-urban contexts. A systematic approach was selected to minimize bias, enhance reproducibility, and provide a comprehensive audit trail of the literature identification and selection process. Search strings combined keywords and synonyms using Boolean operators (AND/OR) within TITLE-ABS-KEY and were restricted to literature focusing on Africa and Sub-Saharan Africa. A full list of search strings and thematic focus areas is provided in Table 1 below.

Theme	Search String (Scopus Advanced Search)	Focus/Rationale
1. Self-help housing and middle class	TITLE-ABS-KEY(("self-help housing" OR "self built housing" OR "self-building" OR "informal housing" OR "incremental housing") AND ("middle class" OR "emerging middle class" OR "formally employed households" OR "asset accumulating households") AND (Africa OR "Sub-Saharan Africa"))	Captures literature on self-help/self-built housing practices by middle-class groups in African contexts.
2. Customary land tenure and housing	TITLE-ABS-KEY(("customary land tenure" OR "traditional authority" OR "communal land" OR "land access" OR "land rights" OR "tenure pluralism") AND ("self-help housing" OR "informal housing" OR "self-built housing") AND (Africa OR "Sub-Saharan Africa"))	Focuses on the role of customary land systems and traditional authorities in enabling or shaping self-help housing.
3. Governance and peri-urban development	TITLE-ABS-KEY(("hybrid governance" OR "customary governance" OR "traditional authority" OR "municipal governance") AND (peri-urban OR "urban periphery" OR "urban fringe" OR "city edge" OR "urban expansion") AND (Africa OR "Sub-Saharan Africa"))	Targets literature on governance arrangements (customary vs. municipal) in peri-urban African contexts.
4. Resilience and peri-urban housing	TITLE-ABS-KEY(("urban resilience" OR "climate resilience" OR "ecological risk" OR "urban sustainability") AND ("self-help housing" OR "informal housing" OR "self-built housing") AND (peri-urban OR "urban periphery" OR "urban fringe") AND (Africa OR "Sub-Saharan Africa"))	Identifies studies linking housing practices in peri-urban areas with urban/climate resilience and ecological risks.
5. Informal urbanism and class dynamics	TITLE-ABS-KEY(("informal urbanism" OR "informal settlement" OR "incremental urbanism") AND ("middle class" OR "emerging middle class") AND (Africa OR "Sub-Saharan Africa"))	Highlights the intersection of class dynamics (middle class) with informal urbanism in African peripheries.

Table 1: Search strings and thematic focus areas (Source: Author's construction, 2025).

4.1 Screening process and PRISMA protocol

The review applied carefully defined inclusion and exclusion criteria to ensure the relevance and quality of the selected studies. Articles were considered eligible if they focused on self-help, informal, or incremental housing within African peri-urban contexts and engaged substantively with issues of customary land tenure, governance, resilience, or middle-class dynamics. Only peer-reviewed journal articles, books and book chapters published between 1994 and 2025 and written in English were included, reflecting both the contemporary relevance of the topic and the need for quality assurance in the sources consulted. Although the date range was set to capture a broad period, the searches ultimately produced articles concentrated within the past two decades, highlighting the relatively recent emergence and growing scholarly attention to middle-class self-help housing on customary land in Africa. Studies were excluded if they were duplicate records, if they fell outside the geographic focus on Africa and Sub-Saharan Africa, or if they did not explicitly engage with housing and land dynamics relevant to the study.

The identification and selection of studies followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, which emphasize transparency, reproducibility, and rigor in review methodologies (Page et al., 2021). A total of 92 records were initially retrieved from Scopus across the five thematic search strings. After merging the CSV files and removing duplicates based on titles, DOIs,

and author details, the dataset was reduced to 67 unique records.Ultimately, 32 studies were included in the final review and synthesis. The flow of records through each stage of the process follows an adaptation of the PRISMA 2020 flow diagram template for systematic reviews (Page et al., 2021), which provides a transparent account of how the initial dataset was refined to the final body of literature analysed.

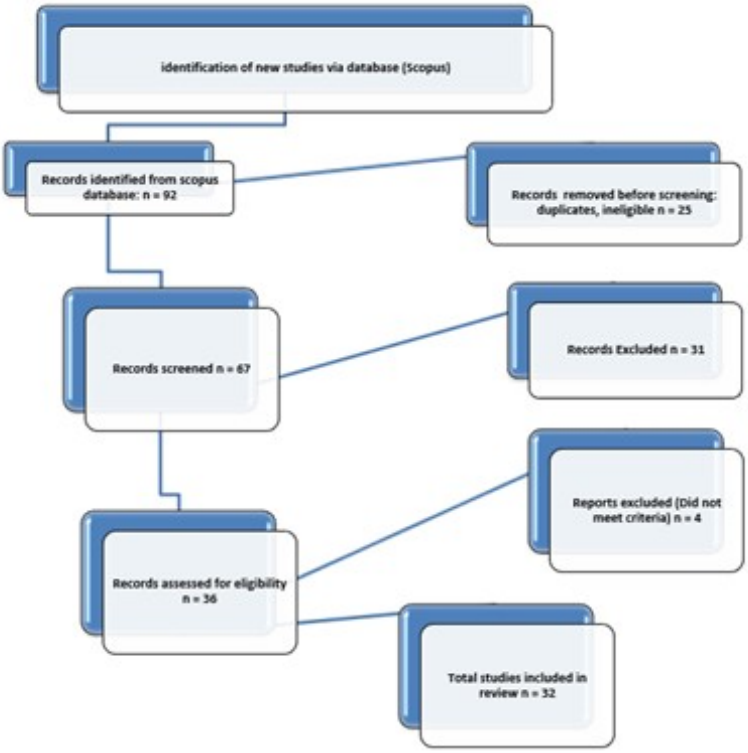

Fig 1: PRISMA Workflow diagram Source; Authors, 2025

5 THEMATIC ANALYSIS

The systematic review of the literature reveals four interconnected thematic domains through which the phenomenon of middle-class self-help housing on customary land unfolds. These themes illustrate the complex reconfiguration of authority, the emergence of hybrid systems, the distinct logics of spatial production, and the consequential challenges to urban resilience.

5.1 The Reconfiguration of Traditional Authority: From Custodians to Land Entrepreneurs

A paramount finding across the literature is the profound transformation of traditional authority structures under the pressures of peri-urbanisation. Customary leaders, once regarded as custodians of communal land heritage, are increasingly functioning as de facto planning authorities and entrepreneurial actors within urban land markets (Ubink & Quan, 2008; Simelane & Sihlongonyane, 2021). This shift is not a simple erosion of tradition but a strategic adaptation, resulting in what scholars' term "neo-customary" land tenure, a system where the outward forms of custom are maintained while the underlying practices become intensely commercialised (Abdulai, 2024; Sumbo, 2022).

In Senegal, Pinard (2021) analyses the contentious consolidation of 'traditional villages' in Pikine, where chiefly legitimacy is constantly negotiated through the control of and access to peri-urban land. Similarly, Sihlongonyane and Sithagu (2025) detail the powerful influence of traditional authorities over territorial governance in Thembisile Hani Municipality, where their role in land allocation creates a parallel planning system with significant spatial implications. This reconfiguration positions traditional leaders not as relics of the past, but as central, albeit contested, figures in the urban development process.

5.2 Hybrid Governance: Institutional Multiplicity and Contested Legitimacy

The collision of traditional land administration with the purported authority of municipal governments generates a state of institutional multiplicity and fragmented sovereignty. This results in hybrid governance arrangements characterised by competing claims to legitimacy, unclear jurisdictional boundaries, and

ultimately, a planning vacuum that is filled by incremental and often contradictory practices (Nchanji & Bellwood-Howard, 2018; Sihlongonyane & Sithagu, 2025). Residents become adept at navigating this complex institutional landscape. Chitengi (2020) examines a potential cooperative model, arguing for partnerships between Lusaka's city council and customary leaders to improve land allocation governance for low-income groups. However, the more common reality is one of strategic negotiation rather than formal integration, as individuals and communities' manoeuvre between systems to secure their claims, as evidenced in the daily practices of land access in peri-urban Ghana and Senegal (Ubink & Quan, 2008; Pinard, 2021).

5.3 The Logic of Middle-Class Self-Help Housing: Security, Investment, and the Production of Fragmented Space

The engagement of the middle class with self-help housing on customary land represents a calculated, albeit often contradictory, spatial strategy. It is a practice born not from a lack of alternatives but from a rational assessment of available pathways to secure a fundamental asset within an uncertain economic landscape. Andreasen and Agergaard (2022) aptly frame this as urban property acting as "security", a bulwark against economic precarity and a tangible store of intergenerational wealth. This logic transcends the mere acquisition of shelter; it is an entrepreneurial venture into real estate, where the house functions as both home and a primary investment portfolio, a finding corroborated by Mercer's (2024) work on the "suburban frontier" in Dar es Salaam, where middle-class construction is a deliberate project of place-making and asset accumulation.

The process is inherently incremental. Unlike state or large-scale private developments, construction occurs plot-by-plot, funded through a combination of savings, formal loans where accessible, and informal financing mechanisms. This incrementalism offers financial flexibility, allowing households to respond to economic fluctuations. However, it systematically prioritises the private dwelling unit over collective urban infrastructure. The result is a distinctly fragmented urban morphology. The city expands through the aggregation of individually rational investments that collectively lack coherence, leading to inefficient land use, a lack of public space, and a critical deficit in shared infrastructure networks for drainage, sanitation, and transportation (Muthama, 2025; Sihlongonyane & Sithagu, 2025). This creates a fundamental paradox: the very act of securing individual household futures through investment in property can actively undermine the collective urban condition, producing a landscape that is ill-equipped to function as a resilient, integrated city.

Furthermore, this process is deeply embedded in social differentiation. The ability to access and develop customary land is not uniform within the broad category of the "middle class." Abdulai (2024) provides a critical lens on this, examining how "emergent neo-customary land tenure" in peri-urban Ghana creates new barriers for non-indigene smallholders. This highlights how the commodification of customary land can reinforce or create new socio-spatial inequalities, privileging those with the right connections, capital, or ethnic belonging, thereby fracturing the notion of a homogeneous middle class and revealing the exclusionary mechanisms embedded within this form of urban expansion.

5.4 Implications for Urban Resilience: Manufactured Risk and the Systemic Adaptation Deficit

The spatial and institutional outcomes described above directly and severely compromise urban resilience, constituting an active process of risk manufacturing rather than a passive vulnerability. Resilience, here, refers to the capacity of urban systems to absorb, adapt, and transform in the face of socio-ecological stresses and shocks. The development patterns driven by middle-class self-help housing systematically degrade this capacity across multiple fronts.

Firstly, the location of these settlements actively manufactures ecological risk. The pursuit of affordable and accessible land directs development towards environmentally sensitive and hazardous zones that are typically avoided by formal, regulated development. Mwonzora and Hamunakwadi (2025) offer a devastating case study of this dynamic in Harare, where the imperative of "securing a roof" for the middle class leads directly to the settlement of vital wetland ecosystems. This not only destroys the ecological functions of these areas (water filtration, flood attenuation, biodiversity habitat) but also places residents in direct harm's way, significantly increasing their exposure to flooding. This is not an unfortunate coincidence

but a direct consequence of a land market and governance system that fails to value and protect ecological infrastructure.

Secondly, the incremental, uncoordinated nature of construction creates a profound infructural vulnerability. The absence of enforceable planning regulations and the plot-by-plot development model prevent the implementation of coordinated, city-scale infrastructure. The consequences are stark: inadequate drainage systems exacerbate flood risk; haphazard road networks impede emergency services; and the lack of formal waste management leads to pollution and public health hazards, as documented by Thakur and Nel (2022) in their study of South African townships. The household-level strategy of incremental upgrading cannot compensate for this initial, systemic deficit in public works. The resilience of a city is rooted in the robustness of its networked infrastructures, and these settlements are characterized by their absence or fragmentation.

Finally, the hybrid governance context creates a critical adaptation deficit. Climate adaptation and disaster risk reduction require coordinated, anticipatory action by a legitimate governing authority. The institutional multiplicity that defines peri-urban areas means there is no single entity with the clear mandate, capacity, or accountability to perform this role. Municipal authorities may disavow responsibility for "illegal" settlements on customary land, while traditional leaders lack the technical and financial capacity for large-scale resilience planning. Wijesinghe and Thorn (2021) explicitly grapple with this governance challenge in their analysis of green infrastructure in Windhoek's informal settlements. This governance void means that even when risks are identified, such as the clear danger of building on a floodplain, there is no effective mechanism to mitigate them, leaving communities dangerously exposed. The result is a systemic failure to adapt, locking these rapidly growing areas into pathways of escalating vulnerability to climate change and other urban stresses.

6 DISCUSSION: RECONCEPTUALISING INFORMALITY FOR RESILIENT FUTURES

The systematic review undertaken in this paper elucidates a profound and complex urban transformation unfolding across Africa’s peri-urban peripheries. The central paradox that emerges is that the very strategies employed by households to achieve economic security through self-built housing on customary land actively manufacture systemic risk and undermine the collective resilience of the urban regions they are joining. This discussion synthesises these findings to argue for a critical reconceptualization of urban informality and to propose a forward-looking framework for planning and policy.

This recency underscores two important points. First, it highlights the novelty of the research agenda, positioning middle-class self-help housing in Africa as an emerging field of inquiry that remains underexplored compared to more established studies on informal settlements and poverty-driven housing. Second, it points to the need for longitudinal and comparative research that can track the evolution of these dynamics over time, given that the bulk of the evidence currently available captures only the initial phases of the phenomenon. In addition to synthesizing current insights, the review highlights the importance of increasing scholarly and policy attention to the intersection of class, land tenure, and resilience in African peri-urban development by placing this paper within the framework of an expanding but still emerging body of literature.

The evidence consistently points to a core contradiction at the heart of middle-class peri-urbanisation. The practices of asset accumulation through self-help housing, while rational and often successful at the household level (Andreasen & Agergaard, 2022; Mercer, 2024), generate significant negative externalities at the city scale. The incremental, plot-based development model precludes integrated planning, leading to a fragmented urban fabric that is inherently inefficient and vulnerable (Muthama, 2025; Sihlongonyane & Sithagu, 2025). Consequently, the middle class, in its attempt to secure its own future, becomes an unwitting agent in the production of risk, ultimately jeopardising the very assets it seeks to build.The hybrid governance arrangements that characterise these zones, while offering flexible pathways to land access, represents thestates limited capacity to steer urban growth sustainably. The coexistence of traditional and municipal authorities often results in a regulatory vacuum where no single entity is accountable for ensuring safety, equity, or sustainability (Nchanji & Bellwood-Howard, 2018; Simelane & Sihlongonyane, 2021). This is not a "governance vacuum" but a governed space. However, it is governed by a logic of commodification and individual transaction (Ubink & Quan, 2008; Sumbo, 2022) rather than one of public welfare and collective resilience.

7 CONCLUSION: TOWARDS A RECONCEPTUALISED PLANNING PARADIGM

The analysis presented herein necessitates a fundamental reconceptualization of urban informality and planning in the African context, where a new, resilience-focused paradigm, one that recognises informality, particularly in its middle-class incarnation as a persistent, complex, and economically significant mode of urban production. This paradigm shift begins with the explicit acknowledgement and strategic engagement with tenure pluralism. The findings suggest a need for policymakers and planners to move beyond the binary of formal versus informal tenure and instead develop frameworks that recognise customary and neo-customary systems as enduring features of the urban landscape. The objective should not be to replace these systems but to regulate them, creating mechanisms for transparency and accountability within traditional land administration to protect against the exclusionary and predatory practices that often accompany commodification, while potentially fostering cooperative partnership models between municipal and traditional authorities.

Building on this foundation of engaged pluralism, the analysis suggests a shift in the role of the state from a direct provider of planning into a facilitator and coordinator of urban development, a role conceptualised as metagovernance. This entails municipal authorities actively engaging with and steering the actions of the diverse actors shaping the peri-urban frontier, including traditional leaders, private developers, community associations, and NGOs. The goal of such metagovernance is to align these often-disparate activities towards achieving common public goals, such as ensuring equitable service provision and, most critically, safeguarding ecological integrity. Indeed, ecological planning must be repositioned from a peripheral concern to the non-negotiable core of urban planning. This requires the assertive use of planning instruments to clearly demarcate and protect ecological no-go zones such as wetlands, steep slopes, and riparian corridors from any form of settlement, a vital step in preventing the manufactured vulnerabilities documented across the literature.

Ultimately, this reconceptualized approach demands a more nuanced and differentiated set of housing policies that respond to the varied drivers of informality. The state's role in relation to the middle class is not necessarily to provide its housing directly but to create an enabling environment that channels its considerable investment potential towards more sustainable and resilient outcomes. This can be achieved by developing and enforcing clear ecological zoning plans, proactively facilitating the provision of bulk infrastructure in developing areas to pre-empt fragmentation, and promoting alternative, affordable formal housing models that can compete with the economic and accessibility allure of customary land. Planning may start to harness the dynamism of middle-class urbanization while firmly minimizing its detrimental externalities by implementing this multidimensional strategy, which prioritizes the environment, embraces pluralism, practices metagovernance, and offers diverse pathways.

1 ABSTRACT

Across sub-Saharan Africa, the rapid expansion of urban frontiers has blurred the traditional boundaries between urban and rural spaces, resulting in complex peri-urban landscapes that necessitate new spatial planning approaches. In this evolving context, Eswatini's accelerating peri-urban transformation necessitates a spatially responsive re-evaluation of the planning, distribution, and governance of public amenities. The rapid expansion of settlement patterns beyond formal municipal jurisdictions, particularly within the Swazi Nation Land adjoining urban centers such as Manzini, Matsapha, and Mbabane, has generated new functional urban regions that challenge conventional planning regimes. These peri-urban zones have emerged as dynamic nodes of socio-economic activity and demographic growth, yet they remain marginal in the allocation of public infrastructure and social amenities. The persistent unevenness in spatial investment, particularly in youth-oriented facilities such as recreational spaces, libraries, sports fields, and community centers, highlights the structural limitations of a planning system that remains bounded by statutory municipal demarcations. This paper interrogates the spatial inequities and institutional fragmentation that have perpetuated the neglect of peri-urban territories within Eswatini's national development agenda. It contends that the inadequate provision of social infrastructure in these spaces exacerbates spatial injustice, reinforces socio-economic exclusion, and constrains pathways for youth empowerment. Anchored in a qualitative research design, the study synthesizes evidence from policy documents, academic discourse, and institutional reports to analyze prevailing trends, governance challenges, and service delivery deficits in the peri-urban planning landscape. The findings reveal that despite their demographic dynamism, peri-urban areas exhibit severe infrastructure backlogs, overcrowded social spaces, and limited public service accessibility. In response, the paper advances a Peri-Urban Youth Amenities Framework (PUYAF) that advocates for integrated spatial planning, redistributive resource allocation, and multi-level collaborative governance between municipalities, traditional authorities, and communities to promote spatial equity and enhance urban livability beyond municipal boundaries.

Keywords: peri-urban transformation, spatial justice, social infrastructure, youth development, Eswatini

2 INTRODUCTION

The development of peri-urban settlements has generated divergent perspectives within urban planning discourse. Turner (1977) frames these areas as adaptive housing solutions for low-income populations, while others portray them as urban dysfunctions, akin to blighted zones that threaten public health and safety (Amoako and Boamah, 2016). Such perceptions contribute to the marginalization of peri-urban communities, restricting their access to essential infrastructure and services despite rapid urbanization and technological advancement (Winayanti and Lang, 2004). Residents are frequently labeled as "unregulated occupants" and face tenure insecurity, including potential evictions or displacement due to policy changes. Consequently, these areas exemplify spatial inequities where economic and political priorities often overshadow the welfare, rights, and environmental sustainability of inhabitants. Peri-urban communities are commonly characterized by deficiencies in critical urban infrastructure, including potable water, sanitation, drainage systems, road networks, electricity, waste management, and public transport (Tutu and Stoler, 2016). Exclusion from municipal extension programs and urban service networks perpetuates socio-spatial marginalization. This deficit adversely affects residents' health, quality of life, and social well-being. Furthermore, peri-urban areas often lack emergency response services, educational facilities, and healthcare institutions, exacerbating vulnerability during crises such as floods or fires (Ansah and Chigbu, 2020). Housing and service provision in peri-urban areas frequently operate outside formal regulatory frameworks. As a result, activities such as water collection, electricity access, healthcare utilization, and informal commerce are often treated as unregulated. The provision of essential infrastructure is constrained by multiple dimensions, including legal, spatial, social, institutional, political, and economic barriers (Sinharoy

et al., 2019; Allen, 2010). Economic constraints, such as limited household income and insufficient municipal funding, inhibit infrastructure investment, while tenure insecurity undermines the establishment of sustainable service delivery mechanisms (Pierce, 2017).

Building on this argument, this research contends that Eswatini's municipal-centric spatial planning framework has inadequately accommodated the dynamics of peri-urban expansion, resulting in pronounced deficits in youth-oriented urban amenities, including public parks, libraries, sports facilities, and multi-purpose community centers. These infrastructural gaps exacerbate socio-spatial inequities, limiting opportunities for recreation, education, social interaction, and civic engagement among young residents. Through a critical examination of the spatial, institutional, and governance-related determinants of this under-provision, the study contributes to the discourse on inclusive urbanization, equitable infrastructure distribution, and the operationalization of the "right to the city" within peri-urban settings beyond formal municipal boundaries (Lefebvre, 1996; Harvey, 2008).

3 CONCEPTUAL AND THEORETICAL FRAMEWORK

Peri-urbanization is widely understood as a process through which rural land is incrementally absorbed into expanding urban systems, often without corresponding institutional integration (Shaw, van Vliet & Verburg, 2020). In African settings, this process is frequently shaped by customary land tenure, weak regulatory oversight, and fragmented governance structures. Scholars argue that peri-urban areas are not merely transitional spaces but enduring socio-spatial formations that require tailored planning responses (Gonçalves et al., 2017). Failure to recognize this reality results in uneven development outcomes, where residents experience urban densities without urban servicesa phenomenon increasingly described as "infrastructural exclusion". The concept of spatial justice provides a critical lens for understanding the uneven distribution of public amenities across space. Public infrastructure is not neutral; it reflects political priorities and institutional power relations (Solis-Navarrete & Bucio-Mendoza, 2025). In peri-urban Eswatini, youth experience compounded marginalization: spatially excluded from municipal service networks and socially excluded from development opportunities. Public amenities, parks, sports grounds, libraries, and community centers are widely recognized as foundational to social inclusion, crime prevention, and human development (UN-Habitat, 2012). Their absence limits young people's ability to build social capital, access knowledge, and participate meaningfully in community life.

3.1 Problem Statement

Despite the rapid growth and functional urbanization of peri-urban areas in Eswatini, these spaces remain excluded from systematic public amenity provision due to planning frameworks that are institutionally confined within municipal boundaries. This exclusion has resulted in persistent infrastructure backlogs and limited youth-oriented social amenities, reinforcing spatial injustice and socio-economic marginalization. The continued neglect of peri-urban territories raises critical questions about equity, governance, and the sustainability of Eswatini's urban transformation. This paper aims to examine the spatial and institutional factors underpinning the uneven provision of public amenities in Eswatini's peri-urban areas and to propose a framework for youth-centered, equitable service delivery beyond municipal boundaries.

The specific objectives are to:

(1) Examine peri-urban growth patterns and governance arrangements in Eswatini.

(2) Assess the implications of inadequate public amenities for youth development.

(3) Identify institutional and planning gaps contributing to service delivery deficits; and

(4) Propose a Peri-Urban Youth Amenities Framework (PUYAF) to guide inclusive planning and governance.

4 METHODOLOGY IMPERATIVES

The Kingdom of Eswatini has a current population of approximately 1,263,016 people. With a total land area of 17,200 km², the country has a population density of about 73 people per km² (or 189 people per square mile). Eswatini remains predominantly rural, with only 31.26% of the population, around 392,638 people, residing in urban areas, and a median age of 22.5 years (Worldometers, 2026). The median age in Eswatini indicates that the country has a predominantly youthful population, which has direct and significant

implications for this study. In the aspect of peri-urban transformation, this demographic profile means that young people constitute the largest and most affected user group of public amenities.

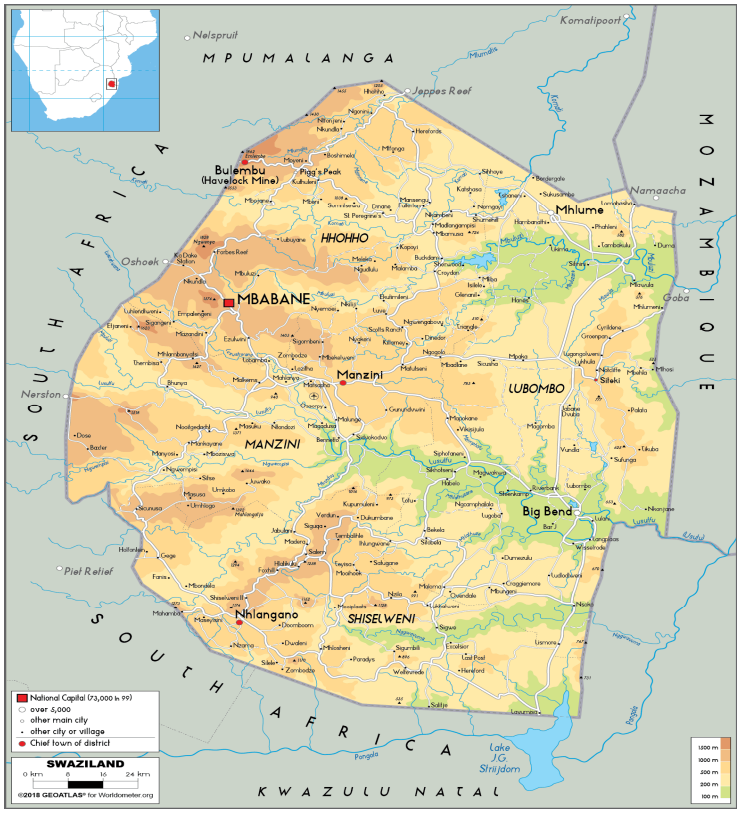

Figure 1: Study Area. Source: Worldometers (2026)

Figure 1 depicts where Eswatini is located. The study employs a qualitative research design grounded solely in secondary data analysis. The data corpus comprises national development strategies and statutory spatial planning frameworks; urban governance and youth-focused policy instruments; peer-reviewed scholarly literature addressing peri-urbanisation, spatial justice, and the provision of public amenities; as well as institutional reports produced by UN-Habitat and other regional development agencies. The use of secondary data analysis is particularly suited to interrogating structural planning constraints and policy discontinuities, especially in settings where primary data collection is limited by institutional barriers and resource constraints (Bowen, 2009). The collected materials were subjected to thematic analysis to distil recurring patterns and analytical themes, notably governance fragmentation, socio-spatial inequality, and the marginalisation of youth within planning and service delivery processes.

5 ANALYSIS AND DISCUSSIONS

A pronounced disparity persists between rural and urban areas in both the extent of infrastructure provision and the quality of infrastructural services available (Eswatini, 2025). The analysis confirms that peri-urban areas in Eswatini have transitioned into functional urban zones, hosting dense populations and diverse economic activities. However, planning instruments continue to conceptualize these spaces as rural, limiting state investment in social infrastructure (UN-Habitat, 2020). The findings indicate acute deficits in youth-focused amenities, such as recreational areas, sports facilities, libraries, and community halls. Where such facilities do exist, they are frequently inadequately maintained, overstretched, or located within school premises, thereby limiting broader public accessibility (Ngwenya, 2024). This lack of infrastructure limits opportunities for structured recreation, learning, and social interaction, increasing youth vulnerability to substance abuse and antisocial behavior (UNODC, 2018). Children born in Khoza, Logoba, Msunduza, Ticantfwini, Nkwalini, Mangwaneni, and surrounding areas have limited spaces to play. Providing public parks would create venues for families to gather, children to enjoy outdoor activities, and communities to come together in celebration (Ngwenya, 2024). However, there are positives concerning per-urban areas, as the Manzini Municipality extends an invitation to all regardless of communities not situated within the jurisdiction of the city (Municipal Council of Manzini, 2022). Fragmented governance among

municipalities, traditional authorities, and the central government is a significant contributor to neglect. The lack of coordinated planning mechanisms creates accountability gaps, leaving public amenities in peri-urban areas without clear institutional responsibility (Watson, 2009).

6 TOWARDS THE PERI-URBAN YOUTH AMENITIES FRAMEWORK (PUYAF)

In response to the findings of the study. The paper proposes the Peri-Urban Youth Amenities Framework (PUYAF), structured around four pillars as shown in Figure 2. The Peri-Urban Youth Amenities Framework (PUYAF) is primarily designed to address the socio-spatial and governance challenges of peri-urban communities in Eswatini, where rapid urban expansion, limited municipal services, and hybrid governance structures involving traditional authorities create pronounced deficits in youth-oriented public amenities. While contextually grounded in Eswatini, the framework's principles, integrated spatial planning, redistributive infrastructure investment, collaborative governance, and youth co-production, are transferable to other peri-urban regions in the Global South that face similar dynamics, such as parts of Malawi, Zambia, and Kenya, where hybrid governance, informal land tenure, and service inequities are prevalent. PUYAF differs from typical Global North frameworks, which generally assume formal municipal governance, established infrastructure networks, and stout service delivery, and often prioritize technological innovation and efficiency over equity and inclusion.

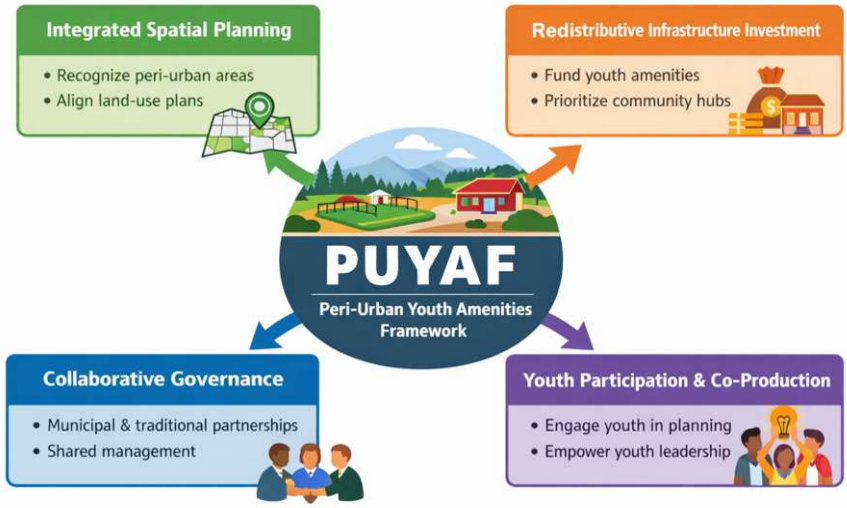

Figure 2: Peri-Urban Youth Amenities Framework (PUYAF).

The proposed Peri-Urban Youth Amenities Framework (PUYAF) responds directly to the persistent misalignment between spatial planning instruments and the lived realities of peri-urban transformation in Eswatini. Despite functioning as urbanized zones with dense populations and complex socio-economic activities, peri-urban areas continue to be framed as rural within statutory planning and development frameworks, resulting in structural exclusion from public investment in social infrastructure (UN-Habitat, 2020). Through formally recognizing peri-urban territories as permanent and integral components of the urban system, PUYAF promotes the integration of national development strategies, municipal spatial development frameworks, and traditional land governance arrangements. This integrated spatial planning approach addresses the fragmentation that has historically constrained coordinated infrastructure delivery in areas such as Khoza, Logoba, and Msunduza, enabling more equitable and efficient allocation of youth-oriented public amenities. Central to this approach is a redistributive logic that prioritizes targeted investment in underserved peri-urban zones, particularly through the development of multi-functional community hubs that expand access beyond school premises, reduce infrastructural overload, and correct spatial imbalances in recreational and learning facilities.

In parallel, PUYAF addresses the institutional and social dimensions of infrastructure deprivation through collaborative governance and youth-centered co-production. The findings reveal that fragmented responsibilities among municipalities, traditional authorities, and the central government have created accountability gaps that undermine the planning, maintenance, and sustainability of public amenities in peri-urban areas. Through formalizing partnerships across governance levels and incorporating civil society

actors, the framework clarifies institutional mandates and builds on inclusive practices such as the Manzini Municipality's open-access provision of recreational facilities (Municipal Council of Manzini, 2022). Embedding youth participation in the design, management, and programming of public spaces further enhances social ownership, ensures contextual relevance, and strengthens community cohesion. This participatory approach responds directly to evidence linking the absence of safe, structured public environments to increased youth vulnerability, substance abuse, and antisocial behavior, positioning youth amenities as preventative social infrastructure rather than discretionary investments. Collectively, PUYAF offers an equity-driven, setting-sensitive planning response that repositions peri-urban youth amenities as a critical component of inclusive and sustainable spatial development in Eswatini.

7 CONCLUSION

This paper has demonstrated that peri-urban areas in Eswatini have evolved into integral components of the national urban system but continue to be marginalized by municipal-bound planning approaches and fragmented governance arrangements. The persistent under-provision of youth-oriented public amenities reflects deeper structural and institutional shortcomings rather than isolated service delivery failures. Through proposing the Peri-Urban Youth Amenities Framework (PUYAF), the study advances a practical and setting-sensitive pathway for reorienting spatial planning, infrastructure investment, and governance toward greater equity and inclusion. Strengthening public amenities for peri-urban youth is not only a matter of service provision but a strategic investment in social cohesion, urban livability, and long-term national development beyond formal municipal boundaries.

1 ABSTRACT

Conflicts over land and ecological heritage increasingly require planners to treat plans not as fixed blueprints but as negotiated agreements over space, values, and future risk. Collaborative and communicative planning traditions emphasise that durable spatial decisions emerge through iterative bargaining – where maps, scenarios, and design proposals act as shared "boundary objects" that help parties externalise trade-offs and explore mutually beneficial solutions (HEALEY, 2020; BAR-SINAI, 2013). However, while negotiation is widely discussed in planning theory, it is still weakly operationalised in everyday practice, especially in multi-stakeholder settings shaped by power asymmetries, competing mandates, and contested evidence (RUMING, 2012; KARTZIOS et al., 2022).

A further challenge is that many land–ecology conflicts behave as complex systems: outcomes emerge from interacting processes, feedback loops, and adaptation across actors and environments, often producing nonlinear change and shifting hotspots over time. In urban science and complexity perspectives suggest that such contested socio-ecological landscapes require an Urban Informatics stance – integrating big data, sensing, and computing to support dynamic, evidence-updated decision-support systems and applications, rather than relying solely on conventional land-use allocation logic and periodic plan revisions (BATTY, 2013; SHI, GOODCHILD, BATTY et al., 2021).

Methodologically, many planning support tools remain oriented toward spatial optimisation or impact assessment, rather than negotiation itself. Multi-criteria frameworks (e.g., AHP) can formalise stakeholder priorities, yet weights often remain expert-driven and opaque. Game-theoretic approaches offer a complementary lens by representing stakeholders as strategic actors with distinct objectives and utilities, enabling systematic testing of stability (e.g., near-equilibrium outcomes) and efficiency (e.g., Pareto-improving compromises) across alternative spatial strategies (ZARREH & GROGAN, 2025). Importantly, negotiation-oriented modelling must remain participatory and transparent, supporting learning and trust rather than acting as a technocratic "black box" (CUHADAR, 2004).

Human-Elephant Conflict (HEC) in Sri Lanka is a particularly urgent arena for such negotiation-capable, informatics-oriented planning support. HEC is not only a conservation challenge but also a land-use and spatial justice problem in mixed agricultural–settlement landscapes that overlap elephant home ranges and corridors (GUNAWANSA et al., 2023). These landscapes are continuously reshaped by cultivation cycles, settlement expansion, infrastructure, and seasonal resource conditions – interacting with elephant movement to create persistent yet evolving conflict patterns – thereby reinforcing the need for dynamic, evidence-driven planning beyond static master-plan prescriptions. This paper advances a GIS-LBS–enabled negotiation framework that couples (i) LUCIS-based suitability and conflict mapping (CARR & ZWICK, 2007) with (ii) LBS-derived GPS elephant movement as an empirical validation lens, and (iii) game-theoretic analysis to

evaluate negotiated outcomes across three strategy families: coexistence, partial separation, and full separation. By explicitly linking spatial modelling, movement evidence, and negotiation analytics, the framework provides a transparent basis to "cherish heritage" through evidence-based, politically feasible landscape sharing – supported by adaptive, data-informed planning applications – rather than purely separation-oriented interventions.

Keywords: Spatial Planning, Landuse Conflict, Human-Elephant Coexistence, Geographic Information System, Participatory Planning and Negosation

2 METHOD OF STUDY

2.1 Conceptual and Methodological Framework

Across Sri Lanka, the struggle between protecting endangered Asian elephants and sustaining rural livelihoods has become one of the most acute land-use planning challenges. Around 40% of the country's population lives within the elephant home range, where more than half of the land is classified as non-forest wildlife area, including extensive agriculture and dispersed human settlements. Each year, 300–400 elephants and 120–140 people are killed due to Human-Elephant Conflict (HEC), giving Sri Lanka one of the highest per-capita elephant and human death rates from HEC globally.

This study conceptualises HEC not merely as a conservation or law-and-order problem, but as a profound land-use and spatial justice issue situated at the interface of heritage conservation, rural development, and climate-resilient planning. Elephants represent both ecological heritage and cultural identity, while smallholder agriculture and village settlements provide the socio-economic backbone of rural regions. The central question is: how can GIS and Location-Based Services (LBS) – particularly GPS tracking of elephant movement – support planners in negotiating spatially explicit, politically feasible strategies for coexistence?

The study develops an integrated decision-support framework that combines:

- GIS- and LBS-based movement analysis of elephants using GPS records to delineate empirical home ranges and movement corridors;
- A GIS-based land suitability model for elephants, agriculture and human settlements;
- The Land Use Conflict Identification Strategy (LUCIS) to identify compatible uses and conflict zones;
- Stakeholder-driven weighting via Analytic Hierarchy Process (AHP); and
- Game-theoretic negotiation to evaluate coexistence, partial separation and full separation strategies.

The key innovation are i.) the explicit use of LBS-derived GPS elephant tracks not only as an input dataset, but as a validation lens – home ranges extracted from GPS data are compared against modelled suitability, revealing where planning assumptions match or diverge from elephants' actual space-use behaviour – and ii.) the use of game-theoretic negotiation to obtain stakeholder-driven weighting when implementing LUCIS-based scenarios.

2.2 Study Area and Data

The analysis is conducted at national scale in Sri Lanka. The GIS database includes land cover, topography, climate, soils, water bodies, protected areas, vegetation structure and existing infrastructure were obtained from open-source data-based and grovment aginces.

LBS is operationalised through:

- GPS records from collared elephants and field tracking.
- Delineation of home ranges and movement corridors (e.g. kernel density and home-range analysis);
- Overlay of these empirical patterns with the elephant suitability model to refine factor weights and thresholds, and to identify under-protected high-use areas and "misclassified" suitable zones.

2.3 GIS–LBS, LUCIS and Game-Theoretic Negotiation

Following LUCIS, the method unfolds in three phases:

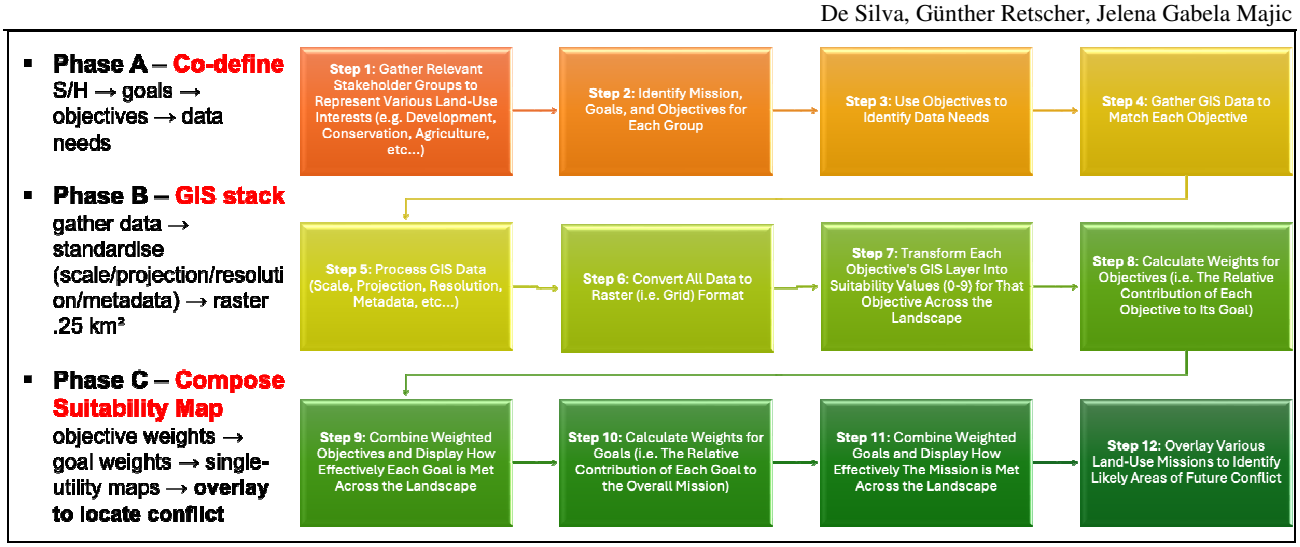

Fig. 1: GIS–LBS–LUCIS negotiation workflow

(1) Co-definition of missions and objectives: Missions such as securing elephant landscapes, safeguarding productive farmland and ensuring safe settlements are decomposed into measurable spatial objectives and indicators.

(2) Suitability mapping with GPS validation: Indicators (e.g. distance to forest, slope, rainfall, access to water, vegetation density, infrastructure) are standardised into 0–9 suitability scores. AHP is used to derive initial weights for objectives and goals for elephants, agriculture and settlements. GPS-based home ranges and corridors are then overlaid on the elephant suitability surface to validate and refine these weights, exposing mismatches between modelled suitability and actual elephant use.

(3) Conflict mapping and game-theoretic negotiation: Composite suitability maps are overlaid to classify land into single-use, compatible multi-use and high-conflict zones. Alternative strategies – coexistence, partial separation, full separation – are spatially implemented. Stakeholder utilities for each strategy, reflecting their weighted objectives, are then analysed using game theory (Nash equilibria and Pareto efficiency) to identify robust compromise solutions. Here, game-theoretic negotiation is used to iteratively adjust and stabilise stakeholder-driven weights and preferences when applying LUCIS.

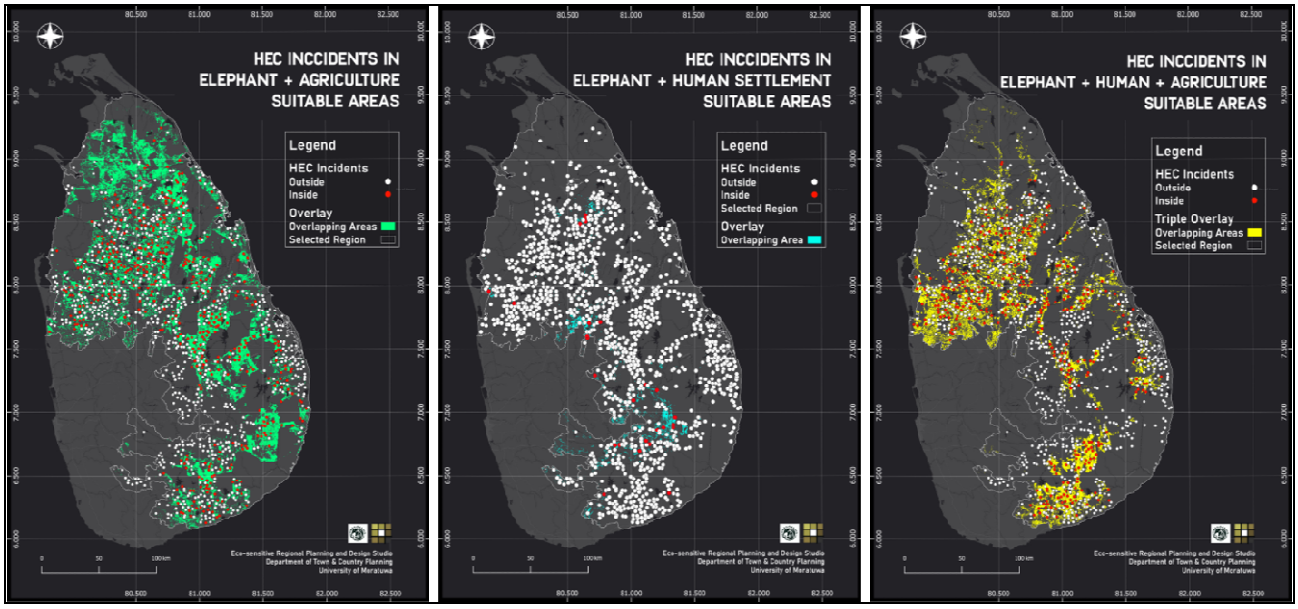

Fig. 2: National-scale overlap of suitability surfaces for elephants, agriculture, and human settlements, highlighting compatible-use zones and high-conflict hotspots where GPS-confirmed elephant use intersects high agricultural/settlement suitability

3 KEY FINDINGS

3.1 GPS–Suitability Compatibility and Conflict Hotspots

GPS-based home ranges confirm that elephants intensively use several zones currently dominated by agriculture or mixed land uses, and highlight high-use areas underrepresented in existing protected networks. Conflict hotspots cluster where:

- GPS-confirmed home ranges intersect areas of high agricultural suitability; and
- Movement corridors are constricted by settlement growth and infrastructure.

Comparing GPS tracks with the suitability model improves habitat prioritisation, helps avoid designating "paper habitats" that elephants seldom use, and sharpens the delineation of critical corridors and buffer zones.

3.2 Planning Strategies and Negotiated Weighting

Three strategy families are tested:

- Full separation (strict elephant/human–agriculture segregation);
- Partial separation (Elephant Conservation Areas allowing seasonal agriculture and eco-tourism);
- Coexistence (habitat restoration, corridor protection, targeted agriculture, compensation and livelihood diversification).

Strategy	Core planning logic	Typical spatial instruments	Governance & livelihood instruments	Expected strengths	Key risks/failure modes
Coexistence	Share landscapes by reducing risk and improving compatibility where overlap is unavoidable	Corridor protection; habitat restoration; buffer zoning; micro-siting of settlements/infrastructure; land-use guidance in mixed mosaics	Compensation/insurance; early warning; crop switching; livelihood diversification; community stewardship	Often higher multi-stakeholder acceptability; flexible and adaptive; can protect "working corridors"	Requires sustained institutions/funding; uneven benefits may trigger distrust; needs strong participation to avoid perceived imposition
Partial separation	Prioritise elephants in defined conservation areas while allowing limited/seasonal compatible use	Elephant Conservation Areas (ECA); controlled agriculture zones; seasonal access rules; corridor widening	Co-management agreements; conditional permits; eco-tourism and benefit-sharing	Clearer spatial structure than coexistence; can reduce peak-risk encounters in hotspots	Boundary disputes; leakage of settlement expansion; may displace risk to edges if enforcement is weak
Full separation	Minimise contact by spatial segregation of humans/agriculture and elephants	Fencing; strict exclusion zones; relocation/resettlement; hard barriers along corridors	Enforcement-heavy management; resettlement packages; strict land controls	Fast visible action in specific sites; may reduce encounters locally if maintained	High social cost and political resistance; barrier maintenance failures; can fragment habitat and intensify conflict at fence lines

Table 1: Summary comparison of HEC strategy families.

Preference elicitation shows overall support for coexistence-oriented options. Game-theoretic negotiation, grounded in stakeholder-driven weights, indicates that GPS-informed coexistence scenarios yield higher combined utilities for farmers, conservationists and state agencies than fencing-only or relocation-centric approaches, and emerge as Pareto-efficient in many settings.

4 DISCUSSION

The proposed GIS–LBS and LUCIS-based framework reshapes Human-Elephant Conflict from a predominantly technical or sectoral problem into a structured arena of spatial negotiation. A central contribution lies in treating LBS-derived GPS elephant tracks not merely as another input layer, but as a validation lens on top of the suitability model. By overlaying empirical home ranges and movement corridors with modelled suitability, the framework forces planners to confront where their assumptions diverge from elephants' actual space-use behaviour. This is particularly important in Sri Lanka, where conservation and land-use decisions have often relied on generalised habitat notions rather than movement-informed landscape functionality. The GPS-based perspective exposes "phantom suitability" areas that look ideal on paper but are rarely used by elephants, as well as overlooked "hot habitats" and corridors that demand higher protection or more sensitive management.

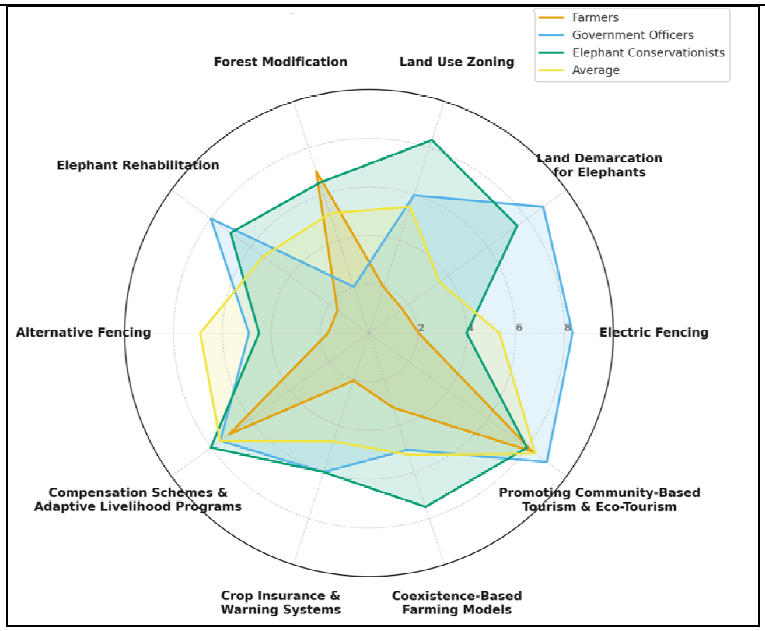

Fig. 3: Stakeholder preference distribution across strategy families (coexistence, partial separation, full separation), summarised by stakeholder group and used to parameterise utility-based scenario comparison.

Equally important is the shift from purely expert-led weighting of criteria towards a game-theoretic, negotiation-centred approach to stakeholder-driven weighting. LUCIS has proven powerful for conflict identification, but in many applications, weights and priorities remain largely in the hands of experts or single institutions. In contrast, this study combines initial AHP-derived weights with an explicit game-theoretic layer, where alternative scenarios – coexistence, partial separation, full separation – are evaluated as strategic options with utilities for farmers, conservationists, and state agencies. Through this, weighting is no longer a hidden technical step: it becomes contested, negotiated, and iteratively adjusted until more stable, Pareto-efficient outcomes emerge. This responds directly to the discourse on whether digital tools and AI truly revolutionise planning: here, technology is not the driver of decisions but an enabler of more transparent bargaining over space, risk, and heritage.

The framework also highlights the promise and the limits of relying on digital evidence in deeply political conflicts. GIS–LBS tools can clarify trade-offs, show where fences or resettlement are unlikely to work, and visualise where coexistence is spatially feasible. Yet they cannot, by themselves, resolve power asymmetries, ensure compensation is fair, or guarantee that communities trust institutions. There is a risk that highly technical models may be used to legitimise predetermined decisions if participation is superficial. Thus, the value of the approach depends on how genuinely stakeholders are engaged in defining missions, interpreting maps, and shaping strategies, rather than merely being shown “finished” products. The work also underscores a broader insight for digital urbanism: AI, LBS and advanced models are most transformative when they illuminate shared problems and create common ground for negotiation, not when they are treated as black-box optimisation engines.

5 CONCLUSION

The GIS–LBS, LUCIS and game-theoretic negotiation framework presented in this study offers a transparent and transferable approach to planning for Human-Elephant coexistence in Sri Lanka. By integrating GPS-based movement data as both input and validation, it grounds conservation and land-use strategies in elephants’ lived geographies, revealing where protected areas, agricultural expansion and settlement growth are misaligned with actual home ranges and corridors. Through LUCIS-based suitability and conflict mapping, it provides a clear spatial language to distinguish compatible-use zones from structural hotspots of conflict. Game-theoretic negotiation adds a governance layer, turning stakeholder preferences and weights into an explicit object of discussion rather than a hidden technical choice. In practical terms, the results indicate that well-designed coexistence strategies – supported by habitat restoration, corridor protection, controlled agriculture, compensation, and livelihood diversification – can deliver higher joint benefits than rigid separation or fencing-and-resettlement approaches alone. More broadly, the study demonstrates the

effectiveness of an Urban Informatics approach – combining complexity science, sensing, data integration, and spatial computing – to support dynamic, evidence-updated planning decisions, in contrast to static land-use master plans that struggle to respond to shifting risk and dayanmics.

Limitations include partial coverage and temporal bias in collaring datasets, sensitivity of suitability outputs to indicator selection and AHP weights, and the coarse national grid that may miss micro-scale barriers and local land-management practices. Future work should: (i) add uncertainty and sensitivity analysis to identify "no-regret" corridors and interventions; (ii) incorporate temporal dynamics (seasonality, crop calendars, rainfall variability) beyond static suitability; (iii) deepen participation through facilitated negotiation workshops to refine utilities, test coalition stability, and address power asymmetries; and (iv) operationalise the framework as an adaptive planning application linked to monitoring, early warning, and compensation targeting. These steps would strengthen robustness and uptake while maintaining transparency and stakeholder ownership.

6 ACKNOWLEDGEMENT

The authors gratefully acknowledge the undergraduateS and academic staff of the Department of Town & Country Planning, University of Moratuwa, Sri Lanka, for their sustained support in conducting this study under the module Eco-sensitive Regional Planning and Design Studio in the BSc(Hons)in Urban Informatics & Planning degree programme.

1 ABSTRACT

Mobility patterns established during childhood play an important role in shaping travel behaviour later in life. While transport planning has traditionally focused on infrastructure and spatial accessibility, research on mobility socialisation emphasizes that children's everyday mobility is strongly embedded in social contexts. This study examines how social environment, infrastructural conditions, and route perception relate to active school travel among school-aged children.

The analysis is based on a multi-site survey conducted between November 2024 and January 2025 at six school sites in rural areas and small towns in Styria, Austria. Pupils aged 6 to 14 years and their parents were surveyed. The study combines information on pupils' school travel behavior with indicators of parental and peer influence, subjective assessments of the school route, and basic spatial and sociodemographic characteristics.

Walking to school was analyzed using a logistic regression approach, while wheeled school travel (cycling and scooter use) was examined using descriptive and bivariate methods due to a limited number of cases. The results show that socialization processes are more influential than infrastructural factors. Walking to school is primarily associated with social environments, particularly peer practices and parental orientations, whereas infrastructure and route perceptions do not exert independent effects once social factors are considered. Wheeled school travel is mainly shaped by peer dynamics and age-related autonomy, with infrastructure acting as an enabling rather than determining condition.

Overall, the findings suggest that strategies to promote active school mobility should extend beyond physical infrastructure and more strongly address social contexts, everyday practices, and peer dynamics in which children's mobility is embedded.

Keywords: Mobility socialisation, Active school travel, social environment, infrastructure, route perception

2 INTRODUCTION AND THEORETICAL FRAMEWORK

The transport sector is among the main contributors to greenhouse gas emissions in Austria. Since 1990, emissions have increased by around 40%, largely driven by domestic motorised private transport (Umweltbundesamt 2026). However, the need for a mobility transition extends beyond climate policy. It is also motivated by public health concerns from insufficient physical activity, car-oriented settlement and transport planning, and inequal access to mobility options. Adult mobility behaviour is strongly shaped by routines and habits, the foundations of which are laid early in life. A successful mobility transition should therefore not be reduced to questions of traffic safety or infrastructure design alone, but must also address health-related, ecological and social objectives, as well as issues of autonomy and participation. This places the following question at the centre of the analysis: how is mobility socially shaped during childhood, and which actors and contexts are particularly influential in this process?

2.1 Childhood mobility socialisation

Mobility is a defining feature of today's society and is deeply intertwined with prevailing lifestyles and economic structures. For a long time, mobility was predominantly approached from a technical or economic perspective, with transport planning and policy focusing on infrastructure provision, efficiency and system performance. Over the past two decades, however, increasing attention has been paid to how mobility patterns are embedded in social contexts. As a result, mobility has become a central topic of social-scientific and interdisciplinary research (Ruhrort, 2025) Mobility behavior can be analyzed from different social-scientific perspectives, including lifestyle-oriented approaches, social-psychological models, and supply- or

system-oriented concepts. The mobility socialization approach offers a particular advantage in that it addresses diverse role models and their mutual interrelations.

Socialization refers to the process by which individuals internalize socially shared norms, values and meanings through ongoing interaction with significant others and social institutions across the life course (Berger & Luckmann, 1966; Giddens, 1984). Key socialization agents or contexts include the family, the spatial environment, peers, school and media. These contexts shape mobility-related orientations and contribute to the development of specific mobility lifestyles. Tully and Baier (2018) conceptualize mobility socialization within a three-level framework, distinguishing between societal conditions (such as infrastructure, spatial differentiation and cultural guiding principles), meso-social contexts (including role models, school and peer groups), and individual conditions (such as attitudes, values, age and gender). Mobility is particularly salient during adolescence, as it enables young people to organize increasingly differentiated everyday lives across spatially separated domains such as school, leisure activities and peer networks. At the same time, mobility becomes an expression of autonomy and identity formation, since independent access to places is closely linked to social participation and self-determination.

2.2 Social environment, infrastructure and route perception

Empirical studies show that children's everyday mobility is shaped by the interaction of social and spatial influences. Parents act as primary socialization agents by structuring everyday mobility routines, communicating norms and safety-related expectations, and serving as role models for their children. Parental personal and social norms, as well as habitualized mobility practices within the family, shaped later travel behavior (Haustein et al., 2009). With increasing age, peers become important reference groups, contributing to the adoption of mobility practices through shared routines and social comparison, particularly in the school context. However, the social contexts of family, peers, school, and media do not stand alone but are interrelated contexts in which mobility-related orientations and practices are learned and stabilized (Baslington, 2008).

Another perspective emphasizes the material and spatial context defined by infrastructure. Research on children's independent mobility indicates that parental perceptions of sidewalk and street safety are closely linked to whether children are allowed to travel independently (Santos et al., 2013). Distance and the availability of walking and cycling infrastructure further provide everyday mobility opportunities (De Meester et al., 2014). Infrastructural conditions do not influence behavior directly but are mediated through route perception, that is, subjective evaluations of safety, comfort, and attractiveness by both parents and children. Together, social environment, infrastructure, and route perception provide a coherent analytical framework for examining how children's school travel behavior is shaped in everyday contexts.

2.3 Planning and project practice in school environments

Projects for the redesign of school environments by traffic planners are typically recommended to be carried out in cooperation with the respective local authorities. Problems with traffic management and traffic hazards around the school are usually first reported by parents to the school or directly to the municipality. Teachers are the second most important group of people who identify and report traffic safety problems in the school environment. If there are problems or requests for changes, schools usually contact the responsible local authority. Similar to socialization research, parental mobility practices and transport infrastructure emerge as factors for enabling active mobility by schoolchildren.

If a project is given to a planner, technical considerations are made as to how the situation in front of and around the school can best be resolved in the interest of all road users, with particular focus on the pupils. Not every street is equally suitable for a 'school street', shared space or other structural or design measures. The type of planning intervention must therefore be carefully considered by experts in each individual case.

In the municipality of Frohnleiten, the primary school and secondary school are located in a school complex on the same street. A new housing development was planned for the same street in 2021. In response, the municipality approached the traffic planning company verkehrplus to implement traffic calming measures for the sensitive school area. The aim was to ensure the safety of pupils and the smooth flow of traffic, especially at the beginning and end of the school day. During the planning process, information evenings in cooperation with the local police were held for the teachers. Feedback and suggestions were included in the planning process. Parents were informed by e-mail after the planning had been completed. In other

municipalities, such as in an ongoing project to introduce a school street in Steyregg in Upper Austria, an information evening is planned before the school street is implemented.

The introduction of walking buses or bike buses ('Pedibus' or 'Bicibus') is often initiated by committed parents or teachers. These projects are usually implemented by local authorities, as was the case in Gleisdorf, for example, who may call in experts for advice and implementation.

Experience in various schools has also shown that the exemplary behavior of individuals influences the whole group. For example, a new kiss-and-go zone was set up at the St. Veit primary school in Southern Styria. The zone is located at an alternative entrance to the school away from the courtyard in front of the school, where buses stop and teachers park. The new entrance was only accepted after the headmistress specifically asked the respective parent representatives of the individual classes to use the new kiss-and-go zone and thus set an example for their classes.

3 STUDY DESIGN AND METHODS

3.1 Context and Research Area

The study was conducted as part of the FFG-funded project "Auf vertrauten Wegen" , which aims to promote active mobility by analyzing school routes together with pupils and co-developing context-specific interventions. The project was implemented at three primary and three secondary schools located in rural areas and small towns in the Austrian province of Styria. At each site, pupils' everyday school routes were examined and discussed, forming the basis for the collaborative development of measures to encourage walking and cycling.

The selected schools differ markedly in the characteristics of their immediate school environments. Some sites already feature traffic-calming measures, such as access restrictions for cars or designated 'school streets', while others are characterized by higher levels of traffic and frequent parental drop-offs, hindering active travel to school by foot or bicycle. Prior to the development of interventions, a comprehensive survey of all pupils and their parents was conducted at each of the six school locations to establish a baseline for the subsequent analyses.

3.2 Data Collection and Sample

The multi-site survey was conducted between November 2024 and January 2025. The extended survey period resulted from different start dates and differing implementation schedules across school sites, which were coordinated locally by teachers (pupil surveys) and school administrations (parent surveys). Primary school pupils were surveyed using paper-based questionnaires administered in class, while surveys at secondary schools were conducted digitally during class time under teacher supervision.

The parent survey was more extensive than the pupil questionnaire and was distributed via school-internal communication channels. Online questionnaires were created and administered using the open-source survey software LimeSurvey. To increase response rates, two reminder messages were sent to parents at each site. Following data collection, pupil and parent datasets were merged into a single analytical dataset. This matching procedure reduced the final sample size to n = 235, as each pupil needed to be uniquely linked to one responding parent for inclusion in the multivariate analyses (see table for response rates and site-specific sample sizes).

Municipality	Inhabitants (2025)	School type	Number of pupils	Sample size pupils (n)	Response rate pupils (%)	Sample size parents (n)	Response rate parents (%)
Frohnleiten	6.690	primary	241	187	78	87	36
St.Veit/Südst.	4.426	primary	94	79	84	31	33
Zeltweg	6.993	primary	229	214	93	75	33
Frohnleiten	6.690	secondary	190	131	69	45	24
Gleisdorf	11.533	secondary	350	219	63	127	36
Zeltweg	6.993	secondary	104	88	85	28	27

Table 1: Overview of study sites and survey samples; source: population data Statistik Austria (2025)

3.3 Analytical approach

Building on the theoretical framework, which conceptualizes children's school mobility as the outcome of interactions between social environment, infrastructural conditions, and route perception, this study examines which socialization agents, spatial factors, and distances are associated with pupils' active school

travel. Two binary dependent variables were specified. The first captures whether a child walks to school (1 = walking, 0 = not walking). The second model examines wheeled active travel, combining cycling and scooter use into a single outcome variable (1 = wheeled mode, 0 = not wheeled). Statistical analyses were conducted using SPSS, complemented by additional data procedures in R.

Survey data from parents and pupils were processed using a standardized multi-step procedure. Data preparation included the removal of duplicate cases, incomplete responses, and identifying information, as well as consistency checks of names, school class identifiers, and school information. Variables required for linking parent and pupil records were harmonized across datasets in terms of formatting, spelling, and variable type, and standardized (e.g., uppercase lettering, trimmed spaces). Address information was manually reviewed and supplemented where necessary. Parent and pupil datasets were then merged stepwise using a composite linkage key (first name, school, class, postal code), supported by manual plausibility checks to resolve ambiguous matches. The final analytical dataset included only consistently matched and valid cases.

Descriptive analyses were used to examine modal split patterns for pupils and parents. Reliability analyses and exploratory factor analyses informed the aggregation of similar items to composite variables. Predictors of walking to school were examined using a multivariate Firth-penalized logistic regression model. The regression model for using wheeled modes did not provide robust multivariate estimates because of a skewed distribution in the outcome variable. Wheeled school travel was therefore examined using descriptive and bivariate statistical analyses. The variables used in the analyses are outlined below.

3.3.1 Transport mode choice

Pupils were asked how they usually travel to and from school under good or bad weather conditions. Parents were additionally asked about their mode choice across several everyday trip purposes, including work or education, shopping, errands, escorting children, and leisure activities.

3.3.2 Parental social norms

Parental attitudes and norms related to children's active travel were measured using items capturing perceived social norms and parenting-related orientations. Descriptive and injunctive social norms assessed how strongly parents perceive active school travel to be supported and valued within their social environment. All norm items were recoded so that higher values indicate stronger pro-active-travel norms.

Parenting style items captured a family-centered orientation emphasizing emotional closeness, shared decision-making within the family, and difficulties with letting go. Higher values thus reflect stronger family embeddedness and parental involvement rather than early autonomy support. Exploratory factor and reliability analyses revealed a stable two-factor structure with good internal consistency, distinguishing mobility-related parental social norms (parent_norms_active) from a general family-centered parenting style (parent_family_centered_style).

3.3.3 Peer mobility shares

For each school class (school_class_id), relative peer shares (0–1) were calculated for walking and for wheeled modes (bicycle, scooter, e-scooter), representing the proportion of classmates using each mode on the school trip (peer_walk_share_class, peer_wheeled_share_class).

3.3.4 Parental active mobility share

Based on parents' reported mode choices across all trip purposes, mean shares of active mobility were calculated. Two indicators were derived and included in the models: the proportion of trips made on foot and the combined proportion of trips made by bicycle, scooter or e-scooter, reflecting parents' everyday preference for walking and cycling (parent_walk_share, parent_wheeled_share).

3.3.5 Infrastructure

Objective assessments of walking and cycling infrastructure are excluded because of multicollinearity issues in multivariate models from low variance between the six school sites. Therefore, infrastructure is measured by parents' ratings of sidewalks and bicycle lanes (infra_rating_sidewalks_new, infra_rating_bikelanes_new). Higher values indicate more positively evaluated infrastructure conditions.

3.3.6 Pupils' and parents' route evaluation

Pupils and parents were asked to evaluate the school route by rating a set of statements using a Likert-type scale. Several factor solutions were tested. An eight-item solution was selected as the best compromise between explained variance and informative value. Factor 1 captures parents' and pupils' evaluations of the route with regard to perceived safety, difficulty and overall comfort, including feelings, like fear or perceptions of well-being and ease when using the route (parent_safety_comfort, kids_safety_comfort). Factor 2 captures parents' and pupils' evaluation of the route with regard to presence of nature elements and the perceived novelty of the route (parent_environmental_attractiveness, kids_environmental_attractiveness). All route perception scales are coded so that higher values indicate more negative evaluations (e.g., higher perceived danger, stress, or discomfort), meaning that odd rations below 1 reflect decreasing likelyhoods of active travel with worsening route perceptions.

3.3.7 Distance

Distances to school were calculated based on geocoded home and school locations (straight-line distance). Address data were prepared and standardized in Excel and then geolocated using an automated geocoding service. Where exact house numbers were missing, locations were approximated using street midpoints or central reference points for the respective municipality or district. In cases with ambiguous address information, conservative assumptions were applied and results were manually checked for plausibility. Exemplary geocoding outcomes were manually verified to ensure spatial consistency and reasonable distance estimates.

Age and gender were included as control variables to account for basic socio-demographic differences that may influence pupils' school travel behavior.

4 RESULTS

4.1 Descriptive results – Transport mode choice

A comparison of modal choice by school grade shows that walking is more common among primary school pupils than among secondary school pupils (good weather: 42% vs. 30%; bad weather: 33% vs. 28%). In contrast, secondary school pupils travel to school by wheeled modes substantially more often (14%) than primary school pupils (3%). This difference can partly be explained by the Austrian "Radfahrprüfung", which is typically completed in the fourth year of primary school and grants children permission to cycle independently in traffic. Primary school pupils are also more frequently driven to school by car (good weather: 23%; rainy/cold weather: 40%) compared to pupils in secondary schools (18%; 27%).

The six school sites differ substantially in modal choice. Among primary schools, St. Veit/Südsteiermark shows the lowest share of pupils walking in all categories (including the return trip), with walking shares ranging from 7% to 21%, and the highest share of car use (up to 73%). In contrast, the primary school in Frohnleiten records the highest proportion of pupils walking to school (41–57%). A plausible explanation for this difference lies in the immediate school environment in St. Veit, which is less pedestrian-friendly and was also perceived as unsafe by respondents in the survey – while Frohnleiten shows more favorable conditions for walking.

Among secondary schools, Zeltweg stands out, showing the highest shares of wheeled modes (up to 10% cycling and 3% scooter) and walking (up to 47%). These patterns may be explained by site-specific characteristics. By contrast, in Gleisdorf, the municipality covers a large geographic area and the secondary school attracts pupils with longer travel distances, which in many cases exceed feasible ranges for active mobility. Consequently, a substantial proportion of pupils rely on public transport, with up to 43% traveling by bus and 10% by train.

A comparison between good and rainy/cold weather conditions further indicates that the primary school with the highest car use, St. Veit/Südsteiermark, also exhibits the strongest increase in car-based travel under adverse weather conditions (from 48% to 73%). Generally, pupils are more likely to walk or use wheeled modes under favorable weather conditions, while car use increases when weather conditions worsen.

4.2 Predictors of active school travel

The logistic regression model for walking to school is statistically significant (LR $\chi^2(12) = 105.13$, $p < .001$) and explains substantial variance in pupils' walking behavior. Overall, the results underline the central importance of socialization processes, while infrastructural conditions and route perceptions show no independent effects once social factors are taken into account.

The strongest predictor of walking to school is the mobility behavior of peers (classmates). The class-level share of pupils who walk to school is very strongly associated with individual walking behavior (OR = 156.31, $p < .001$). Walking appears to be a taken-for-granted and socially reinforced practice when it is common within the classroom context. Parental influences also playges a decisive role. Children are more likely to walk when parents perceive active travel as valued within their own social environment (OR = 3.57, $p < .001$). In addition, a family-centered parenting style has a positive effect (OR = 1.73, $p = 0.39$), indicating that more family-centered orientations are associated with higher odds of walking to school. Beyond norms and parenting style, parents' own walking behavior is a significant predictor (OR = 1.04, $p < .001$), highlighting the importance of everyday role modelling and habitual practices within families.

By contrast, infrastructural variables and route perceptions do not show statistically significant effects in the walking model. Neither parents' nor children's assessments of safety, comfort, or environmental attractiveness of the school route are associated with walking once parental and peer norms are included. This indicates that perceived infrastructure quality and route experience may be necessary but not sufficient conditions for walking, and that their effects are largely mediated through social contexts.

Finally, distance to school, age and gender do not exert significant influences. Taken together, the walking model demonstrates that children's walking to school is primarily shaped by their social environments, rather than by infrastructural conditions or route perceptions.

Table 2 reports the results of a Firth-penalized logistic regression model examining social, infrastructural and perceptual predictors of walking to school.

Predictor	β	SE	OR	95%-CI (OR)	p
(Intercept)	-3.20	1.81	0.04	0.0007–1.61	.089
parent_norms_active (social environment)	1.26	0.32	3.57	1.89–7.69	< .001
parent_walk_share (social environment)	0.043	0.013	1.04	1.02–1.08	< .001
parent_family_centered_style (social environment)	0.55	0.26	1.73	1.03–3.12	.039
peer_walk_share_class (social environment)	5.05	1.26	156.31	13.45–2892	< .001
infra_rating_sidewalks_new (infrastructure)	-0.16	0.26	0.86	0.49–1.47	.574
kids_safety_comfort (route perception)	-0.17	0.27	0.84	0.48–1.52	.562
kids_environmental_attractiveness (route perception)	-0.03	0.23	0.97	0.59–1.56	.889
parent_safety_comfort (route perception)	-0.40	0.32	0.67	0.33–1.32	.253
parent_environmental_attractiveness (route perception)	-0.26	0.24	0.77	0.46–1.26	.305
distance	-0.29	0.16	0.75	0.49–1.02	.095
age	0.04	0.11	1.04	0.83–1.31	.722
gender (male)	0.34	0.47	1.41	0.54–3.85	.489

Table 2: Predictors of walking to school, n = 169, LR-Test $\chi^2(12) = 105.13$, $p < .001$; method: Firth-penalized logistic regression); DV: walking to school (1/0). Regression coefficients (β), standard errors (SE), odds ratios (OR), and 95% confidence intervals.

Due to the small total number of pupils using wheeled modes (cycling or scooter), the dependent variable has too little variance for calculating multivariate regression analyses. Consequently, wheeled mobility was examined using descriptive and bivariate analyses, comparing the groups of pupils who do and do not use wheeled modes. The bivariate results highlight a pronounced peer effect. Pupils who travel to school by wheeled modes visit school classes with significantly higher shares of peers also using wheeled modes ($p < .001$). This finding indicates that wheeled mobility is closely linked to shared mobility practices within the classroom, mirroring the strong peer effects observed in walking. Age emerges as another key factor: wheeled users are significantly older than non-users ($p < .001$), reflecting increasing autonomy, cognitive and motor skills, and formal permission to cycle independently with age.

In contrast to walking, parents play a limited role for wheeled mobility. Neither parental mobility-related norms, nor parents' own wheeled travel or parenting style show statistically significant associations. This suggests that wheeled school travel is less embedded in family routines and parental socialization processes and that the influence of peers becomes more salient with age.

With regard to the built environment, pupils using wheeled modes rate the cycling infrastructure more positively ($p < .05$), indicating that infrastructure supports this mode of active travel. At the same time,

wheeled pupils report higher levels of perceived fear and danger along the school route (p = 0.40), suggesting that wheeled mobility is often adopted despite, rather than because of, high subjective safety.

Overall, the wheeled results point to a mobility pattern that is primarily shaped by peer dynamics and age-related autonomy, with infrastructure facilitating this behavior.

Predictor	Mean rank (other)	Mean rank (wheeled)	Test statistic	p

5 DISCUSSION AND CONCLUSION

5.1 Implications for Planning and Intervention Design

Surveys of parents and pupils as well as the results of workshops in school classes with pupils from 6 to 14 years have shown that children's active travel behavior is strongly influenced by the social norms set by their peers. Schoolmates who jointly walk to school, use the scooter or cycle to school allow children to engage in playing and exploration activities with their friends during the school trip. Parents function as role models and gatekeepers with regards to walking. However, once children have grown older and can safely ride the scooter or the bike, this parental influence diminishes. Infrastructure and route characteristics may provide enabling conditions for active school travel, but their influence is much weaker than the influence of peers and parents.

Projects for redesigning school environments or for school mobility management should therefore target not just children directly, but should also leverage peer or parental dynamics that might emerge once children commence to shift their travel patterns. In particular projects in primary schools should explicitly work not just with children, but should address the parents as well. It must also be taken into account that parents are concerned about the safety of their children. Infrastructure projects in the school environment, such as school streets and shared spaces, can create a safe school environment and, together with the establishment of kiss-and-go zones on the periphery of school areas, make it possible to drop off children safely. However, improving infrastructure alone will most likely yield limited effects unless peers and parents are also engaged in, for instance, competitions or mobility exercises. We thus recommend approaches where schoolchildren are motivated to travel together and where parents are involved to revise their own mobility patterns.

Participation formats in schools make valuable contributions to surveys and polls: on the one hand, playful formats and joint visits allow the motivations of children and young people on the topic to be discovered directly and immediately, and on the other hand, substantial awareness is raised and the students communicate their findings and experiences in their peer groups and families. Role-playing facilitates understanding of different perspectives (parents, teachers, children), and walking to school together allows children to experience the challenges firsthand. With this jointly developed understanding, mobility infrastructures can be planned and implemented in an optimal and needs-based manner.

5.2 Limitations and Outlook

Despite high response rates among pupils (63–93%), the final analytical sample was reduced to N = 235 due to lower response rates in the parent survey (24–36%). As parent-child linkage was required for the multivariate analyses, this imbalance reduced statistical power and limited the applicability of regression models for wheeled school travel.

A further limitation relates to the survey period, which extended from November 2024 to mid-January 2025. Seasonal effects, weather conditions and the timing around the turn of the year may have influenced reported travel behavior. In addition, home-school distances were calculated as straight-line distances. While this approach ensured consistency across sites, it does not fully capture actual route choices or topographical conditions, which may be particularly relevant in rural and small-town regions in Austria.

Looking ahead, the project "Auf vertrauten Wegen" will proceed with the implementation of interventions co-developed with pupils, such as Pedibus stops and routes, cycling training programs or the redesign of a school forecourt. A follow-up survey is planned at the same schools to assess potential changes in mobility behavior and perceptions resulting from both infrastructural and behavior-oriented measures.

Feedback from pupils and parents indicates that the questionnaires were generally well understood and well received. However, the detailed breakdown of parental mobility by multiple trip purposes proved challenging for some respondents and reduced the response rates. Future surveys should therefore aim to balance analytical precision and respondent burden, particularly when addressing children and their parents. Despite these limitations, the consistency of key findings across multiple sites and school levels suggests that the results are robust and informative for schools in rural areas and small towns.

Co-Creating Urban Resilience by Community Engagement in Central Asia

Madina Junussova, Chynarkan Saparova

(Dr Madina Junussova, University of Central Asia, 13 Gagarin Street, Tekeli, 041700, Republic of Kazakhstan, madina.junussova@ucentralasia.org)

1 ABSTRACT

Mountain cities in Central Asia face growing climate-related challenges, including ecosystem degradation, water vulnerability, exposure to natural hazards, and the loss of green infrastructure. Responding to these pressures, the Naryn Urban Resilience Programme (NURP) demonstrates an integrated model of low-carbon, climate-responsive, and community-driven urban development. Drawing on the NURP case, this paper explains how collaborative processes (co-creation) among residents, municipal actors, investors, and technical experts build urban resilience in Naryn.

The NURP introduced multi-level capacity-building programmes for residents, municipal departments, and local businesses, focusing on sustainable landscape design, slope and riverbank stabilisation, public-space management, and the use of climate-resilient local flora. The NURP activities include nature-based solutions (NBS), circular landscape practices, community engagement, and GIS decision-support systems to strengthen Naryn's adaptive capacity. Community engagement activities led to the formation of a local expert group that facilitated co-design, stewardship, and ongoing dialogue between residents and authorities, strengthening social resilience and shared ownership of public spaces. Using NURP cases, the paper analyses which institutional arrangements amplify or inhibit co-created resilience interventions.

The findings show that the combination of participatory greening, native-plant-based NBS, and digital planning technologies creates a practical pathway toward resilient, energy-efficient, and climate-adaptive urban development. The Naryn case highlights the importance of co-governance structures, blended learning approaches, and local ecological knowledge for sustaining NBS in resource-constrained mountain environments. The paper concludes by outlining how lessons learned from the NURP could be applicable across similar urban contexts in Central Asia and beyond.

Keywords: participatory planning, urban resilience, nature-based solution, community engagement, greening

2 INTRODUCTION

Urban areas across Central Asia are becoming increasingly sensitive to climate-induced hazards, including extreme temperature variability, water scarcity, flooding, and ecosystem degradation. These challenges are particularly acute in the remote and mountain cities, where limited institutional capacity and ageing infrastructure intersect with rapid socio-economic transitions. In this context, strengthening urban resilience has emerged as a strategic priority for sustainable urban development. To support the enhancement of resilience in towns/cities across Central Asia, SECO and AKDN agencies have been engaging with the governments of the Kyrgyz Republic and Tajikistan to develop a model aligned with international best practice in the delivery of Urban Resilience Programming in Central Asia. The Naryn Urban Resilience Programme (NURP) aims to build local capacity and implement nature-based and data-informed solutions to strengthen urban resilience in Naryn.

Nature-based solutions (NBS) play a crucial role in enhancing urban resilience by leveraging natural processes to address contemporary environmental challenges. Growing empirical evidence supports the hypothesis that participatory NBS models not only improve sustainability but also enhance acceptance and overall social performance. Puskas, Abunnasr & Naalbandian (2021) have identified that co-created green spaces improve social connectedness and, therefore, better neighbourhood relationships and higher levels of civic participation. In addition to their social effects, NBS projects designed and managed by the community also contribute to long-term environmental sustainability. Ferreira et al. (2020) have argued that projects developed and owned by local stakeholders are more likely to be well-maintained in the long run, thereby reducing the risk of degradation or abandonment. Despite the growing prominence of NBS in urban resilience agendas, a key concern remains that many NBS initiatives are comprehensive engineering interventions that are difficult for local communities to manage or sustain independently. There is a notable scarcity of empirical studies examining how resident engagement can effectively scale NBS down to levels

that are adaptable, usable, and manageable by local communities, with a particular emphasis on capacity building and sustained community participation.

Building on these identified gaps, this paper examines the NURP in Kyrgyzstan as an in-depth case study of co-creating urban resilience through community engagement and nature-based approaches. It investigates how participatory processes embedded within the NURP shape the design, social acceptance, and overall effectiveness of NBS-oriented interventions at the local level. In doing so, the study addresses three interrelated research questions (i) how local community needs drove NBS adoption to increase community engagement, and (ii) which institutional and socio-cultural factors enable or constrain co-creation processes in mountain urban contexts. By systematically addressing these questions, the paper advances the literature on participatory urban planning and community engagement for strengthning resilience, while offering empirically grounded insights for policymakers and practitioners working in Central Asia and other transitional urban environments.

3 LITERATURE REVIEW AND THEORETICAL FRAMEWORK

The involvement of residents in the planning and implementation of nature-based solutions (NBS) is firmly grounded in collaborative governance theories and socio-ecological resilience frameworks, which emphasise the interdependence between institutional structures, local knowledge, and adaptive capacity. Within this literature, scholars conceptualise participation not as a procedural add-on but as a core mechanism that builds trust and delivers long-term resilience outcomes. They argue that when actors operationalise engagement mechanisms in meaningful ways, these mechanisms align interventions more closely with local priorities and everyday practices, thereby increasing both their legitimacy and effectiveness. Empirical studies demonstrate that successful urban greening initiatives increasingly rely on participatory assessment frameworks to evaluate not only environmental performance but also the quality and depth of community engagement, ensuring that local perspectives actively shape project design and implementation rather than merely being consulted ex post (van der Jagt et al., 2022). Therefore, the way participation is structured and enacted is decisive in shaping both trust-building processes and the governance capacity of NBS initiatives, thereby setting the conditions for more advanced and equitable forms of co-creation to emerge.

Co-design and co-implementation models are particularly emphasised as critical pathways for building public confidence in NBS interventions. Ferreira et al. (2020) argue that projects developed in collaboration with local stakeholders are more likely to generate a sense of ownership, which in turn supports sustained maintenance and long-term environmental outcomes. Through such processes, communities move from being passive recipients of top-down policies to becoming active co-producers of urban resilience. Digital participation tools increasingly support this shift by broadening access to planning processes, lowering participation barriers, and enhancing inclusivity across different social groups (Frantzeskaki et al., 2019). Any tools aligned to local communities' actual or developed capacities can strengthen transparency and feedback loops, further reinforcing trust between residents and implementing institutions.

The quality of participation, however, remains uneven across urban contexts mainly because development continues to be imposed from the top by developers or subject experts without careful attention to local circumstances. Arnstein's Ladder of Participation provides a practical analytical framework for distinguishing between symbolic forms of engagement and genuine citizen power, ranging from tokenistic consultation to complete citizen control (Frantzeskaki, 2019). Despite widespread rhetorical commitment to participation, many NBS initiatives remain situated at lower rungs of the ladder, where communities are consulted but retain limited influence over decision-making. This governance imbalance raises critical concerns about equity and inclusivity, particularly in socioeconomically diverse or marginalised urban areas. Tozer et al. (2020) caution that when participatory NBS governance fails to address power asymmetries, it risks reinforcing existing socio-spatial inequalities by systematically excluding disadvantaged groups from meaningful involvement. There is a growing need to move beyond formalised consultation toward creating the institutional conditions necessary for trust, inclusivity, and genuinely community-driven NBS co-creation processes.

Scholars increasingly converge on the argument for embedding inclusivity in the institutional design of NBS governance rather than treating it as a secondary objective. Moving participatory processes beyond symbolic engagement toward material empowerment – where communities can shape priorities, propose interventions, and co-plan implementation – has been shown to enhance both the social acceptance and durability of urban

greening initiatives. Aligning NBS actions with locally articulated needs not only enhances contextual relevance but also fosters trust, a prerequisite for deeper forms of co-creation. Over time, this trust can enable local stakeholders to initiate and lead collective actions, such as the co-planning of green neighbourhoods, thereby strengthening urban resilience through locally grounded, socially legitimate NBS interventions.

Taken together, this body of literature provides the theoretical foundation for a bottom-up analytical framework that integrates collaborative governance, socio-ecological resilience, and participatory planning theories to examine how NBS are co-produced in practice through systematic assessment of those needs, targeted capacity-building, and inclusive engagement mechanisms. Within this framework, local communities are understood not merely as beneficiaries of environmental interventions but as key actors whose knowledge, capacities, and agency are central to the sustainability and resilience of urban systems. Applying this perspective to the Central Asian mountain town case enables an examination of how aligning actions with locally articulated needs can foster trust and enable residents to move beyond passive participation toward the co-development, stewardship, and long-term maintenance of green infrastructure. The study positions bottom-up participation not only as a governance principle but as an operational strategy for embedding NBS within local socio-institutional contexts, thereby enhancing their legitimacy, durability, and contribution to urban resilience outcomes.

4 NARYN CASE STUDY

Naryn town represents a distinctive and analytically valuable case for examining community engagement in nature-based and resilience-oriented urban interventions. Located in the south-eastern part of Kyrgyzstan, the town has an estimated population of 41,681, according to the 2022 Population and Housing Census of the Kyrgyz Republic. Nestled within a high-altitude mountain landscape, Naryn extends as a compact, linear settlement of approximately 25 km along the Naryn River canyon – the largest tributary of the Syr Darya, which flows across multiple Central Asian countries. Its mountainous geography, climatic sensitivity, and physical isolation – approximately 5 hours by road from Bishkek – render Naryn particularly vulnerable to climate change impacts while simultaneously making it a manageable, clearly bounded setting in which to pilot and test community engagement mechanisms.

Naryn is undergoing a period of transition marked by ongoing urban planning activities, development projects, and existing tourism and agricultural economic activities. Recognising both its vulnerabilities and its development potential, several international partners have initiated substantial investments in the town and the wider oblast. Within this context, the Naryn Urban Resilience Programme (NURP) is a five-year planning and proof-of-concept initiative aimed at developing the institutional structures, systems, and local capacities required to transform Naryn into a model resilient mountain town. The programme explicitly links government planning and investment frameworks with initiatives led by communities and national and international partners, creating a platform for bottom-up engagement alongside formal governance processes.

Beyond its physical characteristics, Naryn occupies a unique socio-cultural position within the country. Often referred to as the “original town of the Kyrgyz,” it holds substantial symbolic value for its residents, many of whom express great pride and attachment to their hometown. This strong place-based identity suggests a latent potential for collective action and civic engagement. However, before the initiation of the NURP, observed levels of local activism and organised community participation remained relatively low, highlighting a gap between social attachment and active engagement in urban development processes. This contrast makes Naryn particularly relevant for investigating how trust-building and capacity development can activate community participation in practice.

Naryn’s role as the economic, social, and political hub of the oblast further amplifies the significance of the NURP intervention. The town faces compounded pressures from climate-induced natural hazards and demographic change driven by urbanisation, while also contending with limited economic opportunities. These conditions, combined with its compact urban form, challenging hazard profile, and alignment with ongoing SECO and AKDN initiatives, led to its selection as a showcase for resilient urban planning and development. Recent municipal actions, such as housing and public space projects, improvements to transport and education infrastructure, and reforms such as the acquisition of underutilised industrial land for public use, underscore the town’s readiness to experiment with participatory, community-driven approaches to urban resilience.

4.1 Identifying Local Capacity by Needs Assessments

To operationalise community engagement and align nature-based interventions with local needs, the Naryn Urban Resilience Programme (NURP) adopted an evidence-driven, bottom-up approach centred on systematic surveys and needs assessments. Since its launch in 2022, the programme has conducted a series of citywide and neighbourhood-level assessments to capture residents' lived experiences, risk perceptions, and development aspirations. There are several early diagnostic efforts to inform technical planning but also to create an entry point for dialogue between local communities, municipal actors, and programme implementers, thereby laying the groundwork for trust-building and participatory governance.

A significant milestone in this process was the launch of the Integrated Habitat Assessment (IHA) in 2023. The IHA combined social, economic, and environmental datasets, including multi-hazard exposure, hydrological conditions, geo-botanical characteristics, forestry and soil profiles, demographic trends, and sociological indicators. When analysed in combination, these layered datasets generated a composite spatial index that identified hazard exposure, demographic sensitivity, infrastructure service gaps, and environmental hotspots across Naryn. This integrated analytical framework enabled NURP to translate complex ecological and social risks into spatially explicit insights that could be communicated to both technical experts and residents, strengthening the transparency and relevance of planning decisions.

Building on this analytical foundation, NURP conducted a targeted needs assessment for nature-based solutions between June and August 2024, explicitly linking data-driven risk analysis with community capacity and willingness to engage. Through diagnostic missions and capacity-building sessions, the programme assessed not only local awareness of NBS but also residents' readiness to participate in community, public, and entrepreneurial activities related to urban greening and landscape-based resilience. These engagements introduced participants to basic principles of urban and landscape design while exploring how locally adapted NBS could respond to Naryn's specific environmental and socio-economic conditions.

The findings revealed a critical structural constraint: a severe shortage of highly qualified landscape design professionals and firms with experience in applying NBS, especially those capable of working with native species and mountain ecosystems in Kyrgyzstan. This capacity gap emerged as a key barrier to translating community interest and locally identified needs into high-quality, sustainable interventions. At the same time, the assessment highlighted an opportunity for targeted capacity development, strengthening local skills and knowledge could enable residents and local actors not only to receive externally designed interventions but also to co-develop and maintain green infrastructure. In this sense, the surveys and needs assessments functioned as more than diagnostic tools; they became a central mechanism for aligning NBS actions with local needs, addressing institutional and capacity constraints, and advancing the conditions for meaningful co-creation in Naryn.

4.2 Catalogue of Kyrgyz Flora

The University of Central Asia (UCA) team co-implementing NURP paid dedicated attention to addressing the historical erosion of local flora resulting from Soviet-era urban planning practices, which introduced non-native and often maladapted plant species across Central Asian cities. In Naryn, this legacy has contributed to the gradual displacement of indigenous vegetation that is better suited to the town's harsh mountain climate and fragile ecosystems. Recognising the ecological and cultural significance of restoring locally adapted species, NURP initiated the development of an illustrated catalogue of climate-resilient plants designed to guide both residents and municipal authorities in making informed, context-sensitive planting decisions.

The catalogue responds directly to Naryn's specific climatic conditions and ecological characteristics, while also advancing the notion of a distinctly "Kyrgyz" landscape that reflects local identity, heritage, and environmental knowledge. It documents a carefully curated selection of native and climate-resilient species, including eight tree species, 13 shrubs, 13 grasses, and 2 vines that can thrive in Naryn's urban environment. Beyond their aesthetic value, these species provide measurable ecosystem services, such as reducing dust pollution, improving air quality through carbon sequestration, and enhancing overall urban ecological stability. By foregrounding plants that are both environmentally functional and culturally resonant, the catalogue aligns ecological restoration with place-based identity.

High demand for the catalogue led to its translation into both Kyrgyz and English, underscoring its relevance not only for local communities but also for planners, designers, and external partners involved in urban development. As a participatory tool, the catalogue plays a dual role: it addresses technical knowledge gaps in plant selection while simultaneously empowering residents to engage more actively in urban greening initiatives. By enabling informed choices rooted in local ecology, the resource supports a shift from externally imposed landscaping norms toward community-driven restoration practices. Consistent with existing research, engaging communities in selecting flora has been shown to enhance ecological awareness, foster a sense of ownership, and improve long-term maintenance of public green spaces (Raymond et al., 2021). In the context of Naryn, the catalogue thus functions as both an ecological corrective to historical planning legacies and a trust-building mechanism that anchors nature-based solutions in local knowledge and stewardship.

4.3 Addressing Knowledge Gaps through Targeted Capacity Building

Early engagement activities under the NURP revealed a significant shortage of local knowledge and technical expertise related to urban greening and the use of locally adapted flora. While residents and municipal actors expressed strong interest in improving public spaces and environmental conditions, many lacked practical understanding of landscape design principles, plant selection for mountain climates, and the maintenance requirements of nature-based solutions. This knowledge gap – shaped by decades of externally driven planning practices and limited access to professional training in the region – emerged as a critical constraint on meaningful participation and effective implementation of NBS.

In response, NURP designed a targeted capacity-building strategy aimed at transforming interest into informed and actionable engagement. To overcome barriers related to remoteness, time constraints, and uneven access to formal planning processes, the programme adopted a hybrid engagement model combining face-to-face workshops with online surveys, digital polls, and mobile-based learning tools. Such an approach aligns with participatory NBS governance literature, which emphasizes that strengthening local capacities is a prerequisite for the long-term success and maintenance of urban greening interventions (Kabisch et al., 2016). All online lectures were recorded and made publicly available on YouTube, allowing participants and other residents to revisit the material and extend learning beyond the formal training period.

The capacity-building initiatives targeted municipal officers, forestry personnel, and community members, with the explicit objective of enabling local stakeholders to co-develop, implement, and manage urban greening projects. Launched in 2024 and continuing to date, the training programme covered both foundational and applied topics, including plant grafting, pest and disease management, efficient irrigation techniques, and public space improvement using locally adapted nature-based approaches. By combining technical instruction with hands-on application, the programme operationalized a "learning by doing" approach, which has been shown to be particularly effective in enhancing the performance and confidence of community-based sustainability initiatives (Frantzeskaki et al., 2019).

The practical outcomes of this approach became evident within a relatively short timeframe. After six months of training, participants collectively identified five underutilized open spaces in Naryn and developed site-specific greening proposals, leading to the planting of 60 saplings in two of the town's most environmentally vulnerable locations and the organization of a jointly led tree-planting event formally acknowledged by the Mayor's Office. These outcomes illustrate how targeted capacity building – grounded in local needs and reinforced through practical application – can convert limited initial knowledge into sustained community engagement, strengthen trust between residents and institutions, and establish the foundations for locally driven and maintainable urban greening in Naryn.

4.4 Mudflow Collectors as a Community-EndorsedNBS

The implementation of mudflow collectors in Naryn provides a further illustration of how local stakeholder engagement mechanisms were applied in practice and how NBS-aligned interventions contributed to tangible urban resilience outcomes. Findings from the 2023 Integrated Habitat Assessment (IHA) identified mud and debris flows as one of the most severe natural hazards affecting the town. The assessment mapped seventy-four ravines to the south and six to the north of Naryn that pose direct flood risks to residential areas, roads, and critical urban infrastructure. In total, eighty-eight mudflow sites were classified as high-risk, exposing both human life and property to recurrent hazards. These results were communicated to municipal authorities and local stakeholders, forming the basis for joint prioritisation of intervention sites.

Rather than applying a purely engineering-led response, NURP aligned technical recommendations with local knowledge and institutional capacities. The IHA proposed constructing mudflow baffles, reinforcing channel banks, and developing mudflow storage reservoirs where appropriate. These recommendations were discussed with municipal services, residents of exposed neighbourhoods, and representatives of the Ministry of Emergency Situations, enabling a shared understanding of risk and intervention options. This process contributed to local acceptance and trust, as stakeholders could directly link the proposed actions to the risks identified through participatory assessment.

The resulting implementation at the Mazar-Bulak and Chygysh-Bulak sites in the eastern part of Naryn marked a key programme milestone. The mudflow collectors employed gabion-based structures – wire-mesh containers filled with locally sourced stone – which serve as nature-based solutions by combining natural materials with adaptive engineering. These structures stabilise slopes, slow debris flows, reduce erosion, and enhance flood management while remaining compatible with the surrounding landscape. Their construction not only reduced exposure to recurrent mudflow risks but also strengthened the protection of nearby residential neighbourhoods and critical urban assets.

The intervention demonstrated how NBS can serve as an entry point for co-creation even in technically complex infrastructure projects. Residents acknowledged the works positively, while municipal authorities and the regional subdivision of the Ministry of Emergency Situations emphasised their strategic value, noting that the facilities could benefit approximately 25 per cent of the town's population and significantly reduce the need for costly household resettlement from high-risk zones. In this sense, the mudflow collectors illustrate how aligning NBS actions with locally identified risks and priorities can build institutional trust, enable cross-sectoral collaboration, and deliver resilience outcomes that are both socially legitimate and functionally effective in a mountain urban context.

4.5 Participatory Planning for Urban Greening

The cumulative effects of sustained needs assessments, targeted capacity development, and trust-building engagement under the NURP culminated in a significant governance milestone: an invitation from local government to co-develop the town's future development trajectory. Under the leadership of the First Deputy Governor of Naryn Oblast, a formal Working Group was established to prepare the Green Naryn Five-Year Development Plan. This step reflects what recent studies identify as a critical condition for successful urban greening – namely, the transition from consultative participation toward the meaningful involvement of local populations in decision-making processes, which has been shown to strengthen both project effectiveness and long-term stewardship (Ferreira et al., 2020; Puskas et al., 2021). As part of this initiative, the Government of Naryn formally requested technical and strategic support from the University of Central Asia and the Aga Khan Foundation, recognising the value of expert input aligned with locally articulated priorities.

To ensure balanced representation and coordinated decision-making, the Working Group includes representatives from the Naryn Governor's Office, the Naryn Mayor's Office, the NURP team, and residents. This institutional configuration reflects a deliberate effort to embed community engagement within formal governance structures, thereby addressing the gap between participation in project implementation and participation in strategic planning. Notably, the invitation to co-develop the town's green future emerged from a demonstrated process of capacity building and collaborative action, rather than from symbolic inclusion, signalling increased institutional trust in community-informed planning.

The integration of nature-based solutions into this participatory planning framework further reinforces their role as both ecological and social infrastructure. By involving residents directly in shaping the Green Naryn Five-Year Development Plan, the process aligns NBS interventions with local values, cultural practices, and everyday uses of urban space – factors the literature associates with greater acceptance and sustained maintenance. In this respect, the NURP experience operationalises key insights from participatory NBS research by translating engagement into shared responsibility and long-term commitment.

Through community-based greening projects, structured training programmes, and sustained stakeholder engagement, NURP has enabled residents to move from passive beneficiaries to co-governors of their urban environment. The participatory planning process thus represents both the culmination of earlier engagement mechanisms and the institutionalisation of co-creation, embedding stewardship of green infrastructure within the social and governance fabric of Naryn and laying the foundation for resilient, locally owned urban development in a mountain town context.

5 CONCLUSION

The Naryn case demonstrates that NBS adoption became meaningful and scalable only after aligning interventions explicitly with locally articulated needs, risk perceptions, and capacities. Through iterative needs assessments, participatory diagnostics, and the use of spatial and ecological data, NURP translated abstract resilience goals into locally relevant actions – ranging from native-plant-based urban greening to mudflow risk reduction – thereby strengthening community engagement not as an objective in itself, but as a response to tangible everyday concerns.

The findings further show that engagement deepened as residents moved from consultation to co-development, supported by targeted capacity-building and practical learning. Blended learning approaches – combining digital tools, recorded online lectures, and hands-on field activities – played a critical role in enabling residents to understand, apply, and maintain NBS in a resource-constrained mountain environment. Practical application, mentorship, and site-based experimentation proved especially important in translating theoretical knowledge into durable practice, reinforcing trust and confidence among local stakeholders. In this sense, participation functioned not merely as a governance mechanism but as a learning process through which communities developed the ability to co-create and steward green infrastructure over time.

From an institutional perspective, the Naryn case highlights the importance of co-governance structures in enabling co-creation. The gradual shift from project-level engagement to formalised participatory planning – culminating in the establishment of a multi-stakeholder working group for the Green Naryn Five-Year Development Plan – illustrates how sustained engagement can reconfigure power relations between communities and authorities. Socio-cultural factors, a powerful place-based identity, and local pride in Naryn as a historic Kyrgyz town served as latent enablers of participation. At the same time, initial low levels of civic activism underscored the need for trust-building and capacity development as preconditions for co-creation. Conversely, constraints emerged where technical expertise, financial continuity, or institutional mandates were insufficient to support long-term maintenance, underscoring the need for adaptive management and sustained investment.

Overall, the NURP experience confirms that NBS's success in mountain cities depends as much on social resilience as on environmental design. The combination of participatory greening, native-plant-based NBS, and digital planning technologies created a practical pathway toward resilient, energy-efficient, and climate-adaptive urban development in Naryn. By embedding engagement as a core operational principle rather than a symbolic exercise, the programme enabled residents to transition from passive beneficiaries to active co-creators of their urban environment. As such, Naryn serves as a reference case for how community-driven,

needs-based NBS governance can be operationalised in remote and climatically vulnerable urban contexts, offering transferable lessons for similar towns across Central Asia and beyond.

Overall, the NURP experience confirms that the success of NBS in mountain cities depends as much on social resilience as on environmental design. The combination of participatory greening, native-plant-based NBS, and digital planning technologies created a practical pathway toward resilient, energy-efficient, and climate-adaptive urban development in Naryn. By embedding engagement as a core operational principle rather than a symbolic exercise, the programme enabled residents to transition from passive beneficiaries to active co-creators of their urban environment. As such, Naryn serves as a reference case for how community-driven, needs-based NBS governance can be operationalized in remote and climatically vulnerable urban contexts, offering transferable lessons for similar towns across Central Asia and beyond.

Beyond its empirical insights, this study offers both theoretical and practical contributions for cities and towns facing similar environmental, institutional, and socio-economic constraints. Theoretically, it advances the literature on participatory urban resilience and nature-based solutions by demonstrating how needs-driven, bottom-up engagement operationalises co-creation in practice. The Naryn case shows that community engagement becomes transformative when it is anchored in locally articulated needs, supported by capacity development, and embedded within co-governance arrangements. In mountain urban contexts – often characterised by remoteness, limited institutional capacity, and high climate vulnerability – the study highlights the importance of integrating socio-ecological resilience theory with collaborative governance and experiential learning frameworks. It thus contributes a refined understanding of how trust, local ecological knowledge, and institutional openness interact to enable sustained co-creation beyond project cycles.

From a practical perspective, the findings offer a replicable pathway for policymakers, development agencies, and practitioners working in Central Asia and other transitional or resource-constrained regions. Key lessons include the value of combining participatory needs assessments with spatial and ecological data; the effectiveness of blended learning and "learning-by-doing" approaches in building local capacity; and the role of native-plant-based NBS in aligning ecological restoration with cultural identity and community ownership. The Naryn experience underscores that durable NBS outcomes require institutionalisation – through formal working groups, participatory planning frameworks, and long-term investment in training and adaptive management. Taken together, these lessons suggest that cities seeking to scale NBS should move beyond technical replication and instead focus on process replication: aligning interventions with local needs, fostering co-governance, and enabling communities to act as long-term stewards of urban resilience.

Co-Productive Project Development in Urban and Regional Planning

Sarah C. Schreiner

(Dr. Sarah C. Schreiner, D2S Urban Development Hamburg, Margaretenstraße 39, D-20357 Hamburg, research@d2s-planung.de)

1 ABSTRACT

Co-production is gaining prominence, both as an analytical term and as a conceptual framework applied to urban and regional planning, during the last years (Lee et al. 2024:237). There is no single definition, there are various (Valencia et al. 2020; Bandola-Gill et al. 2023). Often the term is used unspecified.

Here, co-production means the collaborative process where citizens, stakeholders and professionals work together to design, develop, and implement projects or policies to "make a city" or transform regions. Therefore, co-production can be a powerful, people-centered approach to urban and regional planning.

Currently, urban planners, who face complex challenges in terms of population and economic development as well as urban renewal in deprived neighbourhoods, are increasingly discussing planning cultures, actor-specific modes of interaction and communication-based goal achievement. New forms of cooperation can be tested and learning effects generated by examining how mutual expectations, participation and trust-building are handled.

Representatives of private-sector, intermediary or civil society interests are no longer merely the recipients of government procedures, programmes and projects. Rather, as co-producers, they actively shape urban spaces and become relevant cooperation partners for urban planning and economic development. They therefore assume control functions and responsibility for space-forming processes themselves.

The findings of this paper are based on research conducted with qualitative analysis of literature review and of semi-structured interviews with municipal stakeholders and business owners. As a result, a research model for the analysis of co-productive value chains was developed. On behalf of analysis of different examples of value-creation-chains of cultural service and manufacturing firms it is shown that co-production needs equal, networked forms of communication and cooperation as well as specific location conditions.

As a result, co-production should not be seen as a planning tool or technique, but as a paradigm shift for future urban development. It enables to integrate different needs and expectations as well as innovations in all phases of spatial project development at eye level by addressing multi-actor involvement differently from established forms of collaborative planning.

Keywords: Governance, co-production, urban design, collaboration, innovation

2 WHAT IS CO-PRODUCTION ?

Co-production is gaining prominence, both as an analytical term and as a conceptual framework applied to urban and regional planning, during the last years (Lee et al. 2024:237). The concept of co-production can therefore be used to examine regional value creation processes. It can also be used as a tool for project development in urban and regional planning.

There is no single definition, there are various (Valencia et al. 2020; Bandola-Gill et al. 2023). Often the term is used unspecified. Here, co-production means the collaborative process where citizens, stakeholders and professionals work together to design, develop, and implement projects or policies to "make a city" or transform regions. This refers to collaborative production processes with reciprocal exchange relationships at a predominantly horizontal level (s. figure 1).

Co-production never proceeds in a linear fashion, but rather involves a wide range of discussions and deliberations, and does not involve any central decision-making positions. As a result, such processes (often) take place outside the formal procedures of urban planning and economic development, which are anchored in building regulations and fiscal policy, among other things.

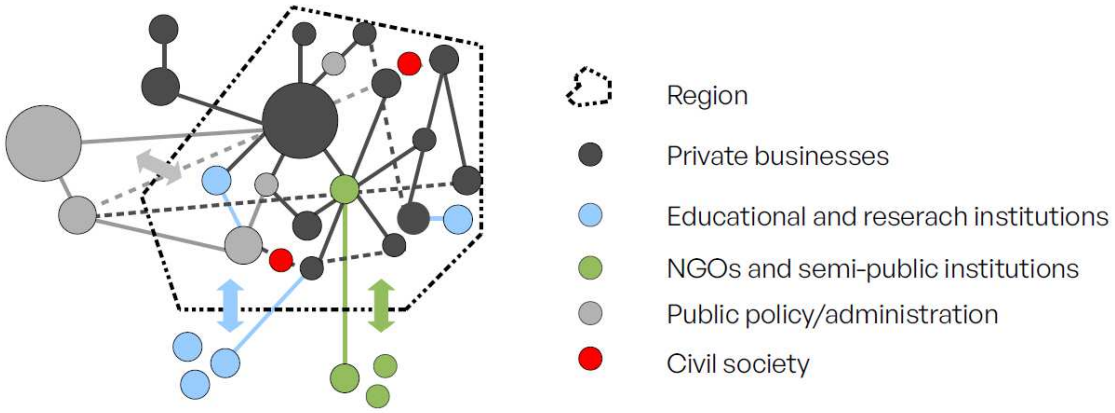

Fig. 1: Reciprocal exchange relationships of various stakeholders within a region (S. Schreiner 2026)

3 THESIS AND RESEARCH METHODS

My thesis is: Co-Production functions different from just participation or strategic urban governance – it involves shared responsibility, shared knowledge, shared infrastructure and shared power to produce sustainable space and shape productive livelihoods. New forms of cooperation and co-production can be tested and learning effects generated by examining how mutual expectations are handled, how participation on an equal footing is achieved, and how trust is built.

If conducted right, co-productive project development can supply integrated, innovative and sustainable solutions for reshaping, restructuring and maintaining urban or regional areas. Aim of this article is to inspire and discuss, how co-production can be more than just participation if it involved shared responsibility, shared knowledge, and shared power.

Findings of this paper are based on research conducted with qualitative analysis of literature review, of case studys and of semi-structured interviews with municipal stakeholders as well as business owners.

4 WHY CO-PRODUCTIVE PROJECT DEVELOPMENT MATTERS FOR URBAN AND REGIONAL PLANNING

Co-production has been considering to play an important role in dealing with various challenges and complex problems (Lee et al. 2024, Matyushkina et al. 2024:721). Therefore the concept of co-production has become increasingly popular across disciplines. The ambiguity of the concept has increased as well.

The term has been researched in different disciplines and areas, e.g. policy management (as a governance concept), public management and administration, healthcare, environmental science and social care (Brandsen et al. 2017; Bandola-Gill 2023). In the field of urban and regional planning there is literature available especially in relation to digital participation, mobility, cultural economic services, urban living labs and also the role of universities (Lee et al. 2024; Valencia 2020:115 ff.).

The concept of co-production had been first mentioned within planning theory around 1970 in the context of citizen involvement in planning processes (Arnstein 1969), but has gained popularity as an transdisciplinary approach to multiactor knowledge production especially during the last ten years (Simon 2021:5). The further development of Arnstein's Ladder of Citizen Participation (Arnstein 1969) focuses today on processes in which professional and civic expertise lead to joint planning outcomes (s. figure 2).

It shows that co-production, as a process of equal and reciprocial partnership and communication, functions differently from established forms of collaborative planning (Lee et al. 2024; Simon 2021). Co-production is based on bottom-up-activities instead of top-down-processes, expert and citizen input instead expert driven, open dialogue instead of limited transperancy, citizens act as co-creators instead of citizens as recipients (s. Matyushkina et al. 2024:722).

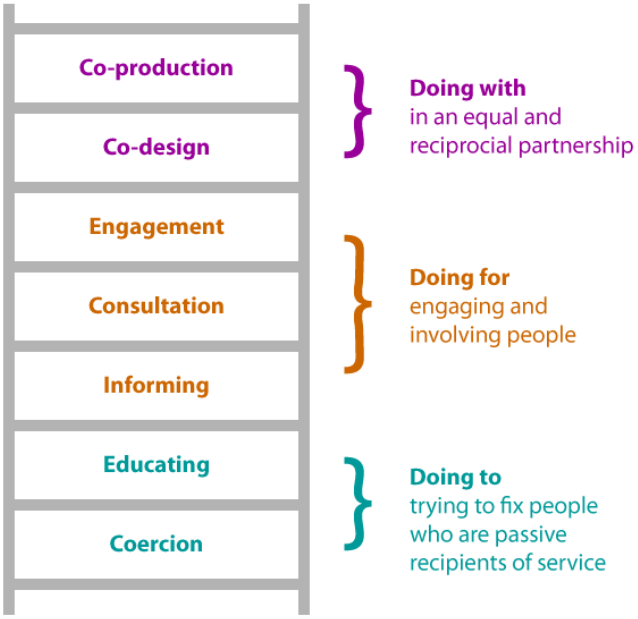

Fig. 2: The co-production ladder (Source: LELAN 2022)

So, co-production shifts planning from a technical task, througouht participation and co-creation as a hybrid governance approach, to a democratic process. That makes the concept of co-poductive project development attractive for urban and regional planning not only in Europe and the United States of America, but also in developing countries. It has been applied by different disciplines and in different contexts, for example, to cope with informal settlements in Asia or lack of water infrastructure in Sub-Sahara Africa (Hoelzel 2024).

Public authorities, from the local to the national level, increasingly expressing their will to integrate participation or co-production into their urban development strategies; they are trying to activate civil society and stakeholders to meet the demand of a changing society and complex spatial problems, especially in urban areas (Brandsen et al. 2017:677). For example, the European "New Leipzig Charta" describes new forms of participation like co-creation and co-design as important aspects for urban development and "productive cities" (BBSR 2020:8). Participation of the public and stakeholders is addressed to "consider their concerns and knowledge" (BBSR 2020:38). Different planning cultures, actor-specific modes of interaction, and communication-based goals come together in planning processes. But, the New Leipzig Charter also acknowledges that there is a "lack of clear and transparent processes, requirements and specific objectives" (BBSR 2020:44) which remains unsolved.

Co-production project development adresses:

- Better fit with local needs
- More inclusive outcomes
- Higher legitimacy and trust
- Greater innovation through diverse perspectives

Threfore, co-productive project development enables groups to take ownership over participatory processes and can foster learning and innovation processes.

This distinguishes co-productive approaches from forms of urban planning and regional governance in which value chains are viewed on the basis of clusters, cultural value creation models or the concept of innovative milieus. Since cooperation activities in clusters are highly institutionalized, they are particularly suited to hierarchical forms of management (s. Porter 2000; Pratt 2015). The cultural value creation model can be used to examine individual activities and actors, their interactions, and inputs and outputs; this allows linear processes to be examined (Canadian Minstry of Industry 2004:13). However, this research model cannot represent exchange and interactions, feedback, and joint product development within spatial context. The concept of innovative milieus allows the innovative power of urban spaces to be examined on the basis of locally networked companies and individuals (Camagni 1991). Personal information exchange and diverse

collaborations lead to collective learning processes; the specific location serves as a resource for innovation. This allows bottom-up processes and interactions to be examined, but they remain diffuse in terms of spatial resources.

5 THE ROLE OF SPACE FOR CO-PRODUCTION

If the concept of co-production shall be applied in urban and regional planning projects, learning processes and stakeholder engagement across phases of co-design, co-implementation and co-assessment need to be enabled and integrated. Outcomes of such projects and processes are difficult to measure because of their immaterial nature. Analyzing the role of space can help to present co-productive project results.

A more concrete analytical model is needed for a systematic empirical investigation of spatially anchored co-production processes. Activities from the private, intermediary, and public sectors should be considered on a region-specific basis in all phases of value creation. Based on literature analysis, and analysis of different examples of value-creation-chains of cultural service and manufacturing firms, I have developed a research model that can be used to visualise and analyse co-productive processes between authorities, companies, intermediary organizations and private individuals – on different spatial scales (s. figure 3).

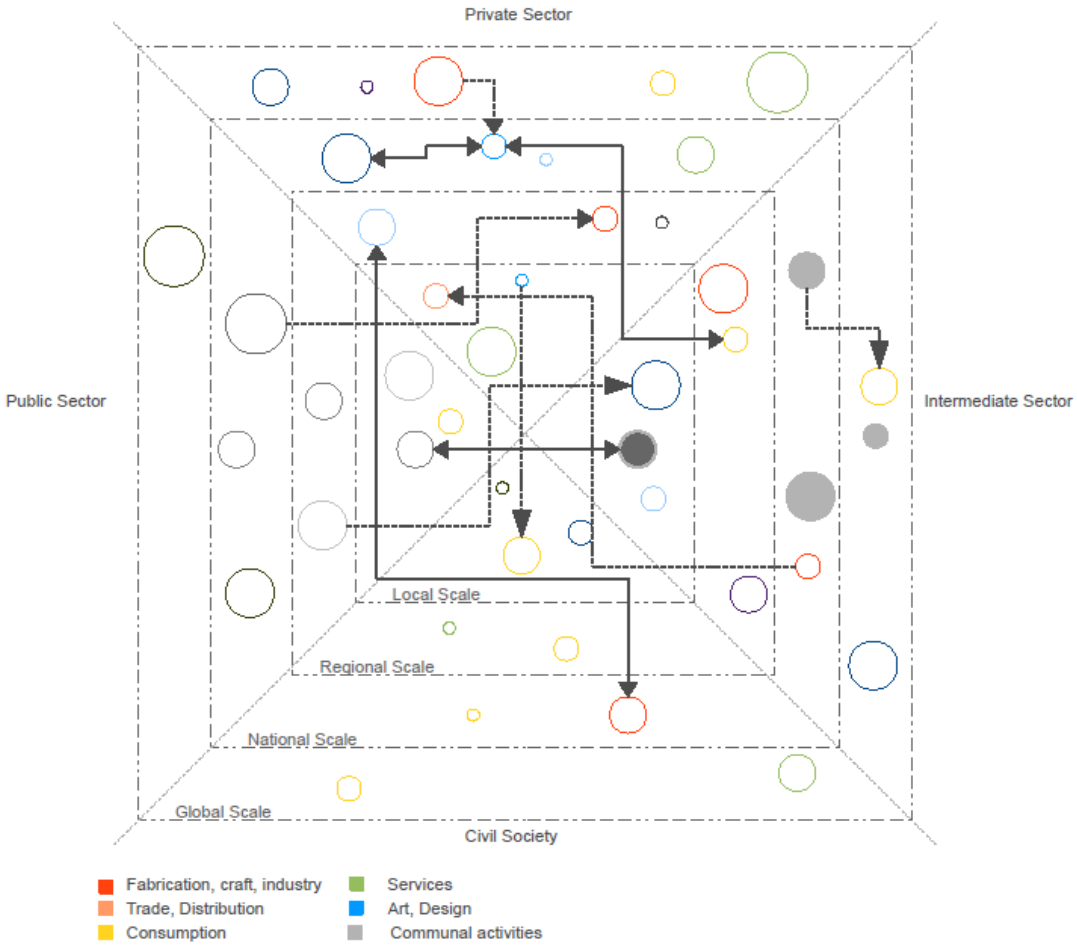

Fig. 3: Research model for the analysis of co-productive value chains (S. Schreiner 2026)

It shows, that the role of space in co-productive project development can be various and needs to be focused on different scales ¬ like the local scale, the regional scale or the global scale:

- Space as a resource (real estate, use of buildings);
- As social and cultural environment where co-production grows;

- As area for innovation processes, like co-creation (as design-construction-distribution as networked communication and production process);
- As arena for discurs or conflicts, e.g. do-it-yourself constructions (e.g. the district of Christiania in Kobenhagen/Danmark as a merely self-organised neighbourhood development processes).

Below, two very different typologies for applying the model are outlined, which were generated from interviews with 30 companies from the fields of architecture, design, planning, craft and industrial production. The companies were anonymised at the request of the interviewees. For each typology, approaches for space-related co-productive project development are outlined.

5.1 Typology: The departing company

The departing company is an typical example of a design company that will relocate its business premises. The reason for this is that their opportunities for local and regional cooperation with industrial manufacturers and craft-based production companies are dwindling. This means that opportunities for cooperation are becoming increasingly limited. In this case, the migrants are a fashion design label with two partners who mainly design unique pieces and small series. They produce the unique pieces themselves. For the production of small series, they cooperate with three freelancers (s. figure 4). For sophisticated collections, they rely on local sewing workshops with several employees as suppliers, who guarantee fast and high-quality production. They rarely need large quantities or intermediate products. Due to lower labour costs, they have these produced in large sewing factories in Poland, the Czech Republic or other international locations. As local cooperation partners for design, production and distribution processes dwindle, those who leave cannot maintain cost-efficient, local manufacturing. As interviews with other entrepreneurs in this field have shown, the comparatively high commercial property prices and labour costs at the company's location lead to high design as well as textile craftsmanship costs. According to the interviewees, this is offset by relatively low acceptance among end customers of the corresponding high end product prices. Since co-productive design and manufacturing processes are important everyday practices for those who are leaving, they are planning to relocate their business to a city with lower commercial property costs. One interviewee said: ‘Actually, it's nonsense to do this just to cover the costs; you might as well not bother.’ To counter this with project development approaches:

This type of business, which combines design, operational organisation, quality control, presentation, sales and the manufacture of fashion products, is particularly suited to studios and lofts with a maximum usable floor space of 100 square metres. The commercial space for this type of business does not need to be centrally located in the city, but should be easily accessible for customers and employees. Dialogue-oriented approaches should focus on expanding contacts and cooperation partners, especially with local craft businesses and small factories, as well as public relations work for expanded distribution channels.

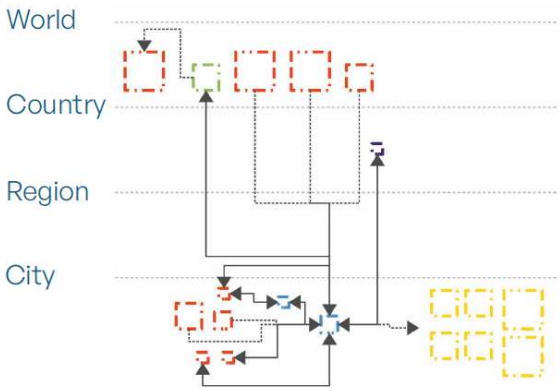

Fig. 4: Co-productive value chains of the departing company (S. Schreiner 2026)

5.2 Typology: The locally embedded company

The typology of those embedded locally develop and implement innovative ideas, themes and technologies from various disciplines of landscape design and horticulture. The city where your company is based always

forms the centre of your activities: ‘We travelled throughout the country, always starting from our office location’ (interview with the owner of the company). However, as there are not enough orders for the company in the region, they also work for clients at various locations throughout Germany. The office is integrated into a diverse network of local, regional and national interactions. The illustration depicts the situation explained in the interview regarding project processing. Creative service providers mainly engage in local and horizontal cooperation (s. figure 5). There is also mutual exchange with a municipal consulting company. Craft businesses mainly act as suppliers at local and regional level. Customers are medium-sized or large companies, city or municipal administrations. The office has been established at its local location for many years. There are no plans to relocate the business, even though there are not enough orders in the region to ensure the economic survival of a company of this size. Accordingly, employees must be mobile and work remotely in order to temporarily work on nationwide projects. This example shows that I can develop a planning company steadily at its location over many years despite difficult local income generation. In this case, this is achieved through constant and diversified exchange relationships: the company operates nationwide and has a wide range of cooperation partners and suppliers from service and craft businesses. This typology also shows that even a micro-enterprise can be sufficiently efficient to handle projects for large end customers in a flexible and professional manner.

Suitable commercial premises for companies such as these are purely office spaces in commercial properties in mixed-use or commercial areas. They should have good transport links. The office space should be available exclusively to a company such as the local embedded company. Shared use of a conference room with other companies in the building is possible (optional). This guarantees short distances for meetings with business partners. Strengthening interdisciplinary contacts supports local stabilisation. Interdisciplinary themed events such as discussion evenings can contribute to this. Specific public relations work tailored to the field of activity can also support local stabilisation as this can promote sales.

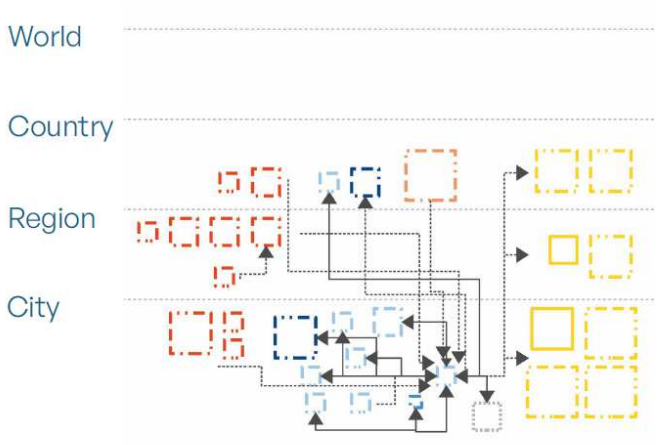

Fig. 5: Co-productive value chains of the locally embedded company (S. Schreiner 2026)

6 PLANNING TOOLS FOR CO-PRODUCTIVE PROJECT DEVELOPMENT

Multi-actor involvement with shared power and responsibility in spatial development projects has to deal with complexity, but can also lead to better outcomes if the right tools are used. Various planning tools can enhance and support co-productive project development in urban and regional planning (s. Matyushkina et al. 2024:733f., Külvik et al. 2021). Recommendations for action to promote co-productive activities, extracted from interviews and literature analysis are as follows:

- Face-to-face communication at community engagement events. Informal communication formats to promote personal contacts and, above all, horizontal cooperation with representatives of companies, government agencies and intermediary organisations;
- Urban (co-)design pilot projects;
- Participatory budgeting of public funds;

- (Digital) Platforms (e.g. citizen portals, online mapping). Establish a national public profile for specific areas of activity in order to improve acceptance and sales of locally developed or manufactured products;
- Affordable real estate;
- Flexible land-use (multi-use options).

Specific cooperation and information events are suitable for supporting the networking of potential business partners and planning stakeholders at a horizontal level. This may require that such activities are not limited to individual sectors, but also involve representatives from trade, industry, commerce, and science on a case-by-case basis.

In this context, planning and funding stakeholders should take on more of a moderating role in order to be able to act on a horizontal level. Their influence should focus on partnership-based cooperation. Local authorities can also support co-productive project development with tools such as building land allocation, flexible land use planning, financial support for certain construction projects, or hands-on support of co-creation processes of public open spaces.

Technology like online mapping tools can enhance co-production, but tech should support – not replace – human interaction. Critics about tech-based planning tools argue that e.g. elderly or marginalised groups might not have resources or knowledge to use such tools (cf. Külvik et al. 2021). Supporters of tech-based planning tools argue instead that it depends on the right type of information, human support and learning opportunities for elderly or marginalised groups to reach digital services and tool. For example, in Estonia online collaboration platforms like TOM/TID+ or Maptionnaire are used by a lot of different citizens, because digital public services are common and spatial data is often used for smarter cooperation.

The integration of digital tools can improve reach and responsiveness. But it can also distract or exclude certain people/groups from project participation.

7 DISCUSSION AND CONCLUSION

In addition to everyday knowledge, co-productive urban development requires a wide range of expertise on the respective planning objectives, as well as mutual trust and openness to new ideas among all those involved. This calls for a specific planning culture that reflects local characteristics, is based on a common language, and is constantly evolving.

Representatives of private sector, intermediary, or civil society interests are no longer merely recipients of government procedures, programs, and projects. Rather, as co-producers, they actively shape urban spaces and become relevant cooperation partners for urban and regional planning. They therefore take on control functions and responsibility for space-creating processes themselves.

Overall, it depends on the project- and location-specific interaction between formal and informal, hierarchical and heterarchical coordination between public and private sector actors. Top-down planning approaches and context-specific control are less suitable for this than bottom-up processes and direct support activities.

Planning tools and resources should be used dynamically, but also complementarily, and should lead to joint decisions. However, this requires intensive coordination across departments and topics. It also requires public sector representatives to question their ability to act on their urban development goals and to take on appropriate roles as mediators, moderators, or co-production partners, or to delegate these tasks to suitable actors.

Co-production should not be seen as a planning tool or technique, but as a paradigm shift for future urban development. It enables to integrate different needs and expectations as well as innovations in all phases of spatial project development at eye level by addressing multi-actor involvement differently from established forms of collaborative planning or urban governance.

1 ABSTRACT

The impacts of climate change create interconnected ecological, economic, and health challenges that act as multiple drivers shaping local social conditions in urban areas. While municipal adaptation strategies increasingly address physical risks such as heat, flooding, and drought, the social dimensions of climate change often remain underrepresented. Vulnerability to climate impacts, however, is not evenly distributed. Certain population groups – such as older people, children, people experiencing homelessness, and individuals with low income – are particularly at risk. Moreover, low-income neighborhoods are often disproportionately affected by heat waves. This is partly due to the fact that these areas typically have below-average access to open spaces such as parks or water bodies. Furthermore, the distance to public recreational areas often increases as household income decrease.

Against this background, the paper presents a case study on heat stress modeling in Bremerhaven, Germany. The analysis focuses on the Goethestraße district, which faces significant socio-economic challenges and holds the lowest social index of the city. Bremerhaven itself is characterized by the second-highest unemployment rate and the highest rate of over-indebtedness among all German cities. The case study employs a top-down approach using scientific data – including environmental parameters, weather observations, and regional climate projections – as inputs for model simulations conducted with the "Tygron Platform". This was complemented by a bottom-up approach involving key stakeholders from the city administration to integrate expert knowledge, local perspectives, and community-based assessments. Through this transdisciplinary and co-creative process, all major decisions – like the definition of the current and future climate scenarios to be taken into account, the potential adaptation measures to improve the thermal comfort (mainly the integration of green spaces, urban trees, and water areas), the integration of aditional stakeholders from the city admistration, the future communication of the modeling results – were taken collaboratively and on an equal footing.

Beyond conventional urban climate modeling approaches and indices commonly applied in Germany, the study also incorporates planning principles from the Netherlands, notably the 3-30-300 rule. In addition to presenting modeling results, the paper discusses possible practical adaptation options and first next steps to strengthen socially inclusive climate adaptation strategies.

Keywords: climate change adaptation, co-creation, social aspects of climate change, urban heat stress modeling , urban resilience planning

2 INTRODUCTION

The impacts of climate change pose ecological and economic challenges that are also influencing and interacting with the local social conditions in urban areas (IPCC, 2022). While physical risks such as heat, heavy rainfall, or drought are increasingly considered in municipal adaptation strategies, social aspects often remain underrepresented (EEA, 2025; Teebken, 2024; Teebken & Schipperges, 2024; Juhola et al., 2022). Certain population groups – such as older people, children, the homeless, or individuals with low income – are particularly more vulnerable to climate impacts (Etzel et al., 2024; Prina et al., 2024; Proulx et al., 2024; IPCC, 2022; Swanson, 2021). Especially heatwaves disproportionately affect low-income urban neighborhoods. This is for example because compared to more wealthy neighborhoods, socially disadvantaged ones often show higher proportions of sealed and developed land. In combination with an associated lack of shades from trees or cooling effects of green spaces and water bodies, these districts can heat up more easily. Additionally, housing conditions in these areas tend to exacerbate vulnerability, as buildings are often poorly insulated and overcrowding limits opportunities for retreat during extreme heat events. Therefore residents are often unable to find relief from heat at home or within walking distance of their homes (Yin et al., 2023; IPCC, 2022; Rehling et al., 2021).

These circumstances for example contradict one of the goals of the Federal Climate Adaptation Act (KAnG)[1] – the German regulatory binding framework for climate change adaptation – aiming to prevent the increase of social inequalities caused by the negative impacts of climate change. Additionally, the German Strategy for Adaptation to Climate Change[2] aims to strengthen the resilience and resistance of ecological systems, the economy, and society to create equal living conditions. In this context, impact assessments are key for developing climate adaptation concepts. However, the use of the commonly used models to examine spatial vulnerabilities often focuses solely on identifying hot spots related to land use and building structures, only indirectly addressing social issues. However, it is important to also consider social aspects from the outset, as a one-sided focus on physical exposure can lead to maladaptation.

Against this background, the paper presents a case study of heat stress modeling for the district Goethestraße in Bremerhaven, Germany.[3] The Goethestraße is characterized by significant socio-economic challenges. It has the highest population and building density in Bremerhaven and is marked by high proportions of residents with migration backgrounds as well as children and adolescents, of which about one-half live in households receiving basic income support for job seekers. Overall, the district has the lowest social index in Bremerhaven – a city that itself in 2024 had the second-highest unemployment rate (14.5%) and in 2025 was the city with the highest rate of over-indebtedness (18.3%) in Germany (Creditreform, 2025; Statista, 2025).

To assess current and future heat stress and to estimate the effectiveness of potential adaptation measures, heat exposure and the impacts of various scenarios were simulated for the Goethestraße district using an urban climate module of the “Tygron Platform”. The analysis also focused on testing the applicability of this modeling tool, which relies on simplified process assumptions and is commonly employed in the Netherlands to support the implementation of the 3-30-300 rule in urban planning (Konijnendijk, 2024; 2023; 2021). This guideline stipulates that residents within a neighborhood should: i) be able to see at least three trees from their home or workplace, ii) benefit from a minimum tree canopy cover of 30%, and iii) live no more than 300 meters away from a green space or park suitable for recreation. A secondary objective was to explore, through scenario-based simulations, how local heat stress is projected to evolve under future climate conditions and to what extent different adaptation measures can contribute to improve the thermal comfort.

The case study includes a top-down approach based on scientifc data – containing environmental data, weather observations and results from regional climate projections – as input for the model simulations carried out by the Tauw GmbH using the “Tygron Platform”. This setting was combined with a bottom-up approach involving local key stakeholders to incorporate local expert knowledge, stakeholder perspectives, and community-based assessments. Based on this transdisciplinary and co-creative approach, all key decisions – like the definition of the current and future climate scenarios to be taken into account, the potential adaptation measures to improve the thermal comfort (mainly the integration of green spaces, urban trees, and water areas), the integration of aditional stakeholders from the city admistration, the future communication of the modeling results – were taken collaboratively.

The paper is structured as follows. Section 3 briefly highlights main aspects regarding the current discussion on social aspects of climate change. Section 4 introduces the destrict Goethestraße as the model region as well as the specific heat stress modeling approach. Section 5 presents and discusses the main results for all four scenarios taken into account. Section 6 concludes by summarizing main results, reflecting on the specific indicators used and highlighting possibel next steps.

3 SOCIAL ASPECTS OF CLIMATE ADAPTATION

It is in general well understood that the impacts of climate change affect different population groups with varying intensity. Older people, individuals with pre-existing health conditions, and children are most frequently identified as vulnerable groups. In addition, pregnant women, people experiencing homelessness, and outdoor workers may also face elevated risks. Socio-economic factors such as low income, insufficient

[2] https://www.bundesumweltministerium.de/DL1322-1.
[3] The specific content of the conducted modeling approach is based on the TAUW final report ‘Hitzemodellierung Bremerhaven – Ortsteile Goethequartier und Klushof’ by Zerhusen & Bauer (2025), which was developed as part of a joint project by the Climate Service Center Germany (GERICS), TAUW GmbH, and the City of Bremerhaven to create a new prototype module for the “GERICS Adaptation Toolkit for Cities”.

financial security, language barriers, and limited educational attainment further exacerbate individual vulnerability by constraining adaptive capacity. Given the high level of exposure and comparatively lower adaptive capacities of certain groups, socially equitable adaptation strategies should place particular emphasis on these vulnerable groups (EEA, 2025; Meer, 2025; Etzel et al., 2024; Prina et al., 2024; Proulx et al., 2024; IPCC, 2022; Swanson, 2021).

A key challenge lies in the fact that individual living conditions strongly shape exposure, and multiple vulnerabilities can overlap, making it difficult to derive generalized conclusions. Moreover, significant differences in adaptive capacities and needs exist both across the general population and within the different social groups. Evidence also suggests that insufficient consideration of social dimensions can further exacerbate existing inequalities within society (Spannagel & Brülle, 2024; IPCC, 2022; Swanson, 2021; Barnes et al., 2020).

Climate risk assessments, however, often focus primarily on exposure, overlooking social characteristics that critically influence susceptibility for climate change impacts. For example, Graham et al. (2018) demonstrate that risk assessments which fail to account for social factors may result in the relocation of socially connected, low-income communities without preserving their social networks – an outcome that could increase vulnerability, further marginalize these groups, and negatively affect their motivation to participate in political decision-making processes. Also the European Climate Risk Assessment (EEA, 2024), the European Commission′s Communication on Managing Climate Risks (EC, 2024), the EC′s Climate Action Progress Report (EC, 2023) and most recently the EU Preparedness Union Strategy (EC, 2025) stress the need for adaptation strategies that prioritise and focus on vulnerable populations to ensure that justice is integrated more broadly into efforts towards adaptation and societal preparedness. This highlights the critical importance of integrating socio-economic contexts alongside physical risks in assessment processes, to effectively reduce vulnerability and lower the escalating risk of maladaptation (EEA, 2025; IPCC, 2022; Shi et al., 2016; Ribot, 2014).

Despite these clear insights, recent research on subnational adaptation plans in Europe conducted by the European Environment Agency (EEA, 2025) illustrates for example a significant gap between recognition and implementation of measures with respect to social vulnerability. The study found that socially vulnerable groups are most frequently acknowledged during the early stages of the adaptation policy cycle, particularly in climate impact and risk assessments, with 68% of local adaptation plans including such considerations. However, this attention declines substantially in later stages: only 45% of plans incorporate socially vulnerable groups into specific adaptation actions, 7% monitor progress related to these groups, and 4% directly involve them in the planning process. Furthermore, only 3% of the plans examined include one or more adaptation goals explicitly addressing climate justice.

Interpreting the outcomes of urban climate analyses presents another specific methodological challenge, as these analyses typically rely on anonymized representations of cities, neighborhoods, and buildings without demographic or socioeconomic context. Nevertheless, empirical evidence indicates that heatwaves disproportionately affect socioeconomically disadvantaged urban areas (Yin et al., 2023). Income-based spatial segregation is also increasingly observable in Germany: lower-income households frequently reside in substandard housing conditions (e.g., insufficient thermal insulation, absence of air conditioning) and have limited access to cool refuges during extreme heat events. Furthermore, access to urban green infrastructure exhibits a strong socioeconomic gradient (Schüle et al., 2017; Wüstemann et al., 2017). For instance, the walking distance from residential locations to the nearest public park, tends to increase as household income decreases (Rehling et al., 2021). Overall, neighborhoods characterized by socioeconomic disadvantage demonstrate below-average provision of open spaces (Senatsverwaltung für Mobilität, Verkehr, Klimaschutz und Umwelt Berlin, 2025).

To assess local vulnerability within impact analyses, a top-down approach is commonly applied, using various indicators and local data to determine exposure. However, a key challenge lies in capturing social aspects based on specific and reliable data, as standardized indicators and externally defined descriptions of vulnerability often fail to adequately reflect the root causes and lived realities of vulnerability (Teebken & Schipperges, 2025).

To design effective adaptation and avoid exacerbating social inequalities, it is therefore essential to integrate social dimensions and justice already at the stage of vulnerability assessments. Early and inclusive

stakeholder engagement in planning, design, and implementation is a central component for ensuring socially just climate adaptation (Leuphana University Lüneburg, 2024; Teebken, 2024; Teebken & Schipperges, 2024; Juhola et al., 2022; Breil et al., 2021; Fedele et al., 2019; Shi et al., 2016). Through this bottom-up approach, local knowledge and diverse perspectives can inform the characterization of local vulnerability. Consequently, both approaches – top-down and bottom-up – are crucial for capturing social vulnerability.

4 MODEL REGION AND MODELING APPROACH

4.1 Model region: destrict Goethestraße

The district Goethestraße is predominantly characterized by dense, impervious residential areas with multi-story perimeter block development. In the northwestern section, there are several sealed residential areas with multi-story linear buildings. North of Frenssenstraße, commercial areas and some vacant lots are located. The eastern Hafenstraße features mixed residential areas combined with commercial premises. Within this district, there are vacant multi-family buildings in need of renovation – some of these so-called "junk properties" have been closed for safety reasons. Most residential buildings are privately owned, with owners often residing outside the city.

A site inspection by the project team in May 2025 revealed a significant need for heat protection measures in public recreational spaces. Although some new trees have been planted and older street trees exist along the Goethestraße and adjacent streets, there remains a considerable need to provide adequate shading for pedestrian and cycling paths. This also applies to public recreational areas. For example, the Zollinlandplatz offers only limited shaded areas, and the Leher Pausenhof consists largely of sealed surfaces with a playground lacking sufficient shade.

This need for adaptation is particularly relevant given the district's demographic and social characteristics. The population density in the Goethestraße district is approximately more than ten times higher than the average density in Bremerhaven. As a designated "arrival neighborhood", the proportion of residents with a migration background is around 51% (Magistrat der Stadt Bremerhaven, 2024), significantly exceeding the citywide average of about 17%. The share of children and adolescents is also higher at around 21% compared to the citywide average of 10%, with this group exhibiting a very high need for language support (over 80%). In general, residents of this district are heavily affected by unemployment and debt, with a substantial proportion of the working-age population (approximately 31%) receiving basic income support for job seekers (Proloco Bremen & plan zwei, 2023).

The social vulnerability of the district has been confirmed by recent monitoring efforts. As part of the social area monitoring conducted in 2023 (Magistrat der Stadt Bremerhaven, 2023), Bremerhaven's districts were analyzed and categorized based on their social situation. The classification was derived from an index value calculated using six indicators: i) need for language support, ii) proportion without a high school diploma, iii) child poverty, iv) share of employable residents receiving SGB-II benefits, v) unemployment rate, and vi) proportion of non-voters. The index value indicates the extent to which a district's social status deviates from the citywide average. The district with the lowest status value is Goethestraße, with a calculated value of -1.6. Finally, the interplay between social vulnerability and environmental stress also becomes evident by a comparative analysis of nine-year mean air temperatures (2017–2024) and the social index at the district level carried out as part of the case study. This analysis suggests a tendency for neighborhoods with lower social status to exhibit higher average air temperatures – and thus more heat stress (Klafka, 2025).

4.2 Heat stress modeling approach

To estimate where heat hotspots occur within the city and to learn about the possible effectiveness of adaptation measures, it is common practice to conduct model simulations using urban climate models. Scenario analyses allow the comparison of urban planning and meteorological scenarios based on high-resolution, spatially comprehensive data (Bender et al., 2025). A key criterion considered in these simulations is human thermal comfort, which can be assessed using various indices. These indices help to describe whether a given microclimatic situation is perceived as comfortable or uncomfortable. This perception is primarily determined by the human energy balance (Höppe, 1999), which is calculated using a combination of meteorological parameters (air temperature, humidity, wind speed) and human factors (clothing type, activity level) to quantify heat exchange at the skin surface and heat transfer within the body.

One commonly applied index – also used in this study – is the Physiological Equivalent Temperature (PET), which expresses results in degrees Celsius, thereby facilitating communication (Matzarakis et al., 1999). The classification of PET values is provided in table 1.

PET-Range in °C	Stress level	PET-Range in °C	Stress level
> 41	Extreme heat stress	13 – 18	Slight cold stress
35 – 41	Strong heat stress	8 – 13	Moderate cold stress
29 – 35	Moderate heat stress	4 – 8	Strong cold stress
23 – 29	Slight heat stress	< 4	Extreme cold stress
18 – 23	No thermal stress		

Table 1: Influence of physiologically equivalent temperature (PET) on the modeled temperature stress on humans (based on Matzarakis et al., 1999).

The calculations used the urban climate model of the "Tygron Platform". To assess urban heat stress, the "Tygron Platform Heat Module" in combination with the "Heat Stress Overlay" was utilized. An autochthonous weather pattern at a summer day was selected for the analysis of urban heat exposure. This weather type is characterized by the formation of cold-air flows during nighttime and pronounced diurnal cycles of air temperature, humidity, wind speed, and solar radiation, which amplify the effects of urban climate phenomena (Oke et al., 2017).

The evaluation of urban heat stress was based on the indicators proposed by Kluck et al. (2020): i) PET, ii) walking distance from residential buildings to public recreational areas not affected by heat stress, and iii) the proportion of shaded areas on public traffic surfaces.

The calculation of shaded areas on public traffic surfaces consider terrain elevation and urban morphology. Walking distance was determined through a network analysis of streets, pedestrian paths, and cycle routes at the building level. This analysis incorporated previously calculated PET values, assuming a threshold of 29°C to define heat-unaffected areas – corresponding to the upper limit of slight heat stress according to established classifications. Additionally, a minimum size of 200 m² was set for potential recreational areas. Private spaces and areas outside the model boundaries were not considered in this approach.

In addition, and to assess local heat distribution based on the PET as well as the effectiveness of adaptation measures, the four scenarios defined in table 2 were devoped and used within the modelling framework.

Szenario	Definition
KliStaRef	Representative current summer day as a reference scenario for describing present urban heat stress. The basis is formed by data from the climatological standard normal period (1991–2020) recommended by the World Meteorological Organization.
KliWaMed	Representative average summer day in the near future, based on the median value of regional climate projections for the period 2036–2065, considering the intermediate emissions scenario (RCP4.5).
KliWaMax	Representative extreme summer day in the near future, based on the maximum value of regional climate projections for the period 2036–2065, considering the intermediate emissions scenario (RCP4.5).
HitAnK	Representative current summer day with adaptation measures to describe present urban heat stress while accounting for the effects of potentially implementable adaptation measures (a combination of e.g. green spaces, building greening, urban trees, and reflective surface materials).

Table 2: Simulation scenarios for assessing heat stress.

5 RESULTS

The assessment of urban heat stress in all scenarios is carried out at a pedestrian-relevant height of 2 meters, using the spatial distribution of PET values. To enable a clearer evaluation of the small-scale urban climatic structure, the district was subdivided into smaller subareas representing typical urban design patterns. For the Goethestraße district, the analysis highlights in detail the following elements: (a) linear development („Zeilenbebauung"), (b) wasteland („Brachflächen"), (c) Zollinlandplatz, (d) perimeter block development („Blockrandbebaung"), (e) Leher Pausenhof, and (f) Goethestraße.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

5.1 Current situation – KliStaRef

5.1.1 Heat stress

At 2:00 p.m., the highest PET values (above 45°C) occur in the Goethestraße district between the linear building structures, in the central part of the Leher Pausenhof, as well as along the southern facades of buildings and within densely built street spaces (figure 1). The most favorable comfort conditions, characterized by slight to moderate heat stress (25°C to 35°C), are found on the shaded northern sides of buildings or beneath tall vegetation. Furthermore, the modeling results indicate that perimeter block development with a west–east building orientation generates significantly more shade compared to north–south oriented linear structures. An exception is the north–south oriented Goethestraße itself, where tree shading locally reduces PET values.

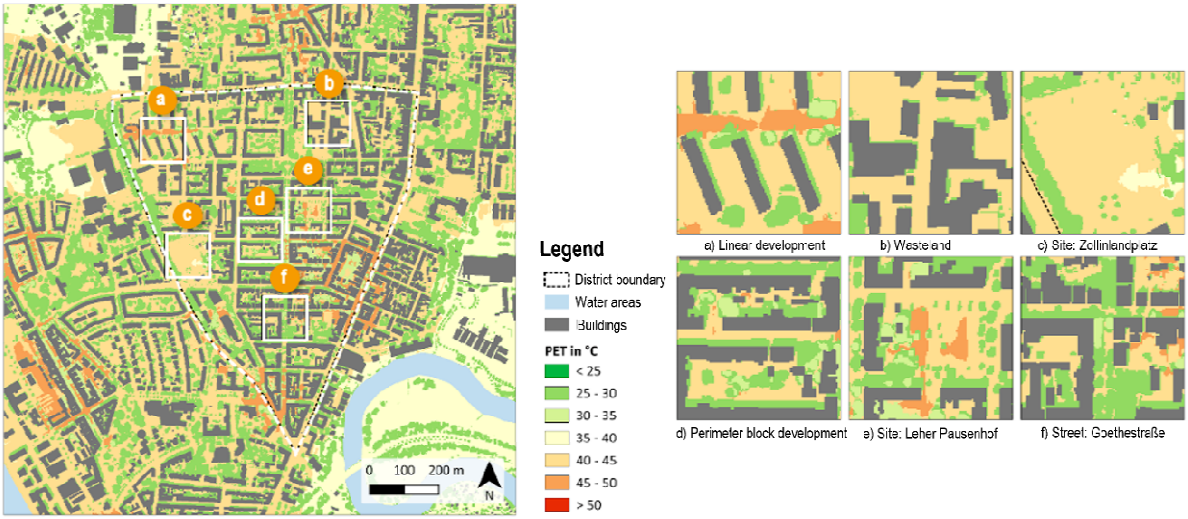

Fig. 1: PET values during the peak heat stress around 2:00 pm in the Goethestraße district for the KliStaRef scenario.

5.1.2 Shaded areas on public traffic surfaces

Between 12:00 p.m. and 6:00 p.m., the proportion of shaded areas on public traffic surfaces in the Goethestraße district varies by subarea, ranging from 41.4% (Goethestraße-North) to 51.2% (Gnesenerstraße). A detailed analysis reveals that areas such as Zollinlandplatz, the central section of the Leher Pausenhof, and many inner courtyards of perimeter block developments lack any shading during this time period (figure 2). Favorable shading characteristics include multi-story buildings, tall urban trees with large crown diameters, and narrow street canyons.

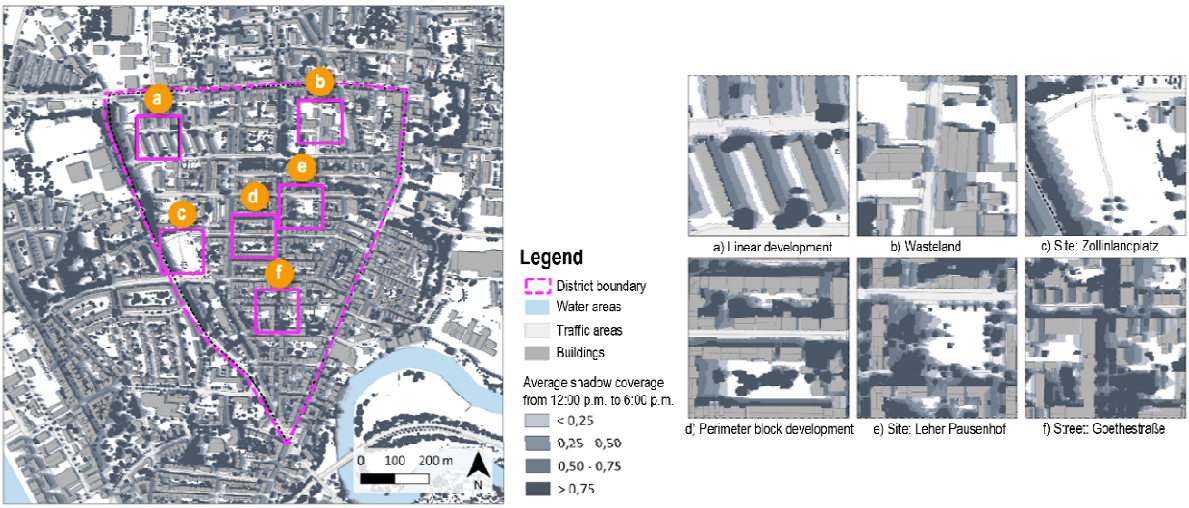

Fig. 2: Share of shaded traffic surfaces between 12:00 p.m. and 6:00 p.m. in the Goethestraße district, scenario KliStaRef.

5.1.3 Walking distance

The modeling of walking distances to heat-unaffected public recreational areas shows that in the Goethestraße district, distances of 400 m or more can occur in the northwestern and southern sections (figure 3). However, this result should be interpreted with caution, as areas with the highest values are located near the model boundaries, making it possible that recreational spaces in adjacent districts could reduce the actual walking distances.

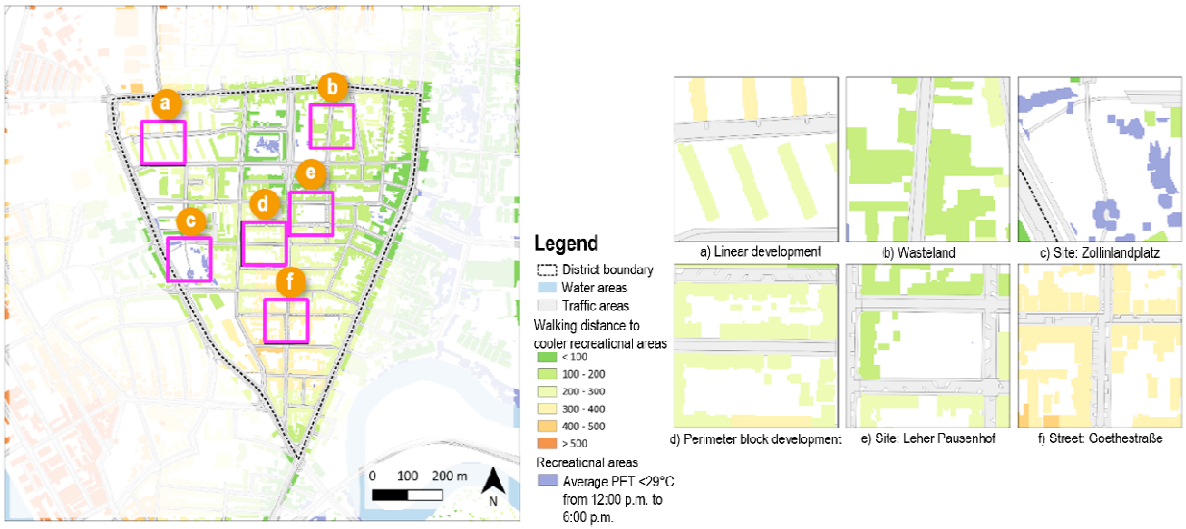

Fig. 3: Walking distance from buildings to heat-unaffected public recreational areas between 12:00 p.m. and 6:00 p.m. in the Goethestraße district, scenario KliStaRef. Areas outside the model boundary have been excluded.

5.2 Future scenarios – KliWaMed und KliWaMax

Both scenarios exhibit a comparable pattern of PET values, although thermal stress is consistently higher than in the reference scenario. Overall, PET values in KliWaMax are approximately 2°C higher compared to KliWaMed. When examining the spatial distribution of PET in the detailed subareas, heat stress in street spaces, inner courtyards, and between buildings increases further under KliWaMed (figure 4) and, in particular, under KliWaMax (figure 5). The contrast between shaded and unshaded surfaces also becomes more pronounced in these scenarios.

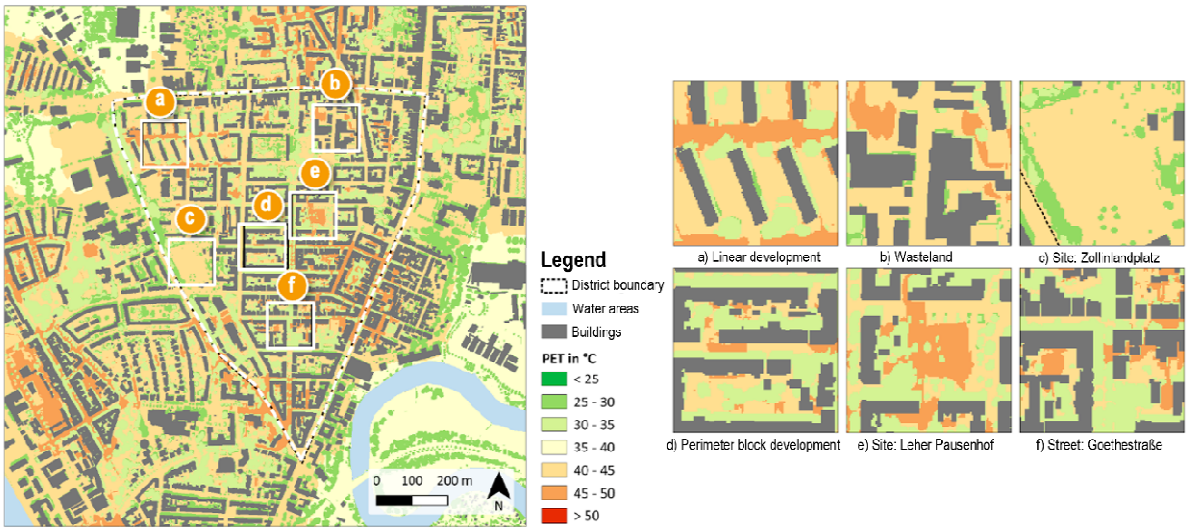

Fig. 4: PET values during peak heat stress around 2:00 pm in the Goethestraße district, scenario KliWaMed.

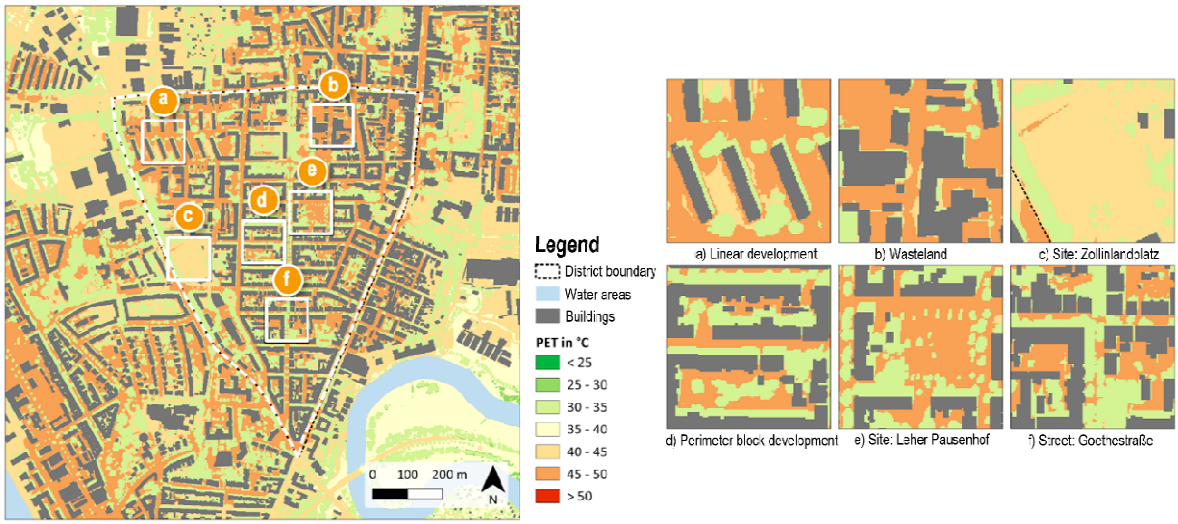

Fig. 5: PET values during peak heat stress around 2:00 pm in the Goethestraße district, scenario KliWaMax.

5.3 Current situation with adaptation measures – HitAnK

This scenario is based on the reference scenario and incorporates adaptation measures that are potentially feasible within the urban area to reduce heat-related impacts. Existing trees, buildings, and traffic surfaces were retained during implementation. Methodologically, the measures were realized by adding various green space configurations in areas such as vacant lots, parking spaces, sealed roadside strips, unused brownfields, sealed commercial fringe areas, and sealed recreational spaces. In some residential sections, tree density was increased (figure 6). In this scenario small trees (10 m height, crown diameter: 5 m), medium trees (15 m height, crown diameter: 10 m), and large trees (20 m height, crown diameter: 15 m) were included, whereas a minimum safety distance of 2.5 m between tree crowns and buildings was maintained. Planting distances were chosen based on two criteria: i) maximizing canopy closure and ii) preserving access points and parking spaces along traffic surfaces. As a measure with theoretically high visibility potential – but currently not beeing feasible in practise –, the former course of the Aue stream in the Goethestraße district was reconstructed in the model using historical city maps. This intervention widened the watercourse to 5 m and added 5 m-wide green strips with scattered tree groups on both sides of the stream. However, it has to be considered, that this model tool cannot calculate PET values above water surfaces, so that positive effects were minimal. In order to obtain a better direct comparison of all measures, another model that can calcluate PET-values over all surfaches has to be used for the modeling.

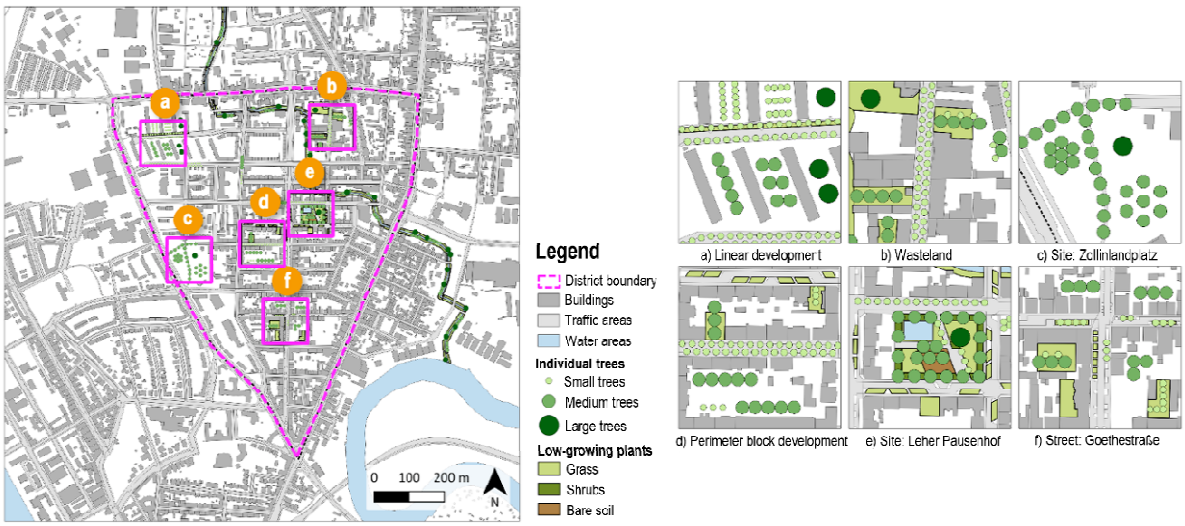

Fig. 6: Structure of the heat adaptation scenario (HitAnK) in the Goethestraße district.

When comparing the current thermal stress with a hypothetical situation in which numerous adaptation measures have been implemented throughout the model area, it becomes immediately apparent that heat stress has decreased by one to two PET classes in many locations. The expansion of shaded areas has

improved conditions between linear and perimeter block developments, in street spaces near wasteland, at Zollinlandplatz, and at the Leher Pausenhof, reducing severe heat stress to moderate or slight levels (figure 7). However, the modeling also reveals that the increased tree cover locally reduces ventilation to such an extent that small areas – such as the wasteland subarea and some southern building façades (e.g., perimeter blocks or Goethestraße) – exhibit a narrowly confined increase in PET values.

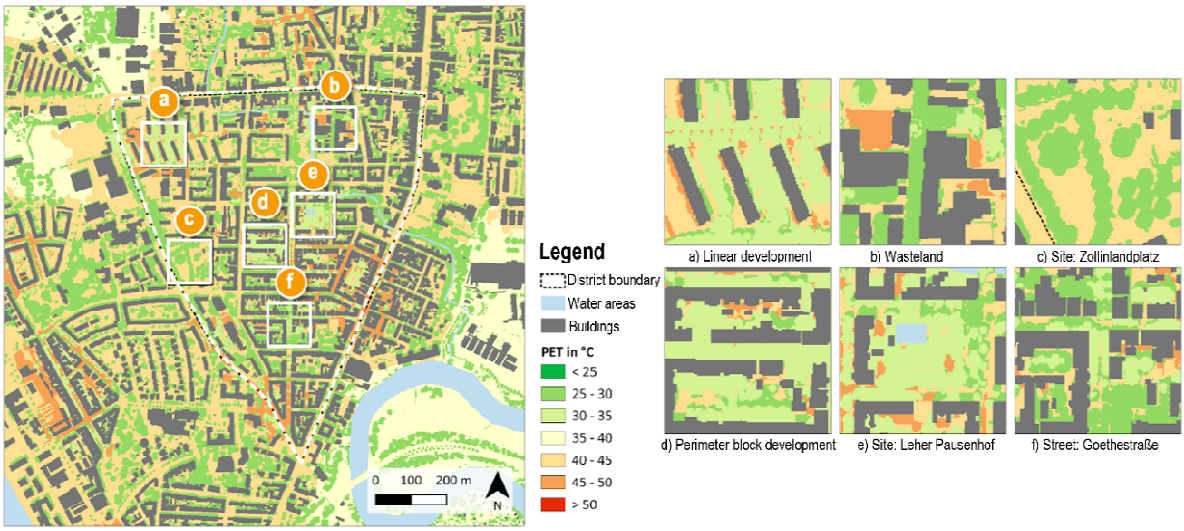

Fig. 7: PET values during peak heat stress around 2:00 p.m. in the heat-adapted Goethestraße district, scenario HitAnK.

The benefits of adaptation measures become evident when examining the difference map (figure 8). At the time of peak heat stress (2:00 p.m.), differences between the reference and adaptation scenarios range from -15.3°C to +2.3°C. Cooling effects in newly greened residential areas with low-growing vegetation reach -1.8°C (e.g., in the northern part of the vacant lots or the southern section of the Leher Pausenhof). In the shade of newly planted trees, PET values decrease up to -15.3°C, and in most cases around -10°C to -15°C. Areas planted with tree groups arranged in an east–west orientation and with close spacing provide more extensive cooling compared to tree groups oriented north–south with wider spacing. In contrast, the reconstructed course of the Aue stream appears to have a limited cooling effect in the Goethestraße district. This – as already mentioned above – can mostly explaint by specific limitation of the model approach.

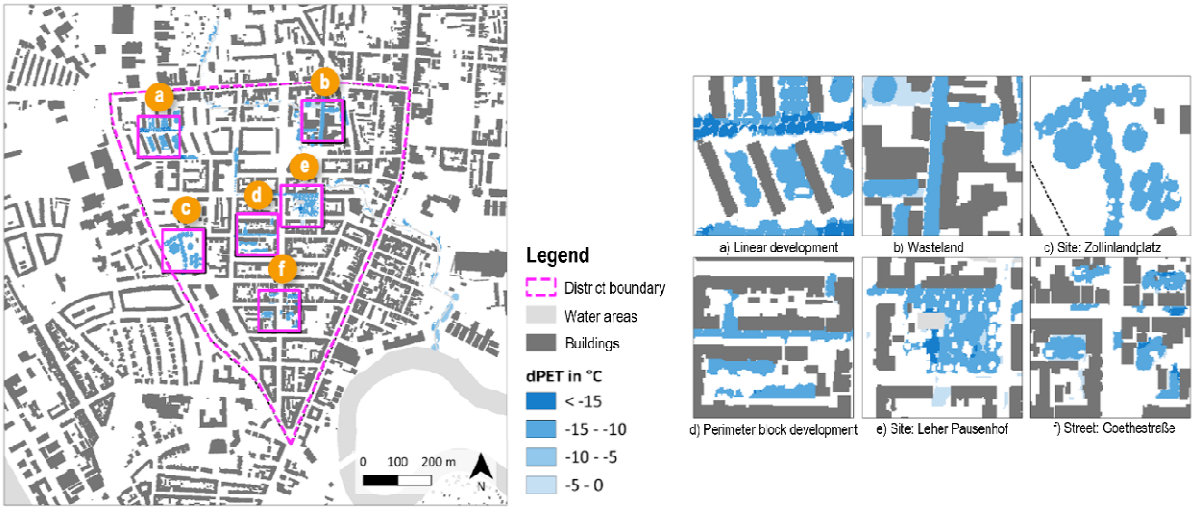

Fig. 8: Difference in PET values between the HitAnK and KliStaRef scenarios in the heat-adapted Goethestraße district during peak heat stress around 2:00 pm.

6 CONCLUSION

The modeling results indicate that the highest PET values occur around 2:00 p.m. on sun-exposed, south-facing sides of buildings or across built-up areas without any significant shading. The most favourable thermal conditions are found where surfaces are permanently – or at least for several hours – extensively shaded. Therefore, adaptation measures should primarily aim to increase shading during the midday and

afternoon hours – especially on sun-exposed facades and roofs of buildings. In addition to the use of large-canopy urban trees and building greening, technical shading elements such as sun sails or parasols can make a valuable contribution.

To provide further cooling, the proportion of shade on public spaces should be examined in more detail by analysing people's usage patterns to answer the following questions: Which traffic areas are used most frequently at which times, and which recreational spaces are primarily visited for leisure activities? From this, one can prioritise the areas and routes that should be addressed first when implementing adaptation measures, in order to improve overall thermal comfort.

As the future scenarios show, heat stress will increase in the absence of adaptation measures. It is therefore advisable to consider improved shading in street space and on public recreational areas, so that these areas can be used during the summer months now and in the future, enabling people to avoid severe and extreme heat stress in other parts of the city. This also includes the routes leading to the recreational areas. It must be taken into account, in particular, that the full benefits of tree shade only materialise once the associated trees have reached the necessary size at the appropriate age, which means that action should start as early as possible.

The spatial distribution of PET values presented here provides initial indications of where high values are to be expected. The computed values are based solely on future changes in input temperatures. Therefore, it must also be assumed that humidity and other PET-relevant variables will change and PET values will additionally shift locally. Regardless of the exact values, however, the results indicate that – and where – increasing the share of shaded surfaces is an effective means of reducing heat stress.

Decisive for the degree of area-wide heat reduction are the planting distances between urban trees and the spatial orientation of tree rows. An east-west orientation has a greater effect than a north–south orientation. Green spaces can also contribute to increasing thermal comfort, but this requires adequate irrigation. Moreover, urban trees and green spaces provide additional ecological and health benefits and help reduce flooding by improving infiltration. To ensure that urban trees can cope with the consequences of climate change in the long term, site-appropriate, climate-resilient (Roloff et al., 2013) and allergy-friendly (Bergmann et al., 2025) tree species should be used. The construction of tree infiltration trenches has proven particularly advantageous, as they retain rainwater and increase water availability for the trees, thereby reducing irrigation effort (Szota et al., 2019).

The indicator "share of shade on public traffic areas" proposed by Kluck et al. (2020) offers, in contrast to the use of thermal indices, a simple approach to assessing heat exposure along streets as well as pedestrian and cycling paths. Its application in combination with an analysis of the time-of-day-dependent use of these areas is a good approach to planning and implementing targeted adaptation measures. By including different scenarios, the effectiveness of individual measures can be made more tangible and communicated more clearly. For this reason, it is recommended to calculate the share of shade not only at the social-area level, but for the entire urban area. It may also be helpful to consider the share of shade on residential buildings at different height levels and with a focus an apartments located under rooftops or with extensive south-facing exposure, frequently experience particularly high indoor temperatures during summer months.

Application of the indicator "walking distance to non-heat-stressed public recreational areas" proposed by Kluck et al. (2020) confirms the need for action identified during the site visit regarding the lack of shading in large recreational spaces, which are of great inportance for vulnerable residents to find cooling outdoors during heatwaves. This means in sum that residents are unable to find relief from heat at home or within walking distance of their homes. As the building-resolved analysis for the Goethestraße neighbourhood shows, there are currently only a few recreational areas with lower heat exposure during the time of day with the greatest heat burden. As a result, walking distances to cooler areas in the north-western and southern parts are in some cases more than 400 m. In particular, these areas should be considered for improving heat protection, including the provision of public buildings that offer thermal relief. The indicator should also be recalculated taking these facilities into account. Additionally, it could be discussed whether free drinking-water stations should be installed at some locations.

Overall, the study shows that the development of joint scenarios and the simulation of heat exposure highlight the necessity of specific adaptation measures for vulnerable groups. Exemplary approaches from the Netherlands can also provide valuable new impulses for planning in Germany. Furthermore, it becomes

clear that the social dimension of climate adaptation must not be treated as an add-on, but should be considered from the outset and be an integral part of all planning phases. This also includes the early integration of social data into impact analyses. Only through the systematic consideration of social issues and the active involvement of vulnerable groups as well as practical decision-makers on site a just and sustainable urban climate adaptation can be achived.

1 ABSTRACT

In Durban, KwaZulu-Natal, inadequate maintenance and limited capacity of municipal stormwater drainage systems have been repeatedly linked to urban flooding, causing significant property damage, health risks, and public dissatisfaction, particularly in the wake of extreme rainfall events such as the 2022 floods. This study investigates community perceptions and responses to municipal stormwater drainage management in urban and peri-urban areas of the eThekwini region, KwaZulu-Natal, South Africa. In 2024, 200 residents participated in structured surveys, with quantitative data analysed using descriptive and correlation statistics and qualitative responses examined through thematic analysis. Results indicate that public satisfaction is closely linked to perceived municipal effectiveness in maintaining drainage infrastructure and mitigating flooding. Communities reported persistent concerns regarding system performance, delayed interventions, and associated health and safety risks, reflecting limited confidence in municipal progress. The findings align with frameworks of urban resilience and participatory governance, emphasising the importance of responsive and inclusive management strategies. The study concludes by recommending targeted municipal engagement, enhanced monitoring and maintenance, and community education to improve trust, resilience, and adaptive capacity in the face of rapid urbanisation and climate-related flood risks.

Keywords: Community Perception, Municipal Governance, Stormwater Management , Urban Resilience, Urban Flooding

2 INTRODUCTION

2.1 Background

Urban and peri-urban areas in South Africa, particularly in the eThekwini region, face increasing challenges related to stormwater management due to rapid urbanisation, ageing infrastructure, and the impacts of climate change (Grab, 2023). The intensification of extreme weather events, including increased rainfall and flooding, has exposed vulnerabilities in existing drainage systems. These issues are particularly evident in communities such as Umlazi, Wentworth, Amanzimtoti, Isipingo, Umdloti, and Tongaat, which experience recurrent flooding, compromised infrastructure, and health and safety concerns (Grab and Nash, 2023).

2.2 Introduction

This paper presents an in-depth analysis of survey data collected to assess public perceptions, experiences, and expectations related to stormwater drainage systems in urban and peri-urban areas. The findings illuminate critical themes such as infrastructure performance, flooding impacts, health and safety concerns, and public satisfaction. These insights contribute to the development of a robust framework for sustainable urban drainage systems (SUDS) and inform strategies to enhance resilience in the face of urbanisation and climate change.

The survey was conducted in the subject areas of Umlazi, Wentworth, Amanzimtoti, Isipingo, Umdloti and Tongaat, and was shared with public primary schools in the local communities. These public schools then shared the survey with members of the community and the survey link was closed once 200 responses were recorded. All survey responses were collected between February and July 2024, just after the expected rainy period of April in the eThekwini region.

2.2.1 Problem Statement

The rapid urbanisation and increasing frequency of extreme weather events in the eThekwini region have exacerbated challenges related to stormwater management in urban and peri-urban areas. Communities such as Umlazi, Wentworth, Amanzimtoti, Isipingo, Umdloti, and Tongaat frequently experience flooding, infrastructure failures, and associated health and safety risks. Despite these challenges, existing stormwater

drainage systems have not been sufficiently upgraded to cope with intensified rainfall patterns, leaving residents vulnerable to recurring impacts. A critical gap in addressing these issues lies in the lack of a comprehensive understanding of public perceptions, experiences, and expectations regarding stormwater management. Current approaches often fail to incorporate community insights, which are vital for developing effective and sustainable urban drainage systems (SUDS). Furthermore, limited local government interventions and inadequate public education exacerbate the situation, contributing to dissatisfaction and mistrust among affected residents.

2.2.2 Research Questions

(1) What are the public perceptions and experiences related to the performance of stormwater drainage systems in urban and peri-urban areas of the eThekwini region?

(2) How do flooding events impact the health, safety, and daily lives of residents in Umlazi, Wentworth, Amanzimtoti, Isipingo, Umdloti, and Tongaat?

(3) What are the key expectations of local communities for government interventions and public education to improve stormwater management?

3 THE PUBLIC PERCEPTIONS

The findings from the Survey Data are presented in 7 broad categories that inform an in-depth opinion from community members with reference to the current stormwater management system endured in the eThekwini region. The survey covered the following categories: Demographic Context, Awareness of Drainage Systems, Flooding, Healthy and Safety Concerns, Public Satisfaction and Municipal Accountability, Broader Infrastructure Challenges and lastly Community Engagement and Climate Resilience.

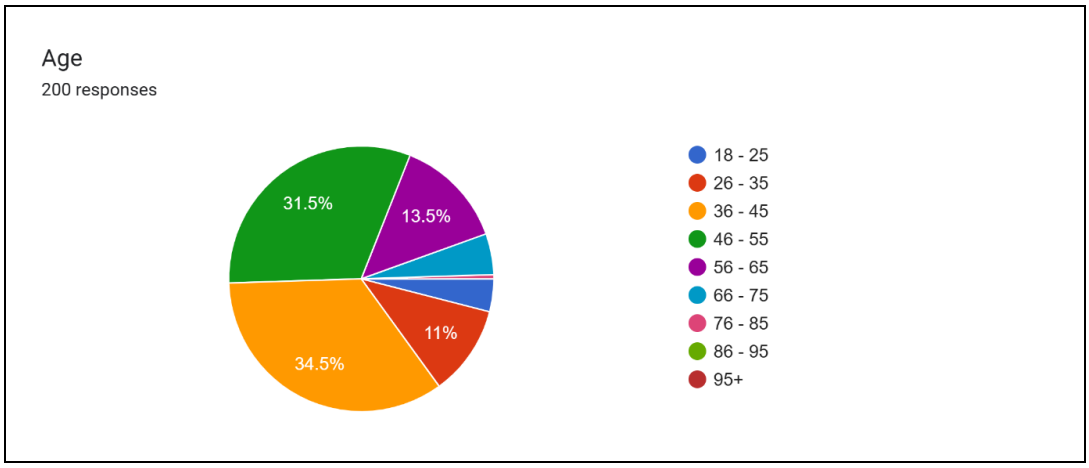

Figure 1: Survey Respondents Age, Moosa (2024)

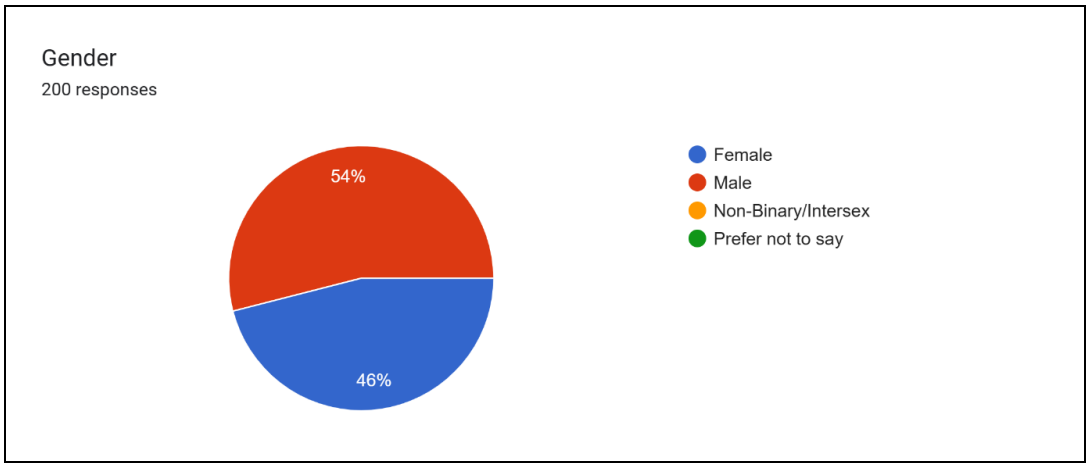

Figure 2: Survey Respondents Gender, Moosa (2024)

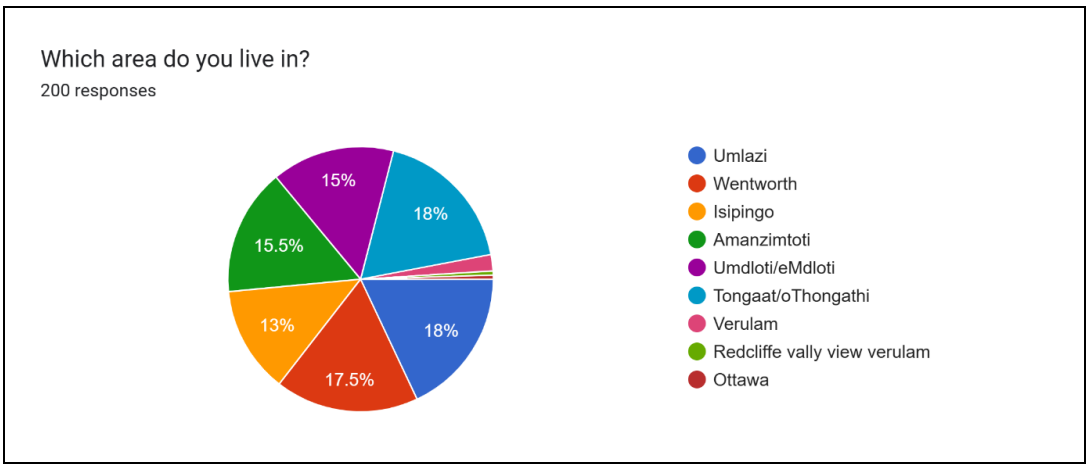

Figure 3: Survey Respondents Area of Residence, Moosa (2024)

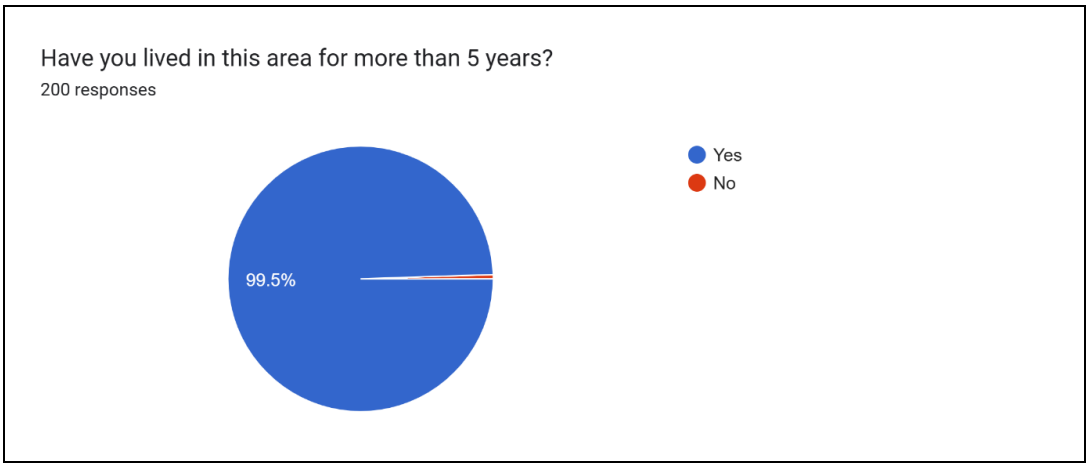

Figure 4: Survey Respondents Length of Stay in Area of Residence, Moosa (2024)

3.1 Demographic Context

The demographic analysis highlights that respondents span a wide age range, with a significant majority (26–55 years) representing active professionals and household decision-makers. Over 90% of respondents have lived in their neighbourhoods for more than five years, reflecting deep familiarity with local environmental and infrastructural conditions. This demographic stability ensures the reliability of responses and provides a longitudinal perspective on drainage system performance.

The above highlights the key demographic indicators to provide reliability to the responses received from the participants, 99.5% have resided in these areas for longer than 5 years, which provides a perspective of familiarity and also a sense of identity which enables accurate reporting. Out of 200 responses, 54% were male, and while the gender marker does not indicate any bias, it can be noted that male respondents were more interested in the infrastructural challenges their communities faced.

3.2 Awareness of Drainage Systems

A substantial portion of respondents (83.5%) reported being aware of the drainage systems in their areas, and 73.5% demonstrated an understanding of how these systems function. This high level of awareness suggests that the community is well-informed and capable of engaging in meaningful discussions about infrastructure improvements. However, the persistence of systemic issues such as flooding and poor maintenance highlights a gap between public awareness and effective municipal action.

The sample revealed that there is a requirement for community based education, improving the education within the public schooling system and improving community awareness related to drainage and stormwater management will improve residents interaction with municipal structures and infrastructure.

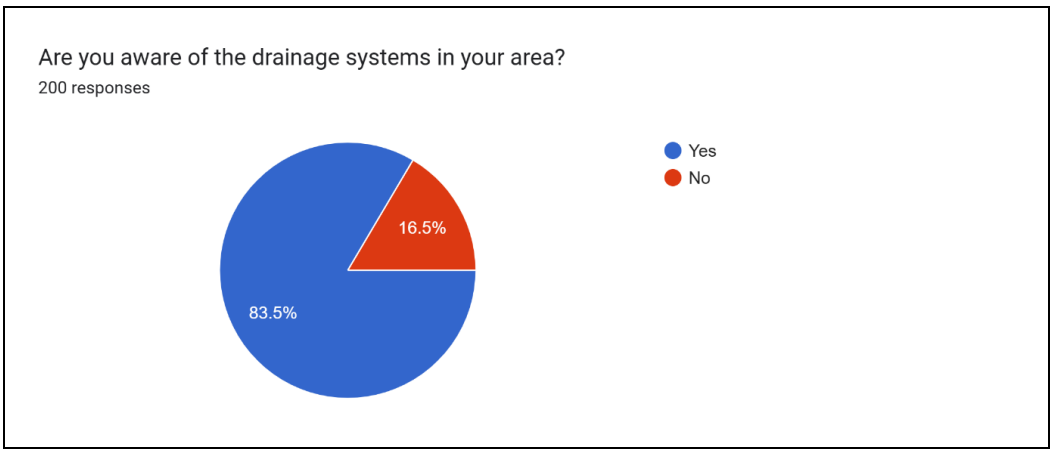

Figure 5: Survey Responses with Drainage System Awareness, Moosa (2024)

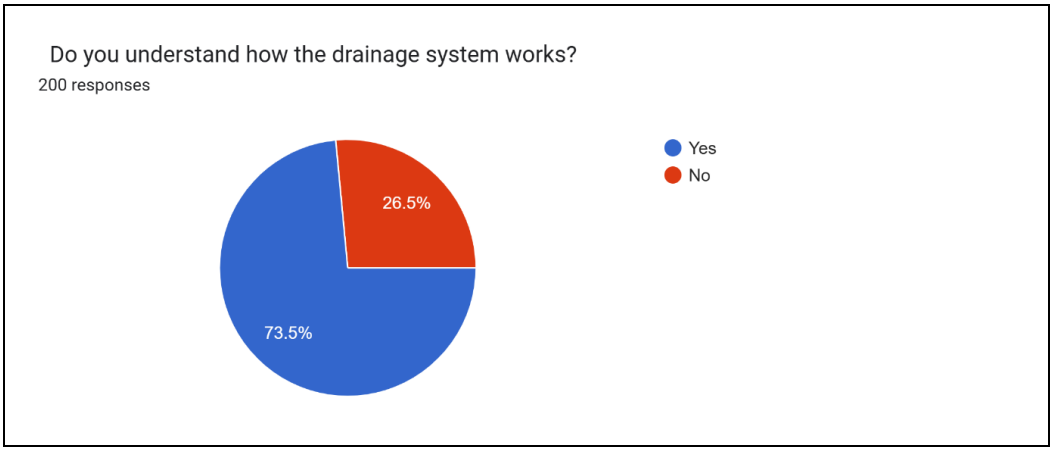

Figure 6: Survey Responses that Understand how Drainage Systems Work, Moosa (2024)

3.3 Flooding and Its Impacts

Flooding is a pervasive issue, with 99% of respondents reporting direct experiences. While some described minor disruptions during rainy weather, others noted severe consequences, including property damage, which affected 25% of respondents. These findings underscore the socio-economic vulnerabilities exacerbated by inadequate stormwater management. Frequent flooding not only disrupts daily life but also imposes financial burdens on households, amplifying the need for resilient infrastructure solutions.

An overwhelming amount of respondents (96.5%) displayed dissatisfaction with the current drainage system in their area – this response clearly depicts a need for improved systems to cope with the needs of the community. While 99% of respondents indicated that they have noticed flooding in their areas during rainy periods, only 25% of respondents have indicated being affected by the consequences of flooding on a daily basis. 25% of respondents expressed that they have experienced property damage due to drainage challenges.

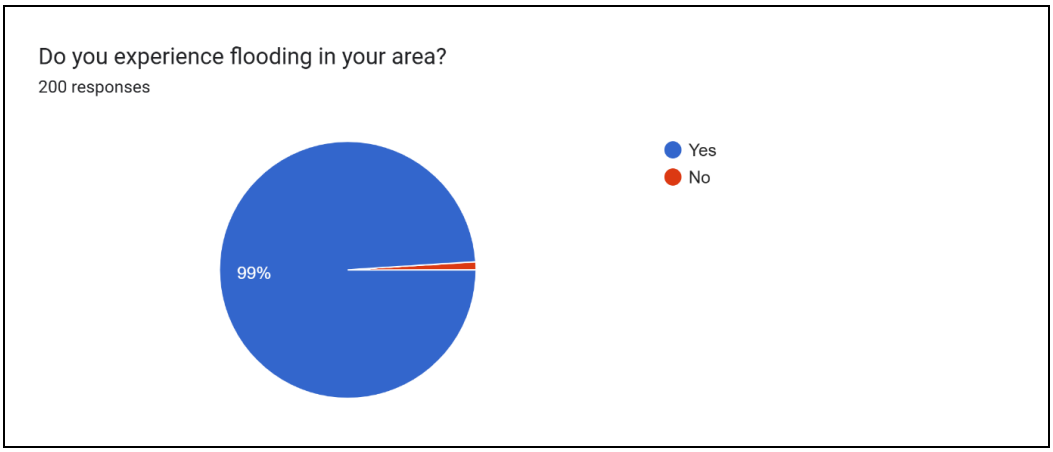

Figure 7: Survey Responses Regarding Flooding Experiences, Moosa (2024)

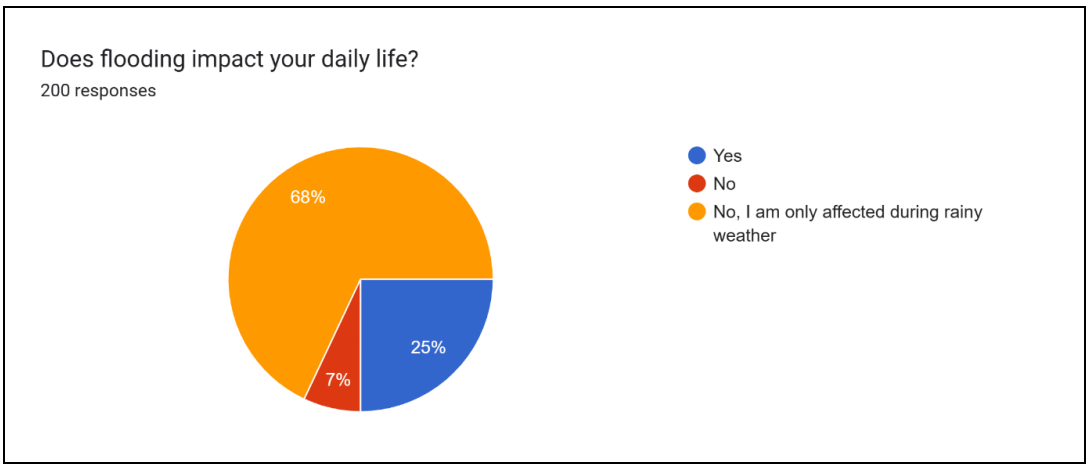

Figure 8: Survey Responses: Daily Life Impact of Flooding, Moosa (2024)

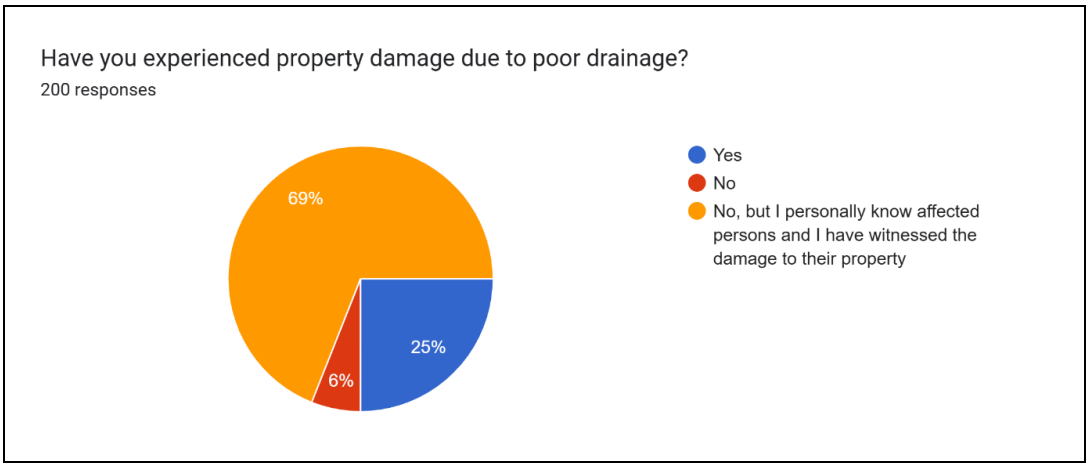

Figure 9: Survey Responses: Experiencing Property Damage due to Flooding, Moosa (2024)

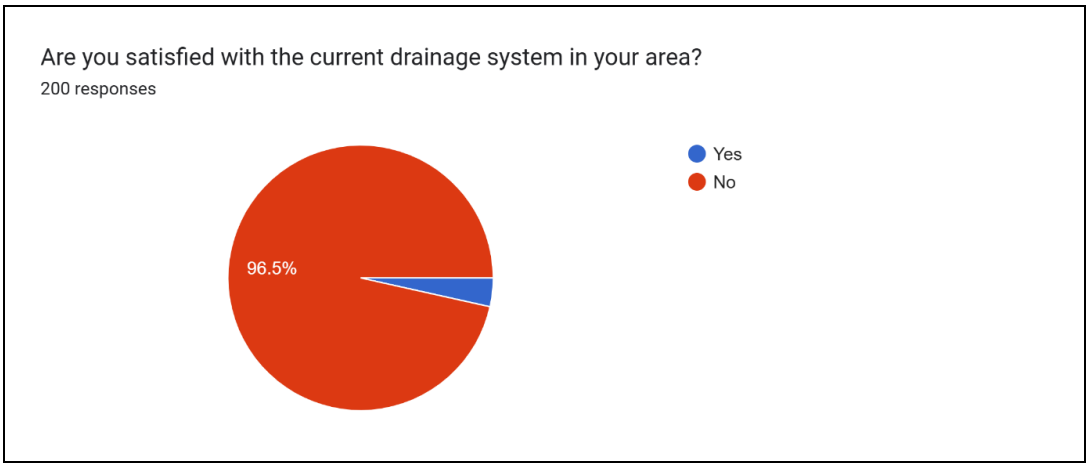

Figure 10: Survey Responses: Current Drainage System Satisfaction, Moosa (2024)

3.4 Health and Safety Concerns

Health risks associated with inadequate drainage were reported by 18% of respondents, while 100% expressed concerns about neighbourhood safety due to poor drainage. Stagnant water was frequently identified as a breeding ground for disease, compounding public health risks in already vulnerable communities. Additionally, flooding creates hazardous conditions, including increased risks of accidents and injuries. These findings highlight the critical intersection of drainage infrastructure, public health, and safety.

An overwhelming 100% of respondents indicated their fear of poor drainage and infrastructure affecting the safety of neighbourhoods. The roadside dumping, overgrown plants and grass impeding walkways and

blocking drains continuously affect the community and impede access to open spaces which should serve as community infrastructure that promote healthy neighbourhoods and safe environments.

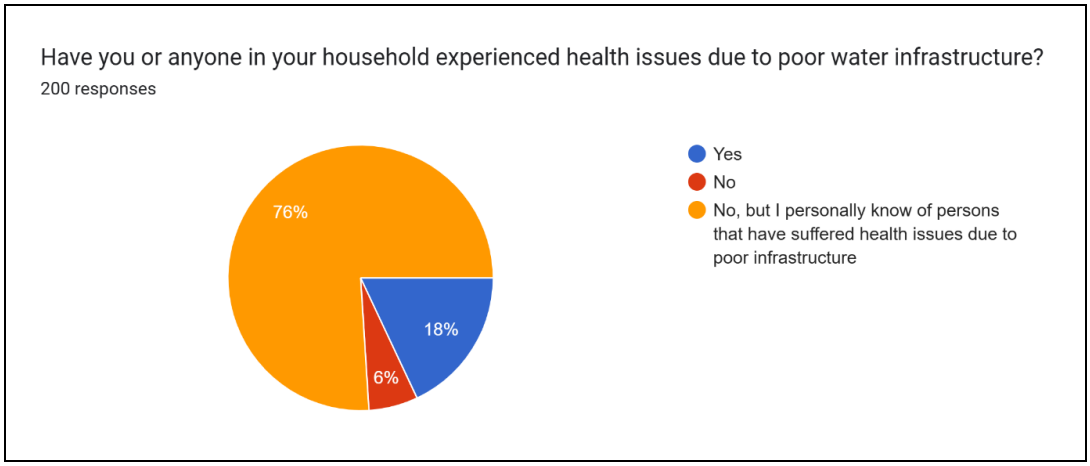

Figure 11: Survey Responses: Health Concerns Related to Flooding, Moosa (2024)

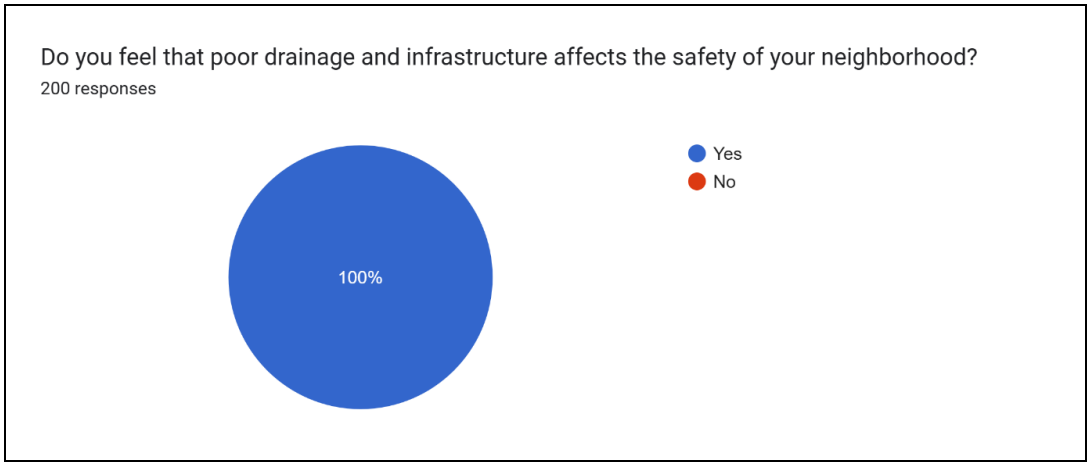

Figure 12: Survey Responses: Neighbourhood Safety due to Poor Drainage, Moosa (2024)

3.5 Public Satisfaction and Municipal Accountability

A striking 86.5% of respondents expressed dissatisfaction with existing drainage systems, citing municipal inefficiency and delayed responses to reported issues as major concerns. This dissatisfaction underscores a growing mistrust in local governance and a perception of systemic neglect. Addressing these concerns requires not only technical improvements but also enhanced governance frameworks that promote transparency, accountability, and public participation.

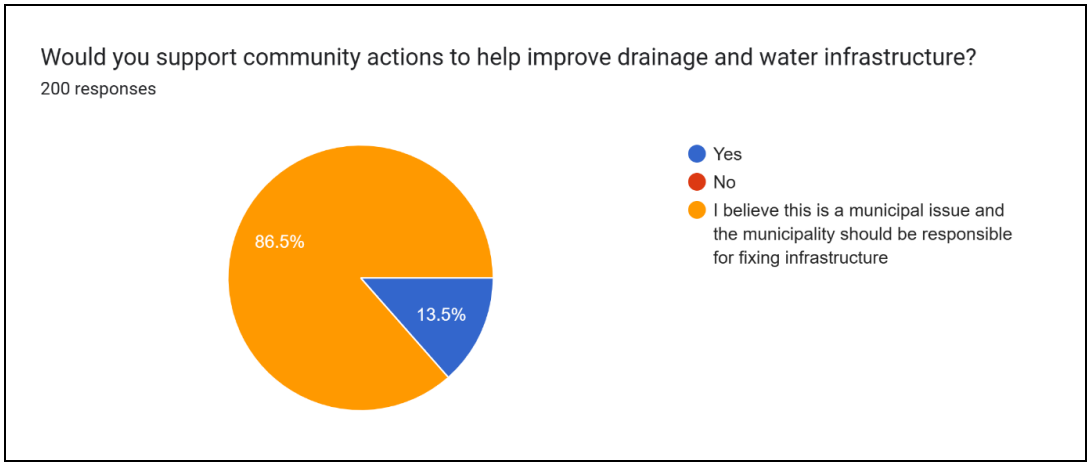

Figure 13: Survey Responses: Responsibility of Improving Drainage and Water Infrastructure, Moosa (2024)

The community sentiments generally indicate that residents believe water infrastructure and drainage systems are the responsibility of the municipality, citing that the community members pay property rates and taxes and expect the municipality to allocate funding for neighbourhood improvement.

4 METHODS

Fife-Schaw (2020) encouraged using a survey to gain insights into key theories within research make for an effective research design and answer the objectives of a study with reliable perspectives from the affected communities. Tomaszewski, Zarestky and Gonzalez (2020) emphasise that survey data should always represent the sample in the most responsible way to ensure high-quality data and insights that reflect the broader community in a considerable way, which holds the researcher to high standards of accountability and accuracy.

The survey was designed to capture quantitative and qualitative data from a diverse demographic of residents across selected study areas. A structured questionnaire focused on key aspects of stormwater management, including awareness, functionality, and community impacts. Participants were drawn from a range of age groups (18–85 years) and socio-economic backgrounds to ensure a representative sample. The data collection process prioritised inclusivity and anonymity, enabling respondents to share candid insights.

The survey was limited to 200 responses from Umlazi, Wentworth, Amanzimtoti, Isipingo, uMdloti and Tongaat – and neighbouring areas. For effective dissemination of the survey, public primary schools were approached within the subject areas and were requested to share the survey with their staff and immediate community. The limitation of 200 responses is intended to complement the findings from on-site observations and provide a reliable foundation for the recommendations made in this study.

The methodology behind the Community Survey on Drainage Systems is designed to gather insights into the impact of drainage systems on the community, contributing to the quality of the findings presented in this study. The survey aimed to assess how drainage systems affect residents, particularly in terms of flooding, property damage, health risks, and overall safety. By collecting this data, the research identified areas where the current systems can be improved and made recommendations for more effective stormwater management.

By targeting residents from specific areas such as Umlazi, Wentworth, Isipingo, Amanzimtoti, Umdloti/eMdloti, and Tongaat/oThongathi. These are regions that are directly impacted by drainage system failure (Grab, 2023), and the survey aims to capture the experiences of those living in these communities. The sampling method used was non-probability sampling, where the focus is on residents who were easily accessible for participation. However, some aspects of stratified sampling were considered to ensure that different demographic groups (such as age, gender, and location) are adequately represented in the data collection process.

To ensure a representative sample, the survey was widely distributed across multiple platforms. It was disseminated through local community networks, neighbourhood social media groups, and with the assistance of public primary schools operating in the subject areas. These groups were instrumental in encouraging participation and provided a platform for sharing the survey link. By leveraging these diverse distribution channels, the survey reached a broad spectrum of the population, including individuals who may not typically engage in municipal consultations or planning discussions.

A total of 200 valid responses were collected, yielding a dataset that included responses from a near-equal distribution of residents from the subject areas. This balanced representation allowed for a comparative analysis of the areas, highlighting any differences in perceptions, experiences, or needs between these communities.

The survey was designed with closed-ended questions that provide clear and quantifiable responses, mainly through "Yes" or "No" answers. This structure allows the identification of trends and patterns in areas like awareness of drainage systems, flooding experiences, property damage, and health issues. Some demographic questions (such as age, gender, and location) were considered to help segment the data for a more detailed analysis. In addition, a few questions allow for additional responses to capture some nuance in the participants' experiences.

Ethical considerations were integral to this study, especially given its focus on community perspectives. The survey was designed to protect respondents' anonymity, and no identifying information was collected to ensure privacy and data confidentiality. Participants were informed about the study's purpose and assured that their responses would be used solely for research purposes. Researchers approached this study with sensitivity toward the community, recognising that flooding is a disruptive issue that may involve traumatic experiences for some residents. Ethical approval was obtained from the University of Johannesburg prior to conducting the survey, ensuring that the study adhered to research ethics guidelines regarding informed consent, confidentiality, and respect for participants.

5 DISCUSSION

The survey findings emphasise the urgent need for policy reforms aimed at addressing governance inefficiencies, particularly in the management of urban infrastructure such as stormwater and drainage systems. Governance inefficiencies often manifest in the form of poor coordination, slow decision-making processes, lack of transparency, and inconsistent service delivery, all of which undermine public confidence and hinder the successful implementation of urban management strategies. These inefficiencies not only result in inadequate infrastructure but also exacerbate social inequalities, as marginalised communities are often the most affected by poor governance and urban planning failures.

To overcome these challenges, it is essential to introduce comprehensive policy reforms that focus on improving the efficiency, transparency, and accountability of municipal governance (Dierkes, Lucke and Helmreich, 2015). These reforms should be aimed at streamlining administrative processes, ensuring that resources are allocated effectively, and increasing responsiveness to community needs (Napier et al., 2018). By introducing more robust frameworks for monitoring and evaluation, municipalities can track progress, identify gaps, and ensure that their actions align with the long-term goals of urban resilience, sustainability, and inclusive development (La Rosa and Pappalardo, 2020).

Policies should encourage the adoption of modern technologies and data-driven decision-making processes that enable better planning, forecasting, and implementation of infrastructure projects (Pappalardo and La Rosa, 2020). Digital tools such as Geographic Information Systems (GIS) and real-time monitoring systems can enhance the ability of municipalities to manage urban drainage, predict flooding events, and allocate resources more effectively (Hoang and Fenner, 2016; Zhang, Wang and Gong, 2024).

The community survey conducted in Durban, KwaZulu-Natal, highlighted significant deficiencies in the current stormwater drainage infrastructure, revealing the widespread impact of flooding on residents' daily lives. Flooding is a frequent occurrence, particularly during periods of heavy rainfall, and has become a persistent challenge in these rapidly urbanising areas. The inadequacy of the existing drainage systems to cope with extreme weather events, compounded by the effects of climate change, has left many residents frustrated and feeling vulnerable to future flooding risks.

The survey analysis provides a comprehensive understanding of the challenges and opportunities in stormwater drainage management within the study areas. The findings illuminate the socio-economic and environmental dimensions of these challenges, offering valuable insights for designing sustainable solutions. This paper contributes to the broader goals of the thesis by bridging empirical evidence with theoretical development and practical implementation, laying the groundwork for resilient and inclusive urban water management frameworks. Although a majority of residents are aware of the stormwater drainage systems, they express dissatisfaction with their capacity and reliability. The ageing infrastructure, coupled with insufficient maintenance, has led to frequent blockages and inefficient water management during storms. This survey also reveals that while residents are aware of these problems, many lack a deep understanding of how stormwater systems function or what role they can play in their maintenance. This underscores the need for public education and greater community involvement in addressing stormwater challenges.

There is an overwhelming consensus among residents on the urgent need for infrastructure improvements. However, the results also show a readiness among the public to collaborate with municipal authorities in finding solutions. Residents are eager to participate in community-driven initiatives, particularly if they receive technical and financial support, indicating a fertile opportunity for partnerships between the community and local government. The survey findings illustrate both the scale of the problem and the potential for community-based solutions. By combining modern infrastructure improvements with public

education and local engagement, eThekwini can take important steps toward building flood-resilient communities that are better equipped to handle the intensifying impacts of climate change.

5.1 Recommendations for Resilient Urban Drainage Systems

The survey findings highlight the critical need for adaptive strategies to mitigate flooding risks and enhance urban sustainability in the face of climate change. Respondents consistently identified frequent and severe flooding as a significant concern, underscoring the strain on existing drainage systems and the vulnerability of urban communities. These insights emphasise that municipalities and urban planners must transition from reactive responses to proactive investments in adaptive and future-proof infrastructure.

Resilient infrastructure is essential for managing the intensified rainfall patterns associated with climate change (Ferdowsi & Behzadian, 2024). Urban drainage systems must be redesigned and reinforced to accommodate extreme weather events while aligning with broader climate adaptation, environmental sustainability, and urban development goals (García & Santamarta, 2022). This includes integrating robust stormwater systems, green infrastructure, and flexible designs capable of addressing both immediate flooding concerns and long-term climate challenges. Green infrastructure solutions, such as permeable pavements, bioswales, and green roofs, are vital components of these adaptive strategies. These natural approaches reduce runoff, improve water infiltration, and provide additional environmental benefits, such as enhanced air quality and recreational spaces. By complementing traditional engineering methods, green infrastructure offers a more sustainable way to manage stormwater and mitigate flooding risks.

Flood resilience in urban planning also plays a crucial role. This involves implementing zoning regulations, identifying flood-prone areas, and promoting flood-resistant construction techniques in vulnerable neighbourhoods. Improving urban landscapes to naturally absorb water and integrating flood resilience into planning processes can prevent urban development from exacerbating flooding risks. Real-time monitoring and forecasting systems further enhance flood preparedness. By tracking rainfall, drainage performance, and flood risks, municipalities can act proactively to address potential issues. Advanced forecasting tools enable early warnings and efficient resource allocation, ensuring that cities are better equipped to handle extreme weather events.

As climate change continues to alter global weather patterns, including more frequent and intense rainfall events, the demand for resilient infrastructure has never been more urgent (Leal Filho et al., 2023). Increasing rainfall intensity and the unpredictability of storm events are putting significant pressure on urban drainage systems, which were often designed based on historical weather patterns that are no longer reflective of current or future conditions (O'Neill et al., 2020). Inadequate infrastructure is not only unable to cope with the heightened frequency and volume of rainfall but also leads to increased flooding, infrastructure failure, and environmental degradation (Wang et al., 2023; He et al., 2024). Resilient infrastructure is critical to reducing the vulnerability of urban areas to these increasingly severe climate impacts (Kourtis and Tsihrintzis, 2021). Poorly managed stormwater systems lead to flooding, contamination, and the spread of waterborne diseases, all of which have far-reaching consequences for both individual and public health (Mukhtarov et al., 2019). Inadequate drainage systems can exacerbate health risks, cause injuries, and result in significant social costs, including loss of life, hospitalizations, and long-term health complications (Nguyen et al., 2024).

Community involvement is another key element of adaptive strategies. Engaging local communities in planning and implementation ensures that solutions align with local needs and priorities. Community-based disaster risk management initiatives can raise public awareness of climate risks, foster collective action, and empower residents to protect their neighbourhoods. Achieving long-term urban sustainability requires integrating climate change adaptation into all aspects of urban planning. This involves prioritising the needs of vulnerable populations, promoting equitable access to resources, and fostering environmental protection. By addressing these challenges holistically, municipalities can create cities that are not only resilient to climate change but also economically and socially sustainable. Ensuring that cities are better prepared for future climate impacts will require a combination of improved infrastructure, adaptive governance, and community involvement, all working in concert to reduce vulnerability and enhance resilience to flooding and other climate-related challenges (Yazdanfar and Sharma, 2015).

1 ABSTRACT

In Austria, regular condition assessments of roads and civil engineering structures have long been established, while cycling infrastructure has often been neglected. However, an efficient, safe, and continuous cycling infrastructure is an essential prerequisite for promoting cycling and shifting journeys to this mode of transport. There are currently considerable differences between the responsible local authorities in terms of the regularity of condition surveys, the parameters recorded, their level of detail, and the survey methods used. While regular condition assessments are planned for tourist cycle routes, such as EuroVelo routes, there is a lack of uniform and binding specifications for everyday cycling infrastructure.

Regardless of the type of cycling facility, a reliable, up-to-date, and comparable database is essential for planning, maintenance, and quality assurance. It enables the early identification of gaps in the network, infrastructural deficits, and deviations from applicable safety and design guidelines. In addition, continuous updating of the Graph Integration Platform (GIP) as the central reference system for public administration for transport infrastructure data is necessary, which requires structured and regular feedback from the responsible authorities.

Against this backdrop, a research project funded by the Austrian Road Safety Fund (VSF) investigates the development of an efficient, objective, and comparable methodology for recording cycling infrastructure. To this end, online surveys were conducted among cycling officials and GIP representatives in the federal states, and supplementary expert discussions were held. Based on 27 relevant quality and safety parameters identified in the specialist literature, ten key parameters were defined in consultation with an interdisciplinary advisory board. In addition, a concept was developed for uninterrupted, sensor-based condition surveys using a cargo bike, and criteria for a continuous cycling infrastructure were defined. Pilot applications in 2026 will serve to evaluate and further develop the methodology in terms of its practical applicability and significance.

Keywords: cycling infrastructure , condition assessment , Graph Integration Platform (GIP), Austria, mobility

2 PROBLEM STATEMENT

Recording the structural condition of roads and engineering structures on a regular basis is common practice in Austria. The approach being pursued is to use a measurement vehicle to provide a comprehensive and objective assessment of the condition of the road network. The vehicle's sensory system records the roads in flowing traffic without any traffic-restricting measures (AIT 2026). Subsequently, the various road sections are categorized based on current guidelines (IÖB 2023). This approach aims to support administrative and political decision-makers in prioritizing future road maintenance and renewal measures throughout the country. Based on the available data and its classification, it is possible to develop a program for road construction and renovation measures can be scheduled.

In contrast, this approach is only being pursued for motorized transport areas and not for cycling infrastructure. Although the importance of increased bicycle traffic for the mobility transition is recognized, the necessary bicycle infrastructure is often neglected and its condition overlooked. Despite the fact that studies on single-vehicle accidents involving cyclists related to infrastructure in Austria and Germany (Zuser

et al. 2023, Francke et al. 2024, Borsellino 2024) and experiences from Denmark show that "Surfaces for cyclists require high quality maintenance, higher than the road surface, as even a small crack or pot hole can have very serious consequences" (Eriksson 2013: 165). A study by the Transport Research Laboratory shows that infrastructural factors such as limited visibility or insufficient road grip are responsible for 26.3% of traffic accidents, while only 6.7% are attributable to vehicle-related causes (e.g. faulty braking systems) (Eriksson 2013). The vast majority of accidents (91.5%) are attributable to human factors, including excessive speed, the influence of alcohol or drugs, attention deficits and orientation problems (Eriksson 2013).

There are significant differences in terms of the regularity of condition assessment of bicycle infrastructure, the parameters measured, the level of detail of the parameters, and the survey procedure itself (with or without technical assistance) in Austria. The quality of bicycle infrastructure surveys therefore varies depending on the authority responsible and the importance given to the network section of the cycling infrastructure. For tourist cycle routes of European significance (EuroVelo), for example, regular condition assessments are necessary, but there are no generally applicable requirements for the subordinate cycling network or everyday cycling infrastructure.

Regardless of the type of cycling infrastructure, a reliable data basis for planning and maintenance is essential to identify gaps and poor-quality infrastructure (e.g., non-compliance with current road safety guidelines) at an early stage and to be able to take appropriate action. In addition, it is necessary to keep the Graph Integration Platform (GIP), the official reference system for authorities and public administrations for transport infrastructure based on a common data standard, up to date. That also means supporting local authorities in regularly reporting to the GIP officers on changes and innovations in cycling infrastructure.

To collect infrastructure information in Austria efficiently, objectively, and in a comparable manner, the requirements for an efficient infrastructure condition assessment methodology must be determined.

3 METHODOLOGICAL APPROACH AND PRELIMINARY WORK

A three-stage methodological approach was chosen to identify key quality parameters for cycling infrastructure (see Fig. 1). First, preparatory work involved conducting a comprehensive literature review and systematizing relevant quality criteria and characteristics of reported problem areas. Building on this, qualitative data was collected through discussions with stakeholders from various federal states, analysis of measurement methods used, and the involvement of an advisory board. In a third step, the results were quantitatively validated and prioritized using an online survey of 29 experts and used to derive requirements for sensor instruments. The result is a survey catalog with the ten key parameters.

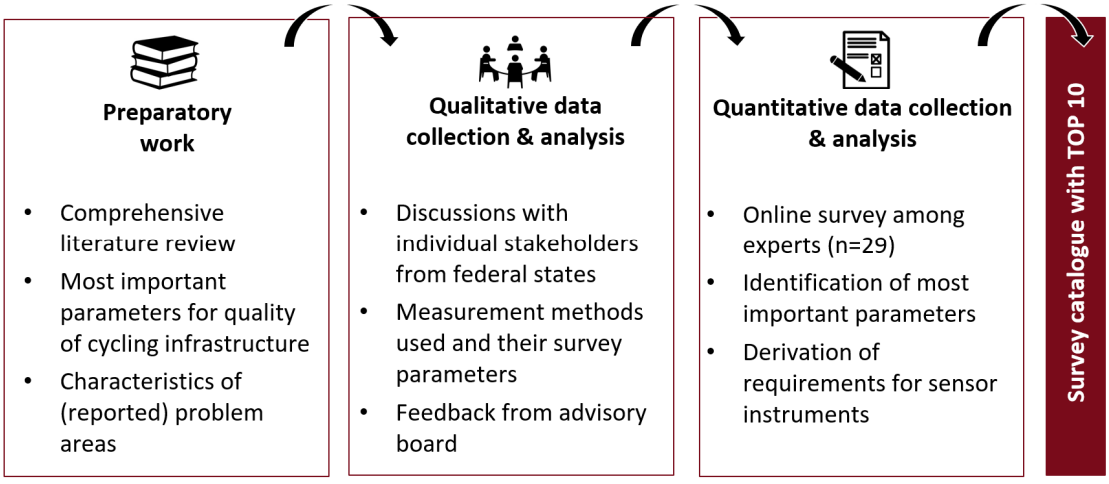

Fig. 1: Methodological approach.

To outline the initial situation, the following paragraphs briefly discuss relevant national and European preparatory work.

In Austria, several studies on the systematic evaluation of cycling infrastructure were carried out at the Institute of Transportation Sciences at the University of Natural Resources and Life Sciences in Vienna. This resulted in standardized survey and evaluation approaches using checklists (Ferstner 2020,

Schnauderer/Vavti 2022), including classification systems and analyses of administrative requirements for app-based reporting systems (Zorzi 2014). The BikeQuality app from Salzburg Research assesses cycling infrastructure based on vibrations, stopping times, and speeds during the ride (Salzburg Research 2021) without providing details on the surface characteristics, signage, markings or clearance.

At the European level, the SABRINA project (Safer Bicycle Routes in the Danube Area) investigated the safety of cycling infrastructure in the Danube region. The results show deficits compared to motorized traffic standards, particularly in terms of equipment and maintenance, and emphasize the added value of bicycle-based inspections (Fischer et al. 2022).

4 STATE-OF-THE ART OF CONDITION ASSESSMENT OF BICYCLE INFRASTRUCTURE

In February 2025, AustriaTech conducted an evaluation of safe cycling networks[1] based on data from the GIP. At the time of the analysis, the cycling network recorded in the GIP covered a total length of 18,724 km. The distribution of lane types by kilometre and federal state shows a clear dominance of roads with a maximum speed limit of ≤ 30 km/h (around 41%), followed by mixed footpaths and cycle paths (around 40%) and roads with access restrictions, except for cycle traffic (around 9.5%) (AustriaTech 2024).

In terms of the percentage distribution of cycling infrastructure across the federal states, Lower Austria leads the way with a share of 18%, followed by Styria and Vienna with 14% each. Vorarlberg is close behind with 13%, followed by Tyrol with 10% and Salzburg and Upper Austria with 9% each. Carinthia and Burgenland have the lowest share with 7% and 6% (AustriaTech 2024). Apart from the high network density in Vienna, which is due in particular to the intensive expansion of inner-city transport connections, Vorarlberg stands out as the second smallest federal state (Statistik Austria 2025) with a comparatively small area, but an above-average level of development of its cycle network.

Although these official figures and a definition of safe cycling infrastructure exist, discussions with the federal states have revealed that the term “cycling infrastructure” is not understood uniformly by the stakeholders. From a legal perspective, the different types of facilities are defined in the Road Traffic Regulations (StVO) and the Road Marking Regulations (BmVO). The guidelines and regulations for road construction (RVS) contain further conceptual distinctions: while cycle facilities comprise all areas where cycling is permitted, cycle lanes refer to those areas for which special usage regulations apply, such as multi-purpose lanes (Radlobby 2024).

It should also be noted that the importance of various cycling facilities varies from one federal state to another. In Tyrol, for example, the focus is on leisure and tourism (see Fig. 2). Accordingly, the characteristics and requirements of cyclists vary depending on whether they are using their bikes for everyday or leisure purposes, as explained in RVS 03.02.13 “Cycling”.

The federal states pursue different approaches to the assessment, expansion, financing and maintenance of cycling infrastructure. While Burgenland, Lower Austria and Tyrol carry out regular condition assessments and inspections, there is no systematic assessment in Upper Austria. Lower Austria, Carinthia and Upper Austria have clear regulations on the distribution of costs between the state and municipalities, especially for supra-regional main routes. Carinthia and Vorarlberg have established supra-regional cycle paths legally and strategically, with Vorarlberg prioritising everyday cycling and using data-based condition assessments. Salzburg and Vorarlberg also focus on everyday traffic, while Tyrol prioritises recreational cycling. Vienna records its cycling infrastructure digitally across the board using its own survey system (Kappazunder). Overall, there are significant differences in terms of responsibilities, quality standards, data bases and the strategic orientation of cycling in the federal states.

[1] A safe cycling network includes the following (cycling) infrastructure: Structured bike paths, bike paths without mandatory use, separate sidewalks and bike paths with and without mandatory use, mixed sidewalks and bike paths with and without mandatory use, bike lanes, bike crossings, multi-purpose lanes, residential streets, shared zones, cycling in pedestrian zones, cycling against one-way traffic ≤ 30 km/h, roads ≤ 30 km/h, driving ban except for bikes ≤ 50 km/h.

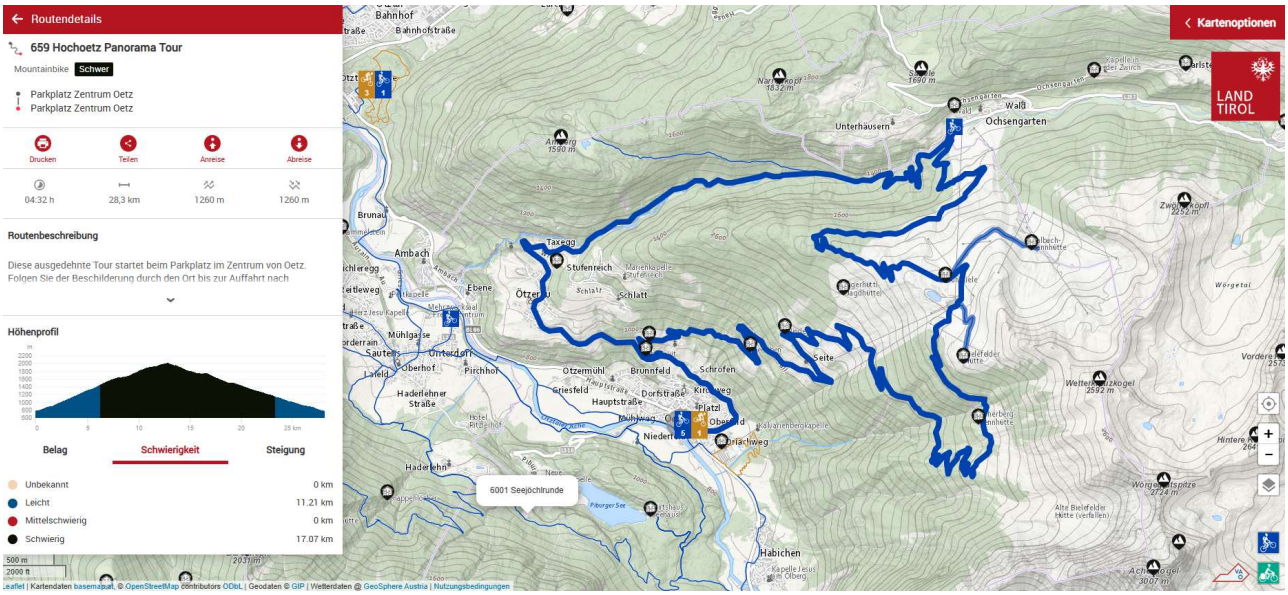

Fig. 2: Tyrol's bike route planner based on GIP data (https://radrouting.tirol/) provides a route description, an elevation profile with information on the surface type and difficulty level as well as travel time and route length.

5 DEVELOPMENT OF A SURVEY CATALOG USING EXPERT FEEDBACK

In addition to discussions with stakeholders, an online survey among experts has been conducted (16 September 2025 to 9 October 2025) to ascertain current access to status surveys of cycling infrastructure and the implementation of data in the GIP. The aim was to identify the most important parameters for condition assessment and to create a survey catalog that allows for systematic inspection of the cycling infrastructure based on these.

A total of 29 questionnaires were evaluated, 22 of which were complete and the remaining six participants answered at least half of the questions. Different questions were asked depending on the job profile, as GIP experts have a different focus than those who collect status data. The complete questionnaire consists of 13 questions. The survey reached experts from all federal states with the following distribution: Vienna – 5 persons, Burgenland – 5 persons, Tyrol – 5 persons, Upper Austria – 4 persons, Lower Austria – 3 persons, Carinthia – 2 persons, Vorarlberg – 2 persons, Styria – 2 persons, Salzburg – 1 person. In terms of the professional orientation of the survey participants, the field of geoinformation (18 mentions) leads the way, followed by bicycle traffic coordination and bicycle traffic planning (with five mentions each). Three respondents mentioned the signage of bicycle facilities, two mentioned the construction of physical facilities, and one mentioned the maintenance of physical facilities.

The survey participants responsible for cycling infrastructure were asked about the current practices for assessing the condition of cycling facilities. The most common response was an inspection without a standardised checklist followed by assessing the condition of cycle facilities by driving along them in a vehicle using a checklist. The evaluation of planning documents, driving along the route in a measuring vehicle, cycling along the route using a checklist and an inspection with a checklist are hardly according to the survey participants. Cycle paths primarily used by tourists are inspected at regular intervals in Austria (every year up to every three years). For everyday cycle paths, the frequency of inspections depends heavily on the responsible authorities and the available budget. However, problem areas are often known and are sometimes reported by the citizens. Responsibilities vary greatly between the federal states. In Vorarlberg, for example, the road maintenance authority is responsible, while in Lower Austria it is the state employees. In some federal states (e.g., Salzburg, Burgenland), it even concerns different stakeholders.

The survey of regularly recorded parameters on the condition of cycle facilities (24 answers) shows a strong focus on basic infrastructural features. A total of 27 parameters from the literature were provided for selection, and the option of entering free text was also offered (Miscellaneous). The most frequently documented aspects are surface type, signage and facility width, while structural condition, road markings and separation from other traffic areas are only taken into account by a small proportion of respondents. Numerous parameters relevant to safety and riding comfort, including gradients, obstacles, drainage, grip and

distances to parked vehicles, are not systematically recorded. In addition, other aspects such as the mere presence of cycle facilities and vegetation in the clearance profile were mentioned in isolated cases. Overall, the evaluation indicates limited and heterogeneous data collection, in which key qualitative and safety-related features are often not taken into account.

Parameter	**Entries**	**Parameter**	**Entries**
Signage (traffic signs in accordance with road traffic regulations and directional signage)	18	Longitudinal gradients	4
Type of surface paving	16	Lighting	4
Separation from other traffic areas (roads, pavements)	15	Clearance	4
Width of the cycle lane	14	Stopping points and stopping times	3
Road markings	11	Metal grilles	3
Changes in road surface	11	Distance to parked vehicles	3
Route images (front, rear and 360° panoramic camera)	11	Driving comfort (vibrations)	3
Obstacles	9	Kerbs lowered at entrances and exits	2
Hazardous areas	8	Cross slopes	2
Structural condition, including type and severity of damage	8	Drainage facilities	2
Uneven surfaces	8	Grip	2
Narrow sections	7	Curve radii	2
Sight lines	5	Miscellaneous	2
Longitudinal edges, kerb edges	5		

Table 1: Survey question “Which parameters are relevant to your daily work (planning, maintenance, transfer to the GIP)?”.

In contrast, respondents were asked which parameters would be relevant for their everyday work (see Table 1). This question was answered by 28 of the 29 respondents. The most frequently mentioned factors were: signage (18 entries), type of surface paving (16), separation from other traffic areas (15) and width of the cycle lane (14). The least frequently mentioned were: cross slopes, kerb ramps, drainage facilities, grip, curve radii, other (2 mentions each). The correct location (in the GIP) was mentioned under the category “Miscellaneous”.

Focussing on the GIP officers among the respondents, the entry of infrastructure data into the GIP was questioned with regard to the information collected as a priority and the frequency of reporting. The survey participants were asked about the types of infrastructure which are primarily included in the GIP (see Fig. 2) and the details on the cycling infrastructure available in the GIP (answered by 15 persons, question “What data is included in the GIP?”).

The minimum standard was mentioned most frequently (12 mentions), followed by “push bike” (8 mentions), “traffic restrictions for cyclists” (7 mentions), and cycle route status (7 mentions). Speed limits were mentioned only five times, difficulty five times, and obstacles twice. Accompanying paths were only an issue for one stakeholder, while details on the experience value and time restrictions for cyclists were each mentioned twice.

To verify the practical suitability of the condition assessment method prior to field testing, an advisory board was established. The advisory board consisted of national and international experts in the fields of cycling infrastructure, cycling safety, and infrastructure data, with national experts from six of Austria’s nine federal states. The ten most important metrics were determined in consultation with the advisory board of which five metrics are to be transferred to the GIP.

(1) Type of surface paving (→ GIP)

(2) Changes in road surface (→ GIP)

(3) Width of the cycle lane (→ GIP)

(4) Road markings quality including pictograms/sharrows or similar

(5) Separation from other traffic areas (roads, pavements) (→ GIP)

(6) Signage (traffic signs in accordance with road traffic regulations and directional signage) (→GIP; a facility type)

(7) Route images

(8) Longitudinal edges, kerb edges

(9) Structural condition including type and extent of damage

(10) Clearance including obstacles

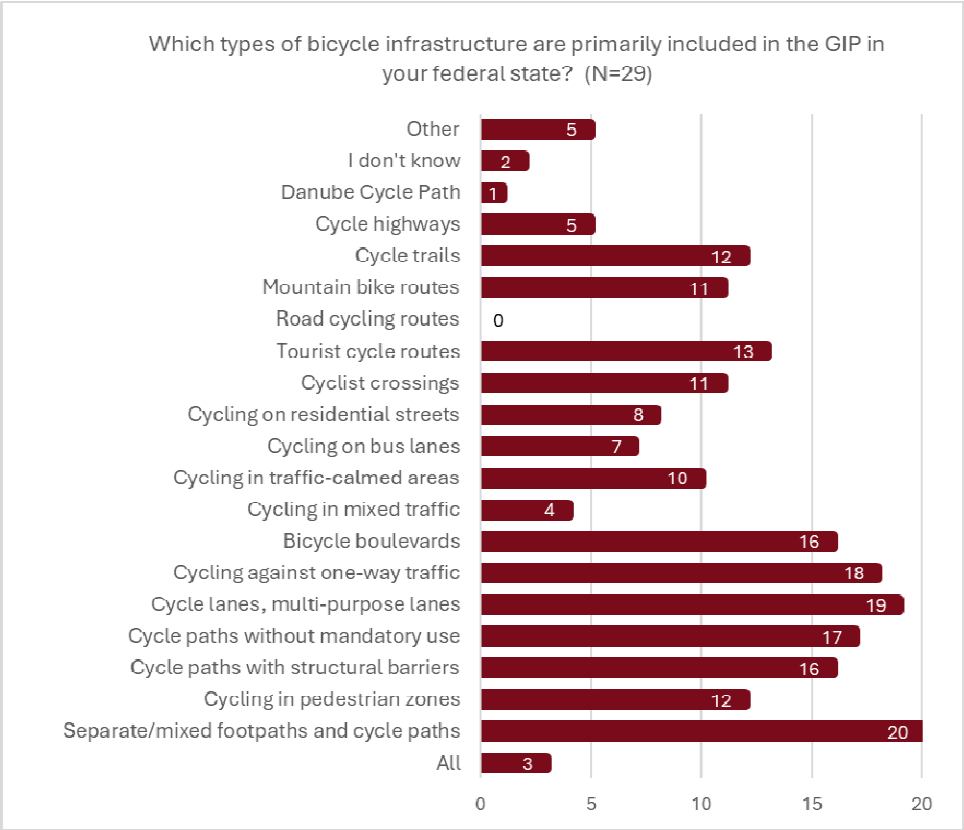

Fig. 3: Survey question "Which types of bicycle infrastructure are primarily included in the GIP in your federal state?".

During the advisory board meeting, it was suggested that on the journey, it should be possible to record signage in both directions, and the side space would also be interesting for obtaining additional information (e.g., signage obscured by vegetation). In addition, curbs and associated vibrations should be recorded at intersections, and with regard to obstacles in urban areas, cars protruding into the bicycle lane would be of interest (percentage evaluation). All elements of the survey catalog must also be described or defined in more detail, and the level of detail of the survey data must be specified.

6 TRANSFER OF SURVEY RESULTS INTO A MEASUREMENT SYSTEM

To record the parameters in a measurement run without interruptions (performed by a cargo bike due to more points of contact with the ground), basic sensor equipment has to be assembled and the level of detail for the condition assessment of cycling infrastructure has to be defined.

A survey of currently existing digitization solutions for bicycle networks shows that camera-based detection systems in combination with GPS are predominantly used. In Germany, Steffen Knab Mobility Consulting offers image-based inventory of cycling infrastructure with a focus on signage (bildbefahrung 2025), while the R4R research project expands on this approach by using additional sensors (including LiDAR and IMU) and automatically merging multimodal data (Laghbani et al. 2025). The Holocene Bike has been developed by Boréal Bikes with the following equipment: GPS, IMU, LiDAR, cameras, on-board computer, interfaces for wireless communication, electric drive (Salzburg Research 2026).

In Denmark, the "ROAD System" has been tested as a comprehensive monitoring tool that records various infrastructure and environmental parameters and visualizes them in a GIS-based dashboard (EIT Urban Mobility 2026). A simplified version uses smartphone images taken from bicycles to automatically detect road damage with high classification and positional accuracy (ROAD SYSTEM™ 2026).

CycleRAP takes a model-based approach, calculating a risk score for cycling regardless of the type of facility by taking into account infrastructure features, accident factors, and, in particular, the distance to motorized traffic (iRAP 2024).

Investigations on sensors available to collect the ten specified parameters resulted in a limitation of basic sensor equipment to the technologies described in Table 2.

Sensors	**Possible measurement parameters**
GPS	Trajectory, curve radius
IMU	Evenness, longitudinal and transverse slope
Stereo cameras	Object positioning, carriageway width, lighting, colour, parking facilities, side distances, cracks/damage
LiDAR	Carriageway width, sight lines, clearance profile, cracks/damage, kerb height, overtaking distances, side distances, speed difference during overtaking manoeuvres
Position sensor (DMU)	Distance travelled
Temperature sensors	Air temperature, carriageway temperature

Table 2: Sensors for recording various parameters.

In addition to selecting the sensory characteristics, the level of detail for the condition assessment had to be determined. The GIP standard description devotes a separate chapter to bicycle traffic and the associated special provisions, which is illustrated with various examples. The most important metrics recorded are the type of cycling infrastructure (cycle path, cycle lane, etc.), the average width, the surface (paved, unpaved, or specification), the type of crossing (intersection area). Apart from that, the assessment of comfort (experience value, difficulty), and regulations according to the StVO (time restrictions for cyclists, speed limits, pushing bikes, restricted through traffic for cyclists), lighting, traffic light control, cycle route status, and obstacles can be implemented in the GIP (ÖVDAT 2021).

The GIP standard description (ÖVDAT 2021) therefore offers a wealth of parameters in the category of bicycle traffic. The definition of road surface characteristics thus comprises 28 options, excluding the option "unknown". The level of detail causes problems when analyzing the data, which is why a simplified approach to data collection is chosen in some cases (see Table 3). In addition to the aspects mentioned in the GIP standard description, other aspects such as gaps in signage and the quality of the road surface, pictograms, and the condition of signs are relevant as well.

Parameter	**Level of detail**
Type of surface paving	Gravel, asphalt, concrete, paving stones, terrain
Changes in road surface	-
Width of the cycle lane	Accurate to ≤ 10 cm
Road markings availability/quality	All markings including pictograms, sharrows; Categories: okay/monitor/replace
Separation from other traffic areas	Infrastructural separation (roads, pavements)
Signage	Existence and condition of signage compliant with traffic regulations and directional signage; Categories: okay/monitor/replace; Identification of gaps in signage
Route images	Front and rear images
Longitudinal edges, kerb edges	Existence and location
Structural condition including type and extent of damage	Identification of cracks etc.; Categories: okay/monitor/replace
Clearance including obstacles	Occurrence and location

Table 3: Level of detail in the collection of various parameters.

Furthermore, criteria were established that a "continuous cycling infrastructure" should meet. This definition incorporated aspects such as adequate directional signage, clear indication of the type of facility through road markings and traffic signage, cycle-specific routing at junctions (cycle crossings, etc.), clear separation/mixing with other road users, and passage (bottlenecks, obstacles). Furthermore, it has been solved from a technical perspective how gaps (e.g., in signage) or bottlenecks (e.g., due to vegetation) are to be dealt with during the inspection.

7 CONCLUSIONS AND OUTLOOK

Safe and attractive cycling infrastructure is a key factor in driving forward the mobility transition. Systematic assessment of the condition of cycling infrastructure is therefore essential. To assist those responsible, the parameters to be collected as standard and the intervals at which they should be collected were identified and this approach was compared with actual requirements. A literature review, an online expert survey as well as discussions with experts and the feedback of an advisory board were used to achieve a systematic approach to assessing the state of cycling infrastructure.

A total of ten parameters were identified that should be collected in order to adequately assess the condition of cycling infrastructure and five of them that provide the necessary data for the GIP implementation: type of surface paving, changes in road surface, width of the cycle lane, road markings quality including pictograms/sharrows or similar, separation from other traffic areas (roads, pavements), signage (traffic signs in accordance with road traffic regulations and directional signage), route images, longitudinal edges/kerb edges, structural condition including type and extent of damage, clearance including obstacles.

Based on the parameters to be collected, suitable sensor technologies were identified and the required level of detail for data collection was determined. As part of sample surveys of various cycling infrastructures starting in Spring 2026, potential weaknesses in the methodology for condition assessment, the sensor technology used, and data processing will be identified. The aim is to verify and ensure the practicality and robustness of the chosen approach to condition assessment.

A total of around 150 km of cycling infrastructure in Austria will be examined. The surveys will be carried out on different types of infrastructure and in several federal states. There is no minimum length for the individual sections; rather, the sections examined should be as diverse as possible in order to comprehensively evaluate the suitability of the measurement methodology and the subsequent data analysis. The collected data will be integrated into the GIP in cooperation with the respective GIP officers of the federal states concerned. The results of the survey will be presented to the advisory board and their feedback will be incorporated into the survey catalog and the list of recommendations for efficient surveying.

8 ACKNOWLEDGEMENTS

This work has been carried out as part of a research project funded by the Austrian Road Safety Fund (VSF) under its 7th call for proposals ("InfraRad"). The authors would like to thank all project members for valuable feedback and their input as well as the survey participants for their time and effort. We would also like to express our special thanks to those who provided Letters of Support and the members of the interdisciplinary advisory board.

Constitutional Energy Mandates and Local Governance in Post-Apartheid Spatial Planning

Khatliso Simon Baas, Thulisile Ncamsile Mphambukeli

(Khatliso Simon Baas, University of Johannesburg, baasks1@gmail.com)
(Prof. Thulisile Ncamsile Mphambukeli, University of Johannesburg, tmphambukeli@uj.ac.za)

1 ABSTRACT

South Africa's post apartheid positions municipalities as key actors in the provision of basic services, including electricity. Section 156 and Schedule 4B of the Constitution empower local governments to govern electricity reticulation within their jurisdictions, granting them original authority independent of national or provincial delegation. This legal empowerment has significant implications for spatial planning, especially in historically marginalised regions like De Aar in the Northern Cape. However, the energy governance landscape is populated by multiple institutions with overlapping mandates. The Department of Mineral Resources and Energy (DMRE), though not constitutionally empowered, plays a central role in policy formulation and regulation through the Electricity Regulation Act. Eskom, a state-owned enterprise, dominates generation and transmission, operating under executive mandate and regulatory oversight. These institutional arrangements create tensions between constitutional decentralisation and centralised energy control. This article investigates how constitutional energy mandates are interpreted and operationalised at the municipal level, and how these dynamics shape spatial planning outcomes. Using De Aar as a case study, the research draws on spatial theory, energy justice, and systems theory to analyze the feedback loops between law, infrastructure, and governance. A qualitative methodology is employed, including document analysis of legal frameworks, municipal Integrated Development Plans (IDPs), and interviews with local officials.Findings reveal that while municipalities are legally empowered to provide electricity, their capacity to do so is constrained by technical limitations, fiscal dependency, and regulatory ambiguity. The recent amendments to the Electricity Regulation Act, which allows municipalities to procure power from independent producers, have opened new opportunities but also intensified institutional friction. Municipalities often lack grid access, planning tools, and intergovernmental support needed to translate legal mandates into spatial energy outcomes. The case of De Aar illustrates how constitutional ideals of decentralisation are challenged by systemic bottlenecks and institutional fragmentation. Spatially, this results in uneven infrastructure deployment, limited integration of renewable energy into local development plans, and a disconnect between national energy priorities and local realities. The article argues for a more coherent, capacitated, and collaborative approach to energy governance, one that aligns constitutional mandates with spatial planning and climate adaptation strategies.

Keywords: Constitutional Mandate, Energy Justice, Institutional Tensions, Renewable Energy Transitions, Post Apartheid South Africa

2 INTRODUCTION

South Africa's post-apartheid Constitution, adopted in 1996, enshrines a developmental vision for local government that includes the provision of basic services, promotion of socio-economic development, and facilitation of sustainable human settlements. Section 152 outlines the objectives of local government, while Section 156 and Schedule 4B explicitly empower municipalities to govern electricity reticulation within their jurisdictions (Republic of South Africa, 1996). These provisions grant municipalities original authority, meaning they do not require delegation from national or provincial governments to plan, manage, and deliver electricity services. This constitutional empowerment is particularly significant in the context of South Africa's energy transition, where decentralisation and renewable energy integration are increasingly prioritised. However, the practical realisation of these mandates is shaped by a complex institutional landscape. The Department of Mineral Resources and Energy (DMRE), though not constitutionally empowered, plays a central role in national energy policy and regulation through instruments such as the Integrated Resource Plan (IRP) and the Electricity Regulation Act (2006). Eskom, a state-owned enterprise, retains control over most generation and transmission infrastructure, creating a vertically integrated monopoly that often limits municipal autonomy. The National Energy Regulator of South Africa (NERSA) oversees licensing and tariff regulation, further complicating the governance terrain. These overlapping mandates produce tensions between constitutional decentralization and centralized energy control, particularly in municipalities with limited technical and financial capacity (Ngcobo, 2024; Tyler &

Hochstetler, 2021) Spatial governance, the coordination of land use, infrastructure, and development across space is a critical lens through which to examine these dynamics. In South Africa, spatial planning has historically been used as a tool of exclusion, with apartheid-era policies producing fragmented urban forms and unequal access to services (Harrison et al., 2008). Post-apartheid reforms have sought to redress these legacies through integrated development planning, yet energy infrastructure remains unevenly distributed, especially in arid and rural regions. The integration of renewable energy into municipal spatial plans presents both an opportunity and a challenge: it requires alignment between constitutional mandates, planning instruments, and infrastructure systems. This article investigates how constitutional energy mandates are interpreted and operationalised at the local level, and how these processes shape spatial planning outcomes in the context of South Africa's energy transition. Using De Aar, a small town in the Northern Cape Province as a case study, the research explores the intersection of legal empowerment, institutional coordination, and spatial governance. De Aar is emblematic of many secondary towns in South Africa: it faces infrastructural constraints, socio-economic marginalization, and increasing pressure to participate in climate adaptation and renewable energy initiatives. The central research question guiding this inquiry is: How does the Constitution empower local governments to provide electricity, and how does this shape spatial outcomes in the context of South Africa's energy transition? By integrating spatial theory, energy justice, and systems theory, the article aims to illuminate the feedback loops between law, infrastructure, and governance, and to contribute to a more nuanced understanding of post-apartheid energy planning.

3 LITERATURE REVIEW

3.1 Theoretical Frameworks in Energy and Spatial governance

(a) Spatial Theory: Production and Relationality of Space

Henri Lefebvre's The Production of Space (1991) remains foundational in understanding how space is socially produced through political, economic, and ideological processes. Lefebvre argues that space is not a passive backdrop, but an active medium shaped by power relations and institutional arrangements. His triadic framework: perceived, conceived, and lived space, offers a lens to examine how energy infrastructure reflects and reproduces spatial inequalities (Lefebvre, 1991; Molotch, 1993). In the South African context, energy infrastructure such as grid networks and renewable installations are often deployed in ways that reinforce historical spatial marginalisation, particularly in secondary towns like De Aar. Doreen Massey's relational spatiality complements Lefebvre's work by emphasizing that space is constituted through interactions across scales: local, regional, national, and global. Her concept of "power-geometry" highlights how different actors experience space differently based on their mobility, access, and agency (Massey, 2004; Taylor, 2024). In energy governance, this means that municipalities, despite constitutional empowerment, may be spatially constrained by limited grid access, planning tools, and institutional support. Massey's framework helps unpack how spatial marginality intersects with energy exclusion, reinforcing uneven development and governance asymmetries. Together, Lefebvre and Massey provide a robust theoretical foundation for analyzing how energy infrastructure both shapes and is shaped by spatial planning, governance, and socio-political dynamics.

(b) Energy Justice: Distributive, Procedural, and Recognition Dimensions

Energy justice has emerged as a critical framework for evaluating fairness in energy systems. Sovacool and Dworkin (2015) define energy justice through three core tenets:

- Distributive justice: Ensures equitable access to energy services and infrastructure. In South Africa, this is challenged by affordability barriers, unreliable supply, and geographic disparities in infrastructure deployment.
- Procedural justice: Advocates for inclusive and transparent decision-making processes. Municipalities and communities often lack meaningful participation in national energy planning, undermining democratic governance.
- Recognition justice: Calls for acknowledging the specific needs, identities, and vulnerabilities of marginalised groups. Spatially remote towns like De Aar require tailored governance approaches that reflect their socio-economic and geographic realities (Jenkins et al., 2016; Scholz & Schuppert, 2025).

Energy justice reframes energy transitions not merely as technical or economic challenges, but as ethical and political imperatives. Applying this lens to South Africa reveals systemic gaps between legal empowerment and lived energy outcomes, particularly in historically disadvantaged regions.

(c) Systems Theory: Feedback Loops and Governance Complexity

Systems theory offers a powerful analytical tool to understand the complexity of energy governance. Donella Meadows (2008) describes systems as composed of interconnected elements that produce patterns of behavior over time. Key concepts include feedback loops, delays, leverage points, and resilience. In energy governance, systems theory helps visualize how legal mandates, planning tools, infrastructure deployment, and service delivery interact dynamically, often producing unintended consequences, for an example, a municipality's legal authority to reticulate electricity (input) may be constrained by lack of technical capacity (system bottleneck), resulting in poor service delivery (output) and reinforcing centralised control (feedback). Radtke (2025) expands this by applying systems thinking to institutional design, showing how fragmented mandates and siloed planning inhibit adaptive governance. In De Aar, systems mapping reveals how decentralisation is constrained by technical bottlenecks, fiscal dependency, and fragmented intergovernmental coordination. Systems theory thus enables a holistic understanding of governance complexity and identifies leverage points for reform such as enhancing municipal planning tools or streamlining regulatory processes

3.2 Energy Governance in South Africa: Centralisation, Reform, and Emerging Complexity

South Africa's energy governance has long been characterised by centralised control, with Eskom historically monopolising electricity generation and transmission. Established in 1923, Eskom remains the dominant actor in the energy landscape, responsible for over 90% of electricity generation and the operation of the national grid (Eberhard et al., 2017). This centralisation has contributed to systemic inefficiencies, financial instability, and persistent load shedding, prompting calls for structural reform. The Department of Mineral Resources and Energy (DMRE), though not constitutionally mandated to oversee local electricity reticulation, plays a pivotal role in national energy policy formulation. Its influence is institutionalised through the Electricity Regulation Act No. 4 of 2006, which empowers the Minister to determine new generation capacity and procurement processes (Trollip & Boulle, 2017). The National Energy Regulator of South Africa (NERSA), established under the National Energy Regulator Act of 2004, regulates tariffs, licensing, and compliance, further reinforcing centralised oversight (NERSA, 2024). Recent amendments to the Electricity Regulation Act, most notably the Electricity Regulation Amendment Act No. 38 of 2024 have introduced mechanisms for municipalities to procure electricity directly from Independent Power Producers (IPPs). This reform aims to decentralise procurement authority, enhance competition, and reduce reliance on Eskom (Esterhuizen et al., 2025). However, implementation remains uneven. Municipalities face significant barriers, including limited grid access, technical capacity constraints, and regulatory ambiguity. Eskom retains control over grid infrastructure, and municipalities must navigate complex licensing and compliance procedures through NERSA and DMRE (SALGA, 2024). This institutional arrangement creates a governance paradox: while municipalities are constitutionally empowered under Section 156(1)(a) and Schedule 4B of the Constitution of the Republic of South Africa (1996) to govern electricity reticulation, they remain structurally dependent on national actors for infrastructure, funding, and regulatory approval (De Visser, 2009). The result is a fragmented energy landscape where decentralisation is legally affirmed but practically constrained. Municipalities like De Aar, despite hosting renewable energy projects, struggle to integrate these into local development plans due to limited planning tools and intergovernmental coordination gaps (Tyler & Haysom, 2021; Borchardt, 2023).This complexity underscores the need for a more coherent and capacitated governance framework, one that aligns constitutional mandates with operational realities and supports municipalities in fulfilling their developmental role in energy transitions

3.3 Post-Apartheid Spatial Planning and the Challenge of Integration

Spatial planning in South Africa has been tasked with redressing the entrenched inequalities produced by apartheid-era urban design. Under apartheid, planning was used as a tool of exclusion, systematically segregating communities and concentrating infrastructure investment in historically white urban cores. This resulted in fragmented urban landscapes, peripheral settlements with poor service access, and spatially embedded socio-economic disparities (Harrison et al., 2008; Todes, 2012). In response, post-apartheid

reforms introduced Integrated Development Plans (IDPs) and Spatial Development Frameworks (SDFs) as instruments to coordinate land use, infrastructure investment, and inclusive development. These tools are mandated by the Municipal Systems Act (2000) and are intended to align municipal planning with national development priorities. However, the integration of energy infrastructure, particularly renewable energy into these instruments, remains limited. Municipalities often lack the technical capacity, financial resources, and institutional support to embed energy transitions into spatial planning processes (Van Niekerk et al., 2020; Sutherland et al., 2022).

Secondary towns like De Aar face compounded challenges. These include low revenue bases, limited professional planning staff, and fragmented land governance systems. As a result, municipalities struggle to incorporate renewable energy strategies into their IDPs and SDFs, despite growing pressure to participate in climate adaptation and energy transition initiatives (Gordon et al., 2020; Cartwright et al., 2021). Moreover, national energy priorities such as those articulated in the Integrated Resource Plan (IRP) often bypass local spatial realities. Energy infrastructure projects are typically sited based on technical criteria such as solar irradiance or grid proximity, with limited consideration of local development plans or community needs (Tyler & Hochstetler, 2021). This top-down approach results in spatial mismatches between infrastructure deployment and socio-economic imperatives, undermining the potential for energy transitions to contribute meaningfully to spatial justice. In De Aar, for example, the presence of multiple solar farms has not translated into significant local development benefits. The town continues to experience high unemployment, limited delivery, and infrastructural deficits. The disconnect between energy investment and spatial planning reflects a broader governance gap: while municipalities are constitutionally empowered to govern electricity reticulation, they are rarely included in strategic energy planning processes. This exclusion reinforces historical patterns of marginalisation and limits the transformative potential of energy transitions. Addressing these challenges requires a more integrated and participatory approach to spatial planning, one that aligns constitutional mandates with energy governance frameworks and recognizes the agency of municipalities in shaping climate-resilient futures. It also demands a rethinking of planning instruments to accommodate the complexity of energy transitions, including land use coordination, grid access negotiation, and community engagement.

3.4 Municipal Mandate and the limits of Local Empowerment

The Constitution of the Republic of South Africa (1996) grants municipalities original powers to govern electricity reticulation, positioning them as central actors in service delivery and local development. Section 156(1)(a) and Schedule 4B explicitly assign electricity reticulation to local government, affirming their authority to plan, manage, and deliver electricity services within their jurisdictions (Republic of South Africa, 1996). This legal empowerment reflects the broader post-apartheid commitment to decentralisation and developmental local government. However, the practical realisation of these mandates is often undermined by systemic constraints. Many municipalities operate with limited financial autonomy, relying heavily on national transfers and struggling to generate own revenue through tariffs and property rates (Steytler & De Visser, 2018). Technical capacity is also unevenly distributed, with smaller and rural municipalities lacking the engineering, planning, and legal expertise required to engage in complex energy procurement or infrastructure development (Mosdell, 2016; SALGA, 2021). Institutional fragmentation further complicates implementation, as municipalities must navigate overlapping responsibilities with Eskom, the Department of Mineral Resources and Energy (DMRE), and the National Energy Regulator of South Africa (NERSA). The Presidential Climate Commission's Municipal Just Energy Transition (JET) Support Programme acknowledges these challenges and aims to build municipal capacity for renewable energy integration, climate adaptation, and inclusive development. The programme provides technical assistance, policy guidance, and stakeholder engagement platforms to enable municipalities to participate meaningfully in South Africa's energy transition (Presidential Climate Commission, 2023). However, its success depends on resolving longstanding tensions between municipalities and Eskom, particularly around grid access, infrastructure control, and revenue collection. Eskom's continued dominance in generation and transmission, coupled with its control over distribution in many areas, limits the ability of municipalities to exercise their constitutional authority. Municipalities often face delays in obtaining grid connection approvals, lack visibility into infrastructure planning, and struggle to negotiate equitable power purchase agreements with Independent Power Producers (IPPs) (Mohlakoana & Wolpe, 2023). These tensions are exacerbated by Eskom's financial instability and its reluctance to relinquish control over strategic assets.

Municipalities like De Aar exemplify the disconnect between constitutional authority and operational feasibility. Despite being legally empowered to govern electricity reticulation, De Aar faces infrastructural neglect, limited planning capacity, and exclusion from strategic energy decision-making. The town hosts several solar farms, yet local benefits remain minimal due to weak integration with spatial planning and limited municipal involvement in project design and implementation (Sutherland et al., 2022). This case illustrates how spatial marginalisation and institutional bottlenecks constrain the transformative potential of constitutional mandates. Addressing these challenges requires a multi-pronged approach: strengthening municipal capacity through targeted investment and training; clarifying intergovernmental roles and responsibilities, and reforming regulatory frameworks to enable local energy autonomy. It also demands a shift in governance culture, from top-down control to collaborative, place-based planning that recognizes municipalities as legitimate and capable actors in South Africa's energy future.

3.5 Comparative Reflections: South Africa and Global Experiences in Municipal Energy Governance

The constitutional framework of South Africa bestows municipalities with original authority over electricity reticulation, establishing them as pivotal participants in local energy transitions (Ngcobo, 2024). Nonetheless, as demonstrated by the De Aar case, this legal empowerment is frequently compromised by infrastructural limitations, inadequate planning capabilities, and intergovernmental conflicts (SALGA, 2017). These challenges are not exclusive to South Africa; however, they manifest differently in various global contexts: The European Energy Award (EEA) is a structured framework that supports interdisciplinary planning and continuous improvement in energy and climate policy, which is advantageous to municipalities in Europe. The EEA is a program in which more than 1,800 local authorities in Switzerland, Germany, Austria, and Romania participate, ensuring that local action is in accordance with the climate goals of the EU and the national government (European Energy Award, 2025; SECO, 2020). Cities such as Judenburg in Austria are prime examples of successful multilevel governance. They were able to expand district heating systems and improve spatial energy planning through coordinated planning at the local, regional, and national levels (Dobravec et al., 2021). South Africa's municipal energy landscape is largely devoid of technical advisors, certification mechanisms, and benchmarking tools, which are essential components of these systems. Brazil's 1988 Constitution similarly empowers municipalities, but implementation has been uneven due to fiscal and technical constraints (Souza, 2001). India's Panchayati Raj system decentralises rural governance, yet energy planning remains largely centralised, limiting local agency (Bhattacharyya, 2013). Germany, by contrast, exemplifies successful decentralisation through its Energiewende, where municipalities and citizen cooperatives play active roles in renewable energy deployment (Morris & Jungjohann, 2016). In the Global South, municipalities encounter comparable obstacles, limited capacity, fragmented land governance, and infrastructural deficits, but have responded by implementing adaptive governance and policy innovation. Participatory planning, digital citizen engagement, and localised renewable energy initiatives have been implemented in cities in India, Brazil, and Kenya. These initiatives are frequently supported by transnational networks such as the Global Covenant of Mayors and C40 Cities (Williamson, 2023; Blanc & Cotella, 2023). These strategies prioritise context-sensitive adaptation, community involvement, and flexibility, which are principles that are in alignment with South Africa's requirement for place-based energy governance. South Africa is characterized by the discord between its progressive legal framework and its centralized infrastructural reality. The Constitution establishes a robust basis for municipal autonomy; however, the execution of energy mandates is inconsistent. The contrast with European and Global South experiences underscores the necessity for South Africa to cultivate hybrid governance models that incorporate legal empowerment with institutional support, spatial integration, and systems thinking.

3.6 Gaps in Current Scholarship

Despite a growing body of literature on energy transitions, climate governance, and spatial planning in South Africa, several critical gaps persist particularly in relation to the constitutional role of municipalities and the spatial dynamics of energy infrastructure. These gaps limit the ability of scholars and policymakers to understand and address the uneven geography of energy transitions, especially in secondary towns like De Aar.

(a) Limited Focus on Secondary Towns

Much of the existing scholarship focuses on metropolitan municipalities such as Cape Town, Johannesburg, and eThekwini, which have greater institutional capacity, access to funding, and visibility in national policy debates (Sutherland et al., 2022; Cartwright et al., 2021). These cities have piloted renewable energy projects, developed climate adaptation strategies, and engaged with international networks. In contrast, smaller municipalities, located in arid, and economically marginalised regions, remain under-researched despite facing distinct challenges: limited grid access, fragmented land governance, and constrained planning capacity. De Aar, situated in the Northern Cape, exemplifies these dynamics. It hosts several solar farms under the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP), yet local development benefits remain minimal. The lack of scholarly attention to such towns obscures the spatial inequalities embedded in South Africa's energy transition and limits the development of place-based policy responses.

(b) Insufficient Integration of Legal and Spatial Analysis

While there is robust legal scholarship on constitutional mandates and municipal autonomy (Steytler & De Visser, 2018; Ngcobo, 2024), and a parallel body of work on spatial planning and infrastructure development (Harrison et al., 2008; Todes, 2012), few studies bridge these domains. This siloed approach overlooks how legal empowerment such as the constitutional authority over electricity reticulation translates into spatial planning outcomes. For instance, municipalities may be legally entitled to govern electricity services, but without integration into spatial development frameworks, these mandates remain abstract. The disconnect between law and spatial practice contributes to fragmented infrastructure deployment, poor alignment with community needs, and missed opportunities for climate adaptation.

(c) Underutilisation of Systems Theory

Systems theory offers a powerful lens for understanding the interdependencies between governance structures, infrastructure networks, and spatial outcomes. It emphasizes feedback loops, emergent properties, and adaptive capacity, concepts highly relevant to energy transitions and climate resilience (von Bertalanffy, 1968; Capra & Luisi, 2014). Yet, its application in South African energy and spatial planning literature remains limited. Most studies adopt sectoral or linear approaches, focusing on policy implementation, technical feasibility, or institutional reform in isolation. This neglects the complex, multi-scalar interactions that shape energy spatiality, such as how national policy filters through provincial structures, interacts with municipal planning tools, and is mediated by infrastructure constraints. Applying systems theory can illuminate these dynamics and support more integrated, adaptive governance models.

Contribution of this article

This article addresses these gaps by offering a place-based analysis of energy governance in De Aar. It integrates constitutional law, spatial planning, and systems theory to illuminate the constructed spatiality of energy transitions in post-apartheid South Africa. By focusing on a secondary town, it foregrounds the lived realities of decentralisation, infrastructural inequality, and institutional tension. It also demonstrates how legal mandates interact with spatial planning instruments and infrastructure systems to produce uneven energy outcomes thereby contributing to both scholarly understanding and policy innovation.

4 METHODLOGY

This study employs a qualitative case study approach to investigate how constitutional energy mandates are interpreted and operationalized at the municipal level, and how these processes shape spatial planning outcomes in the context of South Africa's energy transition. The case of De Aar, a secondary town in the Northern Cape was selected due to its strategic location within the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) and its spatial marginalization within national development frameworks.

4.1 Research Design

A single-case embedded design was adopted, allowing for in-depth exploration of governance dynamics, planning instruments, and institutional interactions within De Aar (Yin, 2018). The study integrates legal analysis, spatial planning review, and stakeholder perspectives to construct a multi-scalar understanding of energy governance.

4.2 Data Collection

The study used document analysis, semi-structured interviews, and systems mapping. Documents included legal frameworks, municipal plans, and energy policy reports to triangulate mandates and institutional roles. Interviews with municipal officials, provincial coordinators, consultants, and community stakeholders explored planning, coordination, and implementation barriers. Systems mapping as shown in figure 1 below, visualized institutional relationships and feedback loops, guiding analysis of multi-scalar governance interactions and spatial outcomes in De Aar.

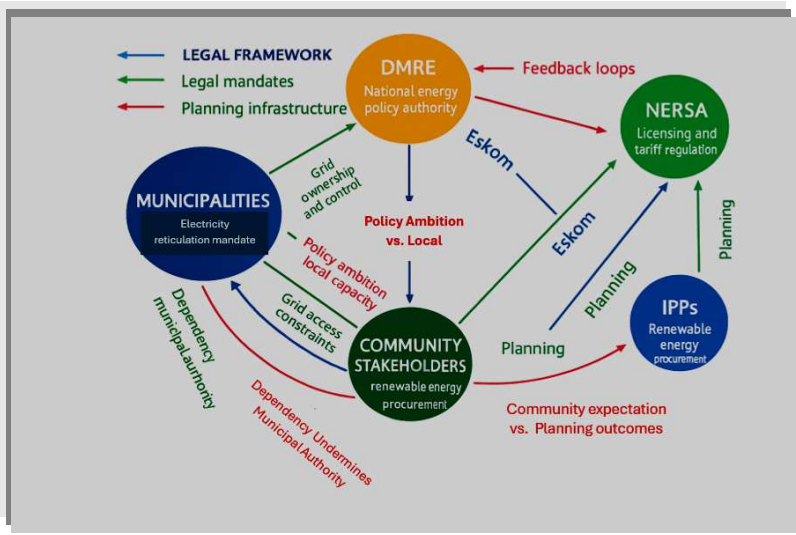

Fig 1: Interactions and feedback loops in South Africa's Local Energy Governance Seystems

Spatial mapping of energy infrastructure and planning zones was conducted using publicly available GIS data and municipal records. Figure to illustrate the spatial mapping of renewable energy around Emthanjeni Local Municipality.

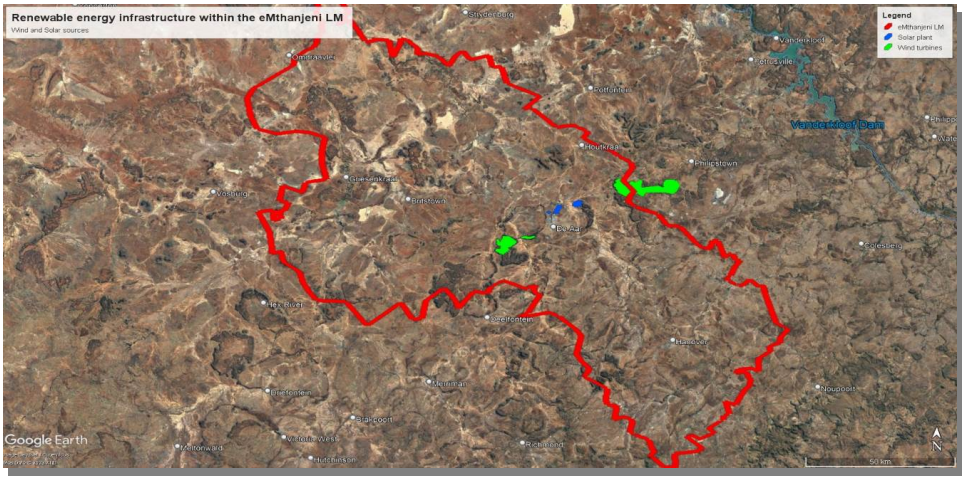

Fig 2: Renewable energy Infrastructure within the Emthanjeni Local Municipality. Source: (Emthanjeni Environmental profile, 2024)

4.3 Data Analysis

The study used thematic coding of interviews and planning documents, supported by NVivo, combining deductive and inductive analysis. Findings show a clear gap between municipal legal authority and operational capacity. Although the Constitution empowers municipalities to manage electricity reticulation, Emthanjeni Municipality lacks the technical skills, financial resources, and planning tools to fulfil this mandate. This reflects deeper institutional weaknesses in South Africa's developmental local government system. Energy governance in De Aar is further constrained by institutional fragmentation. Eskom's control of grid infrastructure and the involvement of multiple national regulators create coordination challenges, regulatory delays, and limited municipal autonomy. While recent legislation allows municipalities to procure electricity independently, practical barriers such as grid access and licensing continue to inhibit implementation. These governance failures have significant spatial and social consequences. Renewable energy projects in De Aar are poorly integrated into local planning and offer limited benefits to local

communities, reinforcing spatial inequality and undermining principles of energy justice. Residents face affordability challenges, unreliable supply, and exclusion from decision-making processes. From a systems perspective, weak alignment between legal mandates, planning instruments, and infrastructure control creates reinforcing feedback loops that entrench centralisation and municipal underperformance. Addressing these systemic bottlenecks requires targeted reforms. Recent policy changes present emerging opportunities, but real decentralisation will depend on strengthened municipal capacity, clearer regulatory roles, improved grid access, and stronger intergovernmental coordination. Without these measures, municipal energy autonomy will remain largely symbolic

5 FINDINGS AND DISCUSSIONS

This section presents the key findings from thematic coding of municipal documents, interviews with local officials, and analysis of planning instruments. It responds to the methodological approach outlined earlier, which combined qualitative document analysis with systems mapping to uncover governance dynamics in De Aar.

5.1 Legal Empowerment vs Operational Reality

The Constitution of South Africa clearly empowers municipalities to govern electricity reticulation under Section 156(1)(a) and Schedule 4B. Emthanjeni Municipality, which governs De Aar, is thus legally entitled to plan and deliver electricity services. However, this empowerment is undermined by operational constraints. Interviews with municipal officials and analysis of the Integrated Development Plan (IDP) reveal that while the municipality acknowledges its mandate, it lacks the technical capacity, financial resources, and planning tools to execute it effectively (Borchardt, 2023; Van Wyk, 2012). The disconnect between legal authority and practical capability reflects what De Visser (2009) calls “institutional fault lines” in developmental local government. Municipalities are expected to be developmental agents, yet they operate within a system that centralises infrastructure control and limits fiscal autonomy.

5.2 Institutional Friction and Fragmentation

The systems mapping of De Aar’s energy governance reveals significant institutional friction. Eskom retains control over grid infrastructure, and municipalities must seek approval from NERSA and DMRE to procure power from Independent Power Producers (IPPs). These actors operate under different mandates and timelines, creating coordination gaps and regulatory ambiguity (Trollip & Boulle, 2017; Tyler & Haysom, 2021). For example, while the Electricity Regulation Amendment Act (2024) allows municipalities to procure power independently, Emthanjeni Municipality struggles to access the grid and navigate licensing procedures. This friction delays project implementation and discourages local innovation. The result is a fragmented governance landscape where decentralisation is legally affirmed but practically constrained.

5.3 Spatial Outcomes and Energy Justice

Spatially, the consequences of this fragmentation are profound. De Aar hosts several large-scale renewable energy projects under REIPPPP, yet these are rarely integrated into local development plans. The municipality has limited influence over project siting, grid connection, or benefit-sharing mechanisms. As a result, energy infrastructure is deployed in ways that bypass local planning and perpetuate spatial inequality (Harrison et al., 2008; SACN, 2015). From an energy justice perspective, this undermines distributive, procedural, and recognition justice. Households in De Aar face affordability barriers, unreliable supply, and exclusion from decision-making. The municipality’s inability to reticulate locally generated renewable energy reflects a broader failure to align infrastructure with community needs and constitutional ideals.

5.4 Feedback Loops and Systemic Bottlenecks

Systems theory helps illuminate the feedback loops that reinforce these challenges. Legal mandates feed into planning tools (IDPs and SDFs), which should guide infrastructure deployment. However, when infrastructure is controlled by external actors, service delivery suffers, and policy feedback is weak. This loop perpetuates underperformance and centralised control. In De Aar, the lack of grid access, technical expertise, and intergovernmental support creates systemic bottlenecks. These are not isolated issues but structural features of South Africa’s energy governance system. Reforming this system requires identifying

leverage points such as enhancing municipal planning capacity, clarifying regulatory roles, and fostering collaborative platforms.

5.5 Emerging Opportunities and Reform Pathways

Despite these challenges, recent reforms offer new opportunities. The Electricity Regulation Amendment Act (2024) and growing interest in distributed generation create space for municipalities to assert their authority. Emthanjeni Municipality could leverage its constitutional mandate to develop local energy strategies, engage IPPs, and integrate energy into spatial planning. However, this requires support. National government must invest in municipal capacity-building, streamline regulatory processes, and facilitate grid access. Intergovernmental forums should be established to align energy and spatial planning across spheres. Without these reforms, decentralisation will remain a constitutional promise rather than a practical reality. Figure 3 below illustrates the systemic interactions in South Africa's local energy governance. It highlights how constitutional mandates for municipal electricity reticulation are undermined by affordability crises and household exclusion (Observed Constraints), while external infrastructure control creates bottlenecks between local planning and implementation (Mandates vs. Local Implementation). The feedback loops visually reinforce the findings in Sections 5.1–5.5, showing how legal empowerment, institutional friction, spatial inequality, and systemic bottlenecks converge to shape energy justice outcomes in De Aar.

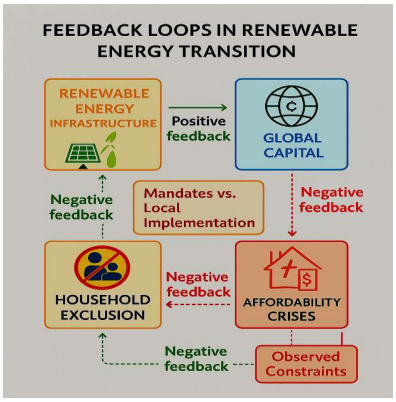

Fig 3: Feedback Loops in Renewable Energy Transition

The diagram provides a unifying visual anchor for findings. In Section 5.1 (Legal Empowerment vs Operational Reality), the annotation "Mandates vs. Local Implementation" illustrates the gap between constitutional authority and municipal capacity, showing how exclusionary feedback loops weaken the execution of electricity reticulation. In Section 5.2 (Institutional Friction and Fragmentation), the negative arrows highlight how external actors such as Eskom, NERSA, and DMRE constrain municipal autonomy, reinforcing the institutional fault lines described in the literature. In Section 5.3 (Spatial Outcomes and Energy Justice), the Household Exclusion loop visually represents distributive and recognition injustices, where affordability crises perpetuate spatial inequality and bypass local planning. In Section 5.4 (Feedback Loops and Systemic Bottlenecks), the diagram itself embodies the systemic bottlenecks: weak policy feedback, affordability barriers, and exclusion cycles that entrench underperformance. Finally, in Section 5.5 (Emerging Opportunities and Reform Pathways), the map highlights leverage points for reform, suggesting that breaking negative loops and strengthening positive ones could enable municipalities like Emthanjeni to align constitutional mandates with practical delivery. By weaving through each subsection, the diagram responds directly to the empirical findings, transforming a methodological tool into a lens for interpreting governance realities and reform pathways.

6 CONCLUSION AND RECOMMENDATIONS

This study has examined how constitutional energy mandates are interpreted and operationalised at the municipal level in post-apartheid South Africa, using De Aar as a case study. Drawing on spatial theory, energy justice, and systems thinking, the research reveals a persistent gap between legal empowerment and practical implementation. While Emthanjeni Local Municipality is constitutionally authorised to govern electricity reticulation, its capacity to do so is constrained by technical limitations, fiscal dependency, regulatory ambiguity, and fragmented intergovernmental coordination. Systems mapping of De Aar demonstrates how these constraints interact across municipal planning, regulatory processes, infrastructure

ISBN 978-3-9504945-5-6

deployment, and service delivery, reinforcing feedback loops that allow energy infrastructure to bypass local planning instruments and fail to address community needs. As a result, the transformative intent of post-apartheid spatial planning is undermined, perpetuating uneven development and spatial inequality.

In response, this study recommends a coherent, place-based model of energy governance centred on six interrelated priorities: strengthening municipal capacity, clarifying regulatory roles, enhancing intergovernmental coordination, integrating energy and land-use planning, promoting spatially just energy transitions, and applying systems thinking as an enabling governance approach. Together, these priorities emphasise that meaningful decentralisation requires more than constitutional authority; it depends on institutional capacity, regulatory alignment, and collaborative planning across spheres of government. By situating energy governance within a spatial justice and systems framework, the proposed approach seeks to align constitutional ideals with practical governance mechanisms, enabling more equitable, climate-responsive, and development-oriented energy transitions in De Aar. figure 4 below illustrates six interrelated priorities required to align municipal energy governance with constitutional mandates, spatial justice, and climate-responsive local development.

1 ABSTRACT

Urbanization in Sub-Saharan Africa has brought both opportunities and challenges, with the rapid expansion of informal settlements emerging as a critical issue for sustainable urban development. The New Urban Agenda (NUA), adopted in 2016, provides a global framework for addressing these challenges; however, its implementation in the region remains uneven and fraught with complexities. This research critiques the application of the NUA's principles related to informal settlement upgrading, focusing on housing policies and their alignment with inclusive and sustainable urban development objectives. Despite the NUA's efforts on inclusivity, resilience, and sustainability, informal settlement upgrading in Sub-Saharan Africa is hindered by systemic barriers, including insecure land tenure, inadequate infrastructure, limited financing, and fragmented governance. Using a systematic review methodology, the study synthesises evidence from academic literature, policy documents, and case studies across the region. The analysis framework is guided by the NUA's core principles of inclusivity, sustainability, and resilience. Findings reveal significant limitations in policy implementation, particularly regarding community participation, tenure formalization, infrastructure provision, and resource mobilization. In response, the study proposes the Localised Inclusive Informal Settlement Upgrading Framework (LIISUF), which provides an actionable pathway for aligning informal settlement upgrading practices with NUA principles. Through stressing flexible tenure arrangements, community-led planning, incremental infrastructure provision, innovative financing, and coordinated governance, LIISUF aims to enhance equity, sustainability, and resilience in African urban development, offering practical guidance implement inclusive and locally relevant upgrading initiatives.

Keywords: New Urban Agenda, Sub-Saharan Africa, informal settlements, housing policies, participatory planning

2 INTRODUCTION

The New Urban Agenda (NUA) serves as a catalytic framework for implementing the Sustainable Development Goals (SDGs) within urban and territorial contexts. Since its adoption in 2016, the NUA has been formally endorsed by 167 countries, including a substantial number of African states, signalling broad international commitment to integrated, inclusive, and sustainable urban development. Since 2018, a series of multi-scalar shocks and structural transformations have produced significant, both positive and adverse impacts across the African continent. These include localized manifestations of climate change, the COVID-19 pandemic, the ratification of the African Continental Free Trade Area (AfCFTA), the implementation of regional economic integration frameworks, shifts in national political regimes, and the persistence of violent conflict and insurgency. Collectively, these dynamics have reshaped urban and regional systems, accelerating intra- and cross-border migration flows, particularly among youth, while intensifying socio-economic inequality, precarity, and vulnerability within many African towns and cities (United Nations, 2022). World Bank (2022), Africa accommodates a disproportionate share of the global population living in extreme poverty, with significant implications for urban development, spatial inequality, and the planning and provision of basic services. Even though the NUA is being implemented in African countries, there are still numerous deficits. By 2020, sub-Saharan Africa recorded the highest global incidence of multidimensional poverty, reflecting intersecting deprivations in health, education, housing quality, basic services, livelihood security, personal safety, and exposure to environmentally hazardous locations. An estimated 71.9% of the rural population (approximately 466 million people) and 25.2% of the urban population (around 92 million people) were affected, highlighting stark rural–urban and intra-urban disparities (UNDP, 2020). Furthermore, many African countries remain off-track to achieve the 2030 target of halving multidimensional poverty, thereby constraining progress towards multiple interlinked Sustainable Development Goals (SDGs) and posing significant challenges for inclusive, resilient, and equitable spatial planning (Alkire et al., 2020). The next section outlines the conceptual elements underpinning informal

settlement upgrading in Sub-Saharan Africa, with particular reference to the New Urban Agenda and related housing policy frameworks. This is followed by a description of the systematic review methodology employed, including the search strategy, selection criteria, and analytical approach. The subsequent section presents and discusses the findings of the review, highlighting critical implementation limitations and emerging good practices in informal settlement upgrading. In response to these findings, the research proposes the Localised Inclusive Informal Settlement Upgrading Framework (LIISUF).

3 NORMATIVE FRAMEWORKS AND IMPLEMENTATION REALITIES

The Global Action Plan for Slum Transformation outlines a coordinated, multi-stakeholder framework that promotes a shared vision of inclusive urbanism and "Cities for All," grounded in the principle of leaving no one and no place behind. It is strategically positioned as an implementation accelerator for the Sustainable Development Goals (SDGs) and the New Urban Agenda (NUA), with a specific operational focus on addressing structural inequalities, spatial exclusion, and service deficits within informal settlements and slum environments (Department of Human Settlements, 2022). Across much of sub-Saharan Africa, fewer than 10% of households possess the financial capacity to access mortgage finance, even for the lowest-cost newly constructed formal housing units (CAHF, 2016). Still in the same region, multiple land tenure regimes, often exceeding five distinct systems, frequently coexist within the same spatial context, generating institutional ambiguity, tenure insecurity, and recurrent land-related conflicts. This fragmented land governance landscape significantly constrains formal housing delivery and contributes to the persistent shortage of affordable housing across the region. The conditions described above are in clear contradiction to the principles and normative commitments of the New Urban Agenda. It calls for diversified and accessible housing finance systems, including alternatives to conventional mortgage markets, to accommodate low-income households and those operating within informal economies (UN-Habitat, 2017). These conditions reflect a significant implementation gap between the NUA's equity-oriented, rights-based urban vision and the prevailing housing finance and land governance realities in sub-Saharan Africa, highlighting the need for structural reform rather than incremental policy alignment.

Despite the persistent structural challenges and implementation gaps, UN-Habitat continues to play a pivotal enabling role by supporting Habitat Agenda partners and governments at national, regional, and local levels to advance housing sector reforms. Through technical assistance, policy guidance, and institutional capacity-building, UN-Habitat facilitates the formulation of housing policies, legislative frameworks, and strategic interventions that promote the progressive realization of the right to adequate housing and advance the objectives of inclusive, safe, resilient, and sustainable urban development, in alignment with Sustainable Development Goal 11 and the New Urban Agenda.

4 METHODOLOGY IMPERATIVES

This study employs a systematic review methodology to synthesise evidence from academic literature, policy documents, and case studies on informal settlement upgrading in Sub-Saharan Africa. Systematic reviews are widely recognised as a precise and transparent approach to knowledge synthesis, particularly in policy-oriented and interdisciplinary research contexts where evidence is fragmented across multiple sources and disciplines (Petticrew & Roberts, 2006). Unlike traditional narrative reviews, systematic reviews rely on explicit, replicable, and methodologically structured procedures for identifying, selecting, and analysing relevant literature, thereby reducing selection bias and enhancing the credibility and reproducibility of findings, as shown in Figure 1. The review draws on both peer-reviewed academic literature and grey literature, including reports produced by international and regional organisations such as UN-Habitat and the World Bank. The inclusion of grey literature is methodologically justified, as significant policy-relevant knowledge, particularly in development planning and housing research, is often generated outside academic journals (Adams, Smart & Huff, 2017). Excluding such sources risks overlooking critical insights into policy design, implementation processes, and institutional practices, especially in settings such as Sub-Saharan Africa, where governance frameworks and development interventions are extensively documented through policy reports rather than scholarly publications.

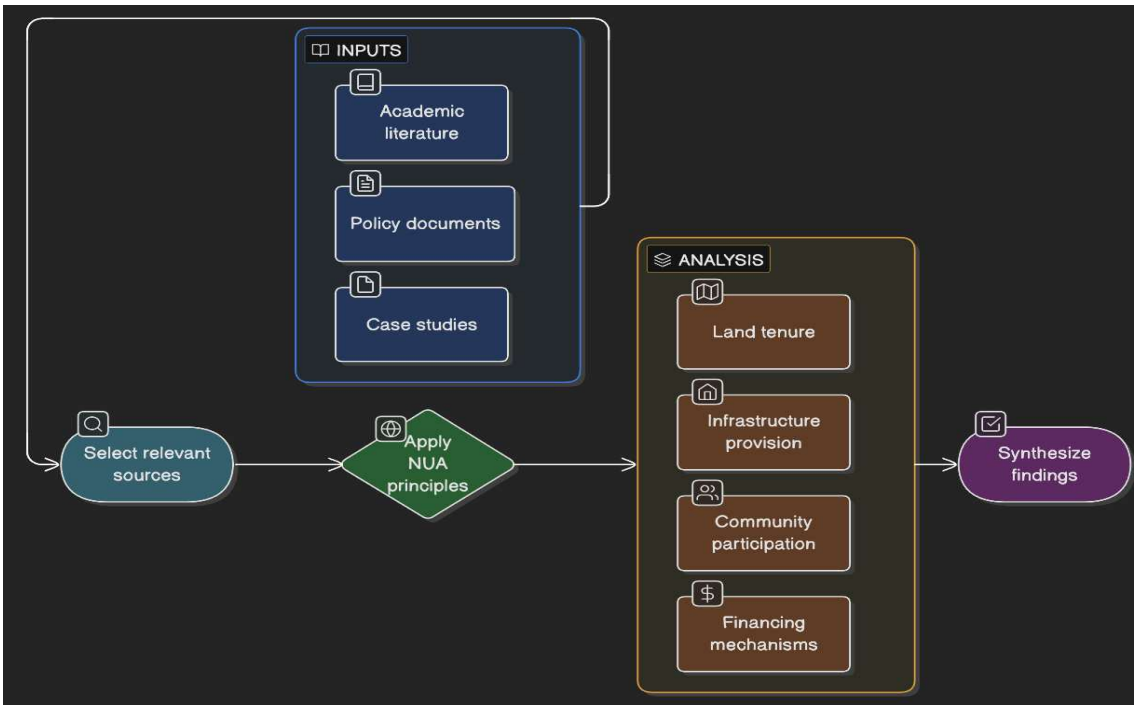

Figure 1: Research Process

To ensure analytical coherence, Figure 1 illustrates that the synthesis of evidence is guided by the core principles of the New Urban Agenda (NUA), namely inclusivity, sustainability, and resilience, which serve as an overarching analytical framework. The use of a predefined conceptual framework is consistent with best practices in systematic review research, as it provides a structured basis for comparing findings across diverse studies and policy texts while maintaining alignment with the study's objectives (Dixon-Woods et al., 2005). This framework enables a critical examination of how global urban development norms are interpreted, localised, and operationalised within housing policies and informal settlement upgrading initiatives in Sub-Saharan Africa. A structured search strategy was developed using predefined keywords related to informal settlement upgrading, housing policy, land tenure, participatory planning, and urban governance. Sources were screened against explicit inclusion and exclusion criteria, focusing on relevance to Sub-Saharan Africa, substantive engagement with informal settlement upgrading, and contribution to policy or empirical understanding. Such systematic screening processes are central to ensuring transparency and methodological defensibility in review-based research (Kitchenham & Charters, 2007; Gough, Oliver & Thomas, 2017). Following selection, data were extracted and synthesised using a thematic synthesis approach, which is particularly suited to systematic reviews in the social sciences where qualitative and mixed-methods evidence predominates (Thomas & Harden, 2008). Through iterative coding and comparison, crucial themes, including land tenure security, infrastructure provision, community participation, and financing mechanisms, were identified and critically examined.

5 ANALYSIS AND DISCUSSIONS

Despite being articulated as core commitments within the New Urban Agenda, the advancement of transparent, inclusive, participatory, and sustainability-oriented urban and territorial spatial planning systems, together with the universalisation of secure land and housing tenure for all socio-economic groups, including women, youth, and other historically marginalised populations, remains a significant implementation deficit. In practice, persistent governance fragmentation, limited participatory depth, weak institutional capacity, and entrenched tenure insecurity continue to undermine these principles, exposing a pronounced limitation between the normative aspirations of the New Urban Agenda and their translation into effective, on-the-ground urban development outcomes (UNECE, 2016). Housing infrastructure is a crucial part of the urban economy. A substantial proportion of the urban population lacks access to, or affordability of, formal housing finance mechanisms necessary for the acquisition or construction of adequate housing (World Cities Report, 2020). Consequently, many households resort to incremental self-provisioning of shelter within informal settlements and slums, located both in inner-city areas and on the urban periphery, often outside formal planning, regulatory, and service delivery frameworks (Bah, Faye & Geh, 2018).

Approximately one quarter of the global urban population residing in slum-like and informal settlement conditions is concentrated in Sub-Saharan Africa, highlighting the region's disproportionate exposure to structural housing deficits, inadequate basic services, and persistent spatial informality within rapidly urbanising cities (World Cities Report, 2020).

The New Urban Agenda (Habitat III, 2016a: 51) elevates spatial planning as a central instrument for steering urban morphology toward more compact, integrated, and efficient spatial configurations. However, this framing insufficiently engages with the empirically established formal–informal continuum that characterises urban development, particularly in rapidly urbanising contexts. The Agenda offers limited operational guidance on how planning systems should meaningfully incorporate existing informally developed areas or address entrenched patterns of unplanned land occupation and informal settlements in Sub-Saharan Africa (Huchzermeyer, 2017). Instead, its normative emphasis implicitly privileges solutions anchored in planned urban extensions and the realisation of economies of scale, thereby underestimating the structural, socio-spatial, and institutional complexities associated with informality and incremental urbanisation. Despite the proliferation of housing programmes aimed at advancing the objectives of the New Urban Agenda (NUA) in South Africa, the national housing deficit continues to widen as sustained rural–urban migration intensifies demand in metropolitan and secondary urban centres. By 2018, the cumulative housing backlog had reached approximately 2.1 million units, underscoring the persistent structural mismatch between housing supply and rapidly growing urban populations (Marutlulle, 2021).

6 TOWARDS A LOCALISED INCLUSIVE INFORMAL SETTLEMENT UPGRADING FRAMEWORK (LIISUF)

The Localised Inclusive Informal Settlement Upgrading Framework (LIISUF) is designed to translate the normative principles of the New Urban Agenda into setting, implementable actions for informal settlement upgrading in Sub-Saharan Africa. The framework responds to the identified limitations between policy commitments and practice, particularly in relation to land tenure insecurity, weak participatory processes, fragmented governance, inadequate infrastructure provision, and limited financing mechanisms. It stresses localisation, institutional coordination, and community-centred implementation as critical enablers of sustainable upgrading.

Challenge Identified	Strategic Focus	Recommended Action	Expected Outcome
Insecure land tenure	Tenure security	Introduce incremental and flexible tenure options (e.g. occupation permits, community land trusts) aligned with local land governance systems	Improved tenure security and reduced risk of displacement
Limited community participation	Inclusive planning	Institutionalise community-led planning and decision-making in upgrading projects	Stronger local ownership and more context-sensitive interventions
Inadequate infrastructure and services	Basic service provision	Prioritise in-situ upgrading with phased provision of water, sanitation, electricity, and access roads	Improved living conditions without forced relocation
Weak localisation of the NUA	Context-sensitive policy alignment	Adapt NUA principles into national and municipal housing and planning policies	Better alignment between global frameworks and local realities
Financial constraints	Innovative financing	Combine public funding, community savings schemes, and private sector partnerships	Increased financial sustainability of upgrading programmes
Fragmented governance and institutions	Coordinated governance	Strengthen intergovernmental and multi-stakeholder coordination mechanisms	More coherent and efficient implementation processes

Table 1: Localised Inclusive Informal Settlement Upgrading Framework (LIISUF)

The Localised Inclusive Informal Settlement Upgrading Framework (LIISUF) in Table 1 proposes a pragmatic approach to advancing the implementation of the New Urban Agenda (NUA) in Sub-Saharan Africa by directly responding to the structural and governance-related constraints identified in the literature. Central to the framework is the recognition that secure land tenure is foundational to sustainable upgrading; however, rather than prioritising full legal titling, the framework supports incremental and flexible tenure arrangements that reflect plural land governance systems common in African cities, including customary and hybrid regimes (Durand-Lasserve, 2015). The framework further stresses community-led and participatory planning, arguing that meaningful resident involvement enhances project legitimacy, improves policy

responsiveness, and aligns with the NUA's "leave no one behind" principle (Habitat III, 2016a). To address persistent service deficits, LIISUF prioritises in-situ upgrading and phased infrastructure provision as a means of improving living conditions while minimising displacement and socio-spatial disruption (Huchzermeyer, 2011; World Bank, 2020). Recognising the difficulty of translating global frameworks into local practice, the framework highlights the importance of localising NUA principles within national and municipal housing and planning policies to ensure contextual relevance and institutional ownership. Given chronic funding limitations, LIISUF advocates for innovative and blended financing mechanisms, including public investment, community savings schemes, and public–private partnerships, which have demonstrated potential to enhance financial sustainability and scale in informal settlement upgrading initiatives (Cities Alliance, 2019). The framework highlights the need for coordinated, multi-level governance, as fragmented institutional arrangements remain a critical barrier to effective implementation across the region. Collectively, LIISUF offers a simplified yet dynamic pathway for aligning informal settlement upgrading practices with the normative commitments of the New Urban Agenda while remaining grounded in the socio-spatial realities of Sub-Saharan African cities.

7 CONCLUSION

This study critically examined the implementation of the New Urban Agenda (NUA) in Sub-Saharan Africa, with a focus on housing policies and informal settlement upgrading. The findings highlight persistent limitations between the NUA's principles of inclusivity, sustainability, and resilience and the realities on the ground, including insecure land tenure, limited community participation, inadequate infrastructure, fragmented governance, and constrained financing mechanisms. These structural and institutional barriers hinder the progressive realisation of adequate, safe, and affordable housing for low-income and marginalised populations. In response, the study proposes the Localised Inclusive Informal Settlement Upgrading Framework (LIISUF), which offers a pragmatic approach to translating NUA commitments into actionable strategies. Through stressing flexible tenure arrangements, participatory planning, in-situ infrastructure upgrading, innovative financing, and coordinated governance, LIISUF provides a pathway for aligning global urban development norms with the socio-spatial realities of African cities. Ultimately, the study highlights that the transformative potential of the NUA in Sub-Saharan Africa depends not only on policy adoption but on its localisation, institutional capacity, and sustained community engagement. Implementing such driven frameworks can enhance equity, resilience, and sustainability in urban development, providing a foundation for more liveable cities across the region.

1 ABSTRACT

Participatory Rural Appraisal (PRA) has long been used in India and globally to enable communities to analyse their own living conditions and co-design development solutions. However, rapid digital transformation, characterized by smartphones, geospatial platforms, IoT sensors, artificial intelligence, and digital public infrastructure, have expanded the scope of PRA into a more powerful, data-driven, and scalable approach, known as Digital Participatory Rural Appraisal (DPRA). DPRA integrates human centred participatory tools with digital technologies to support evidence-based planning, inclusive governance, climate adaptation, and sustainable rural development.

The present article is an attempt to develop a concept for local community participation by the application of digital technologies for preparation of Smart Sustainable Village Development Plan. The paper discusses about the guiding principle and participatory methodology for inclusive digital participation of local community for sustainable village planning and development. In short, the present paper outlines the DPRA framework, methods, implementation model, case applications, and policy directions for Gaindikhata Cluster of villages in Haridwar district of India.

Key words: Digital PRA, Community Participation, Sustainable Development, Village Planning, Smart.

2 INTRODUCTION

Rural development has long been recognized as a cornerstone for equitable and sustainable growth across the globe. It has been a central focus of policy discourse in developing nations, particularly in countries like India, where nearly 65% of the population still resides in rural areas (World Bank, 2023). While traditional approaches have emphasized infrastructure, agriculture, and social welfare, the recent digital revolution has introduced new opportunities for strengthening community participation. Digital technologies, including information and communication technologies (ICTs), mobile applications, social media, e-governance platforms, and artificial intelligence are increasingly being deployed to empower rural communities, improve decision-making, and enhance access to essential services. Conceptualizing Community Participation in the Digital Era refers to the active involvement of local populations in decision-making, planning, and implementation of development initiatives. In the digital context, participation is increasingly mediated through online platforms, digital tools for knowledge sharing, and citizen-led data generation.

Now in the contemporary rural India it is more important to evolve participatory and inclusive rural planning process to understand the rural community needs and over all social and economic development. Seventeen Sustainable Development Goals (SDG) adopted by the United Nations General Assembly in 2015 as '2030 Agenda' representing a comprehensive approach to sustainable rural development. One of the key steps toward achieving higher levels of sustainability and the Sustainable Development Goals (SDGs) is to address economic disparities, climate change, and access to modern technologies and basic infrastructures. The concept of smart rural communities, although somewhat trendy, has gained significant attraction in this regard. While the smart city initiative is well-known, it is complemented by the Indian Smart Village initiative, aimed at leveraging Information and Communication Technology (ICT) to benefit people living in rural areas.

Comprehensively designed smart villages are expected to provide a fundamental framework for rural communities to enhance their participation at the local level, improve their economic, social, and living conditions, and, thereby, increase their resilience. Within the "Digital India" plans, the Indian government envisions a complementary approach, where smart villages not only drive economic growth in rural areas by producing goods and services but also serve as national and international markets. Consequently, there is a pressing need to design and develop villages with strong internal and external connections while preserving their independence in providing employment, services, and a high quality of life.

3 UNDERSTANDING THE CONCEPT OF DIGITAL PARTICIPATORY SMART SUSTAINABLE RURAL DEVELOPMENT.

The development of villages is a crucial factor in the progress of the nation. Therefore, village development should be envisioned in a manner that promotes self-sufficiency in delivering essential services, generating employment opportunities, and fostering strong global connectivity, denoting the concept of a “Smart Model Village”. The term "model" conceptually implies the design of an activity or situation that serves as an exemplary model for replication. In this context, a model village represents a sustainable community capable of generating and sustaining the resources needed to enhance its well-being. This enhancement is achieved by reinforcing the pillars of sustainability, including livelihood, infrastructure, and services. Smart villages rectify social oversights by providing a conducive environment for sustaining family relationships across different generations without disrupting their way of life. The vision behind smart villages is that they can serve as catalysts for development across various domains, including education, health, productive enterprises, clean water and sanitation, environmental sustainability, and participatory democracy. This, in turn, contributes to further progress and improvement. Digital India is a government campaign launched in India with the aim of providing electronic access to government services, improving online infrastructure, enhancing Internet connectivity, and fostering digital empowerment in technology. This initiative encompasses plans to establish high-speed internet networks in rural areas. Digital India revolves around three core components: the development of secure and reliable digital infrastructure, the digital delivery of government services, and the promotion of universal digital literacy.

In the present context the smart dimension of development is more often a sectoral approach. In international as well as in Indian scenario, the present smart approach reveals the piece meal approach of infrastructure development grounded with Information and Communication Technology e.g. Smart Water, Smart Energy, Smart Agriculture etc. A comprehensive approach for analysis of smart initiative and practices integrated with traditional indigenous knowledge-based economy, environment and societal needs fostering innovation of the rural community is missing. “Smart Village Concept” should necessarily be bottom–up integrated approach. The communities should be put behind the steering wheels instead of imposing development paradigms which is incompatible with the community’s desires, their social and cultural environments. An integrated inclusive approach, for felt need, demand and supply is required for making it more sustainable and resilient.

This leads to the basic concept of a smart sustainable rural development. i.e. a process whereby the optimum use of local resources can be sustained over several generations in the context of available technology and skills. To achieve inclusive, smart, and sustainable spatial planning, town planners in India should embrace innovative ideas for public participation. This can be facilitated by harnessing the power of Geographic Information Systems (GIS) and Internet of Things (IOT) technologies. These tools enable more effective and inclusive engagement with the rural community, allowing for the integration of local knowledge and perspectives into planning processes. In today's rapidly changing world, where information and digital technologies are advancing at a remarkable pace and costs are decreasing, leveraging of these technological advancements becomes even more critical. By doing so, town planners can create more dynamic and responsive development strategies that address the evolving needs of rural communities while ensuring the responsible and efficient use of rural resources.

Therefore, the meaning of ‘Smart Villages’ adopted in the paper is identification of local potential, strengths and opportunities of rural communities and to improve resilience through innovative solutions. Present paper frames the process of effective digital participatory model by using IoT technologies. This Model tries to understand and analyze dynamism of a village/ regional ecological-economic cultural system in a participatory approach. Participatory approach adopted in platforms of IoT to be called Digital Participatory Approach. Participatory Rapid Appraisal (PRA) approach, in combination with the use of digital technologies, will lead to empowering rural community by taking the initiative to find practical innovative solutions for both existing complex challenges and appropriate opportunities for sustainable and inclusive rural development. Digital Participatory Rural Appraisal will have to ensure the employment opportunities and skill updation, particularly among the small land holders, the landless labourers, and women to make development inclusive. Conceptually Smart Village Planning Model is an integration of Digital Participatory Inclusive Model and Sustainable Physical Planning Model.

4 SELECTION OF STUDY AREA

In order to identify the idealistic suitable village cluster and also to have true representation of Smart Village Planning Model (SVPM), various types of village ecosystems were studied with the help of Participatory Rural Appraisal (PRA) techniques. Among the various type of village ecosystems studied, Gaindikhata Cluster in Haridwar District, Uttarakhand has been taken as the study area. This cluster is chosen as because of the fact that the Gaindikhata Cluster itself depicts all uniqueness of the village ecosystem. In fact, it is worthwhile to point out here that this cluster itself represents all typical characteristics of different type of village communities (like tribal community, resettlement forest dweller community, advance agricultural community). The present cluster also represents all typical characteristics of physical and geographical setting (like plain, undulating land, hills and mountain topography); the micro-climatic variation, dense forest cover; the various zonation of land-uses in the form of valley zone, above valley zone, semi-arid zone, humid zone. Moreover, located under the shadow of big urban center, Haridwar, this cluster shows cultural cohesiveness and functional linkages. Lastly, the most important characteristic which determined for selecting the cluster is the administratively oneness of the cluster of villages being part of the one Naya Panchayat, one Block, one District

5 METHODOLOGY FOR DPRA

Information technologies in form of IoT have triggered a profound transformation in our way of life in the 21st century. These technologies have not only reshaped human behavior but also have ushered a new lifestyle marked by increased demand for transparency in governance and decision-making processes. The application of IoT Technologies will give planner to analyze the complex rural development problems and issues virtually through development of simulation model of real-world problems providing many options to evaluate the rural development decisions for implementation on the ground. 'Digital Participatory Rural Appraisal (DPRA) through the application of IoT technologies endows sustainable development of rural community by enabling importance for involvement of all levels of community (professional and local) in the process of planning and development leading towards to evolve the 'Digital Smart Participatory Village Planning Model' (DSPVPM). To achieve inclusive, smart, and sustainable rural planning, this innovative approach provides a framework for public participation by leveraging digital tools such as Geographic Information Systems (GIS) and IoT for more effective data collection, analysis, and collaboration among stakeholders. These technologies align with the global trend of rapid changes in information technologies, coupled with cost reduction can be invaluable in enhancing the right decision making for inclusive, smart, sustainable rural development.

The present paper delves into the intricacies of complex smart planning decisions, that are embedded in the procedure for the establishment of a Smart Village Model i.e. 'Smart Participatory Village Planning Model' (SPVPM). Undoubtedly, in the present cybernetics age IoT technologies provide the swiftest means to access, gather, analyze, and disseminate spatial information and also offer innovative and sustainable solutions through digital participatory approaches on the one hand and empowering rural communities and effective governance on the other. However, the adoption of such technologies poses challenges, including technological complexity; high costs, varying literacy levels, societal awareness, and accessibility issues. These challenges contribute to a digital divide, particularly affecting low-income groups. Consequently, the paper endeavors to address the main question of how low income and illiterate society can effectively and democratically access these technologies for participating and providing real-time spatial rural information into digitally tested designs leading into the rural development on the ground.

In overall, the paper frames a "Digital Smart Participatory Village Planning Model' through application of DPRA (intermingling both Geographic Information Systems (GIS) and IoT technologies as a spatial planning tool) to cultivate inclusive, smart and sustainable rural community in Gaindikhata cluster of Haridwar district, Uttarakhand. The central focus of this study revolves around the issue of providing economically disadvantaged sections of the rural community with access to the internet and IoT technologies to enable the effective people's participation in the rural planning and execution of development initiatives.

Indeed, beyond the imperative of achieving sustainable and inclusive development for the Gaindikhata Cluster, there is a pressing need to establish the DPRA with the aid of emerging Information and Communication Technologies (ICTs), such as IoT and GIS. The success of digital model for Gaindikhata Cluster is dependent upon the multiple challenges, like leadership role, skill development, sustainable land-

use planning and fostering a participative and responsive rural community. Gaindikhata cluster faces increasingly complex socio-economic and environmental challenges, especially regarding the competitiveness of the village community for survival. The sensitivity of forest-dwelling communities adds another layer of complexity, underscoring the need for thoughtful and culturally sensitive approaches when applying advanced technologies to address social issues. The establishment of the DPRA offers a pathway to address multifaceted challenges and create a sustainable, responsive, and inclusive future for Gaindikhata cluster and similar rural communities. It requires careful consideration of the local context and active community engagement to ensure the success of these technological advancements in a socially responsible manner.

Recognizing the unique challenges faced by the Gaindikhata Cluster, where a significant portion of the rural community i.e. only 34 % have limited familiarity with internet, smartphones and other digital technologies, thus, it becomes evident that presenting a DPRA in Gaindikhata cluster may not effectively able to connect to local rural community and continue to extend the participatory gap between spatial rural planning and application of IoT technologies. Hence, in Gaindikhata cluster, where planning and governance process evolve within a socially uncertain environment, a more comprehensive "DPRA" is required with collective intelligence, social awareness, and local wisdom of the village community.

To achieve this, a collective intelligence system, by using crowd wisdom is developed with the assistance of IoT technologies in a Common Participative Platform. The Interactive applications is designed to provide rural services and facilitate the implementation of the DPRA. This can then be introduced to the local village communities through smart farming and off-farm activities, efficient rural service delivery, intelligent mobility management systems, streamlined planning processes, and active community participation. Hence, the rural development approach, centers around leveraging the wisdom and collective intelligence of the local community to co-create and implement a Smart Village Planning Model which is not only technically advanced but also socially relevant and inclusive. This encompasses three fundamental elements:

(1) Innovative Technological Solutions: This includes both hard (physical infrastructure and tools) and soft (software, applications, digital platforms) technological innovations.

(2) Local Community: The local community plays a central role. It is characterized by leadership, responsiveness, intelligence, and creative thinking which are essential for active community engagement and contribution to the planning and development process.

(3) Government: The government's role is pivotal in terms of setting policies, rules, governance structures, and demonstrating political will to support and enable the implementation.

This represents a transformation of the smart village planning approach through integrating a social system which empowers the community to create, solve problems, build infrastructure, utilize resources, adapt to changes, secure livelihoods, and more within the context of a ‘Smart Village’ (Figure 1).

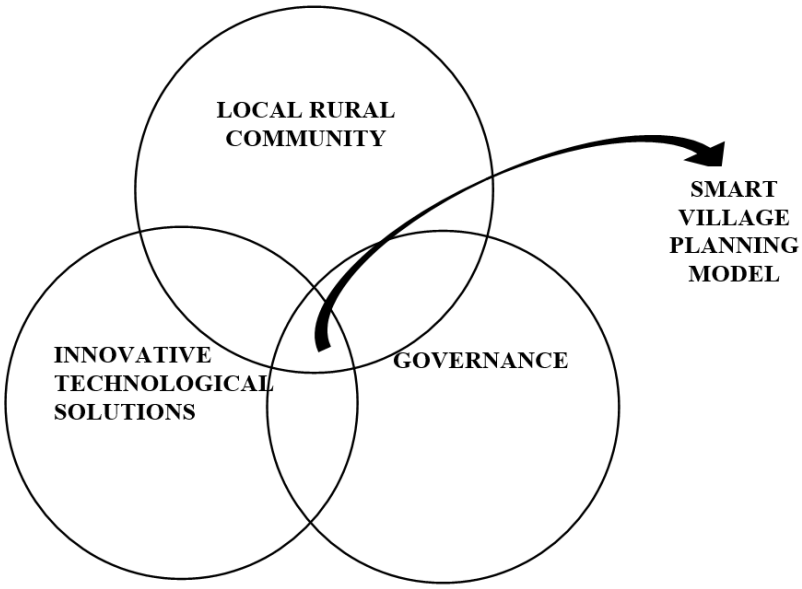

Figure 1: Smart Village Planning Model

In practical terms, the DPRA integrates physical planning and design with the active involvement and influence of the local community, facilitated through a IoT based digital platform This ensures the technologically advanced smart village development process driven by the needs and aspirations of the rural community it serves (Figure 2).

The Gaindikhata cluster system is designed around an input-output model, which serves as a framework for measuring sustainable development and the quality of life within the community. This model encompasses various sub-systems, each contributing to the overall sustainability and well-being of the community. These sub-systems include: Smart Mobility System, Smart E-Governance, Smart Ecological System, Smart Water Management System, Smart Infrastructure System, Smart Community System, Smart Power Management System, Smart Finance Management System, Smart Social Development System, Smart Economic Development System, Smart Environmental Development System, Smart Creative Community Development System etc. These sub-systems collectively contribute to the smart and sustainable development of Gaindikhata cluster and have capability to adapt, repair, and redesign based on the collective intelligence and actions of the community participation. The most important element of the DPRA is the active participation of the local community in governance and the preparation of Smart Participatory Village Development Plan. The crowd-sourcing model, which involves digital participation, plays a pivotal role in this leveraging the wisdom of crowds to generate effective solutions and make collective decisions, ensuring that the planning and development processes are inclusive, responsive, and driven by the insights and needs of the local community.

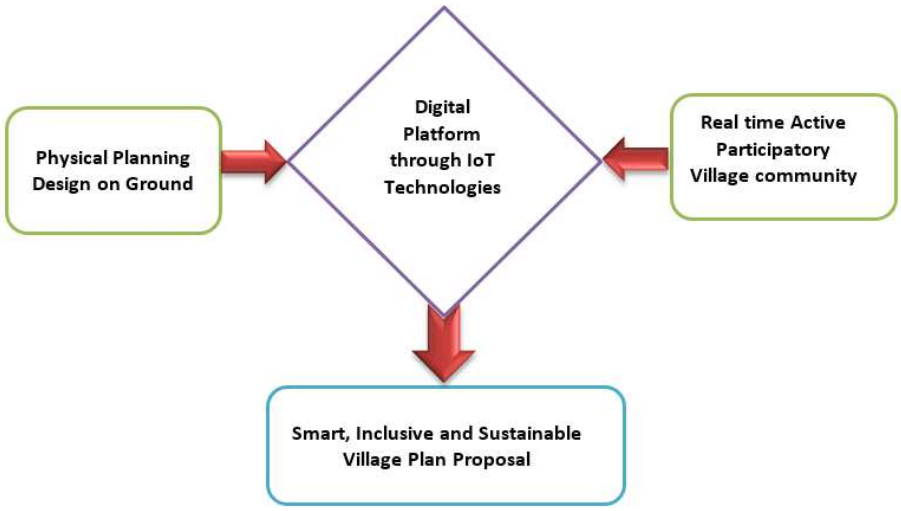

Figure 2: DPRA

6 TECHNOLOGICAL INPUT FOR DPRA

The use of IoT Technologies include social networking sites, like Google Maps Mashups, blogs, YouTube, WhatsApp, and others to disseminate information offering boundless opportunities for social inclusion within the local community, thereafter, transforming rural planning and design into a smart and inclusive process. These technologies encompass participatory web applications that enable villagers to actively participate and create their own content, fostering communication through various mediums such as text, maps, sketches, images, and more. Importantly, these technologies transcend language, culture, and custom differences, making them highly accessible and inclusive and serves as a powerful tool for planners to engage with the local community and vice versa. It facilitates two-way communication and collaboration.

Furthermore, these technologies contribute to transparency in governance by enhancing the interoperability of rural planning processes. It allows greater visibility and understanding in decision-making and resource allocation, ultimately empowering community members to participate effectively in shaping the future of their village. Thus, IoT Technologies in rural planning not only fosters inclusivity but also promotes transparency, enabling active community involvement and collaboration in the planning and development of smart and sustainable villages.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

In essence, this enable the aggregation and analysis of unconventional data sources, offering a wealth of traditional information that can be harnessed to shape smart and sustainable village planning. This data-driven approach enhances the precision and effectiveness of rural development initiatives in the Gaindikhata cluster and similar regions.

Here are some examples of how such data can be leveraged:

(1) Personal Smartphones and Local Cameras

(2) Smartphone Video Recording and Social Networking Sites

(3) GPS-Equipped Vehicles:

(4) Data Mining Techniques

7 CROWDSOURCING FOR DPRA

Establishing the DPRA, especially in a village cluster like Gaindikhata, where only 34 percent of the population has internet access, requires an innovative approach. While the digital divide may pose challenges, it is indeed possible to leverage IoT to establish a Smart Participatory Village Planning Model (SPVPM). To facilitate the effective local community participation, a Core Community Group (CCG) can be formed. Strategy to identify the interested villagers among the least technological savvy village communities who are enthusiastic about supporting the research and to be a part of participatory Core Community Group (CCG) is really a challenging task. These villagers may be referred to as 'LOCAL COMMUNITY FIELDERS' (LCF) at the village level and 'LOCAL COMMUNITY LEADERS' (LCL) at the cluster level. Criteria for selection of LCF and LCL and steps of establishment of SPVM are given below:

(1) Selection of LCF: LCF members should be chosen from various areas within the villages and represent different communities. They should possess smartphones, have a basic level of education, and, most importantly, express a genuine interest in actively participating in the research.

(2) Collaboration: The LCF members will work closely with the researcher. Their role will involve active engagement in analyzing content and solving village-related problems and issues using IoT.

(3) Training and Capacity Building: LCF members are given training for capacity-building and effectively handholding in using IoT applications in their smart phone, for data collection, communication, and disseminating information to the researcher, villagers, planners or managers for further analysis and providing solutions.

(4) Community Engagement: The LCF, in conjunction with the researcher, will engage the broader community to gather insights, share information, and ensure that local perspectives are considered in the research process.

(5) Feedback Loop: A feedback loop should be established to continuously assess the progress, challenges, and outcomes of the research. This iterative process allows for adjustments and improvements based on the experiences of the LCF and the community.

By forming and empowering the LCF and LCL, the research can harness the collective intelligence and involvement of interested villagers to overcome the limitations of internet and smart phone access. This approach enables active participation and ensures that the research benefits from local insights and perspectives, ultimately contributing to the success of the DPRA for achieving the Smart Participatory Village Planning Model (SPVPM).

This digital platform will serve multiple purposes, including:

(a) Access to GIS and Web 2.0 Technology

(b) Information Sharing with Related Agencies.

(c) Storage of Public Information and Databases:

(d) Community Data Analysis

(e) Influence on Decision-Making:

The LCF will feed/ communicate the village development related data to LCL and LCL to planners or village development managers and then planners will upload on common platform or portal. In this way, the digital

platform is managed "by the people," provides information to village planning authorities "for the people," and generates information "from the people." The common platform should be accessible to all members of the local community, ensuring that it empowers individuals with direct access to digital spatial data relevant to the village cluster. LCF and LCL members should be identified for training and access to GIS and IoT technologies, with a particular focus on ensuring the inclusion of marginalized groups such as the poor and women. This approach not only addresses digital exclusion but also reduces the gap between planning professionals and the local public, fostering a more inclusive and participatory approach for inclusive sustainable village development. This Digital Smart Participatory Sustainable Rural Development Planning Approach employs a crowdsourcing IoT platform at all stages of the village planning process, harnessing collective intelligence to create web-based solutions for complex rural problems. The sequence of the DPRA based SPVPM is outlined as follows:

(1) Identification of Problems

(2) Defining Goals

(3) Establishment of e-Platform

(4) Collection of Data through crowdsourcing

(5) Analysis of Data

(6) Solution and Decision Making

(7) Designing Solutions

(8) Implementation of the Plan

(9) Monitoring of the Plan

(10) Evaluating the Plan

In overall, the DPRA led SPVPM for rural development reduces planners' dependency on time and space, gradually transforming traditional planning processes into virtual planning. This approach promotes participatory, transparent, and sustainable village planning that actively involves the local community in problem-solving and decision-making.

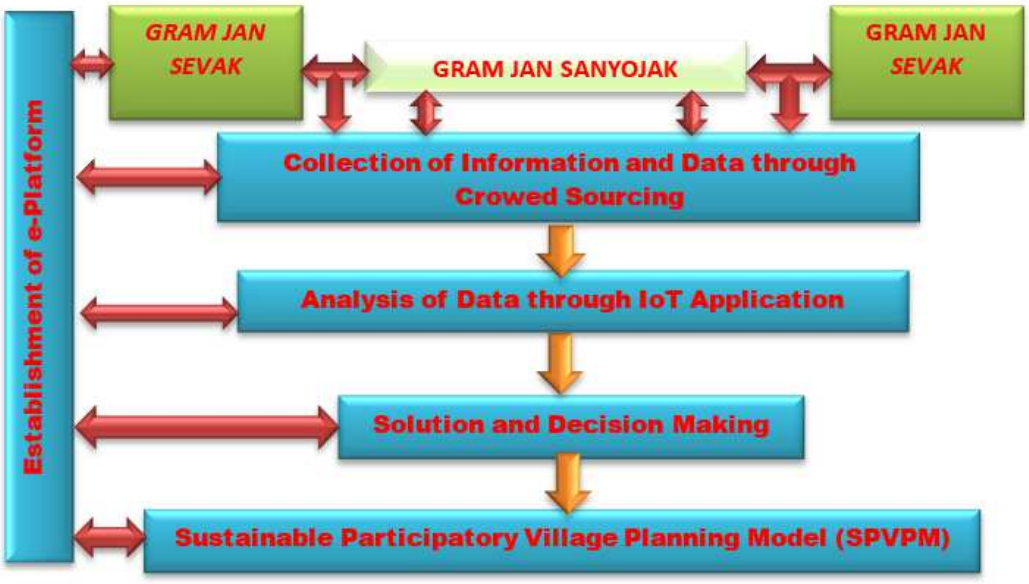

Figure 3: DPRA led Smart Participatory Village Planning Model (SPVPM)

8 CONCLUSION

On the basis of above-mentioned methodology for achieving sustainable, inclusive, integrated, digital participatory spatial planning using DPRA for sustainable development of Gaindikhata cluster, Smart Participatory Village Planning Model tries to understand and analyze dynamism of an existing regional ecological-economic cultural system as an integrated approach on the one hand, and sustainable and inclusive approach adopted on the other. This method aims to overcome digital access barriers. The paper

outlines the functionalities of the digital platform, highlighting its role in accessing, collecting, analyzing, and transferring spatial information. It also emphasizes the platform's role in providing participatory solutions for effective governance and community empowerment. The DPRA approach aims to empower the local village community by giving them the ability to customize the digital platform to meet their specific needs. It enables them to generate and manipulate their own information and spatial data, rather than relying solely on predefined decisions made by higher authorities.

The ultimate goal of DPRA is to make the local community active participants in their village development and planning process. This approach fosters a sense of pride and direct involvement, allowing them to drive their own village's development. the paper appears to propose a noble approach to village planning and development by combining the concept of Smart Village with IoT, ensuring that even communities with limited digital access can actively participate in the process and shape their own development. This approach emphasizes community empowerment and customization of digital tools for local needs.

1 ABSTRACT

The City of Johannesburg (CoJ) has articulated an ambitious vision for digital transformation through its Smart City Strategy, Information and Communications Technology (ICT) Policy Framework, and Integrated Development Plan, positioning digitalisation as a key mechanism for improving municipal efficiency, transparency, and citizen engagement. Multiple digital platforms, including e-Joburg, Joburg Connect, the GIS Spatial Portal, and the My Smart City App, have emerged as core components of this strategy. However, the extent to which these systems align with the City's regulatory, strategic and institutional frameworks remains unclear, raising questions about their capacity to support equitable and reliable service delivery. This study conducts a comprehensive digital systems audit and policy alignment review to evaluate the coherence, readiness, and governance compatibility of Johannesburg's digital municipal service ecosystem.

Using a desktop-based analytical approach, the study draws on publicly available municipal policies, digital strategy documents, Auditor-General reports, technical platform descriptions, and legislative instruments governing local e-governance in South Africa. The analysis assesses system functionality, interoperability, data governance arrangements, user accessibility, and alignment with the Municipal Systems Act, National Digital and ICT policies, and 4IR strategic goals. Findings indicate that although Johannesburg possesses a wide range of digital tools, the ecosystem remains fragmented, with limited integration across departments, inconsistent adherence to data governance standards, and uneven alignment with policy objectives relating to inclusivity, public participation, and service accountability. Significant gaps also exist between regulatory intentions and practical implementation capacities.

The study concludes that Johannesburg's digital tools have strong transformative potential but require greater strategic coherence, interoperability, and regulatory alignment to function effectively within a metropolitan governance context. Strengthening platform integration, adopting unified data governance standards, and establishing a coordinated Smart Governance Framework are essential steps toward enhancing the reliability, inclusivity, and long-term sustainability of digital municipal service delivery.

Keywords: Digital systems audit, Policy Alignement, Municipal service delivery, Smart Governance, E-governance

2 INTRODUCTION

Digital transformation has emerged as an important aspect of how cities currently govern themselves. Cities have turned to digital technology to improve the delivery of services through increased efficiency, transparency, accountability, and by engaging their citizens. The Smart City movement frames digital technologies as tools for enhancing institutional capacities, providing opportunities for data-based decision making in the context of rapid urbanization and increasing pressures to deliver services (Meijer & Bolívar, 2016). In addition, the United Nations (2022) describes digitalization in metropolitan governments in the global south as a method for addressing administrative fragmentation and limited resources, and by doing so, improve the responsiveness of governments to their citizens.

Metropolitan municipalities in South Africa are constitutionally mandated to ensure effective and sustainable service delivery and to promote participatory governance, as outlined in Sections 152 and 153 of the Constitution (Republic of South Africa, 1996). The City of Johannesburg, the largest metropolitan municipality in South Africa, is now using digital transformation as a strategic objective for its development and growth through projects like Joburg Connect and e-portal, and a range of spatial information systems, the Geographic Information System (GIS) applications intended to improve planning, administrative, and service coordination (City of Johannesburg, 2022). These projects reflect the South African government's national policy framework to encourage smart government, innovation, and the use of 4IR technology to enhance the ability of the State to function effectively (National Planning Commission, 2012; Department of Cooperative Governance, 2016).

Although the city has made great strides in improving its service delivery, governance is still unstable, and there are ongoing issues of poor coordination within municipal departments as well as among municipal-owned entities (MOE) in Johannesburg. As such, there are several important questions raised regarding whether or not current digital municipal systems have been implemented in a manner that is consistent with the legislation and/or policy frameworks that were developed to govern how they should be implemented. This paper fills the void created by the lack of research on this topic by completing an audit of Johannesburg's digital municipal systems through the use of qualitative desktop analysis methods; and evaluating how well those systems align with applicable governance policies. The paper argues that the City's digital governance challenges stem less from technological inadequacy than from institutional fragmentation and weak policy–systems alignment.

3 CONCEPTUAL AND POLICY FRAMEWORK

3.1 Smart Governance and Digital Municipal Systems

Smart governance encompasses how governments use digital technologies to support better-informed decisions by improving the integration of stakeholders with diverse backgrounds in governance as well as enhancing collaboration among the various components of a government (Meijer & Bolivar, 2016). As opposed to an exclusively technocratic view of smart cities, smart governance focuses on the institutional and legal context in which smart city technologies are applied because smart city technologies function within pre-existing governmental systems and politics (Connolly & Bannister, 2012).

Municipal digital systems such as Service Reporting Platforms, Spatial Information Systems and Performance Dashboards function as governance Infrastructure for the circulation of information in and out of the State and Citizens. Therefore, these systems will be effective not solely based upon their technical sophistication, but also the degree of Interoperability, Institutional Capacity, and Policy Coherence (OECD, 2020) of the systems. As a result, in contexts with inequality and fragmented administration, municipalities' digital systems could create or enhance existing governance failure unless they are specifically designed to reduce it (Parnell & Pieterse, 2010).

3.2 Policy and Legislative Framework Governing Digital Municipal Governance

Johannesburg's digital transformation agenda is embedded within a multi-layered governance framework spanning constitutional, national, and municipal levels.

The Constitution of the Republic of South Africa (1996) establishes local government's developmental mandate, requiring municipalities to provide democratic, accountable, and efficient governance while ensuring sustainable service delivery (Sections 152 and 195). These principles underpin the normative justification for digital systems that promote transparency, responsiveness, and participation. The Municipal Structures Act (Act No. 117 of 1998) defines the political and administrative arrangements of municipalities, shaping the institutional environment within which digital systems are implemented. Complementing this, the Municipal Systems Act (Act No. 32 of 2000) mandates universal access to basic services (Section 73) and community participation in municipal affairs (Section 16), objectives that are increasingly operationalised through digital platforms.

At the national strategic level, the National Development Plan (NDP) 2030 identifies information and communication technologies (ICTs) as key enablers of state capability and service delivery reform (National Planning Commission, 2012). The Integrated Urban Development Framework (IUDF) further promotes smart governance, specifically through Policy Lever 9: Empowered Active Citizens, as an essential component of urban transformation (Department of Cooperative Governance, 2016). This strategic direction is reinforced by the Digital Economy Masterplan, which focuses on modernising public administration through 4IR technologies. Furthermore, the Protection of Personal Information Act (POPIA) (2013) introduces stringent data governance requirements, necessitating that municipal systems such as e-Joburg (for residents and businesses to manage, view, and pay municipal accounts (rates, water, electricity electronically) balance the drive for transparency with robust privacy protections and secure data management protocols.

Integrated Development Plan (IDP) and Digital Transformation Strategy articulate the City's commitment to digital governance, citizen-centred services, and data-informed decision-making (City of Johannesburg,

2022). Collectively, these frameworks provide a strong normative foundation for digital municipal governance, while simultaneously creating complex coordination demands across institutional structures, often resulting in the siloed technical implementations observed in the current digital ecosystem.

At the local level, Johannesburg's digital trajectory is operationalized through three primary strategic instruments:

- Joburg 2040 Growth and Development Strategy (GDS): This serves as the overarching "normative foundation" for the city. It defines Johannesburg's vision as a "World Class African City," providing the high-level, long-term justification for smart governance as a means to achieve social and economic transformation.
- Smart City Strategy (8 Pillars): This strategy provides the technical roadmap for the GDS. It specifically targets "Smart Governance" and "Smart Institutions" as foundational pillars, aiming to institutionalize digital performance across all municipal functions.
- Group Information Communication Technology (GICT) Scorecard: This functions as the City's internal governance and accountability mechanism. Through the scorecard, the City Manager establishes specific, evidence-based Key Performance Indicators (KPIs) for digital transformation. This ensures that high-level IDP goals are translated into measurable technical actions and departmental responsibilities.

3.2.1 Synthesis: The Coordination Challenge

The review of these frameworks reveals a paradoxical landscape. While a "strong normative foundation" exists, supported by constitutional mandates and local strategies, the practical reality is one of "complex coordination demands".

These demands arise because the frameworks originate from disparate sources: national mandates (National Treasury) often clash with local operational realities, while internal city departments (such as Finance vs. Communications) maintain separate reporting lines. This misalignment between multi-layered policy expectations and fragmented departmental structures leads directly to the institutional silos and technical overlaps identified in this audit.

4 RESEARCH METHODOLOGY

This research is designed as a qualitative, desktop-based evaluation of the coherence of Johannesburg's digital municipal system (municipal digital ecosystem). This research examines the gaps in the relationship between the high-level policy vision for the City and the technical implementation through a systematic review of the "paper trail" created by the City's governance practices.

4.1 Data Sourcing and Selection

The data collected for this research will be derived from secondary source data, thereby providing an overview that captures the full range of both the "promises" made by the city, and the "reality" of its systems recorded in the document collection below. The collection of documents referenced above represents the primary documentation that describes the City's systems and practices and therefore provides the best possible insight into the nature of the system.

- Legislative and Regulatory Frameworks: National laws such as the Municipal Systems Act and the Protection of Personal Information Act (POPIA).
- Strategic Municipal Mandates: The City of Johannesburg's Integrated Development Plan (IDP), Smart City Strategy, and Digital Transformation Strategy.
- Accountability and Performance Records: Annual Reports of the City of Johannesburg and the annual reports of the Auditor-General of South Africa to assess technical and financial oversight.
- Platform-Specific Documentation: Publicly accessible technical descriptions and service delivery portals for e-Joburg, Joburg Connect, the GIS Spatial Portal, and the My Smart City App.

4.2 Analytical Procedure: Document Analysis

The data was examined through a Document Analysis Process, a methodical procedure for examining/assessing both paper and electronic materials. The analysis was conducted in accordance with the framework outlined by Bowen (2009), and the documentation was systematically analyzed to determine data that would help establish empirical evidence related to the relationship between Digital Municipal Systems and the intended Policy Outcomes of those Systems.

This process was operationalized by filtering the gathered data through four critical analytical themes:

(1) Institutional Coordination: Examining how different departments and Municipal-Owned Entities (MOEs) collaborate on digital initiatives.

(2) System Interoperability: Auditing the technical capacity of different platforms to share data and function as a unified ecosystem.

(3) Accountability Mechanisms: Evaluating the "digital paper trails" and feedback loops provided by platforms for service delivery oversight.

(4) Inclusion: Assessing the extent to which digital tools accommodate diverse citizen needs and bridge the "digital divide".

4.3 Ethical Considerations

Since this research relied exclusively on publicly accessible data and did not involve interactions with human subjects, it was not necessary to obtain formal ethics approval for the study. This study maintains its integrity as an academic study using official government documents and existing qualitative analytic methodologies.

5 OVERVIEW OF DIGITAL MUNICIPAL SYSTEMS IN JOHANNESBURG

A major contradiction exists at the center of the Municipal Systems Act (2000). While Section 73 requires that all residents have access to their local government's services, the City of Johannesburg is heading toward a digital-first strategy, which may create a "fragmentation gap." In order to provide context for this agenda, this study will provide a brief overview of the digital municipal systems currently being used by the City of Johannesburg. These include e-Joburg, Joburg Connect, etc. These are the City's primary mechanisms for providing citizens with municipal services, facilitating citizen participation in decision-making processes, coordinating administrative activities, and developing spatial plans.

The table below (Table 1) illustrates the primary function(s) of each of the platforms identified above as well as the users of those platforms and the city's policy goals for those platforms. The table also maps these platforms to relevant legislation and strategies and therefore illustrates the City's formal digital infrastructure and establishes a framework to assess the gaps between the city's policy intentions and its operational practices.

Digital System/Platform	Primary Function	Primary User Base	Policy/Governance Alignment
Joburg Connect	Fault reporting & service complaints	Citizens/Residents	Public Participation: Municipal Systems Act
e-Joburg Portal	Billing, accounts, queries	Ratepayers	Transparency: ICT Policy Framework
GIS Spatial Portal	Spatial planning & land management	City Officials/Developers	Evidence-based planning: 4IR Strategic Goals
My Smart City App	Service coordination & citizen engagement	Mobile Users	Inclusivity: National Digital & ICT Policy

Table 1: Overview of Digital Municipal Systems in Johannesburg

The audit revealed that although the city has been successful in developing different platforms to support its departments, there is no one governing body that oversees how all of these platforms are developed or how their data is managed collectively; therefore, the lack of a unifying data governance framework has created many gaps between what the regulations intend and the ability to practically implement those regulations. These gaps are significant to interoperability and the ability to hold services accountable.

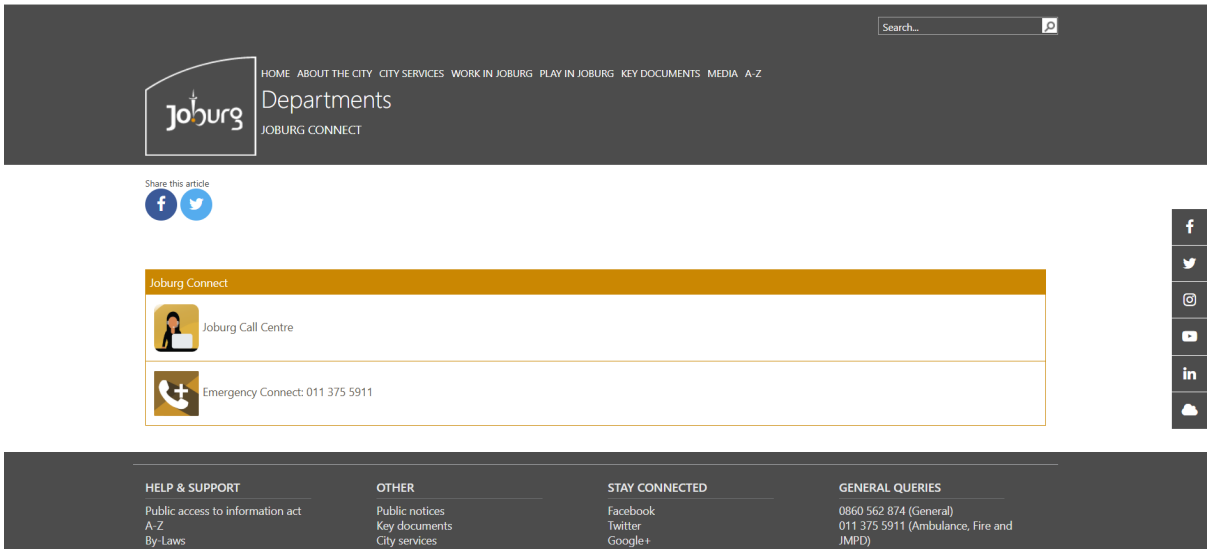

Fig. 1: Joburg Connect.

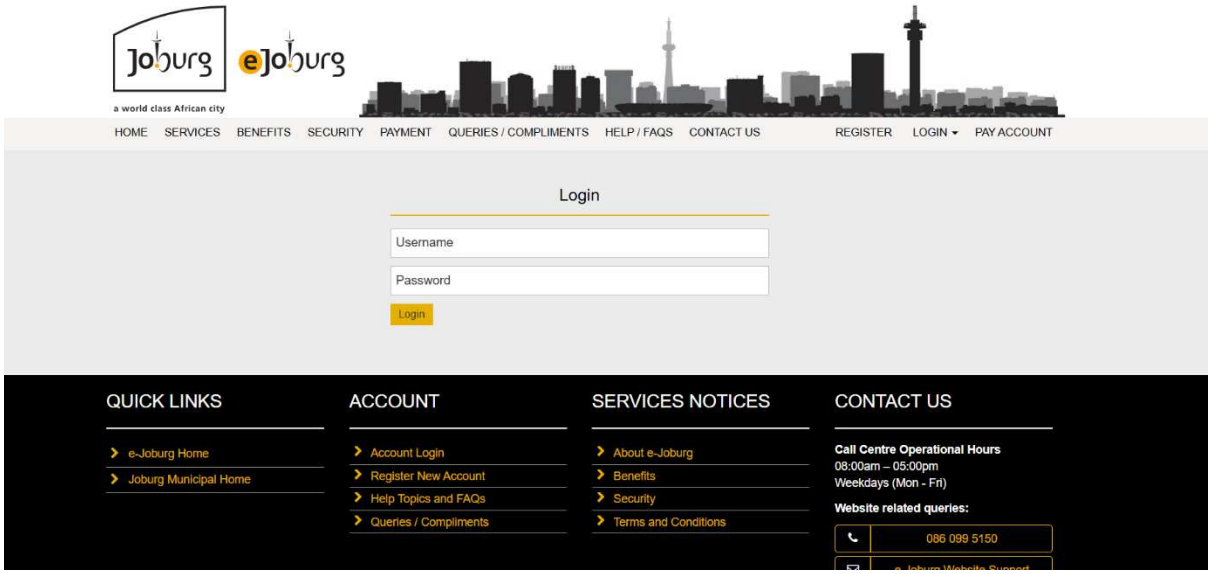

Fig. 2: e-joburg portal.

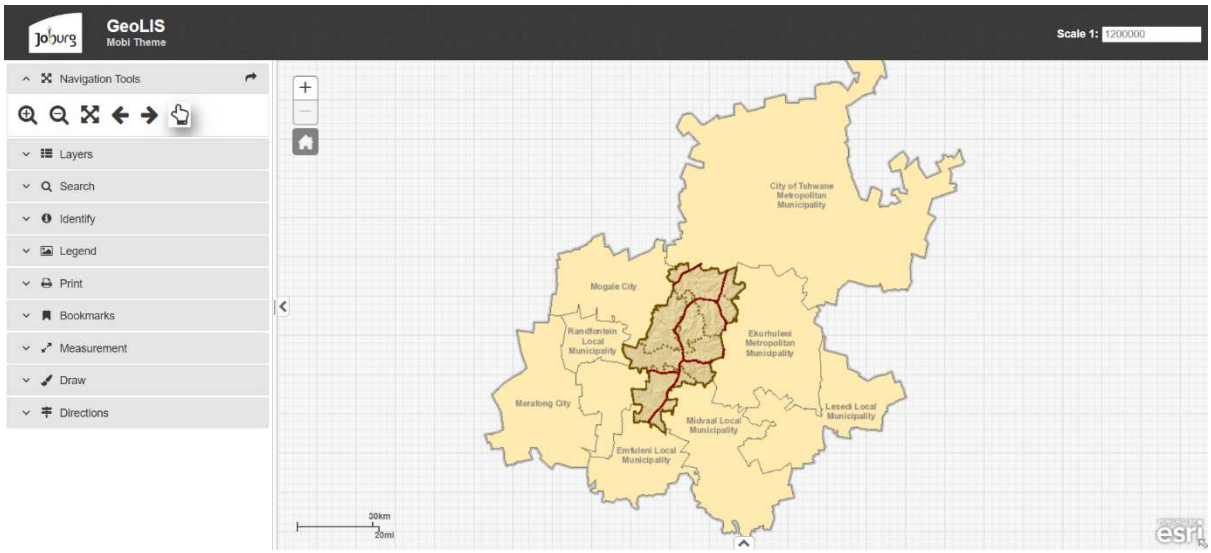

Fig. 3: GIS Spatial Portal.

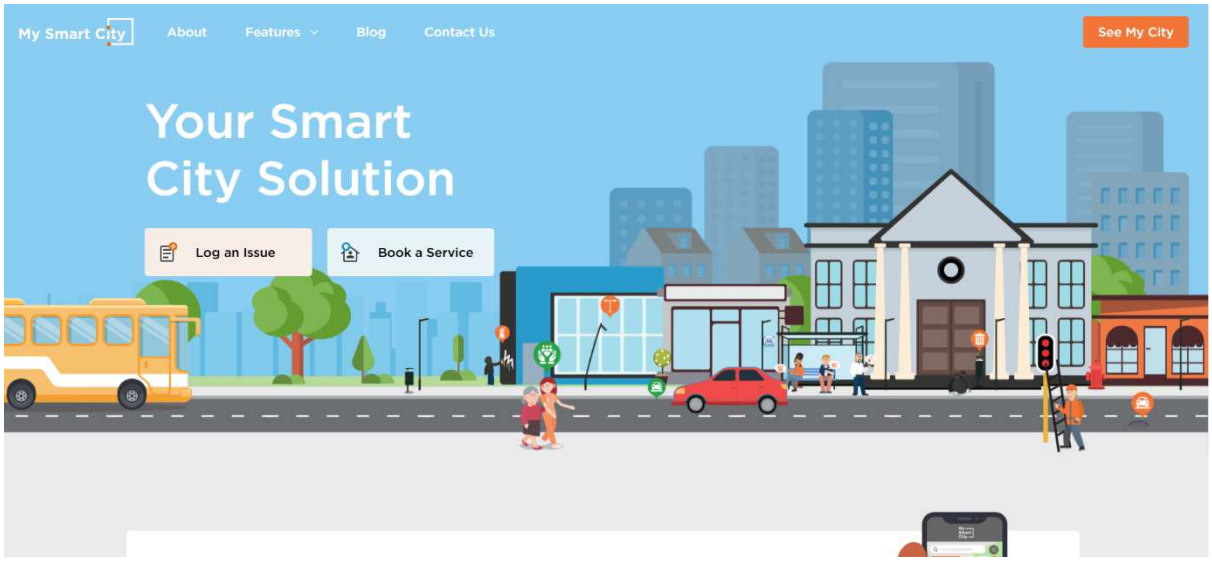

Fig. 4: My Smart City App.

Several digital systems support the operational activities of the City of Johannesburg in various ways. Some examples of these digital systems include; Joburg Connect which allows citizens to report faults with services, the e-Joburg portal that is used to facilitate customer interaction for billing and account management purposes, GIS (geographic information systems), and LIS (land information system) to enable the city's departments to plan for spatial development, and several call center and dash board type systems that are managed on behalf of the city's departments by the city's Metro Offices. While some of the digital systems listed above represent a significant digital investment by the city, the majority of them were developed and are being managed independently of one another at the departmental or entity level. This institutional configuration shapes how digital tools are used and limits their ability to function as integrated metropolitan governance instruments.

6 FINDINGS: DIGITAL MUNICIPAL SYSTEMS AND POLICY ALIGNMENT

6.1 Strategic Alignment with Policy Intent but Weak Operational Integration

The audit shows how, on a conceptual level, Johannesburg's municipal systems digitally support City of Johannesburg (2022), and Department of Co-operative Governance (2016) policy-based mandates around transparency, efficiency, and participation through platforms like Joburg Connect, which represent formal structures for citizens to interact and, in doing so, fulfill the participatory provisions within the Municipal Systems Act.

However, these concepts remain largely theoretical, and there is little empirical evidence of mandatory framework(s) requiring municipalities to ensure digital systems are being used interdepartmentally (MOE), therefore, the translation from policy aspiration to cohesive digital municipal governance practice is only partial.

6.2 Fragmented Digital Governance Across Municipal-Owned Entities

Most of the digital government exists in a fragmented manner among the various MOE's that are responsible for the most important urban service areas (e.g., electricity, water, waste collection, and roads), each of which has its own digital platforms, reporting mechanisms, and data systems, and very little interoperability.

This fragmentation limits the ability of the IUDF to achieve the integrated urban governance it seeks, and limits the city from creating a single, current view of how well services are being delivered (Department of Cooperative Governance, 2016), so that digital systems replicate the existing organizational silos instead of breaking through those silos.

6.3 Uneven Institutional Capacity and Digital Uptake

The audit highlights that there is a wide range in terms of institutional capacity among the different departments and regions. In this respect, while some have developed significant and sophisticated use of

digital dashboards and spatial data, many other departments and regions continue to operate using manual processes or legacy systems. The uneven development and implementation of digital systems and the resulting inability to integrate digital data with strategic decision-making for planning and capital investment are also identified as key barriers (OECD, 2020).

Additionally, the lack of defined digital competences and continuous capacity building initiatives restricts the strategic value of digital systems, which results in their continued use as operational tools and not as governance tools.

6.4 Digital Participation and Data Visibility Bias

While digital platforms have been implemented as a means to enhance citizen engagement opportunities for participation, there is evidence that this opportunity is spatially inequitable. Those locations that have greater internet connectivity and greater digital literacy rates tend to be overrepresented in the digital reporting data generated from the use of digital platforms, whereas informal settlements and peripheral communities are consistently underrepresented in the digital reporting data generated by their use of digital platforms. The result is data visibility bias, which reduces the visibility of digitally marginalized communities to governance systems and may also produce an unbalanced representation in how planners and policymakers make decisions about where resources should be allocated (Parnell & Pieterse, 2010).

6.5 Accountability and Feedback Loop Limitations

The findings indicate a weakness in feedback processes on digital platforms. Citizens may be able to submit complaints about services they are using, but citizens are generally unable to find out when their complaint will be addressed by which department(s) it will be assigned to, or how their complaint will ultimately be resolved. Thus, citizens have little reason to believe that their government is functioning effectively, and therefore, digital technologies cannot provide an effective means for citizens to hold government accountable for its actions (Meijer & Bolivar, 2016).

6.6 Policy Alignment and Fourth Industrial Revolution (4IR) Readiness

The audit also examined how well Johannesburg's digital local government platforms align with the policy and legislative objectives outlined in the Municipal Systems Act (Act No. 32 of 2000), South African national ICT policies, and the overall policy frameworks for the Fourth Industrial Revolution (4IR). Although the City has made significant investments in new digital systems aimed at improving service delivery and administrative processes, the audit's findings indicate that the current configuration of these systems does not provide the transformative governance desired by policy.

The Municipal Systems Act requires municipalities to provide municipal services inclusively by providing all citizens with equal access to these services. The study has found that the current digital platforms for delivering public services have the potential to exclude some residents from accessing municipal services due to a lack of digital technology in their area, low levels of digital literacy among residents, or unreliable digital connectivity in informal settlements and at the periphery of urban areas. If no alternative mechanisms, such as offline or hybrid access, are available to support residents who cannot easily use digital platforms, then they could potentially exacerbate existing social-spatial inequalities rather than alleviate them (United Nations, 2022; Republic of South Africa, 2000).

The policy framework for public participation emphasizes that citizens should be able to have an active role in the development of their local government. The digital platforms available in Johannesburg provide an opportunity for residents to report problems with city services and access information about city programs and policies. However, the current structure of these platforms is primarily used as one-way communications from the city to the resident, limiting opportunities for citizens to engage in deliberative discussions, co-create solutions to municipal issues, and receive feedback on how city policy and/or planning decisions affect them. Therefore, the potential for public participation in the digital governance of the City of Johannesburg is significantly less than what is envisioned by proponents of smart governance and the Fourth Industrial Revolution (Meijer & Bolivar, 2016).

Digital systems can produce "paper trails" for transparency and traceability in terms of service accountability; however, these systems are still not fully integrated to enable monitoring, oversight, or learning within institutions. Although there is a possibility to use digital tools to enhance accountability

through closed-loop feedback, the audit has shown an inability to do so, as there is currently no linkage from citizen input (front-end) to tracking the resolutions to those inputs (back-end).

Overall, it is suggested that Johannesburg has demonstrated partial 4IR-readiness characterized by technology adoption but without sufficient governance integration. A coordinated policy-driven strategy for advancing smart urban management will be required to align the digital system with the objectives of inclusivity, participation, and accountability in South Africa's local government framework.

6.7 Analysis of Audit Findings: The Fragmentation Gap

A substantial gap exists between the City of Johannesburg's strategic vision on how to govern digitally and its day-to-day operations. Although the City's policy debates define digitalization (and its related technological innovations) as an opportunity to make government more efficient, transparent, and to better coordinate services; however, our research finds that the City's digital landscape is a fractured one, limiting the transformative potential of those innovations.

A major barrier to achieving the transformative goals of those technologies is the lack of integration amongst them. The core technology platforms, including the e-Joburg portal, Joburg Connect, and the various geographic information systems operated by different City departments and city-owned entities, are largely incompatible, as they do not interoperate well. The media reports of late responses from the city, duplicated reporting, and unclear responsibilities all demonstrate that there are no integrated city-wide digital coordination tools in place.

Secondly, the study's findings have shown variable levels of governance of data. As a result, weak governance of data has resulted in unreliable, inaccessible, and unsustainable digital services for delivering public services. The lack of data visibility across the city (especially in informal areas) has created governance blind spots, which are likely to reduce the effectiveness of evidence-based planning as well as the ability to intervene at an early stage.

Thirdly, it can be seen that there is a significant gap between the regulatory ambition for enabling urban management through digitally enabled approaches articulated in the City's 4IR and Smart Cities Strategies, and the actual capacity for implementation, which is restricted by unstable governance, fragmented institutional authority, and limited operational integration.

This suggests that the digital challenge facing Johannesburg is less about having the technology and more about the institutional alignment and execution.

Therefore, these three aspects combined indicate that the current state of digital transformation in Johannesburg is characterized by partial adoption with no systemic integration. It is therefore critical to address this "fragmentation gap" to achieve the intended governance, planning, and service delivery benefits for municipalities and the national digital policy framework.

7 FINDINGS: DIGITAL MUNICIPAL SYSTEMS AND POLICY ALIGNMENT

Research suggests that the primary barriers to effective use of digital municipal systems in Johannesburg are largely institutional and governance-related as opposed to technological. The research is consistent with a body of literature from Global South countries, which indicates that digitalisation can only partially compensate for the consequences of a lack of coordination, poor administrative capacity, and fragmentation of authority (United Nations, 2022; Parnell & Pieterse, 2010).

Where digital systems do have some value, it is primarily when there are already high levels of integration and coordination, where they offer considerable opportunities for improved monitoring, planning, and citizen engagement.

7.1 Integrated Synthesis of Policy and Systemic Performance

The findings from the digital systems audit illustrate an extreme disconnect between the City of Johannesburg's "strong normative framework", as defined by the city's strategic frameworks and the actual operationalization of its municipal service delivery system; however, the three key points of tension identified in this synthesis represent the current state of digital governance for the City of Johannesburg.

7.2 The Disconnect Between Strategic Intent and Technical Silos

The audit verifies that "the proliferation of digital systems", including e-Joburg, Joburg Connect, and GIS Spatial Portal, is being developed in departmental silos. In contrast to the vision of an "integrated 'World Class African City'" presented in both the Joburg 2040 GDS and the Smart City Strategy, the current technical state of affairs presents a fragmented system with "little or no inter-departmental integration." Therefore, it can be inferred that the complex coordination demands generated from the overlap of multiple frameworks have resulted in a multitude of departmental function-specific systems (i.e., not integrated into a single, citizen-focused service).

7.3 Legislative Compliance vs. Practical Inclusivity

A contradiction is inherent to the Municipal Systems Act, as it provides for universal access (Section 73); the current "uneven alignment" of digital tools in terms of their inclusiveness does not currently allow for this principle. While platforms such as the My Smart City App are examples of how the community is moving toward Integrated Urban Development Framework (IUDF) Policy Lever 9 (Empowered Active Citizens), they are typically not designed or developed with the "governance compatibility" needed to provide service to all demographics of the city. Without a "coordinated Smart Governance Framework," the transition to digital-first service delivery could create a "digital divide", which would undermine the very purpose of enhancing transparency and citizen participation as provided in the National Development Plan 2030.

7.4 Data Governance as a Barrier to Accountability

The findings of this audit highlight a significant weakness in the City of Johannesburg's (CoJ) Digital Strategy due to an “inconsistent adherence to data governance standards,” as identified by the audit. Although both the Protection of Personal Information Act (POPIA) and the Municipal Finance Management Act (MFMA) require a high level of data integrity and accountability, the absence of “unified data governance standards” across all municipal platforms creates a major obstacle for the CoJ in delivering “reliable service delivery.” Until the GICT Scorecard KPIs advance from platform deployments to evaluate “interoperability” and “system functionality,” the CoJ will struggle to achieve “service accountability” as outlined in its IDP.

7.5 Synthesis Summary: Moving from Platforms to Ecosystems

The evidence presented here illustrates that the digital transformation of Johannesburg is at present platform-heavy; however, it has yet to be "ecosystem light." Therefore, to achieve the "long-term sustainability" described in the Smart City Strategy, the city needs to transition its focus from app development (or individual application) to the creation of an integrated, coordinated smart governance framework. It will require increased "integration of platforms" and "alignment of regulatory frameworks", so that technology acts as a facilitator of effective metropolitan governance, rather than a hindrance.

8 TOWARDS AN INTEGRATED SMART GOVERNANCE FRAMEWORK

To enhance digital municipal governance, this research presents a comprehensive framework to integrate:

(1) centralised digital governance oversight;

(2) enforceable interoperability standards across departments and MOEs;

(3) policy-driven system design aligned with constitutional and legislative mandates;

9 CONCLUSION

This study demonstrates that while Johannesburg has significant digital infrastructure to support governance, it is constrained by institutional fragmentation and poor policy system alignment. Conducting a digital systems audit identifies these problems and further supports the necessity of coordinated, policy-driven approaches to digital governance. To realize the transformative benefits associated with digital local government in cities such as Johannesburg in the Global South, institutional integration and accountability must be strengthened.

District Sub Centres as Foundational Elements in the Implementation of the 15 Minute City Model: Case Study of Albertfalva

Boróka Szarvák

(PhD Student Boróka Szarvák, Doctoral School of Regional and Economical Sciences, Széchenyi István University, bori.szarvak@gmail.com)

1 ABSTRACT

The 15-minute city model aims to enable residents to reach the facilities necessary for everyday life within 15 minutes on foot or by bicycle. This study uses the example of Budapest's Albertfalva (sub)district (neighbourhood) to examine how district sub-centres could contribute to the implementation of this model. It was found that, while certain urban functions are present, community and service spaces do not form a real centre. Developing the area surrounding the former market building could fulfil this role. The results emphasise that designating central spaces is not an end in itself, but can be a vital step towards urban decentralisation and sustainability.

Keywords: 15-minute city, neighbourhood centres, urban decentralisation, mixed-use development, Albertfalva

2 INTRODUCTION

The 15-minute city model is predicated on the promotion of a polycentric urban structure, with an emphasis on the organisation of quotidian life around sub-centres and the concentration of essential functions in a decentralised manner.

The relevance of this city model is particularly evident in the context of contemporary issues, particularly those pertaining to sustainability. It presents a "greener" alternative to the reduction of car traffic, traffic jams, and the resultant pollution, which is an overarching objective. This commitment is further underscored by the European Union's allocation of 30% of its planned budget for the 2021-2027 period to the fight against climate change (europa.eu, 2024).

Albertfalva, is a neighbourhood in the 11th district of Budapest. It was selected for case study because previously it was an independent settlement, and with the revitalisation of the remaining (former) settlement centre (Szabó, 2016), it may be suitable for the creation of a sub-centre within 15 minutes' reach by "applying" the "15-minute city" model. Moreover, the neighbourhood is characterised by a diversity of housing typologies, including residential properties with gardens, panel housing estates constructed during the socialist era, and ongoing development of residential parks, thus providing a diversified urban context for the analysis.

After formulating the key planning–urbanistic and sociological questions related to the 15-minute city model, I examine the centre–subcentre context of the area, with particular attention to whether the traditional centre, through deliberate development, can continue to fulfil a central (core) role in the 21st century. The following research questions are linked to this overarching objective:

- The most important central functions are commercial, transport, and institutional functions. Are the basic institutions and services present within the neighbourhood?
- How can the sustainable concept of a 15-minute neighbourhood be implemented in Albertfalva?

3 LITERATURE REVIEW

3.1 The 15 minute city concept

The concept of the 15-minute city was first introduced by Carlos Moreno in 2016. The model under discussion is predicated on the notion that urban planning should be sustainable, and that cities, or in some cases city districts, should be designed in such a way that residents can reach all essential social functions and services within a 15-minute travel time (on foot or by bicycle) from their place of residence. This encompasses domains such as housing, employment, health and social care, education, entertainment, and other recreational activities (Moreno et al., 2021). The model is based on the concepts of neighbourhoods, diversity, density, digitalisation, and ubiquity (Moreno et al., 2021).

The neighbourhood is the smallest, yet arguably the most significant, unit of the urban structure. The concept of the "neighbourhood unit" was initially explored by Clarence Perry in 1923, with a focus on the planning of American suburbs (Szabó, 2016). As Pozoukidou and Chatziyiannaki (2021) argue, this space fulfils a dual function: it serves to meet the basic needs of residents whilst also facilitating community building and facilitating communication between people. It has been demonstrated that this contributes to the early detection of problems, the development of the local community, and the growth of mutual trust. The theoretical framework of neighbourhood units has exerted a significant influence on urban planning practices in Western Europe and within former socialist countries. The necessity to alleviate the burden on historic city centres was identified, and a potential solution was proposed as the creation of areas with neighbourhood unit functions in the outer parts of the city, involving the remaining centres of formerly independent settlements (Szabó, 2016).

The fundamental problem addressed by the 15-minute city concept stems from the increasing reliance on private car use and from cities that have been planned primarily to serve an automobile-oriented society (Moreno et al., 2021; Pozoukidou and Chatziyiannaki, 2021). In European – and thus Hungarian – cities, a key challenge is that they were not originally designed for cars and are therefore unable to cope with the current scale of motorised traffic. This situation may also entail economic consequences, as time lost in traffic congestion can result in productivity losses (Balletto et al., 2021; Forgács et al., 2010). Pollutant emissions constitute a particularly serious problem (Pozoukidou and Chatziyiannaki, 2021), and car-centred urban planning – often at the expense of public transport – negatively affects overall accessibility.

Researchers conceptualise the implementation of the 15-minute city through three main approaches. These include "avoidance," whereby non-walking and non-cycling travel can be reduced through the development of compact urban forms; "shift," referring to a modal shift towards walking and cycling, making shorter distances easily manageable; and the technological "improvement" of transport systems aimed at enhancing energy efficiency (Balletto et al., 2021).

3.2 Community and the city

Within the field of urban studies, organic thinking across generations can be interpreted as a fundamental principle. The present always reshapes its environment according to its own dynamics (Fülep, cit.Vidor 1977). The key concept of this logic is organic decentralisation (Gutkind, 1977). Within this framework, urban planning is understood as a medium- and long-term work process and set of activities through which "dense urban blocks – based on the example of Albertfalva, such as former industrial districts, etc. – may gradually be transformed into groups of separate residential communities, surrounded by green belts and spatially separated from one another" (Gutkind, 1977, p. 207).

Today, however, the prevailing spirit of the age does not necessarily place emphasis on separated and mutually isolated urban areas, as the 15-minute city represents a planning concept and form of implementation in which the emphasis lies on movement and mobility, as well as on equal access to the roles and functions provided by the city. Urban planning can essentially be understood as the aggregate of these preferences – historical traditions, local communities, families (households), commercial and industrial enterprises, as well as public institutions and the environmental expectations adaptable to them (Häussermann and Siebel, 2004).

4 METHODOLOGY

In accordance with the partnership principles of the European Union, it was hypothesised that representatives of institutions, collectives, and professional groups would be deemed experts on the subject in various prominent (elite) studies (Horváth, 2000). However, in the spirit of social consultation methodology (Letenyei, 2010), local residents were also surveyed, with a particular focus on potential individual actions related to the topic. Thirdly, content analysis was conducted using settlement-historical research, development plans, and the mapping services of Google Maps as primary sources.

In the course of the research, six semi-structured expert interviews were conducted with leading professionals and key stakeholders of Albertfalva. My aim was to reach individuals who not only possess substantial professional expertise in the architectural, historical, or sociological (community-related) aspects of urban planning, but who also have in-depth knowledge of the study area itself. The interviewees included the Chief Architect of Budapest's 11th District, the Head of the Urban Planning Department, a staff member

of the Albertfalva Local and School History Museum and former district cultural officer, the municipal representative of the electoral district and former teacher at the (Albertfalva) Petőfi School, as well as the professional officer and cultural programme coordinator of the Albertfalva Community Centre.The findings of the interviews are presented in the form of paraphrases in the relevant section, in relation to the given topic discussed therein.

The survey of local residents was conducted within a closed Facebook group (Albertfalva neighbourhood forum), which functioned as a bounded sampling frame. The collection of data was facilitated by convenience sampling with voluntary participation. The participants were invited to complete a structured questionnaire, which also incorporated open-ended questions. Furthermore, I sought to interview local residents in depth in order to gain insight into the area's history, their personal attachment to the area, patterns of place use, neighbourhood relations, and their future visions, needs, and expectations. A total of 35 respondents completed the questionnaire, and one additional resident participated in a face-to-face interview.As the research is a pilot study aimed at identifying problems, its results cannot be regarded as representative.

5 RESULTS: THE SITUATIONAL ANALYSIS OF ALBERTFALVA

Both writings on the history of the settlement (Virt, 1999; Hoffmann, 1997) and the Integrated Settlement Development Strategy of Újbuda (2022) shows that Albertfalva currently lacks a space that fully serves central functions. The strategy's objectives include the recultivation of Albertfalva's historic centre over several planning cycles. However, despite the potential benefits of such a space, including improved quality of life for the population, enhanced personal relationships and community cohesion, it appears to be a low priority for the district. As posited by several researchers and prominent figures in the field, Albertfalva's peripheral location within the district has resulted in its development being accorded a lower priority (Virt, 1999).

5.1 Demography and spatial structure

According to the 2022 census data of the Hungarian Central Statistical Office (KSH), the population of Albertfalva is 12,840 (KSH, 2023), which is just over 9% of the total population of District XI (this is directly proportional to the district's territorial distribution: Albertfalva covers an area of 3.05 km2, representing 9% of the district's total area (KSH, 2023).

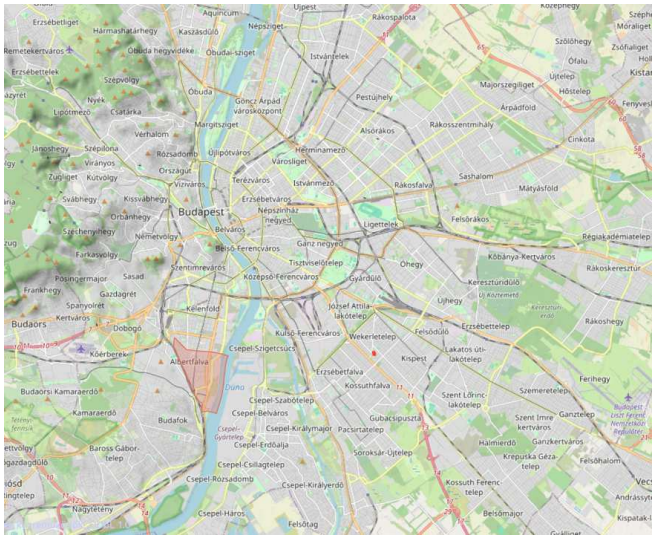

Fig. 1: Location of Albertfalva in Budapest (openstreetmap.org, own ed., 2026)

Researchers from Poland (Techet, 2020) published the capitals of the region in 2015, utilising data from the turn of the millennium. Budapest (primarily Buda) is distinguished by the homogenous appearance of social groups, while Albertfalva is still characterised by the “lower-middle”, “mixed”, and “polarized” category systems (at that time). Thi suggests that while Albertfalva was previously distinguished by its garden-suburban areas with detached houses and the Tisztviselőtelep (Civil Servants' Estate) inhabited by a population of higher social status, the “panel programme” and other mobility processes contributed to the polarisation of the population (Virt, 1999).

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

As demonstrated in the National Atlas of Hungary (Kovács and Dövényi, 2021), a further detailed dataset indicating the entrenchment of the middle class in Albertfalva can also be observed (based on 2011 census data).

Despite the decrease in population, there has been a consistent increase in the housing stock. A new wave of housing construction began in the 2000s, with residential parks being built and continue to being built in the area. today in the district. These successive waves of construction have resulted in the establishment of a diversified neighbourhood. The area is characterised by residential properties with gardens, panel housing estates, residential parks and industrial zones. Furthermore, Albertfalva has direct access to the Danube, thereby further enriching the spatial structure of the district (Halabuk, 2000).

5.2 Overview of thearea and functionalanalysis

The objective of this subchapter is twofold: firstly, to examine the necessary functions of the 15-minute neighbourhood based on previous studies and research, and secondly, to attempt to identify these functions in Albertfalva. The categorisation of functions is defined in accordance with the methodology established by Papadopoulos et al. (2023). This categorisation was utilised as a reference in a survey conducted among the population, in which individuals were questioned on their needs and customary land use practices. The following section will present the findings of the research, including the facilities available in the district and the areas in which there are gaps in services.

The 15-minute city model proposed by Moreno does not necessitate the establishment or development of centres; rather, it emphasises density as a fundamental principle, underscoring the importance of optimising spatial utilisation (Moreno et al., 2021). The areas examined (sub-centres of the city) are not intended to concentrate and fulfil all functions in a single point or space; however, due to the size of the settlement (only 3.05 km2) and its spatial structure, I now refer to these as centers for the sake of analytical clarity and practical feasibility. Their long-standing historical development provides a foundation for their emergence as the central functions of everyday life are still evident in the presence of schools, a church, and an old market building. Residents predominantly move within these areas and along the north-south axis of Fehérvári Road, suggesting that the centralisation of key services and facilities in these areas would be a logical approach.

Furthermore, the study places emphasis on the following aspects of accessibility:

- state of the infrastructure: pedestrian walkways, public thoroughfares, the quality of public transport infrastructure, and the condition of cycle paths,
- availability of transport modes: public transport, smart devices such as scooters, bike-sharing and car-sharing
- car related issues: use of parking spaces.

Nevertheless, the involvement of the population – the promotion of participation – is imperative for the development of all these aspects. For this reason, the opinions of local inhabitants were sought with regard to the aforementioned aspects. Beyond these factors, the role of community constitutes a further key element. Putnam (2000) emphasises the importance of social capital, and Clarence Perry's neighbourhood theory also highlights the positive impact of community relations (Perry, cit. Szabó (2016), while identity, as a community-building and neighbourhood-strengthening factor, can also be key to implementing the 15-minute city model. IIn increasingly atomised and alienated societies, there is a clear need for spaces that foster a shared sense of identity. These could include places of worship, cultural institutions (such as community centres, libraries, theatres, cinemas, and to some extent cafes, restaurants, and bars). The Albertfalva case is distinctive in that it is an area with an extremely strong identity, where preserving traditions plays an important role. However, there is a lack of facilities and events in the district that are able to attract young people. The cultural representative of the Albertfalva Community Center also makes this observation, although he considers the ease of access to the inner part of District XI, the Bartók Quarter, to be a positive factor.

5.2.1 Institutions of education

Albertfalva is endowed with institutions providing primary education; however, residents are obliged to travel further beyond the neighbourhood in order to access secondary schools. Early childhood education and

primary schooling are available within the area with adequate spatial coverage, but only one primary school is publicly maintained and serves children primarily from the local community.

Fig. 2: Institutions of education (Google Maps, own ed., 2024)

5.2.2 Healthcare and social careinstitutions

The district is serviced by one adult and one paediatric GP practice, comprising a total of 9 adult and 4 paediatric doctors. According to the responses to the resident questionnaire, 20 and 15 respondents, respectively, consider this to be satisfactory (with an average score of 4.2 and 4.4 on a scale of 1 to 5). This finding is corroborated by personal interviews.

Dental care and other specialist clinics are only available in private practices within the district. While the function and service are provided, the issue of unequal access to these services may be problematic. However, it should be noted that this is not, of course, a deficiency specific to the district.

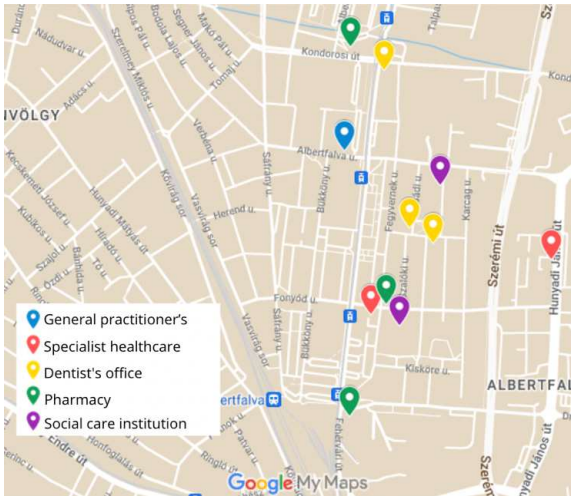

Fig. 3: Healthcare institutions (Google Maps, own ed., 2024)

A positive aspect of the district is the presence of numerous pharmacies, which are dispersed throughout the area.

At present, there are no specialist clinics or hospitals in Albertfalva. In terms of specialised healthcare and hospitals, the nearest facilities are accessible to residents within approximately 20 minutes by public transport.

With regard to social care provisions, the presence of a temporary and day care facility in Albertfalva operated by the Down Foundation is commendable. Despite the presence of a Senior Citizens' Club, it must be noted that the absence of a nursing home within the district constitutes a significant deficiency.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

5.2.3 Administrative institutions

Although several post offices previously operated within the neighbourhood, currently only one is available, located in the shopping centre on the southern periphery of the neighbourhood. Despite the absence of a police station and a fire station in Albertfalva, a district police office was established in the area in 2023. For residents of Albertfalva, administrative procedures cannot be carried out within a 15-minute walking distance; however, in the context of Budapest this limitation is more a matter of administrative organisation than of neighbourhood-level urban planning.

5.2.4 Commercial services

Commercial spaces have functioned as the focal points of urban areas since the early stages of urban development (Vazzoler and Roveroni, 2016). In the case of Albertfalva, it is not the quantity but the quality of commercial services that poses a greater challenge.

The district is home to a substantial shopping centre, which serves as an example of a multifaceted commercial hub. This establishment encompasses not only grocery stores but also a variety of commercial units, restaurants, and a post office, thereby fulfilling its role as a service centre. It was reported by all interviewees that the ability to accomplish multiple tasks simultaneously was a key benefit of the platform in question. The data from the resident questionnaire lends further support to this hypothesis, as it demonstrates that people do indeed use the facility, however, their attitude suggests that they do not consider it a convenient location to “quickly pop into” or “on the way”, but rather consider it a more distant destination.

The survey of the local population revealed that there are currently two supermarkets in Albertfalva (a figure that was three at the time of the survey). In addition to the aforementionedcommercial establishments, there are a number of diminutive retail outlets dispersed throughout the district. However, it is notable that the predominantly single-family residential area is under-served in this respect. Such local shops have the potential to provide a significant degree of support to elderly residents.

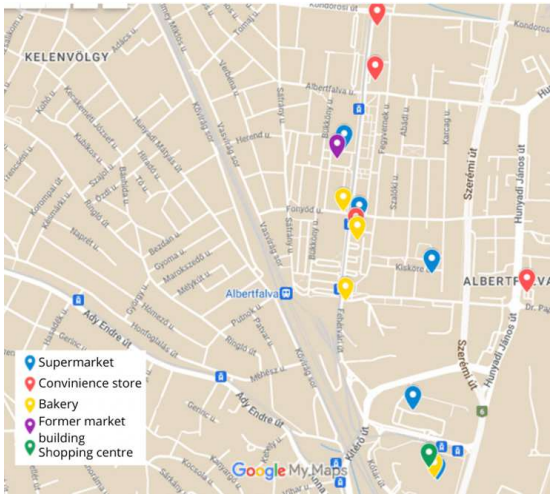

Fig. 4: Commercial services (Google Maps, own ed., 2024)

The inner part of the neighbourhood has a limited number of commercial service providers specialising in non-food items. However, the presence of such professions is shaped by market demand. While they may represent valuable everyday amenities at the local level, they are more commonly concentrated in district-level centres. Consequently, the shopping centre functions as a focal point for a variety of these services. In addition, a variety of smaller commercial enterprises and service providers are located along the northern end of Albertfalva.

5.2.5 Entertainment services

The current situation of hospitality and entertainment venues in Albertfalva presents a distinctive picture. The majority of establishments fulfilling such functions are concentrated along the central “retail strip”. However, the actual usability of these facilities and the quality of the services provided raise several questions. Most restaurants are primarily oriented towards takeaway and delivery services, lack dedicated seating areas or outdoor terraces, or are designed mainly to serve office workers, with opening hours

adjusted accordingly. The place-use patterns reported by residents reflect this situation, as fewer than one third of respondents (ten individuals) visit these establishments on a monthly basis, while the remainder do so even less frequently or not at all.

Albertfalva is a neighbourhood with a single pub, which is currently unable to fulfil its function as a place for civilized social leisure activities or to serve a wide range of age groups. According to the respondents' own statements, 60% of those who completed the questionnaire never attend.

Several interviewees highlighted the absence of a cinema, which could serve as an important venue for entertainment and recreation, particularly given that such a facility had previously existed in the area.

5.2.6 Cultural facilities

The representatives of the Albertfalva Community Center place great emphasis on serving older people and parents with young children, organizing programs, and providing space, however, they find it difficult to reach younger demographics.They agree that it is easier to build on existing communities, and they see the strength of the community center in Albertfalva's strong identity.

The Community Centre organises courses, provides space for civic initiatives and the activities of civil organisations, hosts various interest-based clubs, and serves as a venue for occasional events. Although Albertfalva does not have a theatre, the Petőfi Musical Studio operates within the Community Centre, partially fulfilling this cultural function.

In principle, the Community Centre could be considered one of Albertfalva's main meeting places; however, 40% of respondents to the resident survey reported that they had never visited the facility. At the same time, two respondents indicated that they visit the centre on a weekly basis; both have lived in Albertfalva since birth. These findings are consistent with the observations shared by the interviewees. Furthermore, the neighbourhood is without a public library, a facility that was previously present in Albertfalva.

5.2.7 Religious institutions

In Albertfalva, faith and religion play a significant role as forces of community formation. According to the shared views of the interviewees, the Saint Michael's Church functions as an especially important communal space, particularly for older residents. In the immediate vicinity of the church, a community centre serving the religious congregation has recently been established; this facility supports not only religious activities but also provides space for other organisations and community initiatives.

5.2.8 Recreational areas, parks

Although Albertfalva's suburban character might lead one to conclude that it has a sufficient quantity and quality of green space, the map-based functional assessment does not support this assumption. The assessment concluded that there are seven parks in Albertfalva. According to the assessment, there are seven parks in Albertfalva, but a closer look reveals a different picture: both field observations and residents' opinions indicate that only two of these areas function as genuine recreational spaces. Even in these cases, several shortcomings can be identified, such as limited suitability for all age groups and the lack of complementary functions (e.g. hospitality services or sports facilities). In general, the parks within the neighbourhood tend to be small-scale green areas, in some cases lacking even tree cover.

One interviewee noted the presence of a community garden and a community composting facility in Albertfalva. However, the extent to which the population makes use of the garden located in the garden house area is questionable.

Albertfalva's waterfront location offers untapped opportunities for neighbourhood development, as the area is bordered along its entire eastern side by the Danube. The Árasztó-bank, in particular, represents a high-potential development area due to its direct riverfront connection and its unbuilt character.

Playgrounds are distributed throughout almost all parts of the neighbourhood and are actively used by local residents. They are generally of good quality. These playgrounds play an important role in the life of the local community, as they not only provide a safe and entertaining place for children to play and exercise, but also serve as a meeting point for parents and local residents. This assertion is substantiated by the observation that two respondents who completed the survey regarded the playgrounds as the "heart" of Albertfalva.

The district has a long-standing swimming pool and sports complex, which has recently undergone complete renovation (Albertfalva Local History and School History Museum, 2024).

Fig. 5: Recreational areas, parks (Google Maps, own ed., 2024)

5.2.9 Transportation

Albertfalva is a neighbourhood with strong spatial connectivity and is very well integrated into Budapest's transport network. Several lines of the Buda interlinked tram network pass through the area, including tram lines 17 (connecting Savoya Park and Óbuda), 41 (between Kamaraerdő and Óbuda), 47 and 48 (linking Budafok Centre with Deák Ferenc Square), and 56 (operating along the Budafok–Hűvösvölgy route). In addition, bus line 7 – one of the main east–west corridors crossing the entire city – also runs through Albertfalva, with one of its termini located at Albertfalva railway station and stops at several major transport nodes across Budapest. Bus services connecting Budafok with Móricz Zsigmond Square likewise pass through the neighbourhood.

Albertfalva railway station could also function as an important transport node; however, only a limited number of train services operate from here to Kelenföld railway station or to Kőbánya-Kispest (primarily from the direction of Székesfehérvár). While the rail infrastructure is therefore in place, its more intensive use could represent a further opportunity for improving local and metropolitan mobility.

At the same time, these favourable transport conditions raise questions regarding the feasibility of implementing the 15-minute city model. Several participants in the expert interviews pointed out that Albertfalva's very good accessibility and transport connections may, paradoxically, hinder the development of more locally oriented, proximity-based urban functions.

In my view, strong spatial connectivity should not hinder the emergence and long-term viability of liveable neighbourhoods and accessible local services. Where local transport is supported by appropriate infrastructure – of the kind required for the 15-minute city – residents tend to make natural and routine use of these systems.

A quote from Fred Kent (2005) "If you plan cities for cars and traffic, you get cars and traffic. If you plan for people and places, you get people and places." This principle highlights how the design of infrastructure and urban spaces determines how people use them.

Albertfalva's cycling infrastructure consists of a semi-separated cycling path along the eastern edge of the neighbourhood on a major arterial road, which is located at a distance from the areas most actively used by residents, and a cycling lane running through the low-density residential zone, however, cyclist movement is impeded by cars parked on the lane. The street where tram services operate and the majority of local traffic occurs lacks dedicated cycling infrastructure. This represents a significant development opportunity in implementing the 15-minute city concept. The expansion of the cycling network, particularly in routes connecting residential areas with local amenities, has the potential to enhance the frequency of bicycle use. This has the potential to increase the frequency of bicycle use, which is significant for both environmental sustainability and public health.

The following diagram illustrates the transportation habits of residential respondents. The diagram indicates that walking is the predominant form of transportation in Albertfalva, with cycling being less favoured. The

survey data indicates that the majority the responding local residents primarily utilise public transportation for intra-district and urban mobility. However, in both scenarios, private vehicle usage ranks second.

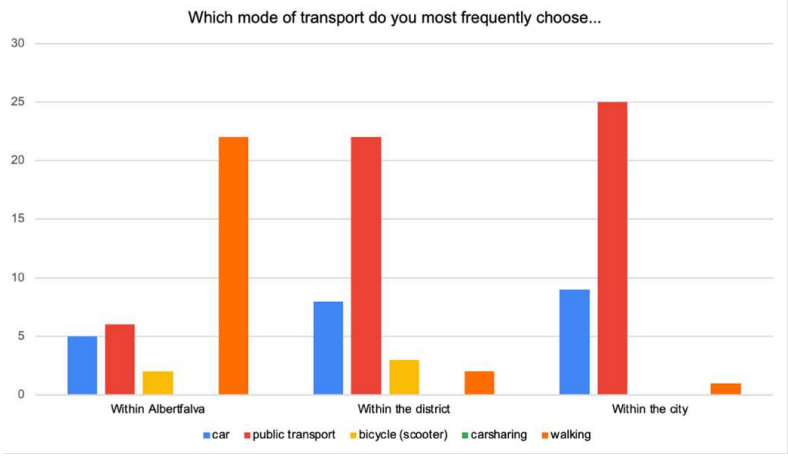

Fig. 6: Mode of transport used by respondents (own ed., 2024)

The concept of the 15-minute city is based on reducing car use, therefore, issues related to automobility warrant particular attention. Several interviewees mentioned the division of parking zones as a problem, as at the time of the data collection Albertfalva lay outside the regulated parking areas and, as a result, the neighbourhood effectively functions as an informal park-and-ride (P+R) area for commuters arriving from the metropolitan agglomeration. This situation implies that parking demand in Albertfalva is shaped not only by local car use but also by the needs of inbound commuters. This trend has a negative impact on the use of space in Albertfalva and the quality of life of its residents in several ways, as the mass presence of cars from the agglomeration increases the demand for parking spaces, making it more difficult for local residents to find free parking spaces near their homes, increased car traffic has adverse environmental impacts and the spatial constraints imposed by increased traffic and the occupation of land by parked cars serve to impede the feasibility of establishing community spaces and green areas, both of which are pivotal components of the 15-minute city concept.

Smart, sharing-based transportation options, such as car-sharing services (e.g., Mol Limo, GreenGo), bike-sharing (e.g. Mol Bubi) or shared scooters (Lime), play a significant role in the future of modern urban mobility. However, it can be observed that the use of these services in Albertfalva is less widespread, based on the fact, that the MOL Bubi system is not currently available within the neighbourhood, on interview reports and the above diagram. However, the integration of these modes of transport contributes to all aspects of sustainability: they are a more environmentally friendly alternative, they can be more cost-effective than owning a car (especially if it is rarely used)and finally, in some cases, they can even have positive social implications, as they encourage community thinking and a culture of sharing. In addition, reducing the number of parking spaces can “give back” space to people.

It is evident that public transport facilitates convenient access to the central areas of District XI and even to the primary centres of Budapest (a direct tram connection between Albertfalva and Deák Ferenc Square). Nevertheless, there is a need for sustainable transport developments within the district that offer local alternatives and aim to ensure a liveable neighbourhood and access to local services (e.g. bike paths and walkable sidewalks).

5.3 Identity and community

Prominent figures in Albertfalva emphasise the profound roots and resilience of the district's identity. According to their interpretation, the origins of this lie in historical factors, as Albertfalva was once an independent settlement with a homogeneous society and significant industrial activity. All this not only evokes the past, but also defines the present identity and cohesion.

They also attribute importance to the fact that in certain areas, such as the Tisztviselőtelep, the population has lived for decades, across generations, in a protected area which, due to building regulations, has been able to preserve its original character and appearance. As a result, the houses still faithfully reflect the former form of this part of the settlement. The strong identity of Albertfalva’s community is further supported by

various tradition-preserving groups and their activities, which play an important role in the preservation and transmission of local culture.

This approach is closely linked to the perspective of the planners and the district chief architect, who emphasise that the past must not be forgotten in the development of the town. They argue that preserving local history is not only about respect for the past, but also about creating a strong and cohesive community.

The interviews and resident questionnaires highlight the importance of community and participation for Albertfalva's residents. The interviewees further emphasize the importance of neighbourly relationships, particularly in the case of the Tisztviselőtelep. Respondents to the residential questionnaire also tend to perceive their neighbourhood relations as rather strong.

The Advent season, for instance, is perhaps the most striking example of this phenomenon. During this period, the houses in Tisztviselőtelep are transformed into a living Advent calendar, and residents gather at the decorated houses.

5.4 Suggestion for a neighbourhood "centre"

So where could a district center emerge that could serve as a starting point for implementing the 15-minute city model? Based on interviews with prominent figures and surveys of residents, this study focuses on the characteristics associated with the traditional centre of the area.

Following the analysis of functions in question, it can be concluded that although Albertfalva does not currently have a clearly defined centre, the most promising area in this respect is Albertfalva Street and its environs, i.e. the historic centre. This area is considered to be in the centre not only in the eyes of the residents but also in spatial terms.

However, Savoya Park should also be mentioned as a new central area defined in terms of architecture and urban planning.

Albertfalva Street and its surroundings were considered the nucleus of old Albertfalva, and even today one can find facilities with a centralising force here (such as a church, schools, and a doctor's office), but by now, several functions have disappeared from the area and thus from the district as well, such as the cinema, restaurants, and pubs. According to one of my interviewees, there were at least ten of the latter (and these services were not separate from each other in Albertfalva's past (Virt, 1999)) in this neighborhood or nearby until 40-50 years ago.

In my view, therefore, if a neighbourhood centre is to be established in this area – which is also geographically located at the heart of the district – or if the emergence of such a centre is to be supported through urban development instruments, particular attention must be given to the reintroduction of community-oriented, recreational, and cultural functions. Not only is there limited space for such functions elsewhere in the neighbourhood, but local traditions and a strong sense of identity also suggest that residents would be most inclined to use these facilities in this location.

Fig. 7: Albertfalva Street and surrounding area: key local functions (Google Maps, own ed., 2025)

At the same time, the mere creation of meeting places (such as cafés or community spaces) is insufficient if these services are not underpinned by appropriate infrastructure. From this perspective, I consider road-

related interventions and traffic restrictions in the surrounding area to be necessary, particularly in the vicinity of the former market. This, however, is complicated by the presence of a supermarket and its associated car park in the immediate proximity of the former market site, as such a large-scale retail facility not only requires substantial space but also generates significant traffic. However, in my assessment, all this only further weakens the former center of social life, whilst reinforcing rapid, task-oriented use, encuraging people to conclude their activities (i.e. shopping) in this location as quickly as possible and depart. In light of this, it is worth to pay attention to various traffic calming (and elimination) measures. The modernisation of the market building, the rehabilitation of its function, and its renovation have the potential to contribute significantly to the enhancement of the quality of life in the district and the promotion of community life.

My interviewees emphasized that the first step would be to modernize the building's heating system so that it could be used all year round. To do this, the local government must attract private investors willing to fund the renovation and operation of the building, contingent upon certain conditions. These include the preservation of the building's original function during the renovation process, thereby ensuring the continuity of operations as a market.

However, the indisputable role of the supermarket can also be approached from another angle. One of my interviewees believes that the proximity of the store would also promote the use of the market and, what is more, would rather revitalize it.

A local government representative from Albertfalva said that the market had never fulfilled its traditional role, and based on this, it was suggested that the building could be treated as a mixed-use area (especially considering that market days do not take place every day), with functions such as a cinema, other retail shops, or various catering establishments, which could have terraces opening from the inside or even outdoor “street-front” spaces (depending on traffic calming/elimination), allowing people to spend their free time in the open air while using the services.

6 CONCLUSION

The 15-minute city model is a potential response to the socio-spatial transformations occurring in contemporary urban spaces. While city centres were once prominent in terms of economic activity and real estate values, today the structure of cities is increasingly being reshaped by a network of decentralised, functionally diverse sub-centres. These areas are capable of functioning independently, but through their rich networks of connections, they become part of the city as a whole – in terms of transportation, services, and community life.

In this study, the role of district centres was examined in the context of the 15-minute city concept, with the Albertfalva neighbourhood serving as a case study. The study revealed that, while the area exhibits certain urban functions, it currently lacks an integrated community and service centre that would be capable of operating in accordance with the principles of the model. The proposed developments are primarily aimed at improving non-motorised transport accessibility, community spaces, and service diversity.

However, it is important to emphasise that the 15-minute city concept is not based solely on the existence or designation of centres. Rather, the model focuses on functional accessibility within the urban fabric, access to services necessary for everyday life, and residents' opportunities to use space. Consequently, the identification of centres is not a prerequisite for the implementation of the 15-minute city, rather the revitalisation of an underutilised area with potential can most effectively become the practical basis for the model.

This pilot study provides a foundation for further, more comprehensive research that extends beyond a single neighbourhood and incorporates multiple urban areas with differing characteristics, in order to examine the feasibility of implementing the 15-minute city model across different urban contexts.

1 ABSTRACT

Cities are hot spots of development and urbanization is a persistently ongoing phenomenon worldwide. Also in Germany, where the urbanization rate is already at the high level of 80%, the ongoing shift towards cities puts increasing pressure on land use and urban planning. The challenge of competing land uses is particularly evident in densely built-up urban areas and their immediate surroundings, where housing, industry, transportation, and open spaces compete for limited space already in the planning phase.

In this study, we investigate a major urban development project by the city of Munich which aims to create a completely new urban district for up to 30,000 new residents. At present, the project has been approved by the city council, and an initial draft plan is already available. This plan is undergoing further review in various areas (e.g., transport, climate, ecology) in order to refine the draft. The practical implementation of the project is scheduled for the 2030s.

To support the ongoing debates on the practical design of the new district, we utilize Earth Observation data with very-high spatial resolution in combination with open geodata to investigate the current status of land use and land cover (LULC) within the study area, as well as the entire city of Munich. On this basis, we focus on the analysis of new urban development areas that were finalized during the past decade in Munich, which serve as practical examples of potential construction in the new district. The effect on LULC is not only illustrated visually but also evaluated quantitatively based on geospatial data. In addition to the analysis of changes in LULC, we also provide a statistical estimate of the resulting living space for the new residents based on Earth Observation and other geodata. Finally, the study examines possible implementations not only of built-up areas, but also developments and potential changes in open spaces.

With this set of data, methods, and geoinformation, this study makes a contribution to the discussion on the design and implementation of new urban development projects. It is applicable to projects at all scales and provides an illustrative view of the impact of planning projects in the targeted area. In addition, it allows to support decision making and also adds to the public debate on competing land uses on limited space, which is particularly crucial in urban areas.

Keywords: Earth Observation, urban planning, land consumption, population estimation, Munich, Germany

2 INTRODUCTION

Urbanization is an ongoing phenomenon worldwide which leads to a persistent demand for housing in cities (Taubenböck et al. 2024). This is accompanied by expansion of cities and continuous development of new districts. However, in many cases around the globe, the construction of new residential districts and the provision of housing do not match the actual demand, resulting in housing shortage and rising prices (van Doorn et al. 2019).

In Germany, with an urbanization rate at the high level of 80% according to official statistics (UN, 2020), urbanization remains steady with a continuous demand for housing (Shahab et al. 2021), especially in economically strong metropolitan areas like Munich (Müther and Waltersbacher 2025). In this context,

targeted and future-oriented land use and urban planning plays an indispensable role not only to meet the demand for housing, but also to preserve the quality of life in cities and enable them for future challenges, e.g. associated with climate change (Gupta et al. 2025).

Earth Observation (EO) has proven a suitable tool for monitoring of land use and land cover (LULC) and to support land use and urban planning (Bielecka et al. 2025). In particular, EO-based data and derived information with very-high spatial resolution (VHR) offer a suitable basis for application in urban environments, where diverse objects and land cover are concentrated in a highly dynamic manner at small spatial scale, and thus, sufficient spatial resolution to capture all details is essential. This allows not only the detailed assessment of LULC and its changes to date within the area under study, but also scenario simulations and relative comparisons across locations for quantification of the impact of planning decisions (Wang et al. 2021). In addition, EO in combination with open geodata facilitates population estimation beyond official census data or planning estimates, providing consistent and area-wide information (Leichtle et al. 2019, Stevens et al. 2015). Finally, EO- and Geographic Information System (GIS)-based methods support the illustration and elaboration of the effect of LULC changes as a result of planning decisions and urbanization on a specific area (Wellmann et al. 2020).

In this study, we demonstrate the potential of VHR EO and open geodata for application in the context of a major urban development project in Munich, Germany. This work aims at the illustration and quantification of potential LULC changes as a result of planning, while also considering different scenarios in an early stage of planning. In particular, we focus on the assessment of residential housing capacity, which is crucial with regard to overcoming the shortage of housing today and in the future.

3 STUDY AREA & DATA

The study area is located in the city of Munich, which covers an administrative area of 310 km² and represents one of the most dynamic metropolitan areas in Germany. At the end of the year 2024, Munich housed around 1.60 million inhabitants, while this number is estimated to increase to 1.83 million in 2045 (Landeshauptstadt München, 2025a). The projected population growth of 14.1 % over the next two decades underlines the urgent need for adequate urban planning in order to meet the housing demand and to ensure sustainable urban development.

3.1 A New Urban District in Northeast Munich

As part of the general urban development plan of the city of Munich, an area of 600 ha in northeast Munich represents one of the major urban development projects of the coming decades (https://stadt.muenchen.de/infos/zukunftsquartier-muenchner-nordosten.html). In this area, it is planned to establish a new urban district for up to 30,000 new residents. At present, the project has been approved by the city council and an initial draft plan is available as a result of an idea competition. It delineates areas of different land use, including built-up areas, green spaces, natural green areas, and activity areas, as well as an initial plan for public and private transport (Figure 1). The initial plan is currently undergoing further review in various sub-areas (e.g., transport, climate, ecology) in order to refine the draft. The practical implementation of the project is scheduled for the decade after 2030.

3.2 Earth Observation and Open Geodata

In this study, we use different sources of geospatial data in order to conduct a comprehensive assessment across multiple dimesnions.

VHR EO data is collected by the WorldView mission with a pixel size up to 30 cm. For Munich, a cloud free WorldView-3 scene covering eight spectral bands is used, which was acquired on 04.07.2019 and provided by European Space Imaging (EUSI, www.euspaceimaging.com). Height information is included through a normalized Digital Surface Model (nDSM) with a spatial resolution of 50cm provided by the city of Munich. In addition, data from Open Street Map (OSM) covering the same time period is employed. Building envelopes are obtained as Open Data from the Free State of Bavaria.[1] For visualization and illustration purposes, aerial imagery from the Open Data Portal of Bavaria are used.

[1] https://geodaten.bayern.de/opengeodata/

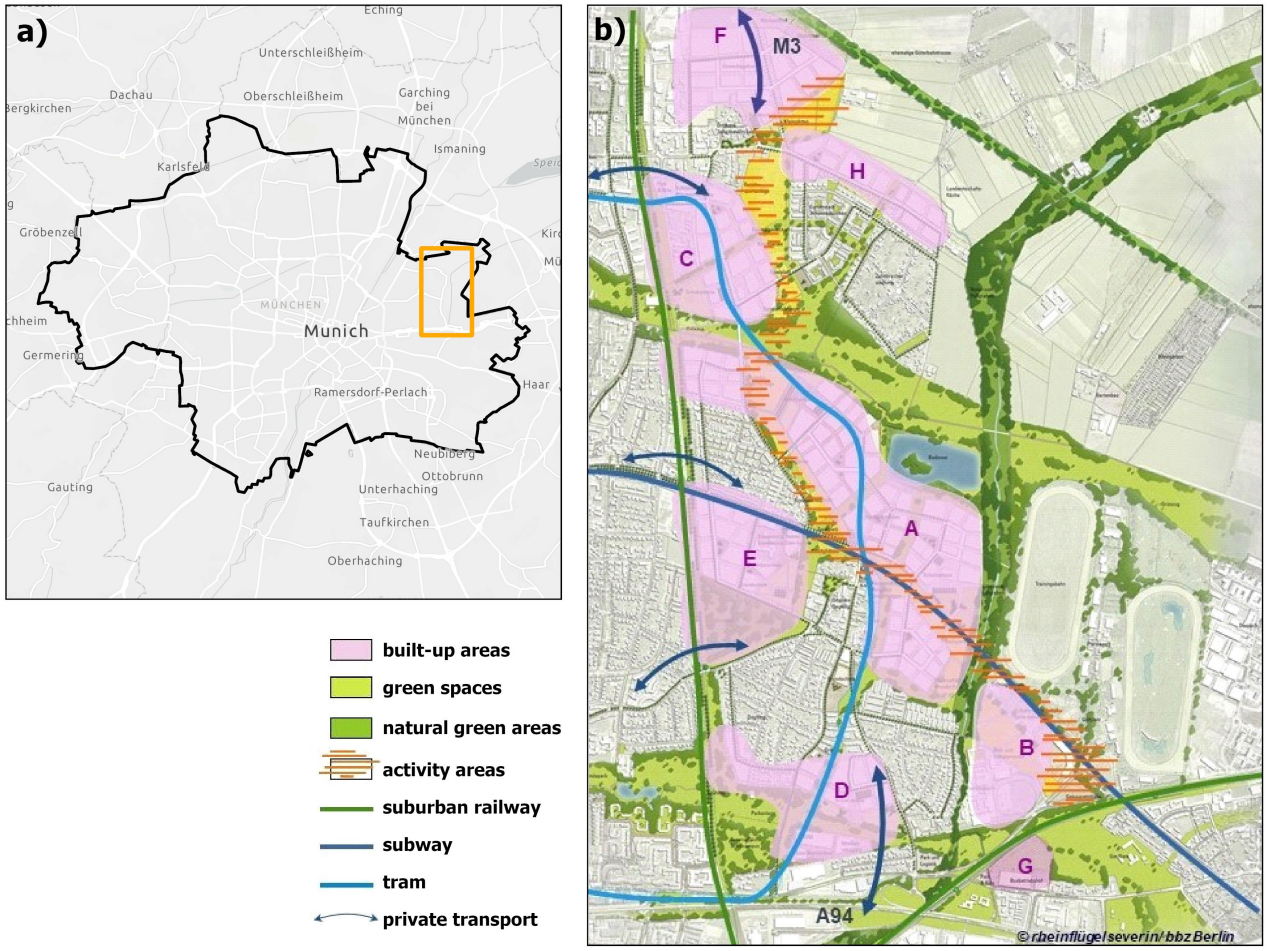

Fig. 1: Location of the study area within the city of Munich (a) and initial draft plan of the new district in northeast Munich (b).

4 METHODOLOGY

The methodology of this work consists of four main steps which are described in the following.

First, in order to derive a spatially consistent data basis on the current situation of LULC, an object-based classification approach based on the methodological foundations introduced in Taubenböck et al. (2010) and Wurm et al. (2011) is implemented. This approach relies on the WorldView-3 imagery, the VHR nDSM, OSM data, and the building envelopes. Target classes include “buildings”, “impervious surfaces”, “bare soil”, “trees”, “low vegetation”, and “water”. The quantitative evaluation of classifiaction accuracy is realized through visual collection of reference samples at randomly distributed locations.

Second, practical examples of existing residential built-up areas and open spaces across Munich are used for evaluating potential realizations of residential construction or types of open spaces in the new district. These are collected across the entire city of Munich, covering open spaces as well as built-up areas. Reference areas for open spaces (i.e. green spaces, natural green areas, and activity areas) are collected regardless of their construction date throughout the city. For built-up areas, we select three new urban developments in Munich that were finalized during the past decade, in order to take current architectural concepts and trends into account.

Third, for the assessment of the potential effects of the new development in northeast Munich, the current land cover of open spaces and built-up areas according to the draft plan is determined based on the EO-based land cover classification. This is compared to the statistical distributions of the land cover classes from the reference areas, i.e. open spaces as well as the three examples of residential built-up areas.

Finally, we conduct a statistical estimation of avaiable living space for the three existing types of residential construction that serve as practical examples of new urban development in Munich. For each individual building, the number of floors is multiplied with the building area to derive floor area per building (Leichtle et al. 2019). The number of floors in each of the three reference areas is assessed by manual inspection and

extrapolated according to built-up areas in the draft plan of the new district in northeast Munich. To account for uninhabited areas within buildings, such as balconies or stairwells, a uniform 10% of the living space per building is deducted (Landeshauptstadt München, 2025b). Based on the available living space, the potential population is calculated using an average living space of 39.5 m² per person (Landeshauptstadt München, 2025b).

5 RESULTS

5.1 Land Cover Classification

Figure 2 shows the result of the object-based classification of land cover using VHR remote sensing. Besides the WorldView-3 imagery acquired on 04.07.2019, the VHR nDSM, OSM data, and building envelopes are considered in this approach. Accuracy assessment based on visual inspection of randomly distributed points within the study area resulted in 88% overall accuracy. For further analysis in this work, the original land cover classes are aggregated as shown in Figure 2.

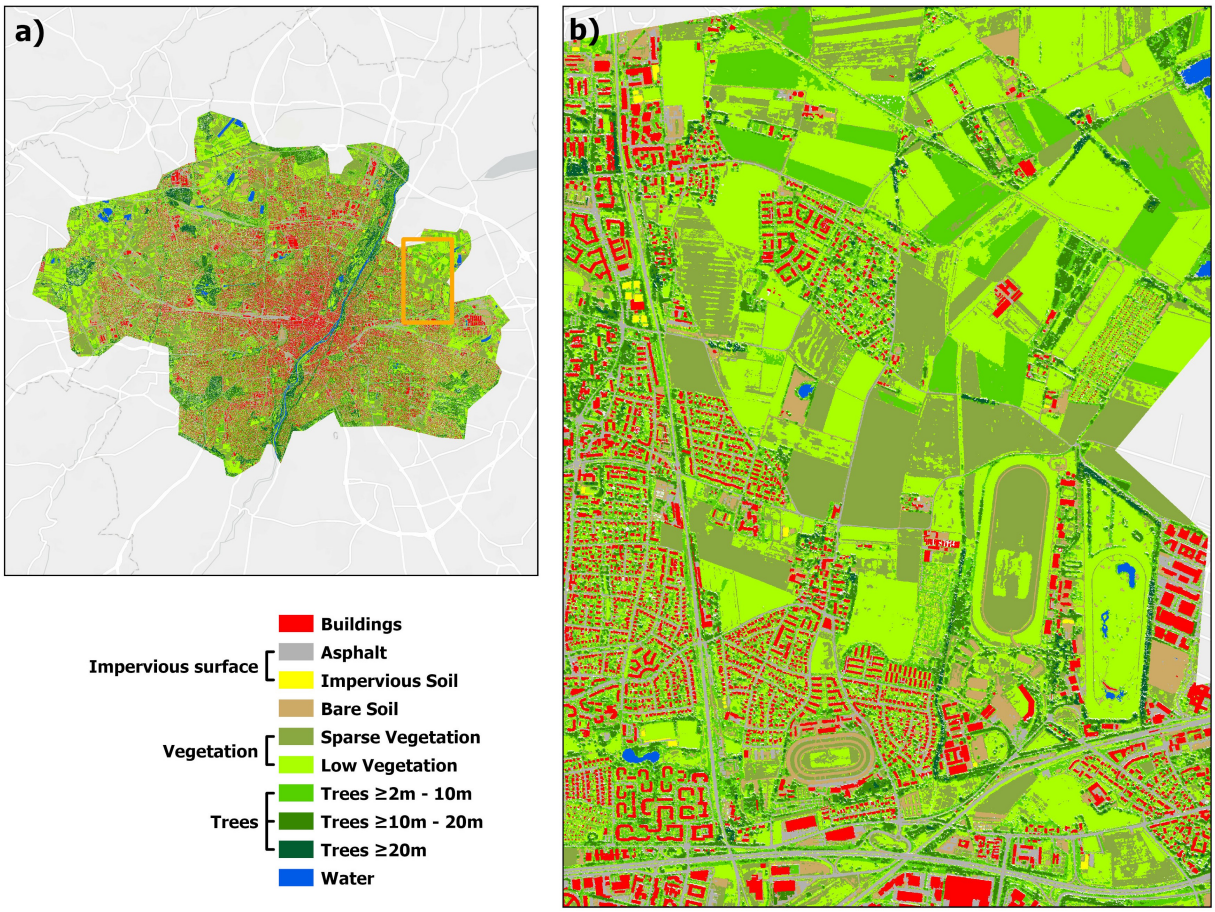

Fig. 2: Land Cover classification based on the WorldView-3 imagery acquired on 04.07.2019, the VHR nDSM, OSM data, and building envelopes. Overview of the city of Munich (a) and detailed view of the new district in northeast Munich (b).

5.2 Collection of Reference Areas

Since the design and implementation of open spaces as well as the type of development on built-up areas in the new district are not yet determined in the early planning phase, reference areas across the entire city of Munich serve as examples of potential realizations. The locations of reference areas for built-up areas, green spaces, natural green areas, and activity areas are illustrated in Figure 3. For built-up areas, three new urban developments that were finalized during the past decade were selected.

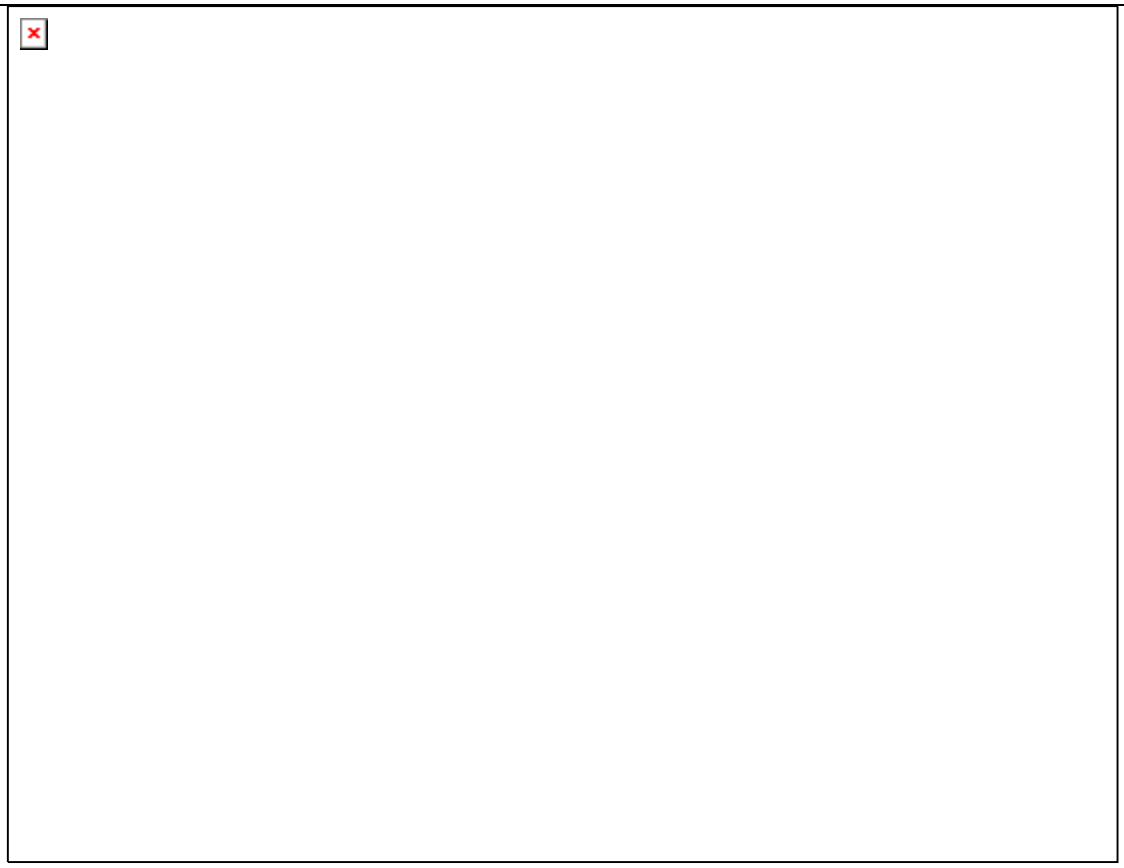

Fig. 3: Location of reference areas for residential built-up areas (new urban developments from the past decade), green spaces, natural green areas, and activity areas within the city of Munich.

Aerial views, spatial statistics of land cover, and illustrations of the three selected new urban developments are summarized in Figure 4.

The first example, “Siemenswerke Obersendling” (Figure 4, left), is a new development in the south of Munich with five high-rise buildings with 15 floors each, which are surrounded by peripheral development with four to five floors. This development was completed in 2014 and features a car-free design with access and parking spaces via the surrounding streets. The land cover of this example has the highest share of vegetation of 51%, with the fewest trees, while building density as well as impervious surfaces are the lowest among the three examples.

The second example, “Neue Gärten Giesing” (Figure 4, middle), is located southeast of the city center and represents a relatively central location within Munich, which was completed in 2014. This development is implemented in a car-free design and features dense residential development with four to seven floors. The land cover of this development features the highest tree density of 8% with medium vegetation cover. Building density of 27% and impervious surfaces of 15% are in the medium range compared to the other examples.

The third example, “Mein Aubing” (Figure 4, right) in the west of Munich, is designed in a conventional layout (i.e. access through motorized individual transport) with buildings of two to three floors. The location of this development can be characterized as a traditional suburban setting; its construction was completed in 2015/16. Due to the presence of roads, this development has the highest share of impervious surfaces of 24% and low values of vegetation and tree cover with 27% and 5%, respectively. Building density of 31% is the highest among the three examples.

Fig. 4: Aerial views (a), spatial statistics of land cover (b), and illustrations (c) of the three exemplary new urban developments. For locations of these areas refer to Figure 3.

5.3 Effects of new development

For the analysis of potential effects of the new development, we use the collected reference areas of open spaces as well as the three selected examples of residential construction to evaluate the impact on the new district.

For the estimation of the effects of planning in open spaces, we assume that tall (>20m) and medium-tall (≥10m-20m) trees are retained, while other areas are altered according to the distibution of land cover in the reference areas. The resulting potential realizations for green spaces, natural green areas, and activity areas are depicted in Figure 5. Overall, vegetation and trees account for the majority of LULC in all three types of open areas. In green spaces (Figure 5a&d), vegetation and trees represent 63.6 and 19.1% of land cover, respectively. In addition, water makes up 10.8% of the total area, which is included through the recreational lake in the center of the planning area (Figure 1b). For natural green areas (Figure 5b&d), vegetation and

trees are more evenly distributed with 52.0 and 37.9%, respectively. As excepted, these areas can be characterized as the most natural, with lowest shares of impervious surfaces and buildings, and highest shares of green space. Finally, activity areas (Figure 5c&d) possess similar distributions of vegetation and trees as green spaces with 62.0 and 16.0%, repsectively. The most pronounced difference are notable shares of buildings (3.8%) and impervious surfaces (9.2%), as well as bare soil (6.8%). Obviously, this is explained by new construction of infrastructure for pedestrian and bicycle traffic as well as areas for sports and leisure activities, which, depending on their use, include both buildings and impervious surfaces. In addition, activity areas also comprise areas for playgrounds, seating, relaxation, and recreation.

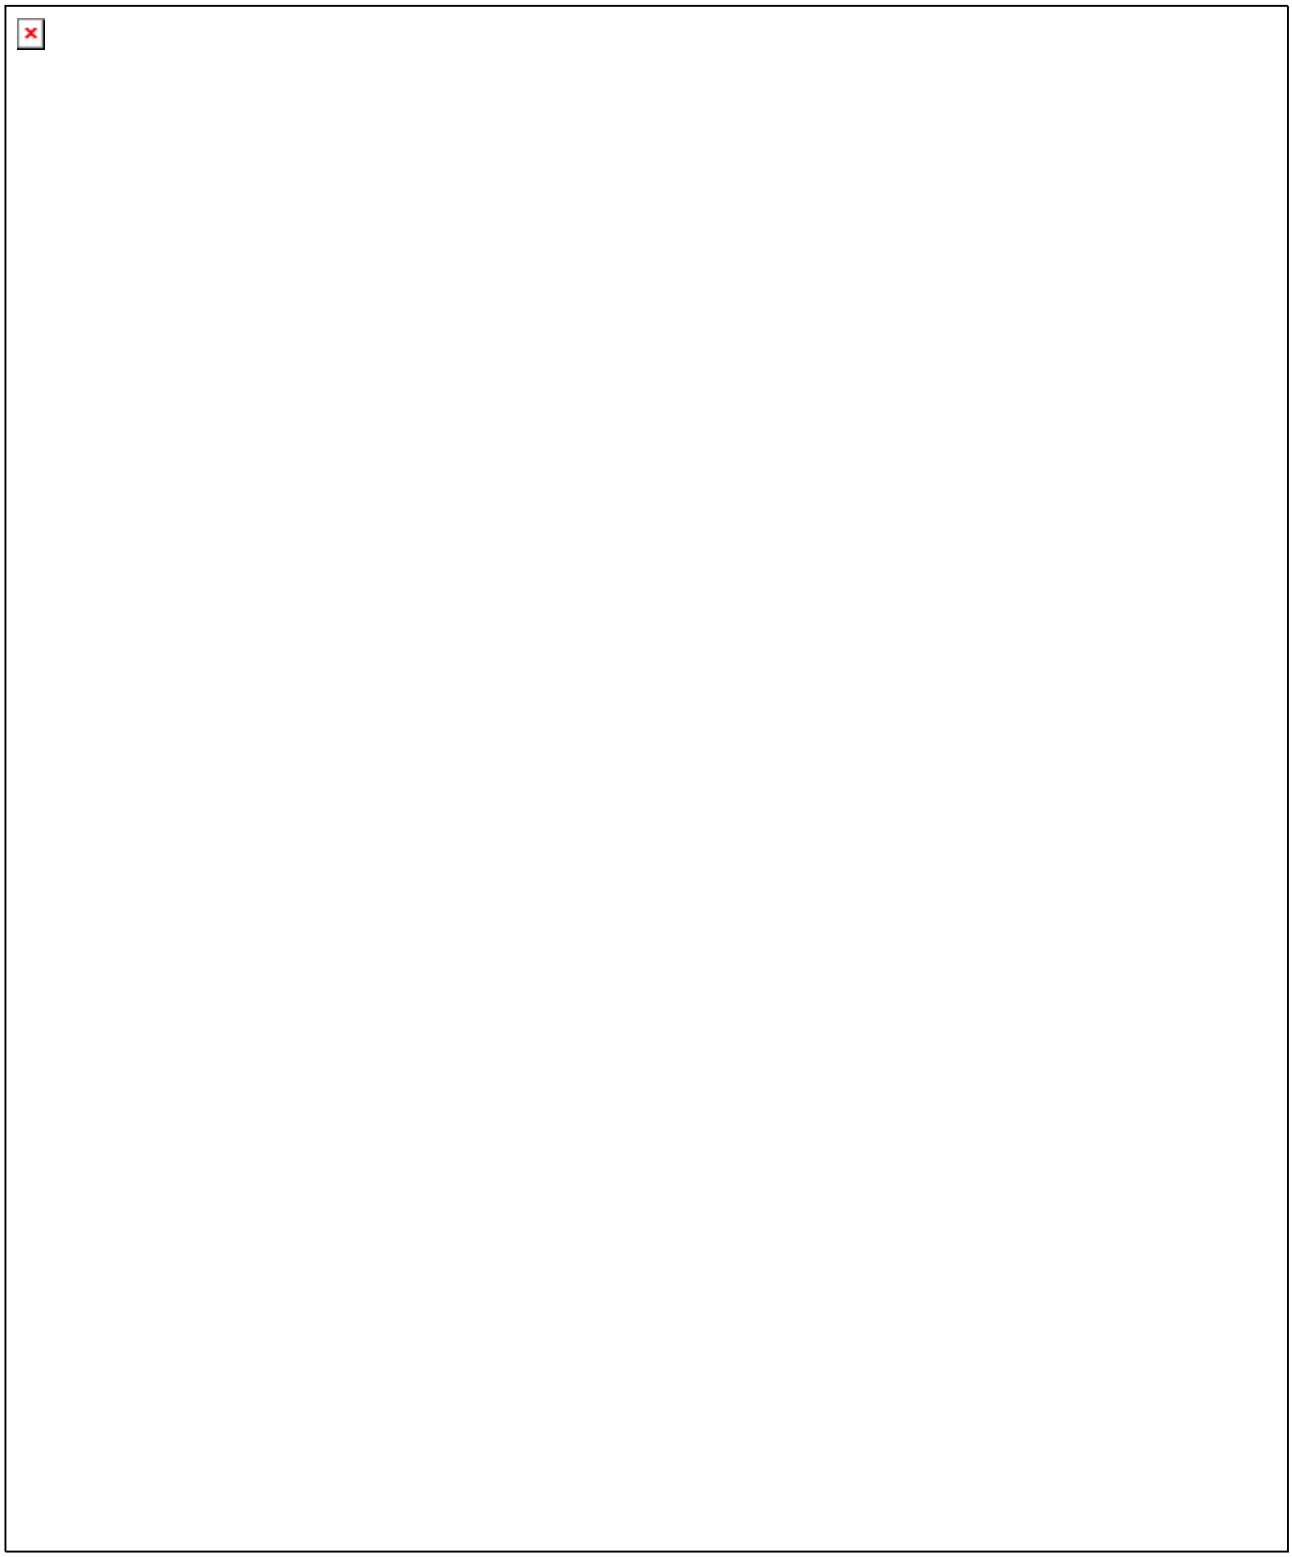

Fig. 5: Potential change per land cover class for green spaces, natural green areas, and activity areas in the new district in northeast Munich.

Editors: M. Schrenk, C. Beyer, T. Popovich, J. Ryser, D. Mawlood
ISBN 978-3-9504945-5-6

For built-up areas, the potential effect of the three exemplary new urban developments is illustrated in Figure 6. On the one hand, new development is accompanied by a loss of natural and near-natural areas, as evidenced by the loss of trees, vegetation, and water bodies in all three examplary new urban developments. On the other hand, new development results in an increase in buildings and impervious surfaces, with the magnitude differing significantly for the three different construction types. The lowest land consumption through built-up areas can be observed for the first example (Siemenswerke), which is very space-efficient based on the high-rise buildings. This is accompanied by a high amount of open space in between the buildings, which is covered by vegetation in this example, resulting in the relatively lowest loss of vegetation. The second example (Giesing) is characterized by a moderate land consumption by buildings and impervious surfaces, whereas the loss of trees is lowest in this example. Finally, the third example (Aubing) of new urban development exhibits the highest building density as well as the highest degree of imperviousness, which can be attributed to the inclusion of motorized private transport and the corresponding space requirements of associated infrastructure.

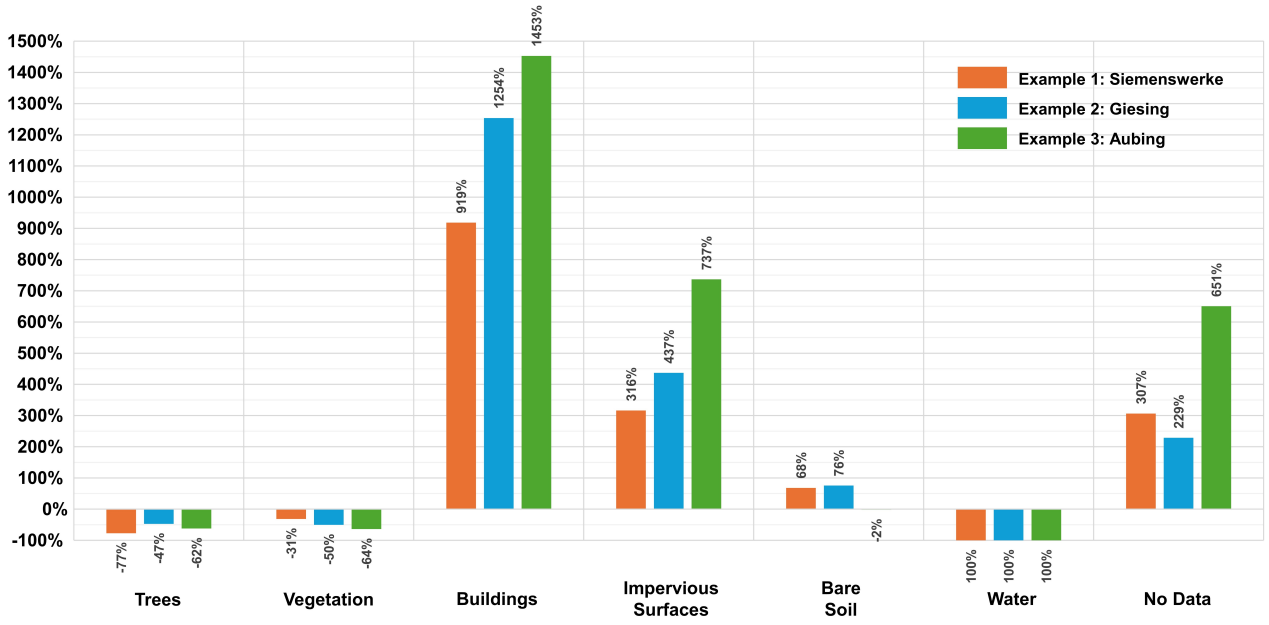

Fig. 6: Potential change per land cover class for built-up areas based on the three exemplary new urban developments in the new district in northeast Munich.

5.4 Estimation of Living Space

The statistical estimation of the potential population capacity based on an average living space of 39.5 m² per person is presented in Figure 7.

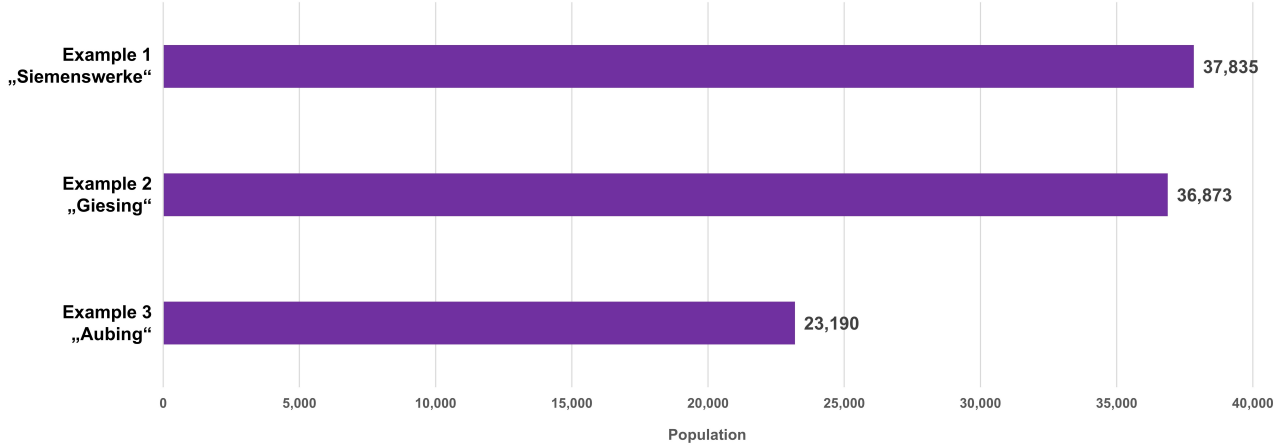

Fig. 7: Potential population capacity for the three exemplary new urban developments in the new district in northeast Munich.

Based on the avaiable areas for built-up development in the new district in northeast Munich, the estimation for the third example “Aubing” is significantly lower, while the other two examples are significantly above

the envisaged population capacity of 30,000 inhabitants from the draft plan. While the estimated population capacities of the first and second examples are close, the two types of construction show clear differences in terms of building density and height, and consequently different possibilities for open space design between the buildings (also see Figure 4). Overall, these results illustrate the potential variation of up to 15,000 inhabitants dependent of different conceptualizations of new urban development, i.e. by implementation of a car-free design and/or construction of high-rise buildings.

6 DISCUSSION

This work demonstrates the capabilities of EO and open geodata for illustration and quantification of potential effects of LULC change as a result of urban planning. According to the draft plan of a major development project in northeast Munich, we demonstrate potential LULC changes differentiated by open spaces and built-up areas, whereas for the latter, three specific of recent residential developments in Munich and their different impacts are examined. In addition, not only the impact on land consumption but also the provision of housing in terms of residential living space is examined.

Compared to existing research on urban land management and planning, the utilized VHR EO data and open geodata was rarely used to date (Bielecka et al. 2025). While VHR satellite imagery – like the WorldView data employed in this study – is usually not freely available and requires some processing effort (Wurm et al. 2011), the derived information is highly valuable to support urban planning. However, despite very-high resolution information, not all aspects can be resolved, e.g. small water bodies or impervious surfaces that are topped by tree crowns and thus, become invisible from a satellite view. In addition, VHR remote sensing classification results usually have a remaining error in the order of 10%, which also entails a certain degree of uncertainty. However, in general, the VHR data basis offers good transferability and applicability to different areas and thus, is a valuable source of information for applications in urban planning.

Overall, the estimated LULC changes in this work are highly dependent on the choice and selection of reference areas that are used to project the effects of planning in the target area. With regard to open spaces, we aimed to collect a high number of different areas across the entire city of Munich in order to reach a sufficient degree of representativeness. Activity areas can take a variety of different forms, combining infrastructure for pedestrian and bicycle traffic with areas for sports and leisure activities, including various proportions and combinations of buildings, impervious surfaces, and bare soil. However, due to their wide range of possible configurations, the specific characteristics of activity areas are difficult to foresee for specific study cases, and individual implementations may vary considerably. With regard to built-up areas, the derived LULC changes are consistent with our expectations, i.e. loss of vegetation and tree cover accompanied by an increase of impervious surfaces and buildings. The three examples of new urban developments in Munich were chosen to serve a range of residential development characteristics; however, their practical feasibility was not assessed within the scope of this work. However, our approach highlights the bandwidth of building density and impervious surface, as well as consequently different shares of vegetation and trees in the neighborhoods that will be constructed. In addition, the estimation of potential living space and population capacity facilitates the illustration of the impact of planning decisions by presenting them in tangible figures not only for experts but also for the general public. This quantification not only shows the potential of variation, but also offers practical perspectives for discussions about possibilities for urban development and design during the planning phase.

In general, planning decisions are often highly influenced by practical and political factors that were not considered in this work. Especially the political aspect of planning decisions is hard to take into account, which is also closely tied to the role of public sentiment and citizen participation (Mitlin 2021). However, it was proven that geospatial data and GIS methods improve public participation in the planning process (Kahila-Tani et al. 2019). From a practical perspective, the feasibility and cost of different realizations for new developments can vary considerably (Hu & Skibniewski 2021), which was not considered in this study. Sustainable urban planning was included from the perspective of housing provision, which plays an important role, particularly in dynamic urban environments such as the city of Munich. However, future research should include other aspects of sustainable urban planning, such as renewable energy, sustainable building materials, and the provision of green spaces. Particularly in view of advancing climate change, aspects of the urban climate and urban green infrastructure will be crucial for urban planning in order to ensure sustainable development and maintain the quality of life in cities.

7 CONCLUSION

This study illustrates and quantifies the potential impacts of a new urban development in northeast Munich. Based on EO and open geodata, we highlight land consumption in different areas of the currently available draft plan of the planning area. This work particularly focuses on built-up areas, where not only the impact of three different exemplary realizations of residential development is demonstrated, but also their population capacity is estimated in order to address the aspect of housing provision.

This work supports the discussion on adequate provision of living space and the demand for housing in urbanized areas of Germany and beyond. Furthermore, our selection of geospatial data, methods and derived information is well-suited to illustrate and elaborate the effect of planning decisions beyond subjective perception, in order to objectify the debate and explain the context and implications also to non-experts.

8 ACKNOWLEDGEMENTS

This work was supported through the project “OptiPlan”, funded by the Federal Ministry of Education and Research (BMBF) under project numbers 033LK007A and 033LK007B. The authors would like to thank European Space Imaging (EUSI) for providing the WorldView imagery and the city of Munich for sharing the nDSM for this work. Special thanks go to Felix Kleinschroth for his support during his internship.

1 ABSTRACT

The growing need for communication systems in urban areas working at high-speed and energy-efficient has led to developing smart city infrastructures. This article exploits the incorporation of Reconfigurable Intelligent Surfaces (RIS), as a sustainable approach, into urban environments to enhance the connectivity and the energy efficiency of the wireless communication, while exploring their architectural and engineering integration into the fabric of smart cities. Unlike previous approaches, which have traditionally focused on electromagnetic optimizations, this paper proposes RIS as an innovative architectural component that has the potential for integrating wireless communication and sustainability into smart cities. The approach utilizes a multi-step methodology, beginning with an analysis of architectural, structural, and communication needs for designing criteria for implementation. Additionally, this paper proposes a co-design approach for designing geometry and RIS implementation at the same time, which will focus on functional efficiency and aesthetic consistency. Optimization of RIS placement and orientation will be optimized using simulation analysis, taking into consideration signal propagation, energy efficiency, in addition to urban context constraints. The specific RIS modules will be integrated into façade panels and architectural elements using material, structural, and visual strategies. Finally, implementation of this integrated solution will then be assessed for performance on communication, energy efficiency, and aesthetic implementation. By the intelligent reflection of the electromagnetic waves, RIS can transform conventional architectural structures into active communication elements to bridge the gap between wireless connectivity and sustainable urban development. The results aid in the development of future intelligent, energy-efficient, and aesthetically pleasing of future cities.

Keywords: Urban Sustainability, Reconfigurable Intelligent Surfaces , Enhanced Communication Systems , Smart Cities, Urban Planning

2 INTRODUCTION

The rapid growth of cities with urban populations and the increasing demand for high-capacity wireless communication systems have made cities to be smart and data-driven environments (Ouafiq, et al., 2022; Sharma, et al., 2024). To provide real-time services, smart cities need seamless wireless connectivity. This includes smart transportation, environmental monitoring, and sustainable energy management. However, the congested architectural landscape and urban environment can lead to significant signal obstructions, multipath fading, and inadequate energy utilization, which makes modern wireless networks less reliable and less efficient (Akyildiz, et al., 2020)(He, et al., 2024).

In the last years, Reconfigurable Intelligent Surfaces (RIS) have become a promising technology for improving communication performance. RIS can turn passive structures like building façades and walls into active surfaces that improve wireless communication by changing the phase of the reflected electromagnetic waves intelligently. This ability makes RIS an appropriate choice to be used in smart cities, where buildings redesigned to include RIS (Alhafid, et al., 2024; Kisseleff, et al., 2020). In addition to RIS functionalities of improving wireless performance and resources optimizing, it is passive and operates at low-energy, so it has a lot of potential for making cities more sustainable and can satisfy the principle of green infrastructure (Amin, et al., 2023; Salim et al., 2025).

From the perspective of architectural engineering and sustainable urban design, it is important to emphasize the role of communications technologies in the built environment. Accordingly, this paper investigates the alignment of wireless communication engineering and urban sustainability through the architectural

integration of RIS. It proposes a framework of integrating RIS into smart city to improve data transmission and facilitate sustainable urban cites, also emphasizes the collaborative aspects of this approach by encouraging communication engineers, architects, and urban planners from different fields to work together to create the promised future sustainable cities.

3 LITERATURE REVIEW

The use of advanced communication technologies in urban infrastructures has emerged as a fundamental aspect of smart city evolution. Researchers over the past decade have investigated and studied many techniques to improve wireless performance in densely populated cities. Some of these studies include massive MIMO technology, high-frequency communication technology (such as millimeter-waves), and network densification. But these solutions often exhibit energy consumption, and require complex deployment, which makes them less useful for sustainable city models.

To mitigate these challenges, RIS has been proposed as a revolutionary paradigm for next-generation wireless communications. Early works, such as (Kisseleff, et al., 2020) and (Bjornson, et al., 2022), proved that RIS can be leveraged to improve signal-strength and coverage in non-line-of-sight (NLoS) urban areas by intelligently adapting the EM reflections. Other works, such as (Basar, et al., 2021) and (Du, et al., 2021), proved that RIS-assisted communications can provide a considerable enhancement in spectral and energy efficiency over other conventional methods such as relaying and beamforming. Recent works have explored the application of RIS for smart city and urban communications. For instance, the work presented in proposed the wireless environment as a service paradigm through RIS that can be embedded in buildings to optimize the wireless environment. Also, the work presented in (Sang, et al., 2024) explored the application of RIS-equipped buildings for filling coverage gaps in urban areas. On the other hand, works (Alhafid, et al., 2024) and (Alhafid, et al.,2023) explored the application of RIS-assisted localization for near-field localization and proposed new methods using multi-RIS configurations and efficient beam sweeping strategies, respectively. Even with these improvements, most of the research is still focused on communications technologies rather than integrating RISs into architecture or urban planning.

From the sustainability and intelligent design principles point of view, the subject of the built environment has become an important issue in modern architectural engineering studies (Ahmed, et al., 2025; Ahmed, et al.,2024). The authors in reference (Kadhim, et al., 2025) prove that adaptive façade systems improve the energy efficiency of buildings based on weather changes and therefore improve the comfort and energy efficiency of buildings. The authors further argue that smart materials and new ideas in quantum energy can improve the adaptability and efficiency of façades and therefore support adaptive façades as a sustainable solution in architectural engineering. The authors in reference (Corti, et al.,2023) investigate photovoltaic shading systems and argue that such systems can be an effective solution in preventing overheating and allowing for renewable energy implementation. The authors further argue that studies on this subject are still limited. In (Fathi, et al., 2025), the authors conduct a comprehensive analysis and indicate that active and passive smart materials for façades can be an effective solution in improving energy efficiency and preventing overheating in buildings. The authors (Almeida, et al.,2023) investigate a dynamic thermal insulation system and argue that such a system can easily and quickly alternate between different insulation values and therefore can be an effective solution in preventing overheating and ensuring comfortable temperature inside buildings.

Despite the increasing research on RIS, most current research on this subject is largely focused on electromagnetic optimization and network-level performance, overlooking the architectural integration and spatial design potential of RIS in the urban context built environment. At the same time, research on architectural design concepts on building façades is largely concentrated on sustainable design, efficiency, and current design trends, often without taking into consideration wireless connectivity needs. This state of affairs points to a significant research gap, since there is currently no comprehensive framework integrating wireless communication performance, architectural design, and sustainable urban development, a necessary synthesis for developing intelligent, efficient, and interconnected smart cities in the future. Building façades, and public structures have a vast number of surfaces that are geometrically varied and extensive, making them an excellent fit for the application of RIS to increase coverage, facilitate sensing capabilities, and lower transmission power. However, studies on RIS applications have rarely investigated their application through the lens of architectural design concepts, material characteristics, and urban aesthetics. To the best of our

knowledge, this issue has not yet been directly treated by current research on this subject. Based on this research gap, this paper proposes to consider RIS applications through an architectural design lens, thus diverging from an exclusively electronic design approach to integrating applications of RIS into urban planning and sustainable development goals, thus promoting a multidisciplinary approach to next-generation smart city design.

4 THE PROPOSED METHODOLOGY

The proposed multi-stage methodological framework in this research combines RIS into building façades in a smart sustainable urban environment. To begin, there is an initial stage where architectural, structural, and wireless communication requirements are considered collectively in setting common design principles. Next, there is a stage where a co-design strategy is employed, where geometric design of façades and RIS are done simultaneously. Third, there is an RIS placement stage where simulations are done based on position, orientation, signal propagation, and urban environment constraints. Fourth, there is a stage where RIS modules are integrated into façades using material, structural, and visual models. Finally, there is an RIS-integrated façade system assessment stage where communication, energy, and architectural design are considered. This multi-stage methodological framework makes it possible to fully integrate RIS technology into sustainable architectural design principles. The overall process of this multi-stage methodological framework is shown in Figure 1.

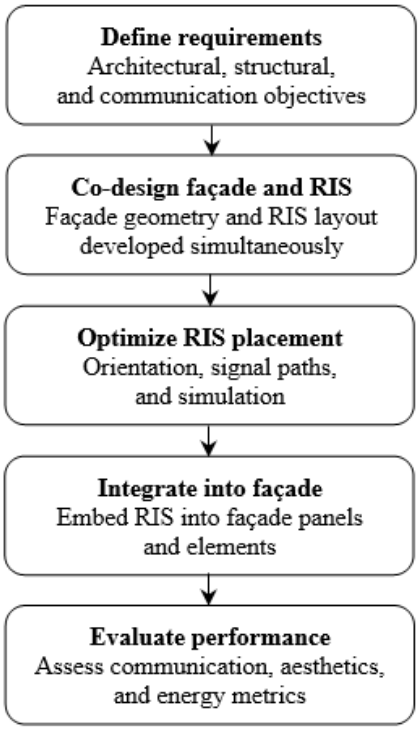

Figure 1 The proposed multi-stage methodology framework

4.1 Development of Urban Geometry Models

In order to properly assess the mutual impact of RIS and the surrounding environment, models of urban geometry can be developed to describe the physical and spatial features of the realistic urban areas for accurate wireless propagation and integration. A typical urban environment (like residential areas, streets, etc.) is first described, with buildings, roads, open spaces, and other environmental features included which can influence the signal behavior. The buildings' geometry is then developed with parameters of footprint, height, and interval between buildings. The façades of the buildings can be specifically described with consideration of their orientation angle, and architectural details like recesses, balconies, and shading. The developed façades are then divided into candidate regions for RIS placement. The regions are described with parameters of orientation angle, height from ground level, surface area, and accessibility. The properties of each surface material for each façade region are described with consideration for surface reflectivity, roughness, and other electromagnetic properties. The regions for deployment of RIS are determined based on their integration with buildings' architecture and relevance to regions with deficient coverage and blocked

areas of urban regions. The process of deployment of urban model for placement of RIS is described with illustrations of each step as depicted in Figure 2.

Figure 2 RIS placement development in urban model

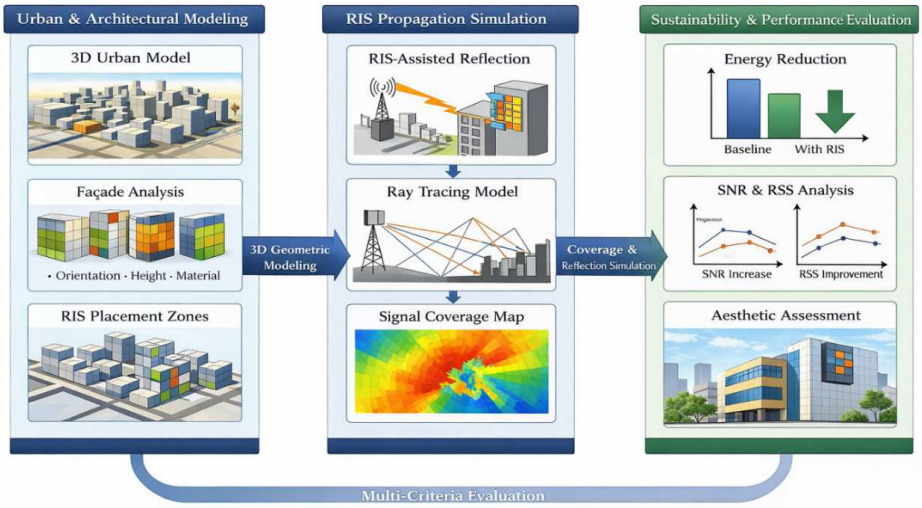

Figure 3 RIS integration in urban environments

4.2 Evaluation of RIS Coverage and Reflection Performancer

Subsequent to the creation of the urban model, the performance of RIS-assisted wireless communication is simulated and evaluated by incorporating the geometric model of the urban environment and communication performance to determine the effect of architectural design on the efficiency of RIS- assisted communication performance. The performance of the communication channel without RIS, which is the baseline propagation scenario, would be simulated first to determine the areas of poor coverage and the non-line of sight (NLoS) areas created by urban structures. The RIS panels would then be virtually placed on the selected areas of the façades, and the panel dimensions, position, and orientation can be varied to determine the effect of the panels on signal redirection behavior. Each RIS would simulate phase and amplitude modulation of the reflected electromagnetic waves to provide beam steering toward desired areas, especially areas with poor coverage in the NLoS region. The performance of the communication system would be measured based on indicators such as the received signal strength (RSS), signal-to-noise ratio (SNR), coverage, and improvement if energy efficiency compared to the baseline scenario. Several scenarios would then be

compared to determine the best approaches for RIS panels placing. Figure 3 illustrates the design and evaluation procedure for incorporating RIS into urban architecture through a multidisciplinary design and evaluation approach.

5 ARCHITECTURAL AND ENVIRONMENTAL INTEGRATION OF RIS-ENABLED FAÇADES

In order for RISs to be incorporated into the façade of buildings, it is essential that these be designed to optimize not only the performance of wireless communication but also take into account architectural and environmental aspects, such as those related to solar exposure and thermal performance of the façade of buildings. Because RISs installed on the façade of buildings are inherently exposed to solar radiation, the angle of installation, size of the RIS panel, height of installation, and material properties will simultaneously impact the efficiency of electromagnetic reflection and may the demand of buildings cooling. Hence, the deployment of RISs can be treated as a multi-objective optimization problem that aims to maximize a combination of communication performance (such as SNR, coverage, and beam steering) and architectural requirements, as listed in Table 1.

From an architectural perspective, RIS panels may be seen as multi-functional façade systems that function similarly to external solar shading systems, perforated metal screens, or double skin façade layers. As such, RIS components may be utilized to mitigate solar gain in highly exposed façades, control glare, and function as a thermal buffer while also re-radiating wireless signals into dense urban environments, as shown in Table 2. At a larger urban scale, dual-functionality provides a means by which buildings may interact with and influence both climates and electromagnetic environments, thus lowering cooling demands, improving pedestrian thermal comfort, and increasing the reliability of outdoor wireless communications. The complete process flow for façade system modeling and placement with awareness of RIS components within urban environment is shown in Figure 4.

Aspect	Communication Perspective	Architectural Perspective	Integrated Outcome
Façade orientation	Determines reflection direction and coverage	Controls solar exposure and heat gain	Orientation-aware RIS placement
RIS surface area	Affects beamforming gain	Influences shaded façade area	Balanced panel sizing
Material selection	Improves LoS and NLoS coverage	Alters solar incidence patterns	Optimized vertical positioning
Phase configuration	Impacts reflection efficiency	Affects absorptance and transmittance	Material-aware RIS design
Solar gain constraint	Maximizes SNR at users	No direct solar impact	Independent control variable
Optimization objective	Not considered in classical RIS	Limits overheating risk	Thermal-safe RIS deployment
Material selection	Maximize SNR / coverage	Minimize cooling load	Multi-objective optimization

Table 1 Communication and architectural criteria for RIS placement

RIS Architectural Role	Solar / Thermal Effect	Architectural Benefit	Wireless Communication Function
External shading element	Reduces direct solar heat gain on exposed façades	Improves thermal comfort and wireless coverage	Redirects signals into non-line-of-sight urban areas
Perforated façade screen	Controls glare and limit solar penetration	Enhances façade articulation and aesthetics	Enables controlled signal reflection and scattering
Double-skin façade layer	Provides shading and thermal buffering	Enables discreet RIS integration	Creates optimized signal reflection paths
Adaptive façade component	Responds dynamically to solar conditions	Facilitates smart building operation	Supports reconfigurable beam steering
Urban infrastructure surface	Reduces cooling demand at district scale	Contributes to smart city resilience	Improves street-level connectivity

Table 2 Architectural and communication functions of RIS-integrated façades

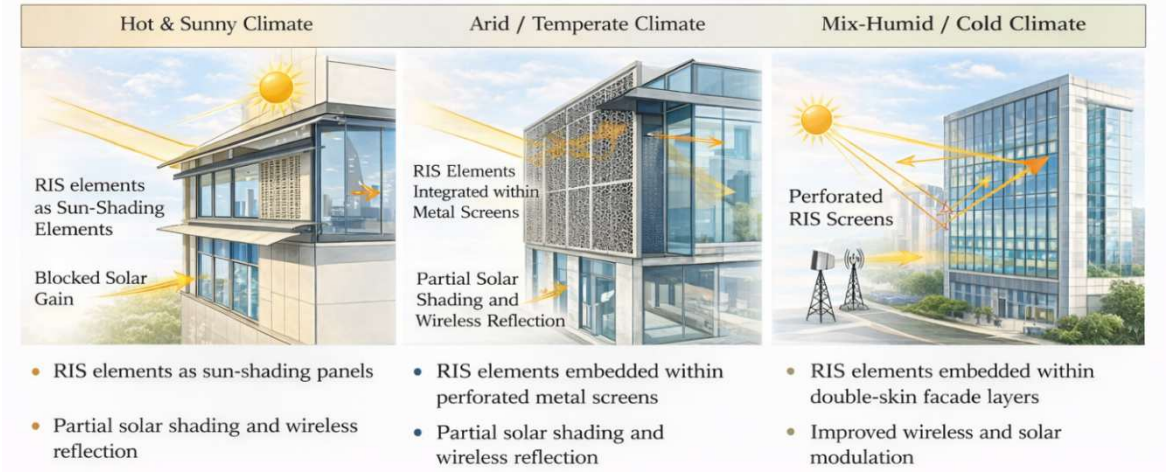

Figure 4 RIS as façade solutions

6 SYSTEM MODEL AND SIMULATION SETUP

The considered system model describes a two-dimensional urban communication scenario, as depicted in Figure 5, where a single BS transmits signals to multiple user equipment (UE) distributed in an area with several building blocks that cause LoS and NLoS propagation scenarios. A set of candidate RIS positions are pre-defined on building walls and urban infrastructure components, considering practical architectural constraints of RIS deployment. Based on this set, two RISs (K=2) are chosen to meet the optimum performance objectives. Three communication scenarios are investigated: (i) a baseline system without RIS, (ii) an RIS-based system with non-optimized RIS positions, where RIS are randomly chosen from the predefined set, and (iii) an RIS-based system with optimized RIS positions, where both RIS positions are exhaustively searched to achieve maximum performance gains. Each RIS is made of certain number of passive elements and employs different phase shift configurations, such as random, quantized, and ideal beams teering schemes. For RIS-based communication systems, received signal powers are calculated considering joint BS-RIS and RIS-UE channels with reflection efficiency, and effects of partial blockages.

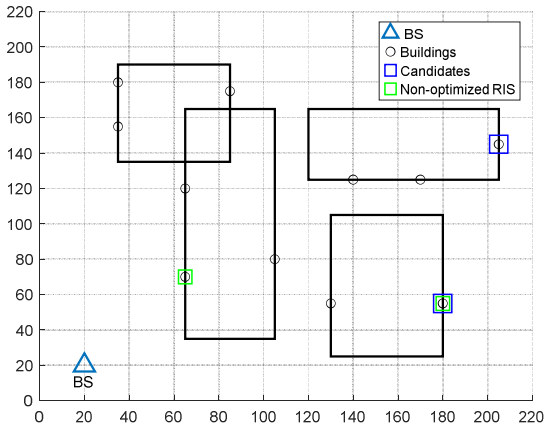

Figure 5 The Considered System Model

The number of RIS elements is assumed to be N elements and $n = 1,2,\ldots N$ is the sequence of each element. System performance metrics are measured by average SNR and spatial SNR heatmaps, as well as by improvements in SNR and in energy efficiency, allowing an overall performance comparison of baseline, non-optimized, and optimized RIS deployment schemes. The received signal observed by the UE can be represented as in (Alhafid, et al., 2023; Alhafid, A.K., Mohammed Ali, et al.,2023):

$$y = h^d x + \sum_{n=1}^{N} Y_n \left(h^f h^b\right) x + n \qquad (1)$$

where h^d is the direct channel between the BS and the UE, x is the known transmitted signal, $h^f$is the channel from the BS to the RIS. $h^b$is the channel from the RIS to the UE, $\Upsilon_n$is the reflection coefficient of the n^{th} element where $n \in \{1,2,\dots N\}$ and $n$is an additive Gaussian Noise.

The reflection coefficient of the n^{th} element possesses an amplitude of Υ and a phase of ψ, which is configured according to the designed profile, so,

$$\Upsilon_n = \Upsilon e^{j\psi} \tag{2}$$

Noting that the channel from the BS to the UE through the RIS is cascaded channel consist of forward $h^f$and backward coefficient h^b.

7 RESULTS AND DISCUSSION

The results shown in Figures 6–9 illustrate the key importance of RIS placement optimization, number of RIS elements, (i.e. RIS size), and phase shift configuration on system performance for dense urban scenarios. As shown in Figure 6, the optimized RIS placement always yields better performance compared to the non-optimized (candidate) placement for all RIS sizes. This highlights that only increasing RIS size is insufficient without appropriate spatial RIS placement, and improper placement is responsible for restricting the possible gain and the beamforming of the reflected signal. Figure 7 further reinforces this observation by showing that optimized RIS placement is responsible for providing significant SNR within the regions of low coverage and NLoS, while the corresponding regions for the baseline case are dominated by the low SNR values due to the blockages created by the buildings.

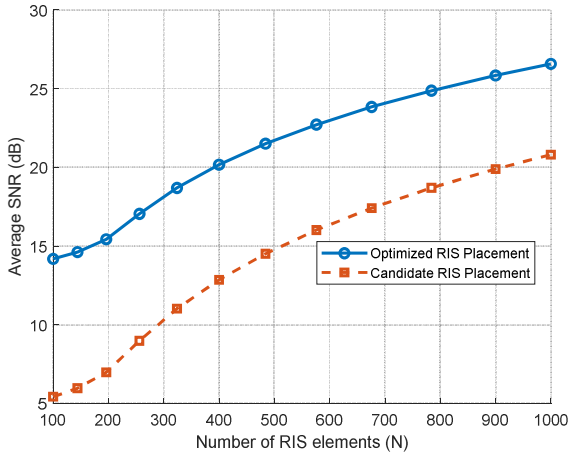

Figure 6 Average SNR versus number of RIS elements for optimized and candidate RIS placement

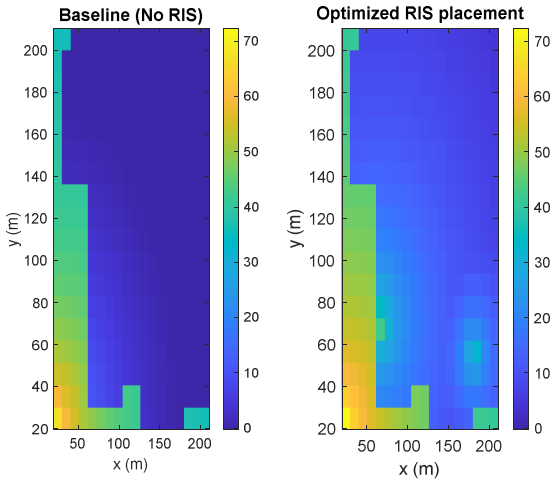

Figure 7 SNR heatmaps for baseline and optimized RIS-assisted communication

The impact of RIS phase profile is then investigated in Figure 8, where ideal beam-steering RIS phase profile provides best SNR gains. Followed by the quantized phase profile which offers a good trade-off between performance and hardware complexity. On the other hand, random phase profile provides little or negligible

performance benefit, emphasizing the need for phase optimization. Finally, it is shown in Figure 9 that properly designed and optimized RIS systems can provide considerable power savings (may reach 60%) for larger RIS sizes. According to these results, communication systems utilizing RISs can significantly enhance SNR, improve coverage, and make energy efficiency better conditioned by the size, placement, and phase profile configuration of the RIS are optimally calibrated.

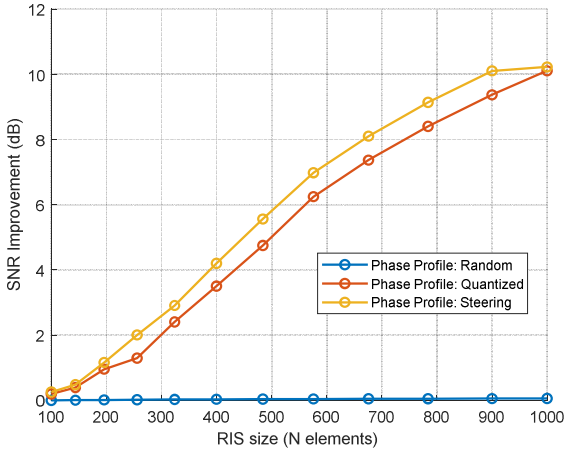

Figure 8 SNR improvement versus RIS size under different RIS phase profiles.

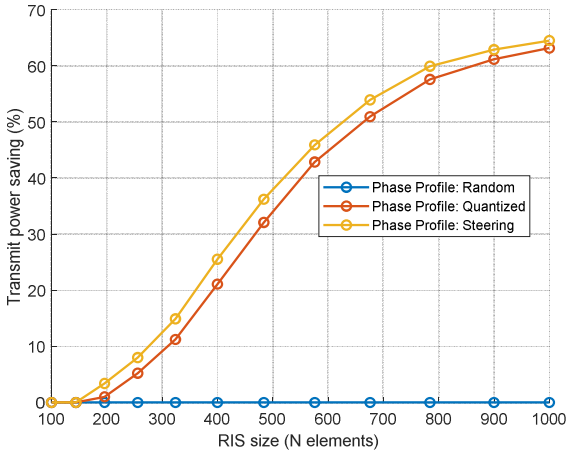

Figure 9 Power saving versus RIS size for different RIS phase profiles

8 CONCLUSION

This paper explored the inclusion of RIS in urban areas from a unified wireless communication and architectural engineering point of view. Unlike most RIS-related research that focuses exclusively on communication optimization techniques, this study considered RIS to have a multifunctional role in façades that could contribute to simultaneous improvements in wireless communication performance and environmentally responsive architecture. A comprehensive framework has been proposed for integrating architectural modeling, geometric of urban areas, and communication optimization. Various RIS placement strategies have been analyzed by simulation. These strategies include communication without RIS, non-optimized RIS placement, and optimized RIS placement by exhaustive search. The results have shown that optimized RIS placement strategies outperform non-optimized strategies significantly, especially for NLoS areas of urban regions. In addition, increasing the number of RIS elements with beam-steering or quantized RIS phase profile has led to considerable improvements in SNR, coverage, and energy efficiencies. The results have shown that RIS are effective in overcoming urban blockage issues while providing considerable energy savings. RIS are thus highly appropriate for sustainable wireless communication. From the architectural engineering point of view, RIS have been found to be integratable with existing architectural façades such as shading devices, perforated screens, or double-skin façades. In conclusion, RIS are identified here as a vital enabling technology for future smart cities where buildings are active participants in wireless communications and environmental regulation. Future works can extend this framework to more practical

urban scenarios, and real-world architectural constraints, as well as explore experimental validation within smart and sustainable city ecosystems.

1 ABSTRACT

In 2025, the city of Johannesburg has been classified among the ten world most dangerous metropolitan cities. This notion is supported by the city's crime index of 80.8% in mid-year 2025. The modern epoch of transportation planning directs more focus and resources towards implementing smart, effective and efficient bus rapid transit systems to commute urban communities. However, there has been evidence of low ridership of bus rapid transits especially by people with disabilities and the root cause is traced to poor safety perceptions catalysed by criminal and violent activities in and around the bus rapid transit systems. The analysis of this effect is not perceived a massive threat in undermining efforts of smart city initiatives particularly where mass surveillances are implemented in the urban built environment. It is common cause that every development in the city attracts opportunists who poses direct threat towards elimination of innovative strategies. This study adopts a descriptive case study approach to investigate the effect of closed-circuit television cameras in improving the safety perception of disabled users of Rea Vaya BRT system in Johannesburg. Furthermore, the study intends to advocate for the popularization of closed-circuit television (CCTV) networks to combat crime activities in and around bus rapid transit network.

Keywords: Closed-circuit television, bus rapid transit, safety, disabled-users, smart city

2 INTRODUCTION

The implementation of closed-circuit television (CCTV) surveillance cameras in public spaces is common in South African metropolitan cities. In Johannesburg, the installation of CCTV surveillance cameras is pivotal in highways, public transport systems, city centre, malls, common places, and private residence (Gorpi, 2018). The high prevalence of CCTV surveillance is influenced by growing concerns over public safety and security, the protection of essential asserts and property. The current legislation of South Africa does not regulate CCTV cameras in public spaces, and such has been identified for rectification because of abuse by individuals, corporates or the state. It is common knowledge that in Johannesburg, the CCTV surveillance cameras rolled out by private security providers are without clear guidelines on how to bridge balance between public safety and security essentials with interest to rights to privacy. To date, efforts have been made for disclaimers arguing compliance with privacy regulations including Protection of Personal Information (POPI) Act of 2013, which has not yet fully realised operational imperatives. People with disability form segment of the vulnerable society that relies heavily on public transport due to affordable fares and convenience, however, they tussle with increasing criminal and violent activities that are prevailing in and around public transport zones. In terms of Rea Vaya BRT system particularly in Ellis Park, efforts have been made to install CCTV cameras to serve as security features and limit criminal activities in and around the BRT station. The implementation of CCTV cameras has been greatly improved and of assistance to disabled persons as they are able to manoeuvrer with ease and without fear of crime (PSIRA, 2019).

3 HISTORICAL CONTEXT OF CCTV AND BRT IN JOHANNESBURG

The implementation of CCTV surveillance cameras in Johannesburg is not a relative new concept however, it is still growing trend in comparison to metropolitan cities in Western countries such as the United States, United Kingdom and Canada (Lukacs, 2016). However, there is popularization of CCTV systems driven by the state, private sector and private security companies in South Africa. This initiative is sometimes drawn back by the fear notion led by civil society and researchers that the growing demand for surveillance will impede on the right to privacy. According to Minnaar (2015), the implementation of CCTV in South African cities can be tracked back to the early 1970s when the mining industry dealing with diamond and gold refineries invented them to prevent the smuggling and stealing of minerals. However, in the early 1990s and early 2000s, the utilization of CCTV surveillance gained popularity in the central business districts (CBDs)

of many cities where retailers initiated the installation of CCTV surveillance to detect, prevent, deviate and manage criminal activities. This notion is supported by the growing evidence of high volumes of CCTV camera systems in the private sector such as banks, warehouses, retailers and residential estates. During the 2010 World cup soccer tournament in South African, concerns around safety and security of tourists enhanced the fresh push that influenced the public-funded extension of CCTV surveillance on sports facilities, highways, city centres and shopping complexes (Meyersfield &Nyembe, 2016). Moreover, this period has seen public transport systems investing trunk of funds towards installing CCTV cameras in their transport facilities especially the public transport system. The bus rapid transit system in Johannesburg extended more facilities around their stations and inside the fleets to combat, control and deter criminal activities. In 2011, Rea Vaya bus rapid transit system at least installed CCTV cameras in more than 50% of their fleets and stations fully fitted with cameras.

4 CONCEPTUAL AND THEORETICAL FRAMEWORK

The concept of CCTV system relates to surveillance abilities that serves primarily as a security force multiplier, enabling surveillance for greater range of an area, more often than it would be possible for security personnel alone (Minnaar, 2012). CCTV system is sued to provide support the comprehensive security cluster by integrating video coverage and security alarm detectors for detection, barriers and control access. This concept is not a new concept around the world; it may be traced back to the early 1950s. CCTV systems are complex and encompasses various components with multi-faceted functions, specifications and features. The most prominent components include but not limited to lenses, cameras, power, lighting, and data distribution centres. CCTV systems regularly undergo feature upgrades to enhance performance in extents such as data storage, digital equipment options, wireless communications, component reduction and automated picture analysis (Moatshe, 2018). This study is grounded on the rational choice theory which perceive views that people intend to achieve results aligned with their goals to amplify their self-interest. Also, when alternative options are made available, individuals resort to the route that maximizes benefit and satisfaction. In this case, this theory is relevant to the study to provided basis for argument that people with disabilities are more likely to use BRT systems when presented with various options for public mode of transportation because security measures are enforced and prioritised for passengers as compared to other modes of public transit. Thus, the proliferation of CCTV cameras in BRT system enhances the amount of ridership of persons with disabilities as they project the feeling of safe mobility options.

5 METHODOLOGY

This study adopts a qualitative research approach to derive an in-depth understanding of how CCTV surveillance enhances safety perception for disabled persons who commute through BRT system in Johannesburg. The research integrates (interviews with municipal transport officials and residents in the city) and secondary data (municipal reports, academic literature and municipal integrated development plans) that are directly related with sustainable public transit and development goals. In a broader context, this research relies extensively on previous arguments and data results which are synced to a dialogue amongst themselves to derive common conclusions on broadened perspectives. Purposive sampling techniques were adopted to guide the study with the target population limited to a total of 30 respondents who responded to structured interviews. Data collection procedures were observed through key informant and stakeholder interviews such as municipal departments (Spatial planning and economic development department; Environmental affairs and Transport department). Secondary data sources consisted of public transport sector plans, annual reports, policies, scholarly publications and spatial development frameworks. Furthermore, thematic approach was adopted to analyse data collected which aimed on outlining key thematic areas, trends and patterns linked to bus rapid transit and CCTV surveillance cameras.

6 THE LEGAL IMPERATIVES OF CCTV SURVELLIANCES IN SOUTH AFRICA

To derive in-depth understanding of techniques which CCTV surveillance dialects to the right to privacy, there is a broader need to envision the notion of privacy and its imperatives. The right to privacy is a basic human right recognised around the world as one of the concepts of modernity which is set to have a universal common underpinning of definition. The call for the right to privacy remains a global phenomenon, but its foundation is rooted in differential interpretation depending to the prevailing community traits, culture and economic power of the time. South Africa builds its legislative mandate on reference to global legal trends;

in which there have been multifaceted trials at deriving a uniform definition of what the concept 'privacy' constitute. Under international law, the right to privacy is recognised by Article 12 of the Universal Declaration of Human Rights (UDHR) together with Article 17 of the International Covenant on Civil and Political Rights (ICCPR) (Meyersfield & Nyembe, 2016). On the other hand, the South African constitution and common law protect the right to privacy which is listed in Section 14 of the 1996 Constitution outlined as: Everyone has the right to privacy.

The overarching law in South Africa discourage interference with the private communication channels of the people. A detailed comprehensive protection of the right to privacy (digitally) is listed in the POPI Act which is not yet fully adopted and implemented (Van Jaarsveld & Minnaar, 2012). The POPI Act outlines that 'Personal information should only be obtained under specific, explicitly confined and lawful circumstances in relation to a function or works of the responsible party'. In the scenario involving the case of CCTV surveillance, such surveillance should not be carried out in a discriminatory system. It should be regulated, legitimate, lawful and should pass limitation test like any other justification for restriction of fundamental human rights in a democratic society. Furthermore, the deployment of CCTV surveillance cameras should be portioned equally to the legal purpose of pursuit. Along with should be a proportionality test which creates a necessary logical intersection between the extent (CCTV surveillance) and the desired outcome (crime detection, prevention and safety) (PSIRA, 2019).

7 PROFILING CCTV SURVELLIANCE IMPACT IN VARIOUS STATIONS OF REA VAYA BRT SYSTEM

Across the city of Johannesburg many serious violent crime categories have been profiled between 2020 and 2025. These violent crimes have targeted the vulnerable societal members in the city centre and spiralling out to the outskirts. These criminal activities include armed robberies, phone snatching, murder, attempted murder, serious assaults and kidnappings. While there were significant decreases in sexual offenses and common assaults; evidence records that violent crime rate for the city is recorded as 1 424 crimes per 100 000 population which is 25% higher than the national crime average. This incline is characterized by 15.5% increase in the number of aggravated robberies in 2024/25 around economic activities of the city. Table 1 depicts the highest number of violent crime incidents in Johannesburg per station identified.

Station Name	2020/2023	2023/2025	Annual change	Rate
Johannesburg Central	4665	5001	4.5%	8654
Hillbrow	4599	4577	-1%	2786
Soweto	2260	2100	-2.1%	1311
Alexandra	3001	2900	8%	1656
Roodepoort	2535	1800	9%	1604
Auckland Park	800	650	10%	1606
Parktown	401	390	15%	998
Sandton	80	65	20%	600
Midrand	100	101	½%	1789
Honeydew	2804	2888	4%	8654

Table 1.

8 REA VAYA BRT USER PERCEPTIONS OF SAFETY IN JOHANNESBURG

The Rea Vaya BRT user safety perceptions of safety or the lack thereof has incrementally shaped user travelling behaviour while contributing to further decline in ridership of Rea Vaya BRT system in Johannesburg- while also contributing further to a decrease in safety (given changes, for example in the way in which people utilize public transit system). Figure 1 below presents the safety perceptions held by Rea Vaya BRT users across the City of Johannesburg.

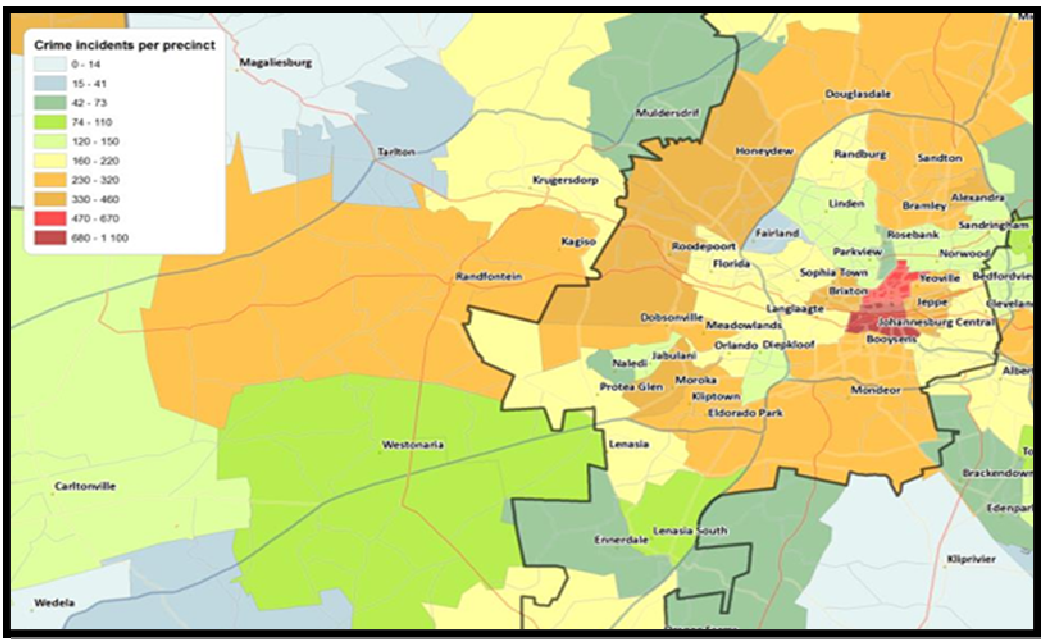

Figure 1: BRT user safety perceptions across the city of Johannesburg

9 AREAS FOR FUTURE RESEARCH

The current legislative frameworks on CCTV surveillance were formulated and adopted in a pre-digital time in which the systems and technologies to detect, monitor and record or appreciate surveillance data was not vigorous. In the current times, societies have made progress with appreciating the role of digital and information technology; not downplaying the huge investments made by those who practise crime activities in digital information and systems. In order to combat crime activities and enhance safety perceptions for the vulnerable communities in city centres it is crucial to invest and encourage extensive research on surveillance data which is intercepted from sensors such as cameras, smartphones and social media. Furthermore, to combat crime in Johannesburg, it is important to adopt legal system that put strong emphasis on public surveillance in every street and public infrastructure.

10 CONCLUSION

The systematic review emphasizes the importance of balancing the legal system imperatives with human safety methods in the city of Johannesburg. In-depth review in this paper, detected that there is a certain degree of overall constitutional framework and urban planning by-laws in Johannesburg that protects human rights while compromising the acknowledgment of public realities in the city. The findings outline that the Rea Vaya BRT user safety perceptions of safety or the lack thereof has incrementally shaped user travelling behaviour while contributing to further decline in ridership of Rea Vaya BRT system in Johannesburg- while also contributing further to a decrease in safety. In order to derive in-depth understanding of techniques which CCTV surveillance dialects to the right to privacy, there is a broader need to envision the notion of privacy and its imperatives. The right to privacy is a basic human right recognised around the world as one of the concepts of modernity which is set to have a universal common underpinning of definition. The call for the right to privacy remains a global phenomenon, but its foundation is rooted in differential interpretation depending to the prevailing community traits, culture and economic power of the time. South Africa builds its legislative mandate on reference to global legal trends; in which there have been multifaceted trials at deriving a uniform definition of what the concept ‘privacy’ constitute

1 ABSTRACT

Sustainable Development Goal 11 (SDG 11) aims to make cities inclusive, safe, resilient, and sustainable, yet implementation at the local level remains inconsistent, particularly in rapidly urbanizing contexts of the Global South. This study evaluates the progress of the City of Mbabane, Eswatini, toward achieving SDG 11 by assessing the effectiveness of existing monitoring and implementation frameworks. Employing a mixed-methods case study design, the research integrates spatial analysis, household surveys, and qualitative interviews with key stakeholders to examine housing adequacy, disaster vulnerability, institutional capacity, and participatory governance. Findings reveal that while Mbabane has integrated sustainability concepts into strategic planning documents, practical execution is hindered by limited data localization, institutional fragmentation, and insufficient community engagement. Informal settlements in flood-prone areas highlight the city's vulnerability and the need for risk-informed spatial planning. Moreover, the absence of a city-level SDG tracking mechanism and misalignment between global indicators and local realities challenge effective monitoring. Drawing lessons from peer African cities, the study proposes a suite of contextually appropriate reforms, including GIS-based monitoring tools, participatory planning mechanisms, and dedicated urban SDG units. These recommendations aim to strengthen institutional resilience and foster inclusive urban development in Mbabane and similar contexts. The research contributes to the discourse on localized SDG implementation by bridging theoretical frameworks with grounded, actionable insights for urban sustainability.

Keywords: Sustainable Development Goal 11 (SDG 11), Urban Resilience, Monitoring and Evaluation Frameworks, Informal Settlements, Sustainability

2 INTRODUCTION

2.1 Background Information on Why the Area of Interest

The journey toward sustainable development can be traced back to the Millennium Development Goals (MDGs), which comprised eight development objectives aimed at reducing income poverty, improving access to clean water and sanitation, reducing child mortality, and enhancing maternal health. The MDGs also played a critical role in promoting universal primary education and significantly advanced the global response to HIV/AIDS, malaria, and tuberculosis (UNDP, 2022). However, evaluations of MDG implementation revealed that approximately 46% of developing countries were off-track in meeting their targets, according to official UN and World Bank assessments (Samman, 2015). This shortfall catalyzed the adoption of a more comprehensive framework: the Sustainable Development Goals (SDGs), launched to ensure that no country is left behind.

In September 2015, the world leaders pledged support for sustainable action around a universally agreed policy agenda (Agenda 2030). This agenda comprises 17 Sustainable Development Goals (SDGs) with 169 specific targets that set out quantitative objectives associated with the social, economic, and environmental dimensions of sustainability to be achieved by 2030, and among these SDGs is SDG11, which focuses on sustainable cities (Osman et al., 2021).

Cities account for most of the global resource consumption and act as critical social, economic, and political hubs. With more than half the global population residing in urban areas, cities are essential actors in the pursuit of sustainability. This is explicitly recognized in SDG 11, which aims to make cities inclusive, safe, resilient, and sustainable (Adamec, Holzinger, & Franz, 2017). SDG 11 states that cities should ensure access to safe and affordable housing, access to public transportation, and public green spaces. It states that cities should be resilient to natural disasters and protect those in vulnerable situations while also minimizing economic loss (National Geographic Society, 2020).

The SDGs offer a structured framework that enables governments to develop and monitor policies aimed at achieving sustainability by 2030. Each goal includes measurable targets – monitored through 232 global indicators – coordinated by the Inter-Agency and Expert Group on SDG Indicators (IAEG-SDGs) (Fritz, 2019). African cities are forecast to be home to an extra 950 million people by 2050; thus, when considering the projected increase in urban population in Africa, cities must be sustainable and a safe place to stay (Marchant, 2021). Eswatini has two officially recognized cities, with Mbabane serving as the capital and administrative center. It has a night-time population of approximately 62,630 (Population Hub, 2020) and a daytime population reaching 76,218 (World Population Review, 2022). The city hosts key government institutions, foreign missions, and a wide range of commercial activities, making it central to national development (Integrated Development Plan, 2019).

Despite its strategic importance, Mbabane faces several urban challenges. Recurrent flooding, limited access to affordable housing, and the expansion of informal settlements have strained urban infrastructure and service delivery. These issues are particularly relevant to SDG 11 targets, such as 11.1 (adequate housing) and 11.5 (disaster risk reduction). As the capital city of Eswatini, Mbabane needs to be one of the leading sustainable environments in the country. Its state of progress also needs to be known to ensure public resources are aligned with effective strategies that genuinely advance SDG 11 targets, rather than wasted on misaligned or reactive interventions. This study aims to track the progress made by the Mbabane City Council towards achieving SDG11 of the United Nations.

3 PROBLEM STATEMENT TO BE EXPLORED

Globally, cities have acknowledged the importance of SDG 11 and are implementing policies to promote urban sustainability. Yet, urban areas continue to grapple with challenges such as extreme poverty, inequality, and environmental degradation. Although cities generate about 80% of global GDP, they are also major contributors to climate change and unsustainable resource use (Osman et al., 2021). Mbabane, like many urban centers in sub-Saharan Africa, is experiencing rapid population growth, primarily due to rural-urban migration. This trend, if left unmanaged, can accelerate environmental degradation and strain essential services such as water supply, energy, housing, and waste management (Vaidya & Chatterji, 2020). Such problems put the urban population at risk and raise a question about whether the city has plans in place to curb these problems and make the city a safe place.

Eswatini is one of the countries under the United Nations that has signed an agreement to the Agenda 2030 Sustainable Goals (Ndongo-Seh, 2020). Thus, as a country, we have a responsibility to consistently check if we are still falling in line with the targets set under the goals, particularly in making cities sustainable (SDG 11). If Mbabane continues unsustainable development pathways, the consequences could be severe, ranging from increased vulnerability to disasters to inefficient use of public resources. Yet, there is a lack of documented information evaluating whether the city is effectively progressing toward SDG 11, which presents a critical knowledge gap. Lack of such crucial information will make the city pursue unsustainable development paths, which will not only put the urban population at risk but also result in a waste of resources due to the reconstruction of damaged urban structures, which are less resilient to threatening urban disasters such as flooding, in the context of Mbabane city.

This study seeks to bridge the existing information gap by assessing Mbabane's progress toward achieving SDG 11. A better understanding of the city's trajectory will not only inform policy and planning but also serve as a model for other urban centers in Eswatini and across the Global South.

4 AIMS AND OBJECTIVES

Aim

This study aims to evaluate the progress made by the City of Mbabane toward achieving Sustainable Development Goal 11, with a focus on assessing the effectiveness of existing monitoring and implementation frameworks.

Objectives

- To assess the current progress made by Mbabane in achieving SDG 11.

- To identify and evaluate the existing frameworks used in Eswatini for SDG monitoring and evaluation.
- To analyze key challenges hindering effective SDG 11 implementation in Mbabane.
- To propose practical frameworks or tools – drawn from successful African city experiences – that could enhance Mbabane's progress toward SDG 11.

5 RESEARCH QUESTIONS

(1) What measurable progress has been made toward achieving SDG 11 in Mbabane?

(2) What are the existing frameworks in Eswatini for conducting SDG evaluation?

(3) What are the existing problems that hinder the progress of Mbabane to get to the desired outcome for SDG11?

(4) What monitoring and implementation frameworks from other African cities could be adapted to strengthen SDG 11 performance in Mbabane?

6 JUSTIFICATION

This research is justified on multiple grounds. Firstly, it seeks to document Eswatini's progress in implementing SDG 11, providing a reference point for comparative studies across the region. Secondly, it aims to address the knowledge gap on how Global South cities, such as Mbabane, are responding to the challenges of sustainable urban development. Lastly, the study will offer insights for policymakers and urban planners, supporting data-driven decision-making to improve urban quality of life in line with SDG.

7 LITERATURE REVIEW

7.1 Global Discourse on SDG 11 and Urban Sustainability

Sustainable Development Goal 11 (SDG 11) aims to "make cities and human settlements inclusive, safe, resilient, and sustainable," acknowledging the crucial role of urban centers in addressing global sustainability challenges (UN-Habitat, 2022). The importance of SDG 11 lies in the fact that cities, despite occupying only 3% of the Earth's surface, contribute to over 70% of global carbon emissions and consume 60–80% of energy (Aquilino et al., 2020). Urbanization is accelerating, particularly in the Global South, where weak institutional structures and informality exacerbate inequality and vulnerability (Ulbrich, 2021).

Although the SDGs offer a comprehensive framework, there are implementation challenges, particularly regarding SDG 11. Research by Thomas, Hsu, and Weinfurter (2020) found that the overabundance of urban sustainability indicators – 484 identified from 40 indexes – lacks consistency, equity focus, and measurable benchmarks, especially in low-income contexts. This poses a serious barrier to tracking real progress.

Monitoring and Implementation Frameworks for SDG 11

Monitoring SDG 11 requires integrating global frameworks with localized urban planning and data systems. However, current frameworks often rely on aggregate, top-down indicators that obscure intra-urban disparities. As Ulbrich (2021) notes in his PhD thesis on Medellín, the disconnect between centralized monitoring and local realities leads to poor representation of marginalized communities in official reports.

Aquilino et al. (2021, 2023) developed and tested improved dasymetric mapping methods to disaggregate population and infrastructure data at the intra-urban level. This approach allows local governments to monitor indicators such as SDG 11.1.1 (access to adequate housing) or SDG 11.3.1 (land-use efficiency) at the neighborhood scale. Similar methodologies are particularly valuable in cities like Mbabane, where spatial data is limited and informal settlements are prevalent.

Koch and Krellenberg (2018), focusing on Germany, emphasize the importance of contextualizing global indicators to national and sub-national planning systems. Their work shows that even in well-resourced contexts, SDG 11 must be translated to the specific urban governance structures, a lesson highly applicable to developing cities.

7.2 African and Global South Experiences: Successes and Gaps

Several African cities are experimenting with various mechanisms to implement SDG 11, yet the outcomes are mixed. For example, in Durban, Ebhuoma et al. (2024) documented how early-warning systems for floods failed due to the municipality's poor communication with vulnerable populations, highlighting the disconnect between technology and local needs.

In contrast, the peer-reviewed study by Letebele et al. (2024) across 14 SADC cities emphasizes the value of risk-informed development (RID) frameworks. This approach integrates hazard data into urban planning, yielding resilient infrastructure investment and governance practices. Given Mbabane's vulnerability to flooding and informal settlement growth, adopting RID principles could enhance its alignment with SDG 11.5, particularly by integrating resilience into infrastructure and spatial planning.

A key lesson from Adamec et al. (2020), who evaluated civil society-driven projects in Hamburg, Vienna, and Prague, is the transformative potential of grassroots initiatives. Their findings underscore that SDG 11 implementation thrives when citizen participation, flexible governance, and cross-sectoral collaboration are encouraged.

Moreover, Metaxas and Metaxas (2022) note the transition from MDGs to SDGs represented a shift from quantitative service access metrics to qualitative outcomes such as inclusion, resilience, and safety. However, most African cities, including Mbabane, are still operating with legacy planning instruments from the MDG era, impeding localized implementation of SDG 11 targets.

8 THEORETICAL AND ANALYTICAL FRAMEWORK

This study draws on two interlinked theoretical frameworks:

a) Participatory Urban Governance

Participatory governance is essential to inclusive urban sustainability. As noted by Muhamad Khair et al. (2020), community-based monitoring can empower residents to influence planning processes, contributing to SDG 11's inclusive targets (e.g., 11.3 and 11.7). When urban planning processes include marginalized voices, policies are more aligned with community realities and needs.

b) Risk-Informed and Adaptive Planning

The Risk-Informed Development framework (Letebele et al., 2024) integrates hazard, socio-economic, and environmental data into city-level planning. This theory emphasizes adaptive capacity, aligning closely with SDG 11.5 on disaster resilience. For Mbabane, this means embedding flood risk data and informal settlement vulnerability assessments into its Integrated Development Plan.

8.1 Key Lessons for Mbabane's Context

- Data Localization is Critical: Mbabane must adopt localized, high-resolution monitoring tools similar to the dasymetric mapping used in Bari and Hainan (Aquilino et al., 2020; Zhang et al., 2021).
- Institutional Reform is Necessary: As Nabiyeva et al. (2023) argue, without public-sector leadership and institutional clarity, SDG 11 becomes symbolic rather than transformative.
- Learning from Peers Works: Mbabane can adapt practical tools from cities like Guilin, Durban, or Vienna, especially those enhancing participatory planning, spatial data integration, and climate risk mapping.

8.2 Research Methodology

This study adopts a case study phenomenological research design, suitable for capturing the lived urban development realities in Mbabane and interpreting them in the context of SDG 11 progress. The choice of this design stems from the need to engage with both policy-level data and community-level experiences, acknowledging that sustainable urban development is inherently multi-scalar and experiential (Yin, 2018).

The research follows a mixed-methods approach, integrating quantitative, qualitative, and spatial analysis techniques. This triangulation allows for a holistic exploration of the subject by complementing statistical

evaluations of SDG indicators with qualitative insights from stakeholders and geospatial assessments of urban resilience.

8.3 Research Design

The case study phenomenological design focuses on Mbabane as a single, bounded unit of analysis. The rationale is to explore how existing monitoring and implementation frameworks for SDG 11 operate in practice, and to capture contextual intricacies such as informal settlement patterns, flooding vulnerabilities, and urban planning mechanisms. According to Creswell (2014), a phenomenological design is particularly useful when the aim is to describe and interpret experiences around a phenomenon – in this case, sustainable urban development in Mbabane.

8.4 Research Approach

This study utilizes a mixed-methods approach, which integrates quantitative and qualitative data to enable robust cross-validation. Quantitative data includes statistical reports on SDG 11 indicators (e.g., housing adequacy, land-use efficiency, disaster impact records), while qualitative data emerges from semi-structured interviews, focus groups, and participatory mapping exercises with community members, municipal planners, and local NGOs.

Spatial data will be analyzed using geospatial tools, specifically GIS-based risk mapping and dasymetric population modeling, inspired by methods applied in Hainan and Bari (Aquilino et al., 2023). This helps visualize spatial inequities and track urban vulnerabilities such as informal settlement expansion and disaster exposure.

8.5 Sampling Design

The study employs both probability and non-probability sampling techniques to ensure representativeness and depth. A stratified random sampling approach will be used to select residents from various urban zones (formal, peri-urban, and informal), ensuring spatial diversity. Meanwhile, purposive sampling will be applied to key informants such as municipal officials, planners, and NGO representatives who are directly involved in urban governance and SDG monitoring.

A sample size of approximately 100 residents will be targeted for household surveys, supplemented by 15–20 key informant interviews to gain policy insights. The household sample will reflect demographic and socio-economic diversity, ensuring the inclusion of vulnerable groups such as informal settlers, women-headed households, and youth.

8.6 Data Collection Methods

The study will collect primary and secondary data. Primary data includes:

- Household surveys to gauge citizens' access to basic services and perceptions of urban safety and inclusivity.
- Key informant interviews to explore institutional frameworks, capacity gaps, and monitoring practices.
- Focus group discussions (FGDs) to foster participatory dialogue and community reflections on SDG 11 targets.
- Participatory GIS mapping to localize urban vulnerabilities.

Secondary data sources include:

- Municipal development plans (e.g., Integrated Development Plan, 2019)
- UN SDG indicator reports and Eswatini's Voluntary National Review (VNR)
- Urban demographic datasets and Eswatini Bureau of Statistics reports

8.7 Data Analysis Techniques

Quantitative data will be analyzed using SPSS or Stata for descriptive and inferential statistics (e.g., correlation between settlement type and housing adequacy). Qualitative data will undergo thematic analysis using NVivo software to identify recurring policy themes, governance gaps, and stakeholder concerns.

Spatial data will be processed using ArcGIS Pro. Techniques such as overlay analysis, risk zoning, and dasymetric redistribution will visualize informal settlements, flood-prone zones, and service accessibility. These results will directly inform SDG 11.1 and 11.5 progress assessments.

8.8 Research Reliability and Validity

To enhance validity, data triangulation will be used by cross-verifying findings across surveys, interviews, and spatial data. The design ensures internal validity through consistent question framing and piloted instruments, while external validity is supported by comparing Mbabane with similar cities using regional case studies (Letebele et al., 2024).

Reliability will be upheld through standardized data collection tools, detailed documentation of procedures, and researcher reflexivity to minimize interpretation bias. Peer debriefing and member checks will also be employed in the qualitative phases.

8.9 Ethical Considerations

Ethical clearance will be obtained from the University's Research Ethics Committee. All participants will provide informed consent, and their anonymity will be maintained throughout the research process. Data will be securely stored and used exclusively for academic purposes.

Efforts will be made to ensure inclusivity and non-exploitation, particularly in engagements with marginalized communities. The research adheres to the principles of do not harm, respecting both cultural sensitivities and participant autonomy.

9 FINDINGS AND RESULTS

This section presents the findings of the study based on the mixed-methods approach, triangulating quantitative household surveys, qualitative interviews and focus group discussions, and geospatial analysis. The data reveal both structural and operational strengths and gaps in Mbabane's pursuit of Sustainable Development Goal 11 (SDG 11), with a particular emphasis on inclusivity, resilience, and sustainability.

9.1 Progress Towards SDG 11 Targets in Mbabane

Household survey data and city documents (e.g., IDP 2019) show that Mbabane has begun integrating SDG 11 themes – such as housing and environmental management – into its plans. However, these commitments have not consistently translated into on-the-ground action, and many objectives remain aspirational due to implementation gaps.

Regarding Target 11.1 (access to adequate, safe, and affordable housing), 68% of survey respondents reported living in informal or semi-formal dwellings, citing high land prices and inadequate mortgage systems as major barriers to formal housing. A significant number of residents (42%) live in flood-prone areas, indicating a direct linkage between housing inadequacy and exposure to environmental risk, an area where Target 11.5 (disaster risk reduction) becomes highly relevant.

Figure 1 illustrates disparities in access to basic services between formal and informal settlements. While over 90% of residents in formal areas report access to potable water, only 54% of those in informal settlements do. Similar gaps are observed in sanitation, transport, and waste services, emphasizing the spatial inequality in urban infrastructure provision. These gaps underscore the city's underperformance on SDG 11.2 (transport) and 11.6 (waste management and environmental quality), particularly in informal zones.

Spatial analysis corroborated these findings. Using GIS-based risk mapping, informal settlements were found to be disproportionately located in low-lying zones along the Mbabane River, which are especially vulnerable to seasonal flooding. These results confirm observations from the Municipal Environmental Management Strategy (2020), which identified growing informal settlements as a critical urban pressure point.

9.2 Institutional and Policy Frameworks for SDG Monitoring

Key informant interviews with city officials, planners, and national policy actors revealed that Eswatini lacks a fully operational, city-level SDG monitoring system. While the National Development Strategy and Vision

2022 broadly align with the SDGs, including SDG 11, there is no dedicated institutional mechanism within the Mbabane City Council (MCC) for disaggregated indicator tracking.

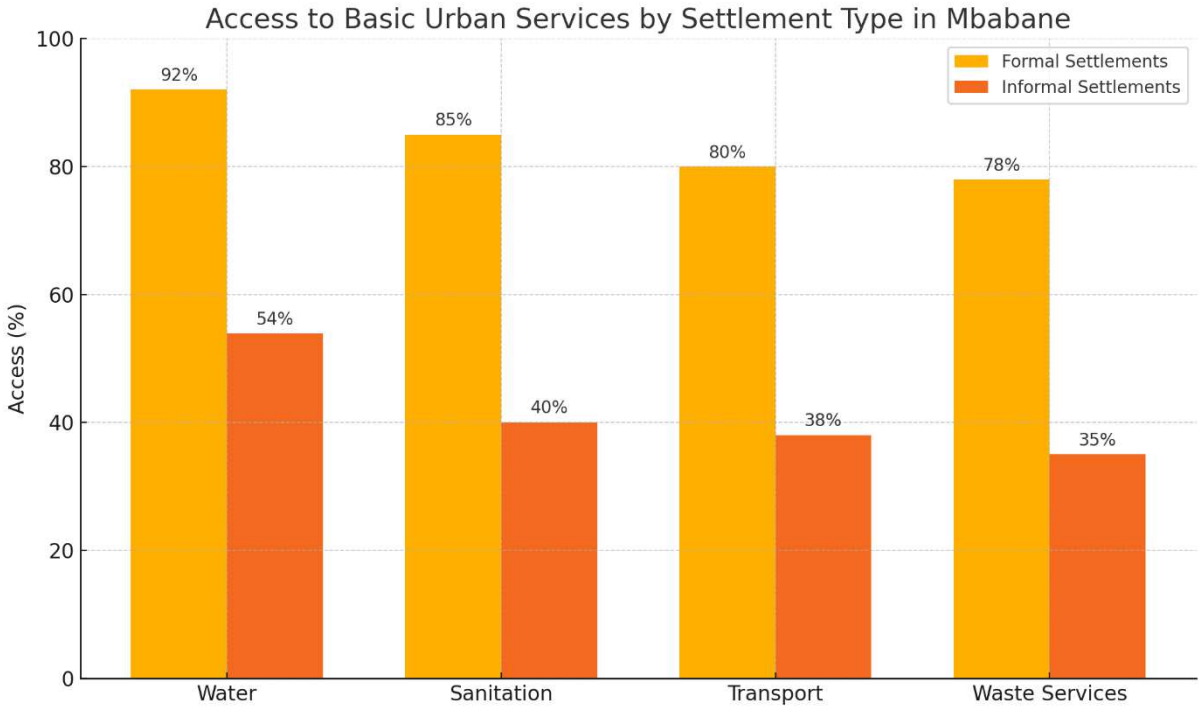

Figure 1: Access to Basic Urban Services by Settlement Type in Mbabane

Respondents from the Ministry of Housing and Urban Development acknowledged that although Eswatini participated in the Voluntary National Reviews (VNRs) of 2019 and 2022, city-level data were minimal or generalized. The absence of subnational dashboards or spatially localized indicators limits the ability of municipalities to operationalize the SDGs effectively. One senior planner noted that “most of the monitoring is reactive; it’s triggered by donor or national government reporting timelines rather than proactive urban policy design.”

Furthermore, there is a misalignment between global indicators and local data systems. For example, SDG Indicator 11.1.1, which requires measurement of the proportion of urban population living in slums or inadequate housing, is not systematically tracked by Mbabane authorities due to data limitations and definitional inconsistencies.

9.3 Stakeholder Perceptions and Challenges in Urban Sustainability

Thematic analysis of focus group discussions with residents from Mangwaneni, Msunduza, and Sidwashini settlements highlighted widespread frustration with service delivery and limited participation in planning processes. Focus group participants expressed frustration over being excluded from municipal planning and budgeting processes, underscoring a disconnect between policy rhetoric and participatory practice (Khair et al., 2020).

Moreover, 73% of respondents indicated that municipal consultations, when they occur, are often symbolic rather than substantive. This resonates with participatory governance literature, which warns of "consultation fatigue" where community input is rarely translated into policy decisions (Adamec et al., 2020).

On the institutional side, MCC officials pointed to chronic budget constraints and a lack of technical capacity to implement integrated planning tools. Planners highlighted that while risk assessments exist, they are not embedded into zoning laws or housing permits. Consequently, informal expansion continues unchecked in environmentally sensitive zones.

9.3.1 Comparative Lessons from Other African Cities

The findings also draw on comparisons with other African cities that have implemented innovative SDG monitoring frameworks. For example, Letebele et al. (2024) describe how Lilongwe and Gaborone have begun integrating climate risk data into land-use planning using the Risk-Informed Development (RID)

framework. These cities have adopted cross-sectoral data hubs that combine demographic, hazard, and infrastructure datasets into dynamic planning dashboards. Mbabane lacks such systems, but officials expressed interest in piloting similar models, particularly to manage risks associated with flooding and informal settlements.

Notably, in contrast to Mbabane's reactive policy environment, cities like Kigali and Cape Town have formalized annual urban sustainability reports aligned to SDG 11 targets. These reports are supported by dedicated monitoring units and participatory review boards. The absence of such structures in Mbabane reflects broader systemic weaknesses in urban governance and underscores the need for institutional reforms.

9.3.2 Spatial Inequities and Vulnerability Mapping

GIS-based analysis revealed sharp intra-urban inequalities in access to services and environmental risk exposure. Informal settlements in Mbabane's peripheral areas demonstrated significantly lower proximity to key services such as potable water, public transport, and emergency services. This pattern aligns with SDG Target 11.2 (access to safe, affordable, and sustainable transport systems), which remains underperforming.

Risk zoning maps indicate that more than 35% of the city's informal settlement areas fall within moderate-to-high flood risk zones, especially along the Mzimnene and Mbabane river corridors. These findings emphasize the urgent need for risk-informed spatial planning tools. If left unaddressed, these vulnerabilities could become exacerbated under climate change scenarios.

9.4 Integration of Local Knowledge and Policy Gaps

One of the most striking findings is the disconnection between local knowledge and official planning instruments. Community-based knowledge on flood-prone areas, infrastructure gaps, and coping strategies is rarely documented or used in formal processes. This disconnect undermines the inclusive ethos of SDG 11, particularly Targets 11.3 and 11.7, which advocate for participatory planning and universal access to public spaces.

When asked to evaluate municipal responsiveness, community respondents rated it an average of 4.1 out of 10. In contrast, municipal officials rated their own responsiveness at 7.5 out of 10. This perceptual gap further illustrates the urgent need for strengthened communication, trust-building, and shared accountability mechanisms.

10 MAIN CONTRIBUTIONS, IMPLICATIONS, AND LESSONS LEARNT

This section synthesizes the key contributions of the study to academic knowledge, policy discourse, and practical urban governance in the context of Sustainable Development Goal 11 (SDG 11). It also articulates the broader implications of the findings and distills actionable lessons that can guide future efforts in sustainable urban development, particularly in rapidly urbanizing cities of the Global South such as Mbabane.

10.1 Academic and Theoretical Contributions

The study advances the scholarly understanding of localized SDG implementation by demonstrating how global sustainability frameworks interact with on-the-ground urban realities in a small but strategically important African capital. Through the application of participatory governance theory (Khair et al., 2020) and the Risk-Informed Development (RID) framework (Letebele et al., 2024), the research bridges a theoretical gap between abstract global sustainability targets and their lived urban manifestations.

Furthermore, the study contributes to the growing body of literature that critiques the top-down nature of global urban sustainability monitoring systems. It affirms the argument by Ulbrich (2021) that disaggregated, high-resolution, and community-informed data are essential to avoid masking inequalities and to ensure truly inclusive urban development. The spatial and qualitative findings from Mbabane validate these theoretical positions and reinforce the importance of locally grounded methodologies in urban SDG research.

10.2 Policy and Institutional Contributions

At the policy level, the research reveals significant gaps in institutional capacity, data systems, and participatory mechanisms that undermine effective SDG 11 implementation in Mbabane. The city's reliance

on generalized, national-level reports for SDG tracking limits its ability to respond to context-specific challenges, such as the expansion of informal settlements in flood-prone areas.

This study highlights the urgent need for subnational SDG monitoring systems that align with urban planning tools like the Integrated Development Plan (IDP) and municipal zoning schemes. Drawing lessons from cities such as Kigali and Gaborone, the study advocates for the establishment of dedicated municipal SDG units and annual sustainability reporting practices at the city level.

Moreover, the research emphasizes the need for institutional reforms to support integrated data collection, storage, and use across government departments. It supports Nabiyeva et al.'s (2023) assertion that without clarity in institutional roles and investment in human and technical capacity, SDG 11 risks remaining aspirational rather than actionable.

10.3 Practical Lessons for Mbabane and Similar Cities

The case of Mbabane yields several practical lessons that have broader applicability for urban planning in other medium-sized African cities:

10.3.1 Data Localization and Integration are Non-Negotiable

The absence of localized, spatially disaggregated data in Mbabane severely hampers evidence-based decision-making. The study shows that leveraging tools such as GIS-based risk mapping and dasymetric analysis is not merely technical – it is foundational to planning for resilience, housing adequacy, and land-use efficiency. Without localized indicators, vulnerable populations remain invisible in planning processes.

10.3.2 Participatory Planning Must Move Beyond Tokenism

Community voices in Mbabane are currently underrepresented in formal urban governance structures. The study illustrates that participatory mechanisms, when they exist, are often symbolic rather than transformative. Implementing structured participatory tools – such as community scorecards, participatory budgeting, and neighborhood SDG audits – can significantly improve legitimacy, responsiveness, and equity in planning outcomes.

10.3.3 Resilience Must Be Embedded, Not Appended

As cities become more vulnerable to climate-related and socio-economic shocks, resilience cannot be treated as an add-on to existing plans. The study shows that in Mbabane, flood risk is spatially concentrated in informal settlements, yet current planning tools do not integrate vulnerability assessments. Incorporating RID principles into zoning codes, housing programs, and infrastructure design can institutionalize resilience at every level of urban policy.

10.3.4 Learning from Regional Peers is a Viable Strategy

Mbabane does not need to reinvent urban sustainability frameworks from scratch. Cities such as Durban, Lilongwe, and Nairobi offer tested models in early-warning systems, community mapping, and integrated transport planning. Knowledge-sharing networks and South-South cooperation – especially within SADC – can facilitate the transfer of innovations that are contextually appropriate and scalable.

10.3.5 Institutional Continuity and Political Will are Critical

One of the persistent challenges identified in interviews was the discontinuity of urban sustainability initiatives due to staff turnover, budget reallocations, and shifting political priorities. Establishing legally mandated SDG tracking units within city structures and embedding sustainability into statutory planning instruments can safeguard against these discontinuities.

10.4 Implications for Future Research and Planning

The findings suggest that sustainable urban development cannot be delinked from questions of governance, equity, and institutional design. Future research should prioritize longitudinal studies to track changes over time and explore the intersection between SDG 11 and other goals, such as SDG 6 (water and sanitation), SDG 13 (climate action), and SDG 16 (peace, justice, and strong institutions).

Additionally, there is scope for piloting community-driven monitoring frameworks using mobile technologies, crowdsourced spatial data, and participatory GIS platforms. Such innovations can empower residents, enhance accountability, and provide real-time feedback loops to city planners and policymakers.

11 CONCLUSIONS AND RECOMMENDATIONS

This study assessed Mbabane's progress toward Sustainable Development Goal 11, focusing on how the city monitors and implements sustainability initiatives. While the city has made some policy strides, actual progress remains limited. Informal settlements continue to grow in high-risk areas, and planning decisions are not supported by localized or disaggregated data. Without clear indicators and spatial tools, the city struggles to track or respond to urban challenges effectively.

Institutional weaknesses further limit implementation. Departments often work in isolation, with poor coordination and limited technical capacity. Planning documents mention sustainability, but these are not backed by strong systems or consistent action. Community participation is minimal, and when it occurs, it often lacks real influence. This undermines the goal of inclusive urban development.

Despite these gaps, there is room for improvement. Mbabane can adapt practical tools used in other African cities, including GIS-based risk mapping, participatory planning, and localized monitoring systems. The city should establish a framework to track SDG 11 indicators at the local level, invest in staff training, and ensure risk data informs planning.

Reforms should also include formal mechanisms for community engagement and learning exchanges with peer cities. With better coordination, stronger data systems, and inclusive governance, Mbabane can take meaningful steps toward becoming a more sustainable, resilient city.

1 ABSTRACT

The efficacy of transportation systems generally relies on the pillars of intelligent transportation systems (ITS) and strategically located transit-oriented development (TOD). Moreover, this study examines the impact of ITS on the operations of Johannesburg Park Station within the framework of its TOD. The paper explores how it optimizes passenger flow within the station by leveraging various transportation modes, improved multimodal transfers, and enhanced TOD. The study uses a case study research design to investigate traffic management and passenger flow. Additionally, the study adopts both quantitative and qualitative research methods to gather relevant data. Interviews and questionnaires were used as tools to collect data. The preliminary findings reveal that it significantly contributes to Johannesburg Park Station by improving efficiency, accessibility, and the transportation network within the Gauteng region. The study concludes that it is data-driven and serves as a key tool for a thriving transportation ecosystem.

Keywords: Multimodal Transportation, Intelligent Transportation Systems, Johannesburg Park Station, Transit-Oriented Development, Spatial planning

2 INTRODUCTION

Contemporary cities, particularly in developing countries, face concerns regarding the efficacy and accessibility of public transport systems. The efficacy of transport systems generally rests on the pillars of intelligent transportation systems (ITS) and strategically positioned transit-oriented development (TOD). As such, there has been growing research on ensuring the sustainability of public transport systems (Balasubramaniam et al., 2017; Khazraeian and Hadi, 2019; Tran et al., 2023). This global shift has prompted various countries to adopt context-specific approaches to improving their transport systems. In China, for example, efforts have focused specifically on improving transportation infrastructure and advancing IT (Bešinović, 2020). These improvements have been driven by increased investment in the traffic management system, resulting in more efficient, convenient, safe, and intelligent public transport. The ultimate goal is to upgrade the current conventional cities into more intelligent, ecologically friendly, and economical cities.

On the other hand, Jimenez (2018) noted that many developing countries are falling behind in installing new transportation infrastructure in their cities, a concern that Gumbo et al. (2022) concurs with. To keep up with global advances in ITS technology, developing countries need to develop well-established transport policies to facilitate the rollout of innovative public transport systems (Gumbo et al., 2022). This would enhance the management and operation in a cost-effective manner. Similarly, Oeschger et al. (2020) argued that integrating new public transport modes could enhance accessibility and lead to modal shifts away from private vehicle use. To assess this potential for TOD, it is important to study these new modes in the context of access and egress trips to and from public transport, as several time-varying components affect optimal operation.

Haggag (2022),Hörcher & Tirachini (2021),& Ceder (2021) contend that previous studieshave investigated interdependent infrastructures as dynamic systems and connectivity for sustainability. Hörcher & Tirachini (2021) observe that empirical studies on ITS's role in enhancing public transport hub operations, specifically in TOD settings within the context of developing urban spaces, remain limited.To address this gap, the study proposes a hybrid ITS-TOD framework for up-and-coming urban hubs, where ITS data-driven tools (e.g., optimised AI scheduling) improve TOD diversity and density, at the same time accounting for local challenges such as spatial inequality. This framework complements Bešinović (2020)'s findings by incorporating resilience metrics for multimodal disruption in Gauteng.

3 RELATED WORK

Public transport system authorities require strategies to inform investments aimed at improving operations and services, both to retain current commuters and attract more users. Globally, there has been an increase in studies on TOD strategies and principles. The '6Ds' have been used to integrate urban development and transport by promoting higher density, encouraging land-use diversity, enhancing urban design, improving access to key destinations, reducing travel distances, and implementing demand management strategies. These seek to inform land types and densities along a transport corridor. Sung and Oh (2011) found that transit ridership is positively affected by the business and residential density and land-use mix index. Later, Ewing et al. (2021) evaluated the benefits of TOD and joint development throughout the United States. The study noted that a higher transit proximity premium of housing prices is most likely to occur in places with more mixed land use. While Ali et al. (2021) assessed the air quality across regions with urban areas. The study noted that transit-oriented development is linked with better air quality.

Modern communities face serious challenges in transportation systems, including accessibility, safety, and pollution. ITS has gained increasing attention and importance in TOD strategies and principles. By seamlessly integrating vehicles and sensing devices, cities can build smart, intelligent transportation systems. A study by Qureshi and Abdullah (2013) found that ITS is not limited to traffic research; it also provides hardware, positioning systems, sensor technologies, and services, and is implemented in navigation systems, air transport telecommunications, data processing, virtual operations, and systems. Due to such complexity, many developing countries are yet to fully realise the merits of ITS. Moreover, the implementation of ITS in these contexts is frequently constrained to pilot projects, hindering its ability to transform public transport systems at scale. In developed countries, local authorities are installing roadside infrastructure, such as cameras and sensors, to collect data on ecological and traffic conditions. These advances in ITS and Information and Communication Technologies (ICT) have led to sustainable transportation systems in these contexts (Guerrero-Ibáñez et al., 2018).

4 METHODOLOGY

This study adopted a mixed-methods approach, combining both qualitative and quantitative data collection techniques to yield a comprehensive understanding of the impact of Intelligent Transportation Systems (ITS) on Johannesburg Park Station and transit-oriented development (TOD). The study also included semi-structured interviews with four officials from CoJ's Department of Transportation, including two from the Johannesburg Road Agency, and 20 daily commuters. Both officials and commuters were selected purposively to ensure relevant and diverse perspectives. The quantitative data complemented the qualitative data from the interviews through structured interviews, which gathered comprehensive insights into the effectiveness and use of the ITS and TOD at Johannesburg Park Station. This methodology expedited a yield analysis of how ITS contributes to multimodal transfers and efficient passenger flow, supporting the overall efficacy of the transportation network and the TOD in Johannesburg.

5 RESULTS

5.1 ITS Impact on Passenger Flow and Multimodal Transfers in Johannesburg Park Station

The implementation of the ITS at Johannesburg Park Station has remarkably enhanced passenger flow within the public transit hub in the TOD vicinity of the station. The questionnaire data from 20 daily commuters indicated an average of 35% reduction in observed congestion during peak hours. 65% of participants reported that waiting times for multimodal transfers were under 5 minutes, compared to pre-ITS levels of 10-15 minutes (City of Johannesburg, 2023). 40% of daily commuters indicated that the nucleation of taxi ranks is the root cause of localised bottlenecks.

The public transit hub in Johannesburg Park Station includes Metrorail, the Wanderers long-distance taxi rank, the Bridge local Taxi rank, the Gautrain rail station, Gaubus, the MTN taxi rank, the public bus station (local, long-distance, and international), Rea Vaya, and E-hailing services (Uber and Bolt). Data collected from daily commuters indicate that rail transit hubs have reduced congestion during peak hours through real-time information displays and ticketing systems. Furthermore, the collected data indicate congestion during peak hours due to clustering of taxi ranks, as Johannesburg Park Station is the main TOD in the City of Johannesburg. The rail systems at Johannesburg Park Station form part of the ITS; these features streamline

passenger movement by providing timely updates on train (Gautrain and Metrorail) and bus schedules. This system allows commuters to make well-informed decisions, facilitating smooth passenger flow in the TOD vicinity of Johannesburg Park station.

Electronic ticketing has also improved the commuter experience, with users reporting faster, more predictable transit arrival and departure times, with mean reported boarding times decreasing from 4.2. minutes to 2.8 minutes. The seamless, comprehensive integration of various transport modes, enabled by the ITS, has also improved the efficiency of multimodal transfers, particularly at Johannesburg Park Station. The Johannesburg Park Station serves as a pivotal junction for multiple transportation services. The ITS solutions, such as coordinated transfer points and scheduling, have been instrumental in foreshortening transfer time between these modes. For clarity, Real-time coordination between Gautrain, Metrorail, MTN taxi rank, Bridge taxi rank, Rea Vaya, Metrobus, Gaubus, and e-hailing services ensures minimal wait time for passengers transferring between modes. Subsequently, the Johannesburg Park Station is a complex area; however, real-time directional signage helped commuters navigate the station with ease, reducing confusion and improving the overall effectiveness of multimodal transfers.

Additionally, interviews with CoJ and Johannesburg Road Agency officials, as well as daily commuters, have underscored the significant role of ITS in promoting a more user-friendly, accessible transit environment. The officials have adequately highlighted the strategic merits of ITS in-traffic management, noting that data-driven insights enable the optimization of service schedules and the allocation of services to meet passenger needs. Commuters, on the other hand, have indicated appreciation for the ITS, noting that the transition between various transport modes is now smoother and that they experience fewer significant delays. This synergy between TOD and ITS principles has not only enhanced the operational efficacy of Johannesburg Park Station but also contributed to a more integrated and sustainable urban transportation network in the CoJ.

5.1.1 Transport modes at Johannesburg Park Station ITS

The Johannesburg Park Station serves as an essential hub for various transport modes, all seamlessly integrated through ITS. This station is not only the biggest in Gauteng but also accommodates a variety of transport services including Metrorail for regional train travel, Gautrain for high-speed connections to key economic zones, Bus Rapid Transit (Rea Vaya) for swift urban commuters, taxis (The Bridge and MTN taxi rank) to connect to local townships and e-hailing services such as Uber and Bolt for flexible and shared rides. The ITS therefore simplifies efficient multimodal transfers by synchronizing schedules, providing transportation information and updates, and ensuring easy navigation via digital signage. This interconnection not only enhances the overall commuting experience but also fosters the use of public transportation by making it more accessible, user-friendly, and reliable. The following figures show images of various transportation modes at the Johannesburg Park station ITS.

Fig. 1: MTN Taxi Rank [Source: The Author (2025)]: The images show the MTN taxi rank during the day at peak hours.

Fig. 2: The Bridge Taxi Rank [Source: The Author (2025)]

Fig. 3: Wanderers Taxi Rank [Source: The Author (2025)]

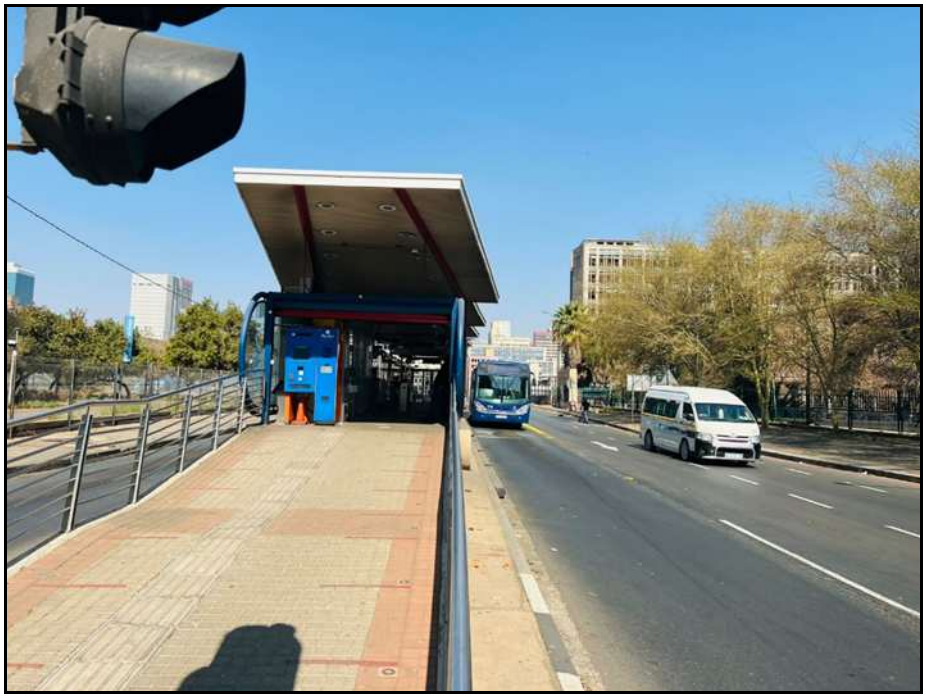

Fig. 4: Bus Rapid Transit (Rea Vaya) [Source: The Author (2025)]

There are three taxi ranks within the vicinity of Johannesburg Park Station's ITS. These are MTN Taxi Rank, The Bridge Taxi Rank, and Wanderers Taxi Rank as depicted in figures 1, 2, and 3, respectively. The MTN taxi rank is well known for connecting the local township with the city centre. These include taxis to areas in the north of Johannesburg, such as Alexandra township, Thembisa, Sandton, etc. The Bridge Taxi Rank connects daily commuters from the South of Johannesburg, such as Soweto, Zola, Dobsonville, and Meadowlands, to the Central Business District of Johannesburg. This network transports commuters into economic activities. The Wanderers Taxi Rank connects commuters to all the provinces in the country. It is also known to service international neighbouring countries such as Malawi, Zimbabwe, Botswana, etc. The ITS at Johannesburg Park Station also includes Bus Rapid Transit (BRT), in particular the Reya Vaya BRT, as depicted in the figure below.

The Rea Vaya is a swift transport that is the lifeblood of Johannesburg's Corridors of Freedom. As one of the first BRT systems implemented in Sub-Saharan Africa, Rea Vaya represents a strategic intervention to address the spatial fragmentation inherited from apartheid-era planning (Togo, 2016). It moves commuters from spaces like the Soweto corridors to the Johannesburg Park Station.

Fig.5: Metrorail [Source: The Author (2025)]

In the Johannesburg Park Station ITS, there are two rail transportation systems. These are the Metrorail and the Gautrain, as shown in Figures 6 and 7, respectively. The Metrorail is the lifeblood of Johannesburg Park Station. This rail transportation not only connects the 7 regions of Johannesburg, but also connects to the provincial regions such as Pretoria, Vereeniging, Germiston, and Springs. The Gautrain, on the other hand, is a high-speed rail offering an efficient and fast option for long-distance travel in the 3 metro cities. It connects OR Tambo International Airport, Pretoria, and Johannesburg. Complementing the Gautrain service is the Gaubus, a feeder and distribution network that extends the rail system's reach. It extends the train's reach, integrating rail and road transport.

Fig.6: Gautrain and Gaubus [Source: City of Johannesburg (2025)]

Figure 8 below is a Sankey diagram that uses width arrows proportional to the flow quantity to visualise how volumes move and distribute through various phases of the system. In this case, it specifically underpins

seamless integration at Park Station by indicating the scale of passenger transitions from primary rail lines to various last-mile transport modes.

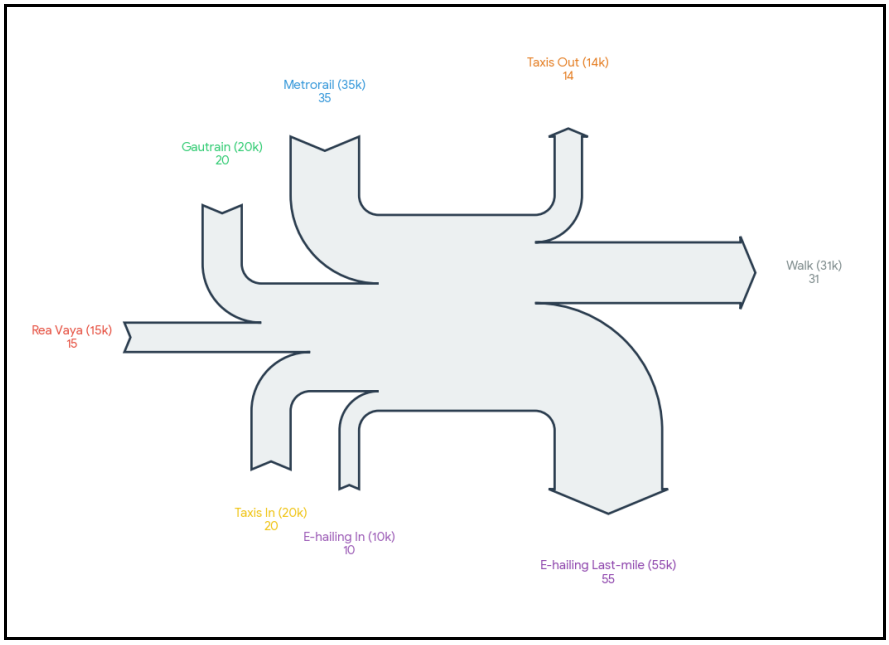

Fig.7: Passenger flow and seamless integration (Sankey Diagram)

5.2 ITS Contribution to TOD Success in Johannesburg Park Station

The ITS has adequately reinforced the success of the TOD at Johannesburg Park Station by improving the overall effectiveness and accessibility of the transportation network. The successful integration of the ITS solution, including the real-time tracking of Gautrain and Metrorail and automated ticketing, has developed a more elegant and user-friendly transit environment. However, the daily commuters indicate that the Johannesburg Park Station precinct is more transit-oriented. Moreover, interviews with daily commuters have indicated that these adjustments have provided them with public transportation options for daily commuting. Subsequently, supporting the core objectives of the TOD, which aim to adequately reduce the reliance on private transportation and encourage urban mobility and sustainable urban development. The data collected indicated that by enhancing the reliability and convenience of multimodal transportation options, the ITS has adequately contributed the role of promoting higher ridership levels and fostering a shift towards more sustainable commuting habits.

The implementation of ITS in Johannesburg Park Station has also catered to better urban development and land use in the vicinity. City of Johannesburg officials and daily commuters have also indicated that, with enhanced transportation services, the vicinity has experienced evident overcrowding and traffic congestion. This has emanated from business attractions and fostering the residential development within walking distance of the station. The principles of TOD align with the densification of ITS, which advocates mixed-use development integrating recreational, residential, and commercial spaces within a walkable distance of transit hubs. It is remarkable that this ITS has enabled efficient accommodation and management of increased passenger flow and volumes. This reinforces Johannesburg's transportation infrastructure to support the growing demand without compromising service quality. The economic vitality and liveability of the surrounding areas are also enhanced by improvements in ITS accessibility, reinforcing the TOD framework.

Subsequently, ITS has enabled a more data-driven approach to transportation management in Johannesburg and to the city's urban planning, both of which are vital to the long-term success of TOD initiatives. Passenger behaviour, transit system performance, and peak usage time have been analysed using real-time data collected via ITS applications; moreover, this data is processed by Gautrain, Gaubus, and Metrorail. Withal, urban planners and policymakers can utilise this available data to make sound, informed decisions about future development, service, and infrastructure investment. This proactive approach ensures transportation networks remain responsive and adaptable to the evolving needs of the urban population. By supporting sustainable and efficient transportation solutions, ITS has improved the operation of

Johannesburg Park Station and reinforced TOD goals, contributing to a more integrated and sustainable urban future for Johannesburg.

5.3 Commuters' Perceptions and Satisfaction with ITS

User feedback on the proficiency and reliability of ITS features at Johannesburg Park Station has been positive among daily commuters. The daily commuters have adequately demonstrated that the ITS provides the convenience of real-time information display, particularly at the Gautrain, Metrorail, Rea Vaya, and the local and long-distance buses. This feature has adequately minimised the stress and unreliability associated with waiting for public transportation. Daily users have also expressed positive sentiment toward the automated ticketing systems used by Gautrain, Gaubus, Metrorail, and Rea Vaya. This feature has also enhanced the efficacy of public transport, allowing commuters to swiftly purchase tickets and avoid long queues.

This study also reveals remarkable input through a comparison of satisfaction levels before and after the implementation of ITS, which improved commuters' movement and perceptions. Prior to the deployment of ITS, many daily commuters and CoJ officials reported frustration stemming from delayed services, inefficient transfer processes, and a lack of information. Recent data indicate that commuters have confidence in public transportation. Subsequently, the statistical analysis also supports a decrease in average waiting time for the next transportation and a reduction in the frequency of missing connections due to the provision of transportation information. The ITS has contributed to a more predictable and smoother commuting experience. These improvements have not only fostered higher ridership but also enhanced individual satisfaction by integrating e-hailing services, supporting the aims of TOD.

The key themes from the qualitative interviews with daily commuters have provided deeper insights into the lived experience of using the ITS at Johannesburg Park Station. Daily commuters have also indicated the value of planning journeys more effectively through real-time updates. It is noteworthy that the daily users reported that the ITS has also made it easier to coordinate transfers between different modes of transport, such as Rea Vaya, Gautrain, Gaubus, Metrorail, and taxis. Further, daily commuters noted that there are various transport modes at the Johannesburg Park Station ITS; these options offer diverse options for commuters.

Table 1 and Figure 8 below compare the Pre and Post ITS Data to demonstrate the historic performance and the current impact.

Metric	Pre-ITS (Baseline)	Post-ITS (Current)	% Improvement
Average Wait Time (min)	12.5	7.2	42%
Satisfaction Score (1-5)	2.8	4.1	46%
Daily Ridership (000s)	150	210	40%
Missed Connections (%)	18	7	61%

Table 1: Sources: Derived from questionnaire data and supplemented by Gautrain Annual Report (2024) and CoJ Transport Stats (2023)

6 DISCUSSIONS

The study's findings underscore the significance of ITS in enhancing TOD. In practice, the study found that the essence of ITS at Johannesburg Park Station has led to remarkable improvements in multimodal transfers and passenger flow. This implementation has reduced waiting times and increased commuters' satisfaction, thereby enhancing the appeal and efficiency of public transportation. The positive impact on urban development and land use around the station, particularly, underpins the strategic value of ITS in supporting the objectives of TOD. These practices paved the way for urban planners and policymakers in other cities seeking to adopt a similar system in their transportation planning. The collected data provides a nuanced understanding of how ITS contributes to the operational success of the transit hub and the TOD objective. The study underscores the significance of real-time data and automated systems in enhancing the reliability and convenience of public transport by boosting ridership and reducing reliance on private vehicles. Subsequently, the study identifies critical areas for future research, such as the long-term sustainability of ITS investments. By identifying and bridging the gap between practice and theory, this study proffers

invaluable contributions to the ongoing discourse on sustainable urban transportation and the role of modern technology in shaping future cities.

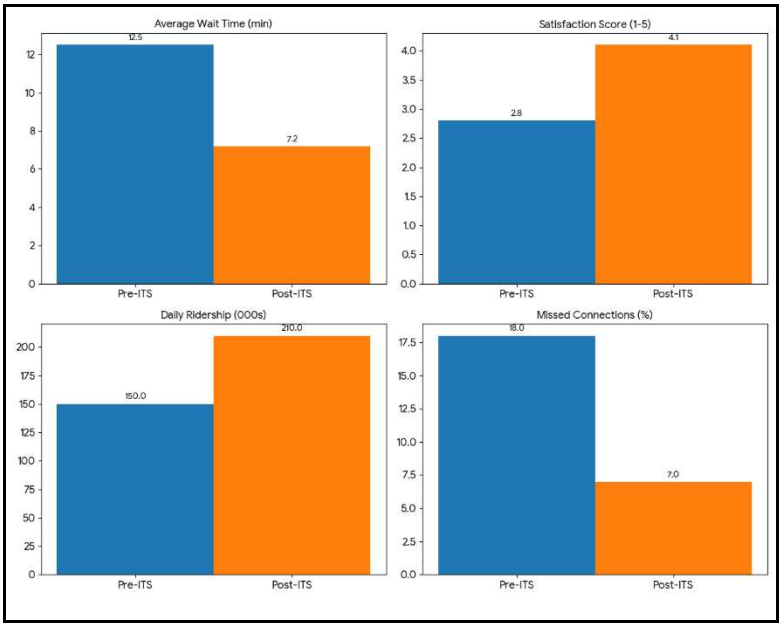

Fig.8 Pre and Post ITS performancemetrics at Johannesburg Park Station

The findings of this study make a significant contribution to both the theoretical understanding and the practical implementation of ITS in the context of TOD. The practical implications are vividly evident in the enhanced passenger flow and multimodal transfer efficiency at Johannesburg Park Station. This has adequately reduced waiting time and increased commuter satisfaction. For that, the study recommends integrating this initiative into land-use planning to enhance safety and security at Johannesburg Park Station, as the station is overcrowded and unsafe.

7 CONCLUSION

The study has highlighted the implementation of ITS at Johannesburg Park Station, as it has enhanced accessibility to the CBD and fostered the effectiveness of the TOD in the vicinity. The study has surfaced that ITS has not only improved multimodal transfer but has also optimised passenger flow. The ITS has significantly improved the integration of the vicinity of Johannesburg Park Station and enhanced the user-friendly public transportation network. The findings underscore the significance of data-driven solutions in contemporary urban planning, helping develop a more sustainable and efficient transportation ecosystem in Johannesburg. The study also revealed that the benefits of ITS are clear; however, it underscores the need for ongoing investments to improve safety and security in the vicinity, particularly in overcrowded areas. Withal, future research can focus on the long-term sustainability of ITS and its wider impact on sustainable urban development.

1 ABSTRACT

Spatial planning must resolve increasingly complex land-use conflicts that arise from competing demands on land and space (Hersperger et al. 2015, p. 6, Danielzyk and Münter 2018, p. 1932). These divergent interests stem from heterogeneous stakeholder groups involved in spatial development processes, resulting in multidimensional planning concepts that must integrate socioeconomic, ecological, cultural, technical and ethical dimensions (Bottero et al. 2019, p. 1).

Ongoing digitalization in spatial planning (cf. van Winden and Carvalho 2017, p. 3; Pallagst et al. 2022) is accelerating the adoption of Spatial Decision Support Systems (SDSS), which promise not only faster but also more transparent and evidence-based decision-making within planning processes (Crossland et al. 1995, p. 226). Yet, despite their increasing relevance, SDSS remain insufficiently conceptualized with regard to their decision logic, technological architectures, and underlying data foundations. Ghattas (2018) suggested that further research is needed to better understand the various assessment tools available in sustainable spatial planning.

This contribution deals with the first integrative systematization of SDSS by linking theory on decision making in spatial planning with data and software engineering. Within the research project Ageing Smart – Designing Spaces Intelligently, researchers from various disciplines have collaboratively designed a classification framework through iterative workshops, in-depth research on theory and learnings from selected SDSS samples that merge theoretical insights from planning decision processes with perspectives on functionality, technology and data. This allows for a revised perspective and understanding, empowering researchers to better assess the significance and possibilities of digital tools in planning in the future.

Keywords: Spatial decision support systems, SDSS, decision making in spatial planning, stakeholder in spatial planning, data basis

2 INTRODUCTION

Spatial planning is engaged with coordinating different and often conflicting types of land uses to be allocated in a particular planning situation. From a governance perspective, it also operates as a public task being interdisciplinary, cross-section-oriented, and integrated in a multilevel system (Danielzyk and Münter 2018, p. 1932). It must be understood as a decision-making process. The development of space involves a multitude of different perspectives and concepts from various stakeholders and specialized disciplines, which means that the development and planning of space might be confronted with strong conflicts of interest and the planning solution can strongly vary (Pinson 2004, p. 509). To arrive at a decision that considers and balances the various interests, spatial planners use various intuitive as well as more analytical assessment methods (Scholles 2018, pp. 222-223).

The megatrend of digitalization as a global and multi-disciplinary phenomenon has also arrived in spatial planning (Van Winden and De Carvalho 2017, p. 3; Pallagst and Liggesmeyer 2022). On one hand, this creates challenges for spatial planning, and, on the other hand, it opens many new opportunities that have the potential to provide planners with new methods to improve planning tasks. One of these opportunities addresses the already mentioned complexity of the planning tasks and actors involved, which requires a reliable and comprehensible decision-making process. Digitalization is moving us to digital solutions such as a Spatial Decision Support System (SDSS). An SDSS is a tool to facilitate these day-to-day decisions by digital means (Sugumaran and Degroote 2010, p. 14). It combines different types of spatial and non-spatial data, performs analyses and visualizations, and can thus suggest possible solutions (Keenan and Jankowski 2019, p. 64). SDSS can make processes more efficient and enable decision-makers to make better decisions

faster (Crossland et al. 1995, p. 226). One prerequisite for the efficient use of SDSS is the availability of qualitatively suitable data. Thus, the technologies, functionalities, and data types employed vary significantly. This, at times, also affects the type and quality of the benefits derived from a SDSS for spatial planning. Furthermore, it is crucial to distinguish which user groups are utilizing the program to discern whether it constitutes an expert tool or rather an application designed for a broader user base. However, practice shows that the term SDSS is not always easy to systemize and categorize.

To gain knowledge about the types of SDSS at hand in spatial planning and their application in practice as regards best practice examples, this contribution provides a suggestion for a classification of SDSS used in spatial planning. Various technical, data-related, and spatial planning-related aspects are applied to formulate different assessment criteria. The research on this topic emerged in connection with the interdisciplinary research project Ageing Smart – Designing Spaces Intelligently and it aims at developing a systematized research grid for comparative case studies in this field.The authors have provided a detailed description of the derivation of the classification model in Pauly et al. (2026) and, in Pauly et al. (2025), ventured an exploratory comparison of different SDSSs using the classification model as a methodological approach. The most important findings from this research are now compiled and described in this contribution.

When selecting the appropriate methodology for the investigations, the authors placed great emphasis on ensuring that the various areas of expertise could be utilized to the greatest possible extent due to the different professional backgrounds. However, when different scientific disciplines come together, conflicts can inevitably arise, e.g., with regard to methodological approaches, understanding of terms, and lines of argumentation. Therefore, iterative workshops were chosen as the core methodology for the research, in which the various perspectives on SDSS were shared and discussed without any predetermined conclusions. This allowed for a sharpening of conceptual understandings and the exploration of possibilities for developing a taxonomy-like model that would enable SDSS to be classified using categories that were as precisely defined as possible. In addition to the workshops, however, the research is also based on an in-depth investigation of existing theories, from which key content was compiled to help create the classification model for SDSS.

The next three sections of this article deal with the three different areas that were used to derive the classification model. First, we look at which decisions are made in spatial planning by which stakeholders and where SDSS can come into play. Next, we look at the various technologies and functionalities that are necessary to provide decision support and that can be found in SDSS. Finally, the third area examined is the topic of databases, which have a significant influence on the possibilities for decision support. The classification model resulting from the findings in the above areas is then presented and explained. The researchers' findings that need to be considered for the further development of the model are described.

3 DECISION MAKING IN SPATIAL PLANNING

3.1 Different interests and conflicts of land use

Based on the understanding that spatial planning is a public task that aims to coordinate different demands for the use of a defined space or land (Fürst und Mäding 2011, p. 11; Danielzyk und Münter 2018, p. 1932), the underlying consideration here is that the existence of a space or land is, by its very nature, also a problem. Spatial planning is therefore in the role of problem solver. Hersperger et al. (2015) specifies the problem mentioned and discusses a conflict that arises from the fact that land is a scarce resource. There are different perspectives on a defined land, which ensure that there are different ideas, proposals and claims as to what should happen to it and what function it should take on in the structure of the larger context, e.g. a city or a region. The resolution of this conflict is therefore described by Hersperger et al. (2015, p. 6) as conflict negotiation and thus also defines the goal of land use planning. It is further explained that planning processes therefore also mean conflict anticipation. From a governance perspective, however, it should be noted that planning processes, as the main action carried out in spatial planning, are interdisciplinary, cross-sectional and integrated into a multi-level system (Danielzyk und Münter 2018, 1932). This specifies the problem of the conflict of use and clarifies the dimension of the different perspectives from which the various interests emerge. According to Bottero et al. (2019, p. 1), these have their origin in various actors involved in planning processes, resulting in multidimensional concepts, e.g. from socio-economic, ecological, cultural, technical and ethical perspectives. Bottero et al. (2019) refers to the aforementioned

problems in spatial development as decision problems. This makes it clear that spatial planning implies having to make decisions.

However, the observations on planning that coordinates and anticipates conflicts must be relativized to some extent by the fact that spatial planning and the associated governance structures are conceptualized differently in each country and are shaped by different planning cultures within the meaning of (Knieling und Othengrafen 2016). If one wants to compare these possible conceptualizations according to categories such as planning instruments, administrative levels, regulatory frameworks and their material content, one can speak of planning systems or models of spatial planning (Pallagst 2018, p. 1762; Dühr et al. 2010, p. 35). The understanding of spatial planning as a coordinator and conflict solver can be linked particularly well with the "Comprehensive Integrated" planning system category proposed by Dühr et al. (2010). However, it is clear that the other categories, especially "Land Use Management", but also "Regional Economic" and "Urbanism", are also based on the coordination of land use demands. Even in the countries mentioned by Pallagst (2018, p. 1768) of the Global South, in which spatial development is largely characterized by informal settlement activity, fundamental decisions on the use of a particular land must be the basis, even if there may not always be a balanced consideration of different interests. In general, it can therefore be said relatively universally that spatial planning as a public task deals with land use conflicts and considers and coordinates different interests in order to find solutions. The statement that spatial planning means that decisions are made about the development of an area can also be generalized.

3.2 Planning process

Planning processes depict the processes of coordinating, finding a solution and making a decision and how they interlock. In order to understand the handling of conflicts in spatial planning in depth, a planning process model must be used to operationalize the procedures (Hersperger et al. 2015, p. 7). Also models of planning processes are strongly conditioned by the prevailing planning system. Nevertheless, there are also general aspects that can be operationalized and in reality may have modifications in sequence or other details depending on the country. Hersperger et al. (2015, pp. 7-8) proposes the model of Steiner (2008) for this purpose. This has its origins in landscape planning, but is adapted slightly by Hersperger et al. (2015, pp.7-8) and applied to spatial planning processes in general.

Steiner (2008, pp. 10-11) proposes a process flow with eleven steps. The process starts with the first step, the identification of problems or opportunities, and is completed with the last step, the administration and monitoring of the final plan. After the second step, in which the goal is defined and established in order to address the problem, various steps follow in which inventories, analyses and detailed studies are carried out. Based on this, concrete concepts and options are developed, which then lead to the development of a first plan. This is followed by the citizen involvement step. The plan is then concretized through detailed designs and then implemented in step 10. It is noticeable that the various steps can occur in a different order in the reality of spatial planning depending on the planning system, which can even be regulated by law in some cases. One example of this is the citizen involvement. Hersperger et al. (2015, p. 8) have therefore placed public participation at the center, which makes it clear that on the one hand it is independent of the steps of the planning process and at the same time can be involved in all steps. Another important modification is that Hersperger et al. (2015, p. 8) turn the process into a cycle. This makes it clear that the administration and evaluation at the end of planning also identify problems and opportunities that initiate new planning. It is also made clear that conflict anticipation and conflict resolution are integral parts of the planning process.

3.3 Decisions within the planning process

From the considerations on planning processes and the task of spatial planning to resolve conflicts, conclusions can be drawn about the types of decisions that take place in spatial planning. In the planning processes proposed by Steiner (2008) and Hersperger et al. (2015), the initial point is the identification of problems and opportunities and the resulting planning objectives. Further on, after various studies and consideration of different aspects, there is then the point of creating planning concepts and a concrete design. This means that, particularly at the beginning of the process, attention is initially focused on the option to act and finally the decision to act on the basis of observations and monitoring with the identification step. Later, a decision must be made in order to define planning concepts and develop a concrete design. As planning can

also change during the course of a process by taking other perspectives into account, the same type of decision also applies to the development of any preliminary planning alternatives.

In addition to the perspective of planning processes on decisions in spatial planning, the perspective of planning barriers can also be taken. For this purpose, the execution of planning must be understood as a creative act. However, the creative act of planning is limited by barriers (Schoen 2018, pp. 20-21). The planning system in Germany should serve as an example of this. Here, there are normative regulations with regard to planning limitations that are anchored in construction and planning law. These are the requirement of necessity ("Gebot der Erforderlichkeit"), the weighing-up for balancing requirement ("Abwägungsgebot") and the mandatory legal principles ("zwingende Rechtssätze") (Schoen 2018, pp. 21-22). The requirement of necessity states that planning must take place insofar as the circumstances make this necessary. It therefore describes the start of planning within the planning process. It is therefore the normative equivalent of the identification of problems and opportunities and the planning objectives formed from this as described by Steiner (2008) and Hersperger et al. (2015). The weighing-up for balancing requirement obliges planners to resolve the conflict arising from the different interests and to weigh up the various interests in a meaningful way. This is now the normative equivalent of Steiner's (2008) and Hersperger's et al. (2015) creation of planning concepts and a concrete design. This makes it clear that the two decision typologies already derived from the perspective of planning processes also arise from the perspective of planning barriers: The decision to act and the decision on a detailed design and planning alternatives.

In contrast, the third planning barrier from the example from Germany, the mandatory legal principles, is not a type of decision. Mandatory legal principles are about necessary knowledge of legally binding regulations that restrict the freedom of planners. Rather than a decision, it is therefore a type of consideration that can and must be one of many bases for deciding on a detailed design and planning alternatives. The other considerations proposed by Steiner (2008) and Hersperger et al. (2015) on which planning is based – in particular inventory, studies and citizen involvement – must therefore be extended to include consideration of legal barriers.

Further necessary additions result from the considerations on the influence of the planning culture context and from the fact that land use conflicts arise from different interests. In this respect, the consideration of the different interests of actors, the consideration of different technical interests and the consideration of existing norms and convictions must also be added.

In summary, it can be said that there are two core tyspes of decisions within planning processes that planners have to make: (1.) Decision to take action and (2.) decision about detailed design and planning alternatives.

At this point, however, it is important to note that this classification can only be considered a broad abstraction. Many different decisions made in spatial planning can be assigned to the categories mentioned above. The decision to act, for example, is accompanied by many questions that require a large number of proper sub-decisions: Should an intervention take place at a specific location? What are the objectives? Would it be worth the investment? Does the outcome compensate for the cost and effort? Decisions about detailed design and planning alternatives also raise procedural questions that require sub-decisions: Are there alternative locations, and what criteria are decisive in identifying the best location? What size, dimensions, scale, etc. are necessary? What exactly is the spatial distribution? In conceptual design projects, every single line sketched is ultimately also an independent decision.

However, when considering planning process models and planning barriers for derivation, it is not possible to achieve such a detailed breakdown and meaningful sorting of decision topologies. This would require independent in-depth basic research. However, since this article focuses on the systematization of SDSS, the authors have deliberately chosen to accept the abstraction based on two core decision types in planning processes.

The two decision typologies are framed by different considerations that serve as the basis for decision-making. Fig. 1 illustrates this approach.

The findings on the decision typologies within planning processes shape our understanding of which decisions can be supported by SDSS. At the same time, however, it must be made clear at this point that the two typologies of decisions considered only refer to the core of a planning process. Political decisions on planning, which are made by legislative bodies, for example, and can also be normatively demanded as part of spatial planning, are deliberately not considered. In addition, even after a planning process has been

completed, decisions are made by potential stakeholders about whether or not to make use of the opportunities made possible by the planning. This makes it clear that our understanding of SDSS refers to a tool that addresses the core of spatial planning and its planning processes and probably mostly serves to support planners.

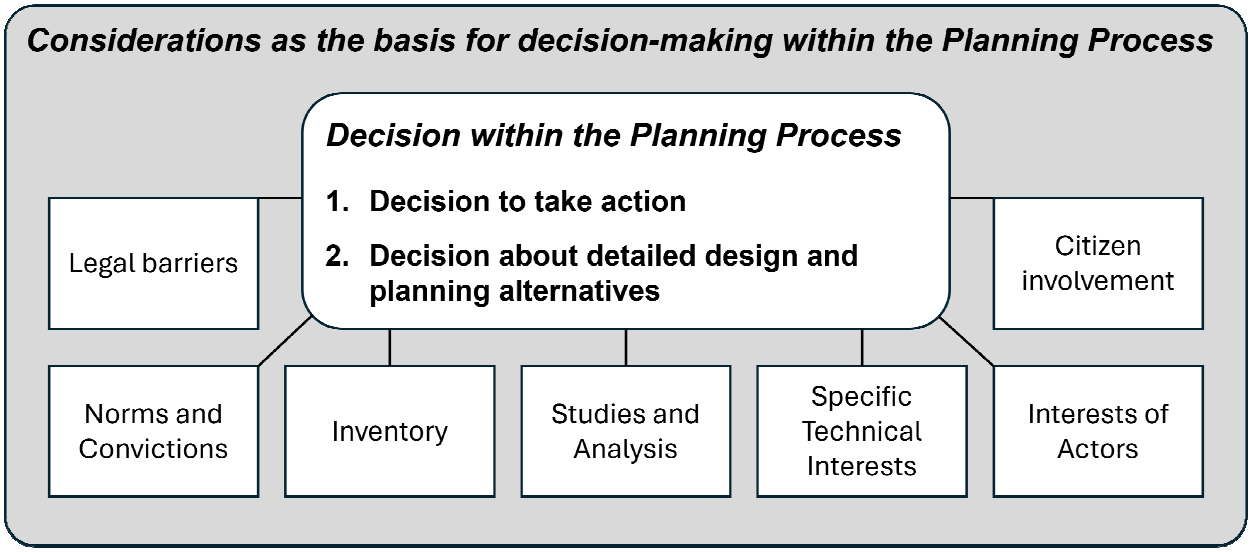

Fig. 1: Decision Typologies in Spatial Planning (translated from Pauly et al. 2026, p. 263)

3.4 Stakeholder in Spatial Planning

When focusing purely on the actors involved in planning processes, it becomes clear that the aforementioned differing interests originate from them, are rooted in them, and are articulated by them. Since planning processes require a solution, but differing interests clash, some form of cooperation is inevitable. The various participants have relationships with each other that are defined by conflict. During cooperation, relationships can be positively influenced if authentic dialogue takes place (Innes and Booher 2010, p. 37). This makes it clear that there must be certain factors, such as specific participation and moderation formats, that enable the best possible compromise to be reached. Ultimately, however, it remains the task of spatial planners to coordinate and weigh up conflicting demands. A decision is then made on the basis of intuitive and analytical evaluation methods (Scholles 2018, pp. 222–223). In order to gain a better understanding of the various actors involved in planning processes, two studies were examined which, for the purposes of their investigations, provide an overview of those involved in planning and their interconnections.

Hölzl and Nuissl (2014) examine urban governance structures in Santiago de Chile and divide the stakeholders into public, private, and civil society groups. They assign influence indices to these groups to illustrate their importance for urban governance. In the public sector, the authors name the responsible ministry, municipalities, the central government with other relevant ministries, regional secretariats, and the regional government. In the private sector, real estate developers, infrastructure companies, the Chilean Chamber of Construction, and other private stakeholders are named. In the civil society sector, individual politicians and universities are mentioned in addition to citizens. The allocation of the influence index is irrelevant at this point, as the influence and role of the various stakeholders can vary greatly depending on the context of the country under consideration. This also applies in part to the allocation of individual stakeholders to the categories proposed by the authors.

Källström and Smith (2023) scientifically accompanied the planning process for regional planning in a Swedish county through several workshops and other events and conducted qualitative interviews. The authors list the actors involved and divide them into ‘internal’, ‘primary’ and ‘secondary’ stakeholders, as well as citizens as a further group of actors. The ‘internal’ stakeholders include a ‘county politician’, the chair of the ‘regional development committee’, the regional planning manager, the project manager, the project team, and the chairs of the thematic working groups. The ‘primary’ stakeholders are listed as the municipality politicians, the members of the ‘regional planning council’, the managers of a municipal association, and the ‘public officials’ of the participating municipalities. National authorities and other secondary participants are listed as ‘secondary’ stakeholders. The group of citizens is not further subdivided. It should also be noted in this example that the proposed structure is strongly influenced by the given

context. However, sorting according to the degree of participation in the process can be very useful, as it allows the role of stakeholders in the planning process to be better classified.

Public/Private: **Spatial planner / Project manager**	*internal*	*Strategic core decisions*
Public Sector: **Executive and legislative bodies with decision-making power**	*primary*	*Political decisions*
Public Sector: **Other by planning activity affected executive and legislative bodies**	*secondary*	*Expression of interest (/vetos)*
Private Sector: **Real estate/Private individual developer and others**		*Economical decisions*
Private Sector: **By planning activity affected organizations and companies**		*Expression of interest (/vetos)*
Civil Society: **Citizens**		*Participation*
Civil Society *(can be additionally public or private sector as well)*: **Universities and other driving forces**		*Participation and expertise*

Fig. 2: Stakeholder within Spatial Planning and their types of decisions (translated from Pauly et al. 2026, p. 265)

These considerations were taken up and resulted in a proposal for the classification of stakeholders in spatial planning (see Fig. 2). A distinction is made between 'internal', 'primary' and 'secondary' actors. These categories define the degree of participation in the planning process. The right-hand column shows the decision typologies. It is clear that the core decisions in spatial planning – the decision to act and the decision on specific planning content – are mainly made by the top group of actors. This underlines our understanding of an SDSS as a support system for planners. However, it is also obvious that planners' decisions can be accompanied by other types of decisions from the primary and secondary stakeholder groups in the planning process. This makes it necessary to also classify an SDSS based on the decisive stakeholder group.

4 TECHNOLOGIES AND FUNCTIONALITIES USED IN SDSS

In addition to looking at SDSS from the perspective of spatial planning and which decisions are made by whom, it is also important to examine the underlying technologies that can result in different functionalities and represent another dimension for classifying SDSS.

In general, available data can be used in various ways in spatial planning. This includes different types of data and also different data sources (sensors, statistical data, etc.). It is obvious that the origin and frequency of data collection have therefore a massive impact on meaningful technologies.

From statistical data to Information and Communication Technologie (ICT) to big data applications, there are dozens of digital concepts and tools that could be considered. For the purpose of decision-making, however, real-time data can be disregarded, as only longer planning horizons are considered in spatial planning.

Other aspects that should be taken into account are the digital skills of planners and their digital environment. End users should have at least basic digital skills, and the underlying digital infrastructure should be provided. Another aspect is certainly the question of how often a digital tool is used. Since this is not static, usage would have to be tracked over time. Since such data is usually not available, this point is not taken into account here. Finally, it could be relevant to what extent end users were involved in the development of the tool. However, this is not easy to determine, which is why it is neglected in the following.

When talking about technology here, a distinction must be made between software and hardware. Since hardware usually plays a subordinate role from the user's point of view, the following analysis focuses on the software aspects of SDSS, whereby the following points can be used to classify SDSS:

Application type	Examples of application types can be smartphone apps, desktop apps or a web-based system. As the questions for spatial planning are usually complex, we assume it is very likely to have tools on a desktop PC, laptop, or maybe tablet PC.
Code ownership	The question if a tool is an open-source product is important. Sometimes, even the programming language (and which libraries are used) can have a massive impact on the usage of the tool. Obviously, an open-source tool usually has a larger community for development and extensions of the tool.
Extendibility	Usually, a new tool is not developed from scratch, that means existing tools or building blocks are taken and extended. From a spatial planning perspective, it might be interesting to discuss the extendibility of the tool. New features might be desired so the question is if they can be added to an existing tool might be of interest.
GUI design	The tool can contain different information in form of text, tables, graphs, and maps. The style and complexity of the tool (number of tables, charts, …) can vary and might be of interest for a comparison.
Interactivity	For a tool, you need to consider if the user can interact with the tool. In other words, the question is if the tool only displays values, tables and charts or if the city planner can set different values as input to obtain different results. Hence, we can classify the tool in interactive tools and static tools.
Analysis	We can group the different analysis methods in terms of classical machine learning methods, wich can be sub-goruped in a) supervised learning, b) unsupervised learning or c) semi-supervised learning. More details and more examples in the context of resilience of interdependent critical infrastructure systems can be found in (Alkhaleel, 2024, p. 3-6). In supervised learning, you usually have labelled data, meaning each dataset has a pre-defined output and the goal is to find an accurate prediction of new data, based on the data labels of known data. In other words, supervised learning usually covers aspects like classification, prediction, or regression. Most important examples are image classifier or prediction tasks (e.g. weather forecast or stock market prices). Typical algorithms are for example decision trees, support vector machines, different regression techniques or artificial neural networks. It should be mentioned that a simple statistical regression is a very basic but supervised learning technique. Unsupervised learning has, in comparison to supervised learning, no labels. In other words, you try to find patterns or structures in the data. The most prominent task is clustering where data points are put into clusters based on their similarities. An example for an unsupervised learning application would be the clustering of people according to their web surfing behaviour, to provide individual advertising. Typical algorithms are K-means clustering or dimensionality reduction techniques like principal component analysis. Semi-supervised learning is a mixture of supervised and unsupervised learning: the labels of the data are only available for parts or a subset of the data. In this case, special generative methods create artificial labels which can be used to adjust the machine learning model.

Tab. 1: Categories to classify technologies used in SDSS in terms of software aspects, own representation

5 DATABASE USED IN SDSS

The quality of the output and results of an SDSS is strongly determined by the quality of the underlying data, whether used directly or through models derived from it. The data should adequately represent and model the addressed spatial problem and contextual factors in such a way that the SDSS can make effective use of all relevant information to achieve optimal results. Understanding the underlying database is therefore a central aspect of classifying an SDSS. Data can be evaluated and categorized according to various criteria, including content domain, publisher, and technical aspects (Van Nuffelen 2024). Depending on the investigator and use case, different aspects may be given more weight. Such assessments can be carried out at varying level of detail; however, this degree of granularity is beyond the scope of this report. The choice of data-relevant dimensions for classifying an SDSS involves balancing the aim of a simple and clearly comprehensible classification structure against the inherent complexity of data and metadata, especially in a broad and multifaceted application domain such as planning.

5.1 Transparency

Is there a website, manual or similar source that provides information on the data used in the SDSS? In the absence of such documentation, it might be difficult to answer most of the following questions correctly.

5.2 Implicit data

Implicit data refers to information that is not explicitly stated or directly provided. Does the system use statistical parameters that have been derived from data or does it employ AI models that have been trained on training data?

5.3 Domains

Demography and socioeconomics	This data might include population statistics (e.g. age distribution and gender ratio), household data, and employment statistics.
Land use and spatial planning	This includes official planning documents, including development plans, land-use plans and zoning plans.
Infrastructure and supply	These datasets include utility network information such as electricity grids, water supply networks, and gas pipelines, service data like maintenance records and outage reports, and transportation infrastructure data.
Transportation and mobility	Relevant data may include traffic flow information such as vehicle counts and congestion levels, public transport data including bus and train schedules, as well as user mobility data such as bicycle-sharing and car-sharing usage patterns and pedestrian counts. This can be considered dynamical information about the usage of infrastructure.
Environment and climate	This domain covers data on air quality, weather data including temperature, precipitation, and humidity, and information on green spaces like the locations and sizes of parks and urban forests.
Health and safety	This domain includes health statistics such as disease incidence rates and hospital admissions, safety data like crime rates and emergency response times, and health service accessibility.
Economy	Economic data might encompass business information such as the number of businesses and types of industries and employment data including job vacancies and wage levels.
Education and culture	Relevant data include school data such as enrollment numbers and graduation rates, information on cultural institutions like museums and theaters, and data on cultural events.
Housing	Housing data can include information on housing stock such as the number and types of housing units and occupancy rates, real estate data like property values and rental prices, and assessments of housing conditions including the age of buildings and renovation needs.
Public services	This domain involves data on the location and availability of public facilities such as hospitals, schools, and libraries.

Tab. 2: Different possible domains of data used in SDSS, own representation

5.4 Data types

The term ‘data type’ is used here to provide a technical overview of the data used without delving into the details of specific data formats. While satellite data, for instance, also falls within the scope of geodata, this type of classification specifically highlights special cases that are of particular relevance for an SDSS investigation.

Geodata	Various spatial structures are used in SDSS. Those contain administrative regions like federal states, municipal borders and districts. Relevant points of interest might be doctors or schools. Detailed maps of infrastructure such as roads and supply lines might also be included.
Sensor data	Air quality, noise and temperature sensors are among the most used sensors in cities. There are also sensors in public transportation and to control traffic.
Remote sensing data	This includes LIDAR data, satellite images, radar data and aerial imagery.
Statistical data	All qualitative and quantitative information that is collected und saved in a structured way like census data.
Images and videos	This could contain surveillance footage, aerial imagery and photographs of public spaces.
Text documents	Any kind of accompanying documents like protocols or documentations
User generated content	This refers to any form of content – text, images, videos, reviews, and other forms of media – that is created and shared by individuals rather than by professional content creators or organizations. This content is typically made publicly available through online platforms, social media, websites, and other digital channels.

Tab. 3: Different possible data types used in SDSS, own representation

5.5 Origin, openness and legal matters

The license under which a data set is made available defines the terms and conditions for its use, sharing, modification and redistribution. Of particular interest is whether the data is openly accessible and therefore freely usable. On the other hand, it must be considered separately whether sensitive data is being used that warrants special protection.

5.6 Timeliness

For some applications, the quality of the results depends on the timeliness of the data used. Are regular updates available, or are there options to update the data? Additionally, is real-time data being used?

5.7 Linking, integrationand export

Of interest is to determine whether users are able to upload or input their own data. Additionally, the availability of interfaces, such as connections to open data portals or other applications, that facilitate data integration is a relevant consideration. Moreover, it is crucial to ascertain whether the system supports the export of results or provides direct connections to other tools for further use of the results.

6 RESULTS

6.1 Classification model for SDSS

Based on the above, a classification according to three overarching categories of indicators is proposed:

(1) Type of decision

(2) Technology an functionalities used

(3) Data basis

The three higher-level categories contain indicators that describe the central characteristics of an SDSS. However, the indicators differ in terms of their response modality. Based on an application to be examined that is classified as an SDSS, the indicators require a binary, descriptive, or nominal response. An example of a bionary indicator is the decision to act, which can be classified as either given/applicable or not given/not applicable. In contrast, the indicator analysis is a descriptive modality, since no choice from predefined categories would be conceivable here, but rather a case-by-case description is required. The situation is different with the nominal modality, where it is expected that an assignment to a predefined selection of categories is possible. An example of this is the data type indicator.

Regardless of the response modality, however, the indicators serve taxonomic-like purposes, enabling SDSS to be classified. For the sake of better understanding and content-related organization, however, we recommend following the order of the three superordinate categories.

The following figure combines the most important findings on the classification of SDSS in spatial planning.

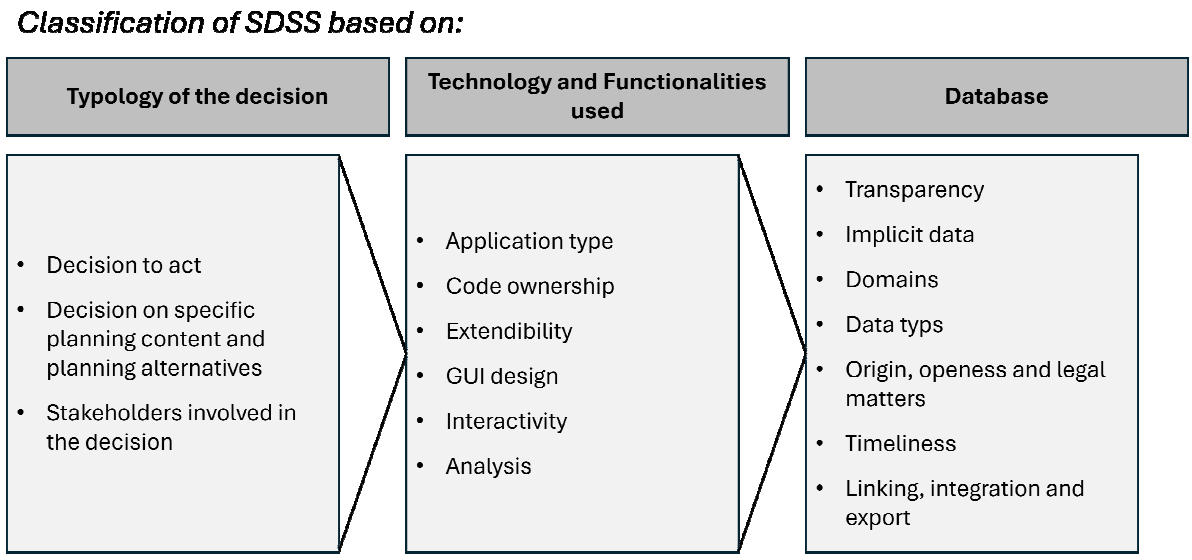

Fig. 3: SDSS-classifying indicators (translated from Pauly et al. 2026, p. 273)

The typology of decisions provides information about which specific decisions are made. Based on the authors' research, these are core decisions within planning processes. On the one hand, the use of SDSS can make users aware of planning needs that were previously unknown. This can lead to the decision to take action. On the other hand, the decision to take action may already have been made as a starting point. In this case, SDSS can make it easier to make decisions about specific planning content and planning alternatives. Furthermore, the group of actors who are supported in their decision-making is another important feature of SDSS. Although it has already been made clear that the core decisions are actually only made by internal actors, political decisions by primary actors could also play a role, for example, if applicable in a given application.

The technologies and functionalities used in SDSS represent a further step toward classification. SDSS can differ in terms of their type of application, code ownership, expandability, GUI design, interaction, and analysis options.

As a final step, classification according to the database is proposed. The database is so important in SDSS because it provides the basis for all functionalities. The quality of the entire SDSS also depends on the quality of the data. In terms of the database, SDSS can differ in terms of data transparency, implicitness, domains, data types, origin, openness, legal aspects, data currency, and data linking, integration, and export.

6.2 First attempts of an application

In Pauly et al. (2025), the authors conducted a study in which they tested the classification model as a method for comparing four selected SDSS. The aim was, on the one hand, to validate the defined indicators and, on the other hand, to identify initial patterns that could indicate certain regularities in SDSS. When selecting the four SDSSs to be compared, care was taken to ensure that they differed from each other as much as possible, particularly in terms of their basic usage concept, in order to enable a differentiated analysis. So, the four SDSS were deliberately selected for their heterogeneity in application domain and methodological approach.These are described in the following paragraphs.

Urbanist AI was developed by two private companies that combine expertise in the fields of software development and spatial development. The basic idea behind Urbanist AI is to highlight alternative design options, particularly for public spaces, thereby identifying areas where action is needed, which can ultimately support decision-making. To this end, the software generates images of the space using AI technology (Toretei S.R.L., SPINUNIT Lab OY, SPINUNIT OÜ, n.d.).

Daviplan was developed by the company Gertz Gutsche Rümenapp Stadtentwicklung und Mobilität. The application was commissioned and provided by the Federal Institute for Research on Building, Urban Affairs, and Spatial Development (BBSR) and the Federal Ministry of the Interior in Germany. The idea behind Daviplan is to analyse the location and supply structures of public services using map-based visualizations, thereby providing targeted support for spatial development decisions (Gertz Gutsche Rümenapp Stadtentwicklung und Mobilität GbR, n.d.; Gertz Gutsche Rümenapp Stadtentwicklung und Mobilität GbR and BBSR, 2023).

Maptionnaire was originally developed in the academic sector, which ultimately led to the founding of a private company (Mapita Oy, n.d). The developers themselves describe Maptionnaire as a geographic information system (GIS) for public participation. The basic idea is to allow the population to generate data on specific topics in which they are involved, which can then be used by planners. This highlights areas where action is needed, which can serve as a decision-making support for those responsible (Mapita Oy, n.d.b).

HEC-RAS was developed by the Hydrologic Engineering Center, part of the United States Army Corps of Engineers. However, the application is also made available for civilian use. The software calculates water flows and visualizes them for flood scenarios (USACE Hydrologic Engineering Center, n.d.).

Now a short summery of the outcomes of the comparison will be given: With regard to the decision-making criteria, it was found that all four applications fundamentally support the decision to act by highlighting deficiencies in the current situation. While Daviplan, Maptionnaire, and HEC-RAS point out these deficiencies directly, UrbanistAI does so more indirectly through idealized representations that do not necessarily correspond to real planning conditions.Daviplan and HEC-RAS in particular provide support for decisions on specific planning content and alternatives, as scenarios are a central component of these

applications. Depending on how it is used, Maptionnaire can be used both for pure deficit assessment and for evaluating planning options. UrbanistAI, on the other hand, is primarily used to visualize imaginary possibilities and does not support realistic planning decisions.All applications are primarily aimed at internal, strategic decisions by spatial planners. Daviplan is more suited to supra-local planning, while HEC-RAS is typically used in specialist planning. In addition, all tools can support political decision-making processes. Maptionnaire plays a special role here, as it involves residents who do not make decisions themselves, but support planning considerations through their input.

In terms of technology and functionality, the applications differ in their technical implementation and accessibility. While HEC-RAS must be installed as a desktop application, UrbanistAI, Daviplan, and Maptionnaire are browser-based, with Daviplan requiring a one-time Docker installation. The licensing model also varies: UrbanistAI and Maptionnaire require a license, HEC-RAS is free of charge, and Daviplan is available as open-source software, which is the only application that allows for extensibility. All tools offer cartographic visualizations. In addition, UrbanistAI displays generated images, Daviplan displays tables and diagrams, and HEC-RAS additionally displays hydrological parameters such as water flows or elevation profiles. The interaction options range from importing your own photos (UrbanistAI) to integrating POIs for accessibility analysis (Daviplan), creating participation questionnaires (Maptionnaire), and parameterizing complex water flow models (HEC-RAS). Methodologically, UrbanistAI uses generative AI, Daviplan uses accessibility models and forecasts, Maptionnaire primarily uses cartographic visualization of user-generated data, and HEC-RAS uses simulation-based hydrological models.

In the area of databases, transparency was examined first. Only limited information is available for UrbanistAI and Maptionnaire, as no detailed documentation is available. In contrast, Daviplan and HEC-RAS offer comprehensive manuals that provide insights into the data used and model assumptions. UrbanistAI does not disclose any information on the training or background data for its AI, andMaptionnairesimilarly does not allow any statements on this subject. Daviplanoperates without implicit data assumptions, whereasHEC-RAS is based on a water flow model with corresponding assumptions. In terms of content, the applications cover different domains, including land use, environment, infrastructure, demographics, mobility, and health, Maptionnaire poteappears capable to integrate all urban topics. All SDSSs utilize with geodata; in addition, photographs and texts (UrbanistAI), statistical data (Daviplan), user-generated content (Maptionnaire), and model-based hydrological data (HEC-RAS) are used. Users can import their own data into all applications. However, statements regarding openness, timeliness, and data protection aspects remain largely unclear, with the exception of Daviplan, which partially relies on openly accessible official statistical data.

6.3 Outlook

The comparison of the four SDSS UrbanistAI, Daviplan, Maptionnaire, and HEC-RAS reveals the diversity of possibilities offered by data-based decision support in spatial planning. It became clear that SDSS are difficult to conceptualize in a general understanding due to this heterogeneity. One reason for this is that their possible applications differ greatly from one another. Applying the SDSS typology clearly shows where the differences lie and how they influence its use as a spatial planning tool.

Since existing SDSSs are found in very different contexts, it is necessary to use a methodology that enables comparative analysis and maps the core characteristics. In this respect, it can be said that the classification approach proposed here offers a good opportunity to gain a better understanding of SDSSs.

Exploring further classification options could expand this understanding even further. For example, the introduction of defined SDSS subject areas would be conceivable. In addition, the development of maturity criteria could add an evaluation level to the typology.

It is striking that for some criteria, such as the ‘openness’ or ‘legal aspects’ of the database, no statement could be made for all or a majority of the applications examined due to a lack of information. This could be due to the selection of the four SDSS and must be critically examined. In further investigation, an expansion of the methodology, in particular through qualitative interviews with the developers, would be conceivable.

All in all, the contribution shows that research into the classification of SDSS helps to better understand their growing importance for spatial planning. New digital tools are increasingly being used in the context of spatial planning, leading to changes in the working methods of spatial planners. Data-based decision support

systems are designed to make them more efficient and have the potential to contribute to better and faster decisions in spatial planning, thereby supporting the planning process.

We could learn, that SDSS mediate spatial thinking by structuring how geographic information is represented, analyzed, and visualized. Importantly, SDSS do not introduce fundamentally new types of spatial decisions; rather, they operationalize and support existing decision-making processes by structuring complex spatial information and, in some cases, lowering the threshold for non-specialist users to engage with spatial decisions making. Research on the classification of SDSS promotes understanding in this area.

The purpose of this contribution is to provide a framework for future research into questions surrounding the potential, benefits, and possible areas of application of emerging digital tools designed to support decision-making in spatial planning. Comparative case study analyses using the framework proposed here appear to be suitable for this purpose.

The findings on decision typologies in spatial planning processes should be understood as a by-product of this contribution. The authors see this as a worthwhile starting point for conducting in-depth basic research in order to better conceptualize decision typologies in the future.

1 ABSTRACT

The proposed contribution analyses how short- and long-term strategies in urban planning can foster urban resilience and a circular economy by comparing technological measures, nature-based solutions and integrative communication processes. In examining how authorities engage the public to address emerging hazards, this study demonstrates the role of pre-disaster planning in catalysing sustainable innovation. We highlight communication as the key driver for inclusive, resilient long-term policy.

Our case studies include Graz (AT) and Ljubljana (SLO). Though confronted with similar ecological and socio-demographic challenges, the two cities address these challenges in markedly different ways, reflecting culturally biased divergent policy priorities and communication strategies. Using Graf et al.'s 2026 introduced Aware–Prepare–Act (APA) lens as a heuristic, the paper conducts a comparative policy analysis of two contrasting urban governance models. The paper tests the thesis that technological upgrades (e.g., expanding tram networks, cycling infrastructure, digital tools and AI) only produce urban resilience when anchored in sustained communication and participatory processes, a relationship made visible through an overarching APA lens on prevailing practices. In addition, inclusive, participatory formats are crucial for the achievement of a Social Licence to Operate, needed for boosting involved stakeholders' acceptance to redesign cities for enhanced biodiversity, integrate green infrastructure, and organizational learning on all levels.

Keywords: Urban resilience, Participatory Urban Planning, Communication Strategies, Circular Economy, Nature-Based and Technological Solutions

2 INTRODUCTION

European cities are increasingly exposed to compound and cascading risks arising from climate change, demographic shifts, and infrastructural ageing. Heatwaves, flooding, biodiversity loss, and energy insecurity challenge established urban development models and strain institutional capacities. In this context, disasters are no longer isolated events but manifestations of long-term structural vulnerabilities. Urban governance has often been characterized by a predominant focus on response and recovery. Recent research increasingly emphasizes anticipatory and preventive approaches to disaster risk management, highlighting the need to reduce vulnerability before hazardous events occur (Botzen & van den Bergh, 2009). These approaches embed disaster risk reduction within broader sustainability objectives, as articulated in the Sendai Framework for Disaster Risk Reduction 2015–2030 (UNDRR, 2015). Analyses of the Sendai Framework further interpret this shift as a move toward risk-informed and preventive governance that extends beyond reactive disaster management (Kelman & Glantz, 2015). Beyond climate-related hazards, urban mobility systems constitute a persistent and underestimated risk domain in European cities. According to the DEKRA Road Safety Report 2025, road traffic remains one of the leading sources of preventable fatalities in urban environments, with vulnerable road users accounting for a growing share of deaths, particularly in cities undergoing rapid mobility transitions. The report emphasizes that technological upgrades alone (such as digital traffic management or vehicle automation) do not reduce systemic risk unless accompanied by behavioural change, governance coordination, and sustained public communication (DEKRA Verkehrssicherheitsreport 2025).

Pre-disaster planning has emerged as a governance arena where risk anticipation, infrastructural investment, and institutional learning intersect. This paper builds on this premise, thus asks: How does pre-disaster planning shape the relationship between risk communication, circular economy strategies, and urban resilience? To address this question, the paper compares Graz (Austria) and Ljubljana (Slovenia), two

medium-sized European cities facing comparable ecological and socio-demographic challenges but pursuing markedly different governance and communication strategies. The analysis draws on the Aware–Prepare–Act (APA) lens as a supportive conceptual heuristic, which supports the comparative interpretation to how communicative purposes (awareness-building, preparedness-oriented communication, and action-oriented signals) and temporal orientations are articulated across policy domains (Graf et al., forthcoming). By focusing on communication and participation, the paper advances the argument that technological and infrastructural innovation only becomes transformative when socially embedded and publicly legitimised.

Demographic comparison of Graz and Ljubljana			
Indicator	Graz	Ljubljana	
Country	Austria	Slovenia	
Settlement type	regional city (mid-sized)	capital city (mid-sized)	
Area (total)	127.58 km²	163.8 km²	
Population (most recent value stated)	345.391	301.268	45,983 (total Ljubljana)
of which EU citizens	52.563	5.686 (Osrednjeslovenska region)	
of which non-EU citizens	50.092	no data	
Population density	2. 707,25/km²	1. 839,24/km²	

Table 1. While 15.3% of Ljubljana's inhabitants are foreign nationals, the specific breakdown for EU citizens is only designated at the regional level for Osrednjeslovenska (SiStat 2026a, 2026b). Numbers are considered most recent (01.01.2026 for Austria, Second Half Year 2025 for Slovenia).

The demographic profile of Graz consists of 50.55% female and 49.45% male residents, with the 25–30 age bracket representing the most prominent cohort across both genders. In contrast, Ljubljana's demographic structure is older, with the 40–44 age group being the most populous, while the 25–30 bracket ranks fourth, accounting for approximately 13% of the total population (SiStat 2026). These demographic characteristics are relevant insofar as they shape participation potentials and legitimacy structures in urban mobility governance. Statistically, members of Gen Z and Millennials are more inclined to adopt digital and shared mobility solutions, which generally fosters more sustainable urban transport systems (Arsovski et al. 2025; Little 2024). Demographic change further amplifies the relevance of inclusive mobility planning. OECD analyses show that ageing societies require adaptive transport systems that integrate accessibility, safety, and participation, reinforcing the need for anticipatory governance in urban mobility transitions (OECD, 2001).

Despite these demographic potentials, a critical disparity arises regarding political agency. In Graz, 29.7% of inhabitants lack Austrian citizenship, and only 15.2% of this group (those holding EU citizenship) possess municipal voting rights (Stadt Graz 2026). This exclusionary framework significantly impacts local governance and social cohesion (Statistik Austria 2025). The restrictive nature of the Austrian franchise becomes particularly evident when compared to the Slovenian model. While Graz excludes third-country nationals from local elections, Slovenia grants municipal voting rights to all foreign residents with permanent residency, regardless of their country of origin. Furthermore, Slovenia's National Council facilitates "functional representation", allowing foreign workers to participate in interest-based elections (Waldrauch 2022).

Finally, urban safety remains a critical metric for both cities. In 2024, Graz recorded 1,655 traffic accidents involving personal injury, resulting in 2,003 casualties and 7 fatalities (Statistik Austria 2026). Though there are no final numbers for Ljubljana 2025, it had zero road fatalities in 2024 (DEKRA Verkehrssicherheitsreport 2025).

3 THEORETICAL FRAMEWORK

3.1 Urban Resilience and Circular Economy

Urban resilience has evolved from a predominantly technical concept concerned with robustness and recovery toward a socio-ecological framework that integrates governance, participation, and learning. Contemporary resilience research emphasizes adaptability, transformability, and the capacity of urban systems to reorganise in response to long-term stressors. Parallel to this development, the circular economy paradigm has gained prominence as a sustainability framework aiming to decouple economic activity from resource consumption through reuse, regeneration, and closed material loops.

Resilience and circular economy approaches both challenge linear planning models and highlight the need for cross-sectoral coordination. In urban contexts, circular economy strategies often materialise through mobility transitions, green infrastructure, energy systems, and waste management. Their success, however,

depends not only on technological feasibility but also on governance arrangements and public acceptance. Recent research highlights that transitions toward circular urban systems critically depend on everyday practices and lifestyles. Studies focusing on urban communities demonstrate that circular economy strategies are only effective when infrastructural change is accompanied by shifts in consumption patterns, mobility behavior, and social norms, reinforcing the role of communication and participation in enabling systemic transformation (Szabó et al. 2024).

Recent mobility research further demonstrates that circular economy strategies in transport systems simultaneously reduce environmental pressure and systemic risk exposure. A large-scale review of urban mobility transitions shows that cities integrating reuse-oriented mobility services, shared infrastructure, and demand-management instruments experience lower rebound effects and higher system robustness than cities focusing exclusively on electrification or digital optimisation (Zhang et al., 2023). A systematic synthesis of circular economy strategies in the transport sector shows that interventions focusing on reuse-oriented services, shared infrastructure, and lifecycle optimization tend to produce broader environmental and operational benefits than narrow electrification or digital optimisation strategies (He et al. 2023). Recent scoping reviews of urban mobility literature highlight that integrated planning for sustainability and resilience, especially through multimodal systems and redundancy, enhances both environmental outcomes and systemic robustness in the face of disruptions (Sassaron et al. 2025).

3.2 Pre-Disaster Planning as a Transformative Bridge – from Participation to Social Licence to Operate

Pre-disaster planning has evolved from reactive emergency management into a transformative governance space that reshapes development trajectories before disasters impose urgent constraints. It functions as a temporal bridge, aligning short-term risk awareness – defined by the interaction of hazard, exposure, and vulnerability (UNDRR 2017) – with long-term infrastructure cycles. The ETSC PIN Annual Report (2025) validates this by showing that sustained safety gains result from institutionalised preventive governance and public engagement rather than isolated technical investments. Thus, anticipatory planning serves as a risk governance mechanism that synchronizes safety, sustainability, and behavioral adaptation (ETSC 2025).

Securing an SLO is critical for sustainable transformation, requiring both capable institutions and active stakeholder involvement to develop legitimate solutions (Borrás et al. 2025, Wenander 2024). Within the spectrum of participation, cities must move beyond a one-sided transfer of information (where experts define goals) towards the co-production of knowledge based on joint problem definitions (Schneider et al. 2018). This shift is essential for implementing the demand-side measures and lifestyle changes that the IPCC (2022) identifies as central leverage points for mitigating climate risks in urban mobility and infrastructure systems.

3.2 The Aware-Prepare-Act Lens

The conceptual foundations of the APA lens build on empirical insights from a systematic scoping review of risk and crisis communication research, which identified persistent fragmentation between short-term warning-oriented communication and long-term adaptation-oriented approaches (Graf et al. 2026).

Building on these empirical findings, the APA lens was subsequently developed as a conceptual heuristic through iterative analytical synthesis and interdisciplinary expert consultation (Graf et al. forthcoming). It distinguishes three interrelated communicative purposes: awareness-building, preparedness, and action.

Awareness refers to the communication of risks, uncertainties, and long-term challenges to diverse publics. Preparedness encompasses planning instruments, institutional capacities, and resource allocation.Action refers to communication related to concrete measures and infrastructure interventions as they are presented in policy documents, without implying an assessment of their implementation or effectiveness. s. The analytical value of the APA lens lies in its capacity to make patterns of emphasis and potential communicative gaps analytically visible, particularly situations in which technical planning advances without corresponding social engagement, as well as configurations where participatory communication reinforces policy coherence and legitimacy.

3.3 Social Licence to Operate in urban transformation

Originally developed in the context of extractive industries, the concept of Social Licence to Operate (SLO) has gained relevance in urban governance. Large-scale transformations, such as mobility transitions or the reallocation of public space, often generate social conflict and resistance. Formal legal approval alone is

insufficient to ensure long-term legitimacy. In urban contexts, SLO refers to the ongoing acceptance of policies and projects by affected communities. It is generated through trust, transparency, and meaningful participation. This paper adopts SLO as an analytical bridge between risk communication and pre-disaster planning, arguing that anticipatory governance can strengthen legitimacy by involving publics before crises escalate.

4 METHODOLOGY

The paper follows a qualitative comparative case study design. Graz and Ljubljana were selected due to their comparable size, regional context, and exposure to climate-related risks, combined with divergent governance and communication approaches. Primary sources include urban development strategies, sustainable urban mobility plans as issued by the respective cities, environmental indicators, and institutional publications. In order to achieve comparability the selected document are mobility plans and strategies of the respective cities that aimed for a vision 2020 and 2040, respectively. This choice allows the APA lens to render long-term goals set in the earlier document in context of the later (Graf et al. 2026). Due to the separated publication of the Graz documents, the mobility plan as well as connected documents such as the plan's measures and goals are added. This is true for both Styrian policy documents. The following table provides a overview of the used sources. Document analysis was complemented by a qualitative content analysis. A coding manual was developed based on a semi-deductive, semi-inductive approach. The deductive perspective was structured using the theoretical Aware-Prepare-Act lens. Furthermore, coding focused on three analytical dimensions: (1) technological measures and infrastructural interventions, (2) nature-based solutions (NBS) and circular economy (CE) elements, and (3) communication strategies and participatory formats.

In a first step, the main coding categories were derived deductively from the research questions and relevant literature on urban governance, risk and crisis communication, disaster risk reduction, and sustainability planning (Fereday & Muir-Cochrane, 2006; Mayring, 2014, Ellen MacArthur Foundation 2017; CE Center | Circular Economy Policy Research Center 2019).

This initial framework was subsequently discussed and critically reflected in an interdisciplinary expert round involving four researchers with backgrounds in trauma studies, sociology, linguistics, environmental systems sciences, psychology, and history. The purpose of this exchange was to assess conceptual clarity, identify overlaps or gaps, and ensure the analytical applicability of the coding categories across disciplinary perspectives. In a second step, the coding scheme was iteratively refined through inductive engagement with the empirical material during pilot coding of selected policy documents, resulting in the specification of category definitions, inclusion and exclusion criteria, and illustrative examples.

The APA lens was subsequently applied as a comparative analytical framework to examine how awareness-building, preparedness, and action are aligned or decoupled across the coded policy domains. The comparative approach allows for identifying patterns of alignment and misalignment between planning, communication, and implementation. This study remains mindful of the potential for verification bias. Following Popper's principle of falsification (1963), the framework is employed not merely to confirm the necessity of participatory communication, but as a diagnostic tool to identify where these assumptions might fail or where technological excellence, as seen in the Graz case, partially compensates for communicative gaps. The comparative design specifically looks for 'disconfirming evidence' – instances where resilient outcomes occur despite a lack of integrated participation.

5 CASE STUDY: GRAZ

5.1 Governance context

Graz positions itself as a regional innovation hub with a strategic emphasis on climate mitigation and sustainable mobility. However, the city's governance landscape is characterized by structural fragmentation, with policy responsibilities dispersed across multiple municipal departments. While high-level strategic documents articulate ambitious sustainability targets, the lack of cross-sectoral coordination often hinders the translation of these goals into a cohesive urban vision.

5.2 Technological measures and circularity

Technological interventions in Graz are robust, focusing on the expansion of the tramway network, significant investments in cycling infrastructure, and the deployment of digital traffic management systems. These measures are effective in driving a modal shift and reducing emissions. Nevertheless, circular economy principles remain weakly institutionalized, surfacing primarily as isolated, sector-specific initiatives rather than as an integrated pillar of urban resilience.

5.3 Communication and participation

The analysis of the Graz Mobility Plan underscores the systematic, dialogue-oriented integration of the Climate Advisory Council into action planning, aiming to incorporate long-term climate-related considerations. In the so-called district dialogues, held over three evenings, there was a clear match between what people wanted and the action plan presented. The mobility dialogue, attended by 300 participants, was rated as uncritical and positive, suggesting approval of the existing concept. At the same time, there is a high level of interest in participation on the part of the population, who want to have a say and be actively informed. However, the selection of target groups and stakeholders is not described transparently in the plan. It also remains unclear how the results of the online mobility survey, which had around 3000 participants, will be integrated into the further development of the concepts. Although the survey provides valuable information on preferences and needs, it does not explain how these findings will be incorporated into concrete measures.

Compared to earlier concepts such as the Graz Mobility Concept 2020, there has been clear progress: these predecessors contain virtually no references to citizen participation or stakeholder involvement. Only the city of Graz's mobility strategy mentions the need to raise awareness, but it does not specify how this should be achieved. For the city of Graz, it also remains essential to coordinate transport policy objectives and planning measures with higher-level planning authorities (the province of Styria, the federal government, ÖBB, and the EU). This serves to protect urban interests and requires targeted lobbying to address overarching problems in the transport sector. Overall, the Mobility Plan 2040 shows a significant increase in consultation elements, especially in the integration of stakeholders and expert committees, but there is still room for improvement in systematically integrating survey results and in the transparent selection of stakeholders.

A primary example for bridging academic research and municipal practice is the city’s involvement in the FLOODPREP project (a pre-disaster planning instrument), which targets extreme weather and heavy rainfall management through the development of advanced planning tools and high-resolution hazard simulations (Stadtportal der Landeshauptstadt Graz, 2025).

5.4 Circular Economy Measures in Mobility Assessment

Austria's Mobility sector has decreasing GHG emissions by 17% in comparing the years 2022 and 2023 considering the whole of the sector. In detail the reduction is due to the decrease in heavy commercial vehicles (WKÖ 2024). The UBA reports the same trend for 2024 with a reduction of 2,7% of emissions in the mobility sector, mainly due to decline in diesel sales, particularly in freight transport). In personal mobility the numbers of use have risen. In 2024 still 19,5 Mio. tons of CO2-eq are attributed to the mobility sector (Environment Agency Austria 2026). 12.3% more cars newly registered than in 2024, leading to 5.29 million passenger cars registered in Austria closing 2025 (Statistik Austria 2026). In Slovenia, the number of newly registered cars rose to 6% compared to the previous year. (Statistics Slovenia 2025). In 2023 Slovenia’s emissions linked to the mobility sector comprised the biggest share (37%, 5,4 CO2-eq) of the countries emissions, which totalled at 14,6 CO2-eq. (European Commission 2024).

To sum, the mobility sector has reduced emissions but not in personal mobility. Mobility services consume resources as well as energy, which need to be reduced in a climate friendly mobility system Based on the principles of circular economy (CE). The VCÖ has put forward a version of the 9Rs circular economy to better mobility's environmental balance (VCÖ 2022). Within the scope of this paper the version has been tailored to the CE measures that apply to cities and their governmental scope. As stated by the Ellen MacArthur foundation cities can plan a major role in implementing CE measures in the fields of urban planning, the design of mobility offers as well as infrastructure (Ellen MacArthur Foundation 2017).

To assess how the selected urban mobility plans incorporated an innovative circular economy perspective literature research concerning mobility measures was conducted. From these categories of CE measures

suitable for urban policies was derived. Subsequently, the documents were screened for the defined categories. Studying the VCÖ report it becomes apparent that the cites leverage in CE application in urban mobility is among the first Rs, focusing on intelligent use and production of infrastructure

Prominence is given to measures within the scope of urban policies. Measures targeting R4 (reuse) and higher were not observed as cities do not have high leverage to influence these factors. Instead, a focus was given to R1 refuse, R2 rethink, and R3 reuse (see fig. 1).

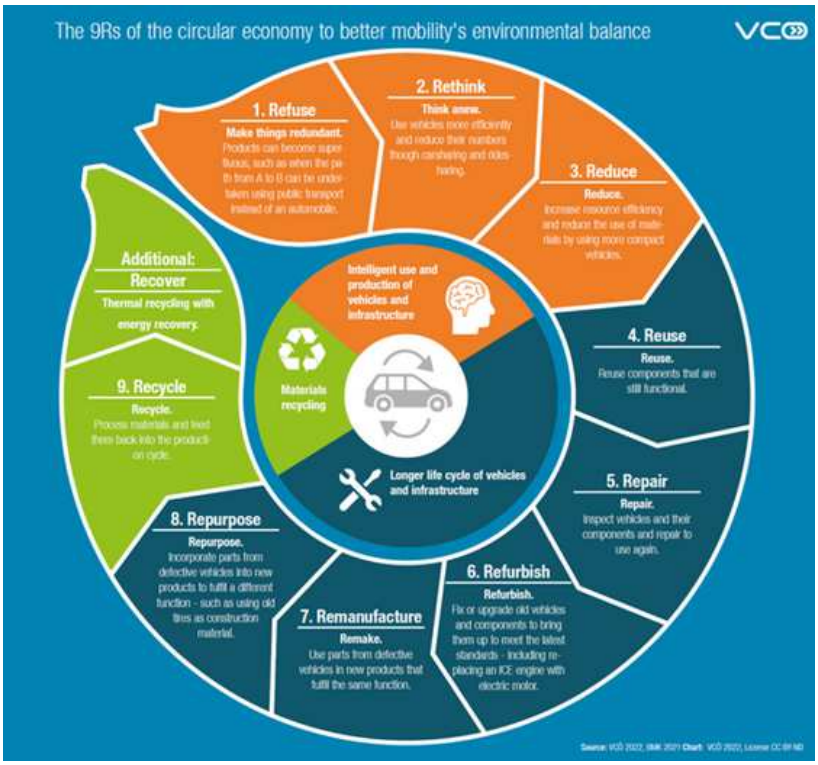

Figure 1: Measures targeting R4 (reuse) and higher were not observed as cities do not have high leverage to influence these factors. Instead, a focus was given to R1 refuse, R2 rethink, and R3 reuse. Illustration from VCÖ.

A non-exhaustive list of mobility measures implementing a circular economy follows and is used as criteria for the assessment of the selected policy documents:

- Cars (car-sharing, rental, carpooling park and ride, etc)
- Cycling (rental, storage, etc.)
- Public transport (micro-public transport / small buses /on-demand buses etc.)
- Walking (pavements, connection of mobility services, pedestrian etc.
- Monitoring (of traditional public transport, walking measures such are.

(Ellen MacArthur Foundation 2017; CE Center | Circular Economy Policy Research Center 2019)

These measures will serve as categories for the Table of Circular Economy Measures (in the Appendix). The results of the policy document assessment and a comparison is found

5.5 APA assessment

The Graz mobility governance portfolios are dominantly structured by preparedness and implementation logics. Awareness-building is present, but its integration varies across instruments. Analytically, the case comprises two policy strands: The Mobility Strategy 2020 is an integrated package (GZ-MOB-2ABC: guideline, targets, and measures), while the Mobilitätsplan Graz 2040 (GZ-MOB-01) is a consolidated long-term strategy document.

The APA profile shows that the dominant purposes for the GZ-MOB-1ABC package are to Prepare and Act. Preparedness is established through planning standards, measurable targets, and steering logics. Action is embedded in a structured implementation measures program. Awareness remains supportive and focuses on the upstream guideline component through normative framing and behavior-oriented messaging. The

package is clearly long-term focused, using hybrid implementation pathways, including phased roll-out of measures. Communication occurs mainly through information and consultation, with little explicit evidence of feedback loops covering the whole portfolio.

GZ-MOB-01 outlines a scenario-based approach, long-term targets, and institutionalized evaluation cycles as the path forward. Awareness serves as legitimizing framing, presenting mobility transition as a shared societal challenge. Action is carried out through implementation pathways and downstream measures programs. Participation formats, such as consultation, workshops, and co-creation, are more explicitly documented than in the 2020 package. This supports the interpretation that participatory elements in the planning cycle are gradually strengthening. Both Graz policy papers show the focus is on Prepare and Act. Awareness-building is included, but not always in every public relations activity. Initiatives such as FLOODPREP illustrate Graz's high institutional preparedness capacity: hazard knowledge is systematically translated into planning instruments through expert-driven collaboration, reinforcing a strong 'Prepare' logic within the APA profile, while post-event social recovery and circular innovation remain weakly addressed.

6 CASE STUDY: LJUBLJANA

6.1 Governance context

Ljubljana follows an integrative governance model that treats sustainability as an inseparable component of its long-term urban identity. Environmental objectives are strategically framed as quality-of-life improvements, a narrative shift that facilitates political continuity and seamless cross-sectoral coordination. Ljubljana's integrative governance approach is reflected in its long-term socio-demographic and mobility indicators. Official municipal statistics show comparatively lower population density pressures and a stable modal shift towards public transport and active mobility, which the city explicitly links to quality-of-life narratives rather than risk avoidance alone (City of Ljubljana, Ljubljana v številkah 2025).

6.2 Technological and nature-based solutions

The city views sustainable mobility, green corridors, and biodiversity-sensitive design as interconnected facets of a singular urban metabolism. In Ljubljana, technological upgrades are intentionally paired with NBS, creating a redundant and adaptive infrastructure that enhances systemic resilience.

6.3 Communication and participation

While the mobility plans of the City of Ljubljana include consultative elements, these remain largely expert- and institution-driven. The plans refer to workshops involving more than 300 experts and other stakeholders, as well as coordination processes with municipalities, ministries, and specialised institutions. Alignment with parallel planning instruments, such as the regional spatial development plan, is also highlighted. The resulting dialogue partnerships are therefore primarily oriented toward formal actors and expert communities. The role of the general public is largely confined to receiving information and fostering acceptance. Participation primarily serves to gather expert knowledge, provide feedback on predefined concepts, and build consensus within institutional frameworks. There is no evidence of joint problem definition with the population, nor of shared decision-making power. Long-term co-governance structures involving users, or forms of equitable knowledge co-production, are not established.

Problem framing, scenario development, and modelling logics remain consistently expert-defined. Public input is advisory rather than binding. Although the documents normatively emphasise the need for active participation of the general public, they do not specify concrete mechanisms for joint decision-making, such as co-design processes, citizens' panels, or participatory decision formats. Consequently, participation in practice ranges from passive information provision to consultation: input is collected, but decision-making authority remains with institutional actors. Co-creation is conceived exclusively within the circle of professional stakeholders, while citizens and the wider public are not actively involved in shaping outcomes. Recent sustainability research further indicates that participatory urban governance enhances policy coherence and long-term system resilience, particularly when mobility and environmental strategies are framed as shared societal projects rather than sector-specific interventions (Abujder Ochoa et al. 2025).

6.4 APA assessment

The mobility governance portfolios of Ljubljana are dominated by preparedness logics. It is evident that awareness-building and action are embedded as supportive elements across the policy instruments. The case is clear: there are two policy strands. The first is the regional guideline and project brochure Public Transport in the Ljubljana Urban Region (LJ-MOB-01). The second is the Sustainable Urban Mobility Plan of the Ljubljana Urban Region (SUMP) (LJ-MOB-02). This is a long-term strategic planning document (anticipatory/pre-disaster logic).

The primary purpose of the Policy guideline "Public Transport in the Ljubljana Urban Region" is to prepare, primarily through expert guidance, long-term regional planning instruments and to institutionalise coordination and harmonisation across governance structures (e.g. ticketing systems, timetables and regulations). Awareness-building is a key part of the solution to the structural problem framing of unsustainable mobility (traffic congestion, air pollution, CO2 emissions, noise, and quality-of-life impacts). This legitimises coordinated regional action. Action is included through concrete public transport improvements and infrastructure modernisation measures. These are described as planned and phased steps that depend on institutional and financial conditions. LJ-MOB-01 is long-term oriented, combining long-term governance coordination with hybrid implementation trajectories.

LJ-MOB-02 clearly shows a more balanced configuration. Preparedness remains dominant through its strong emphasis on regional coordination mechanisms, institutional capacity-building across municipalities, and integration of climate and mobility objectives into long-term planning frameworks. Awareness-building is explicitly documented and functions as a guiding narrative by framing sustainability and mobility transition as a shared regional responsibility linked to quality of life. Action is operationalised mainly through strategic priority initiatives and implementation pathways. These are delegated to follow-up programmes and stepwise realisation. Participation formats, including workshops, interviews, online surveys and GIS-based input formats, are explicitly integrated and accompanied by iterative monitoring and evaluation elements. This indicates a comparatively strong learning- and feedback-oriented governance logic.

7 COMPARATIVE ANALYSIS: GOVERNANCE CULTURES AND CE-INTEGRATION

The comparison of mobility policies in Graz and Ljubljana demonstrates that technological capacity alone is insufficient for resilience. Instead, the governance culture determines how pre-disaster planning translates into sustainable innovation. While both cities share a multimodal technical baseline, their strategic execution reveals distinct approaches to the APA-Lens:

- Ljubljana: Risk-Aware Integration. Ljubljana's strategy (LJ-MOB-01) is unique in its explicit consideration of failure. By including scenarios for unsuccessful measures, the city demonstrates a high level of Awareness regarding implementation risks. This transparency, combined with radical measures like city-center access restrictions, suggests an integrative communication style that prioritizes long-term legitimacy over quick technical wins.
- Graz: Developer-Led Preparedness. Graz focuses heavily on the Prepare phase by institutionalizing the "City of Short Distances" and contracting private developers to provide decentralized mobility hubs (car-sharing, bike services). While technically advanced, this decentralized "action" lacks the centralized, high-visibility communication seen in Ljubljana, potentially leading to a fragmented perception of resilience.

The CE is silent: A key finding is the total absence of Circular Economy as a term, despite the systematic use of CE-strategies (R1-Refuse through access restrictions; R2-Rethink through short distances). Both cities fail to leverage the CE-paradigm as a marketing or narrative tool to secure an SLO. This indicates that while the technical Action is circular, the Awareness phase remains disconnected from the broader sustainability discourse, leaving a significant potential for public engagement untapped.

7.1 APA

This section compares the governance logics underlying urban mobility planning in Graz and Ljubljana. It summarises the results of the qualitative content analysis conducted using the APA lens (see Chapter 4). The comparison matrix summarises the APA-based coding results by aggregating the communication purposes and their temporal orientations.

As shown in Figure 2, the analysed Ljubljana policy documents (LJ-MOB-01, 2010; LJ-MOB-02, 2019) are characterised by a dominance of preparedness-oriented communication in the long-term temporal horizon. In both documents, awareness-raising is coded as present and supportive, accompanying preparedness-oriented communication across long-term planning horizons. Action-oriented communication is coded as supportive and predominantly hybrid, indicating the co-existence of short-term measures and long-term infrastructure development as articulated in the documents. Across both Ljubljana documents, awareness-raising and preparedness-oriented communication precede and accompany action-oriented communication in terms of temporal positioning.

The Graz documents display a different distribution of communicative purposes (Figure 2). In the aggregated policy package GZ-MOB-01-ABC (2010/2012), preparedness-oriented and action-oriented communication are coded as dominant in the long-term horizon, while awareness-raising is coded as supportive and is primarily located within the strategic guideline component. In the later document GZ-MOB-02 (2025), awareness-raising is coded with increased prominence in the long-term horizon, reflected in explicit narrative framing within the policy text. Preparedness-oriented communication remains dominant, structured through scenario-based planning instruments and evaluation cycles. Action-oriented communication in GZ-MOB-02 is coded as hybrid, combining references to immediate measures with long-term infrastructure development.

To summarize, the documents differ in the distribution and temporal positioning of awareness-raising, preparedness-oriented communication, and action-oriented communication across the analysed policy documents. These differences reflect document-level patterns of communicative purpose and temporal orientation within pre-disaster urban mobility planning.

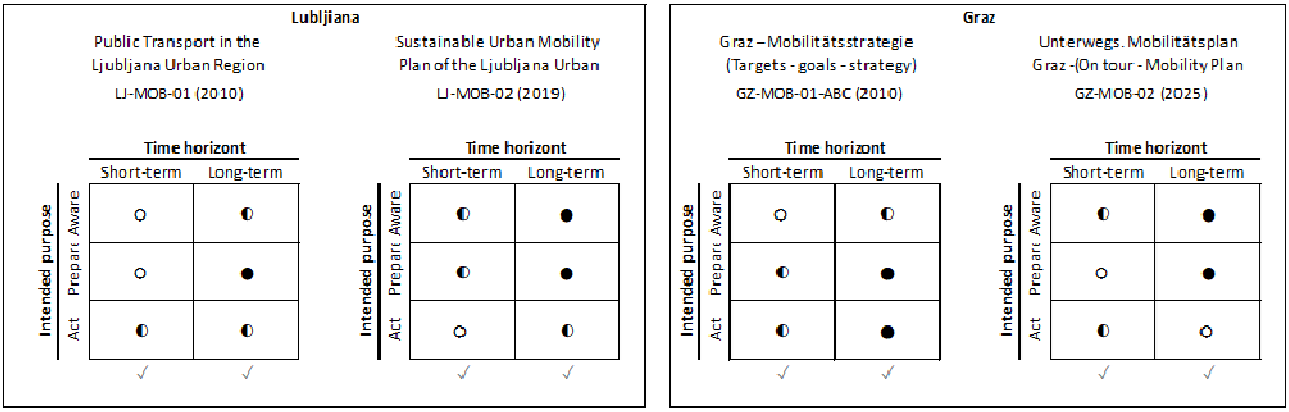

Figure 2 Comparative APA-based matrix of communicative purposes and temporal orientations in urban mobility policy documents for Ljubljana and Graz.

The matrix summarises the results of the qualitative content analysis by mapping the dominance of awareness-raising, preparedness-oriented communication, and action-oriented communication across short-term, long-term, and hybrid time horizons for each analysed policy document.

8 DISCUSSION: PRE-DISASTER PLANNING BEYOND URBAN POLICY

The findings underscore that pre-disaster planning operates as a cross-sectoral logic rather than a localized, city-specific practice. In comparing Graz and Ljubljana, it becomes evident that the efficacy of anticipatory governance depends on whether communication is treated as a technical add-on or a foundational infrastructure. Their instruments function as pre-disaster planning mechanisms, embedding long-term risk anticipation into everyday urban governance rather than treating disasters as exceptional events.

In Graz, the policy documents from the Abteilung für Verkehrsplanung and the city's Klima- und Umweltstrategien demonstrate a high level of technical proficiency in areas such as emissions reduction and digital traffic management. However, the discussion points to a communicative rupture. While the Graz Museum project Becoming Urban: Stadtentwicklung sehen und verstehen attempts to bridge the gap by making urban development visible and understandable, the participation model remains largely consultative. This top-down approach, focused on informing rather than co-creating, often fails to secure the SLO necessary for radical shifts, such as the reallocation of public space for green infrastructure. From a future-oriented perspective, global mobility foresight studies caution against a purely technology-centric transition

pathway. The Arthur D. Little Future of Mobility 5.0 Report stresses that without strong social acceptance, governance legitimacy, and behavioural alignment, digitalisation and electrification may even amplify systemic vulnerabilities by increasing complexity and dependency. This reinforces the paper's core argument that Social Licence to Operate constitutes a critical precondition for resilient and circular urban mobility systems (Little 2025).

Conversely, Ljubljana exemplifies a balanced APA configuration where communication is an enabling infrastructure. The Regionalni razvojni program (Regional Development Programme) and the Strategija prostorskega razvoja (Spatial Development Strategy) of the City of Ljubljana do not treat risk as an isolated hazard but embed it within a broader narrative of urban metabolism. As evidenced in the Ljubljana public transport – Brochure, environmental objectives are strategically framed as quality-of-life issues, fostering trust and collective learning. This integrative approach reinforces the argument that anticipatory governance is most effective when it transcends sector-specific silos.

Furthermore, these parallels are not confined to city governance alone. Comparable anticipatory strategies are observable in broader European research, such as the Interreg Europe Good Practices initiatives, which emphasize that technological infrastructure must be paired with inclusive public discourse to succeed. As highlighted by Graf et al. (2026), the transition from short-term hazard warnings to long-term adaptation requires a fundamental shift in how institutional knowledge is shared with the public.

Ultimately, this discussion reinforces that anticipatory governance, transparent communication, and resource efficiency constitute a broader transformation paradigm. SLO is not a static permit but an ongoing process of social learning and trust-building. These findings suggest that for European cities to move from crisis management to sustainable growth, they must align their technical Action with deeply embedded Awareness and Preparedness strategies. While the results largely support the APA-logic, a Popperian perspective invites us to consider potential falsifications. One might ask: Could a city like Graz achieve sufficient resilience through purely technical and institutional 'Preparedness' (e.g., FLOODPREP) without broad public co-creation? Our findings suggests that while technical 'Action' provides immediate protection, the long-term SLO, essential for the CE, remains the point where purely technical models are most likely to be falsified in practice. The implementation of CE in both cities primarily targets the higher levels of the 9R hierarchy, specifically R1 (Refuse), R2 (Rethink), and R3 (Reduce).

- R1 & R2 : Graz's City of Short Distances model and Ljubljana's access restrictions in the city center effectively encourage citizens to refuse private car use in favor of shared or active mobility.
- R3: Both cities emphasize a reduction in GHG emissions through modal shifts, though personal mobility remains a challenge as car registrations continue to rise in both Austria and Slovenia.
- Gaps in R4-R9: Strategies for higher-order R-measures, such as R4 or R9, are largely absent from urban policy documents as municipal authorities have less leverage over the industrial lifecycles of vehicles.

The analysis reveals a critical disconnect between technical implementation and strategic communication. While both Graz and Ljubljana are successfully operationalizing the higher-order 9R strategies (specifically R2 through modal shifts and R3 through optimized infrastructure) these are often framed as isolated transport projects rather than a systemic transition toward a CE. The analysis of Graz reveals a critical tension: although technical excellence in projects like FLOODPREP and tram expansions provides high-performance Action within the APA framework, it functions as a fragile buffer rather than a sustainable foundation. Without integrated Awareness and co-creation, a communicative rupture emerges that threatens the SLO. Consequently, technical success becomes a systemic risk: It secures immediate hazard mitigation but fails to foster the public trust and behavioral alignment essential for radical CE transformations. As demonstrated by Ljubljana's more integrative approach, true resilience requires that technical measures be harmonized with, or even secondary to, foundational communicative processes.

9 CONCLUSION

This paper has shown that pre-disaster planning can catalyse CE transitions and urban resilience when technological measures are embedded in participatory governance and effective risk communication. By anchoring the comparative analysis in externally documented safety, mobility, and governance risks, the study confirms that pre-disaster planning is not merely a preparatory instrument but a decisive leverage point

for preventing cumulative socio-technical failures in urban systems. Using the APA lens, the study demonstrates that communication is a critical infrastructure of transformation rather than a supplementary activity. The comparative analysis of Graz and Ljubljana highlights the importance of securing an SLO for anticipatory urban policies. For European cities facing increasing climate risks, integrating pre-disaster planning with circular innovation and inclusive communication offers a viable pathway from crisis management to sustainable growth. Future research could test the APA lens across additional urban contexts to further explore its applicability beyond mobility governance.

1 ABSTRACT

Hedgerows provide a variety of essential ecosystem services, acting as a major tool for carbon sequestration to counteract the impacts of climate change. However, determining the amount of carbon stored in hedgerows at a regional level has been challenging. Field surveys can be precise but are time-consuming and labor-intensive, primarily deriving biomass from stem measurements under the canopy. Whereas remote sensing technologies can cover large geographic scales, they often lack the ability to estimate the detailed sub-canopy structure of linear woody features at the local scale. To bridge this gap and calibrate remote sensing models using local field data, a method was developed in this study to estimate hedgerow carbon storage by integrating field survey data with canopy height model (CHM) volume estimation for the Salzlandkreis region in central Germany.

Field sampling was conducted across three study sites, where diameter at breast height (DBH) and height were measured for 4,382 woody plants (diameter > 3.5 cm). Based on this data, forestry form-factor equations were used to calculate individual tree volumes, and above-ground biomass was subsequently estimated based on species-specific wood density. To generalize these localized measurements to the regional scale, volume-to-biomass ratios (VBR) were established. These VBR values were derived from correlations between field-measured biomass and volumes obtained from multi-resolution remote sensing datasets.

By multiplying the converted woody biomass by the canopy volume, the regional estimates of hedgerow above-ground carbon storage ranged from 96,538 to 104,341 Mg C (354,294 –382,931 Mg CO_2e). This corresponds to carbon densities ranging from 57 to 70 Mg C ha^{-1} when normalized to the total hedgerow area in Salzlandkreis.

This research demonstrates that moderate-resolution state datasets, when properly calibrated and validated against field measurements and high-resolution UAV data, can produce regional-scale carbon estimates, which would be impossible through field-only approaches. This study provides a framework for integrating remote sensing data with varying spatial resolutions and field validations, supporting evidence-based regional carbon estimation.

Keywords: Hedgerow carbon storage, Multi-resolution remote sensing, Volume to biomass ratio, Field-remote sensing integration, Regional carbon estimation

2 INTRODUCTION

Hedgerows serve many important functions in terms of providing ecosystem services. These services include carbon sequestration, provision of habitat for biodiversity, protection against soil erosion, regulation of water flow, and natural pest management (Heath et al., 2017; Montgomery et al., 2020). Specifically, their role in carbon sequestration is especially relevant as this is considered an essential tool to mitigate the local and global effects of climate change (Drexler et al., 2021).

Biffi et al. (2023) estimated that 3- to 6-year-old hedgerow stands contained approximately 8.34 Mg C ha^{-1}(megagrams of carbon per hectare), whereas mature stands (>39 years old) contained approximately 40.42 Mg C ha^{-1}. Additionally, studies conducted in Germany indicate much higher totals, with an average biomass carbon stock of approximately 105 ± 11 Mg C ha^{-1}, of which approximately 40% was stored in the root system (Drexler et al., 2023). Drexler et al. (2021) reported that the average amount of aboveground biomass present in hedgerows is about 47 ± 29 Mg C ha^{-1}.

In order to accurately determine the carbon sequestration potential of hedgerows across all regions, in terms of both location and extent, species composition and health condition, extensive assessments over broad areas will need to be conducted (Staley et al., 2023). Traditional on-the-ground survey methods, however,

are labor-intensive, expensive and often impractical or unable to be applied at large scales such as a regional or national level. Given these constraints, there is currently increasing interest in using remotely-sensed data from technologies such as unmanned aerial vehicles (UAVs) equipped with high-resolution cameras (Broughton et al., 2025).

UAV-based photogrammetry can generate centimeter-scale digital surface models (DSMs), Orthomosaics and point-cloud based 3-D models of individual hedgerows enabling precise measurements of their structural properties including height, width and volume. On the other hand, state aerial imagery data generally offers lower spatial resolutions, typically ranging between 20 cm and 1 m per pixel (ground sampling distance), when compared to the near range capabilities of UAVs; however, it enables the creation of large-scale topographic information through digital terrain models (DTMs) and DSMs which can be used to create canopy height models (CHMs) for biomass estimations (Bazzo et al., 2023). By integrating fieldwork data (ground truth data) and high-resolution UAV data for calibration and medium-resolution state datasets for regional coverage, a scalable framework for hedgerow carbon storage estimation becomes achievable.

This study has two objectives: 1) to provide a remote sensing methodology to extend those estimates to larger areas by using canopy height model (CHM), and 2) to provide an estimation of the carbon stored in hedgerows across Salzlandkreis, Saxony-Anhalt, Germany. Through this approach, this study demonstrates the potential of combining high accuracy field sampling with broad area remote sensing analyses, which could provide the policy relevant information concerning the ecosystem services carbon storage estimation provided by hedgerows, supporting data-driven climate action and landscape planning.

3 MATERIALS AND METHODS

The multi-stage methods applied in this study comprised two distinct components: field surveys using multi-resolution remote sensing and biomass estimation; and remote sensing data acquisition and processing.

(1) Field Surveys and Biomass Calculation: In order to determine hedgerow characteristics (type of tree, diameter, height, and width) field surveys were conducted at three sample sites in Salzlandkreis. These characteristics were then used to determine carbon storage.

(2) Remote Sensing Data for Volume Calculation: Multi-resolution Remote Sensing data were collected, including digital surface model data obtained from a drone system (6 cm / pixel resolution), high resolution aerial data that are part of the iDSM (image-based DSM; 20cm / pixel resolution), and medium resolution aerial data that are part of the DSM (1 m / pixel resolution). From the DSMs the volumes of hedgerows were calculated.

(3) Correlation Coefficient: In this step, a correlation coefficient was calculated to quantify the relationship between the field-determined biomass (Step 1) and the Remote Sensing-determined hedgerow volumes (Step 2).

(4) Regional Scale Quantification : A CHM was created from the DSM and iDSM data to calculate the volume of all hedgerows in Salzlandkreis. The total carbon storage for the entire region was then calculated by multiplying the total volume of hedgerows by the correlation coefficient established in Step 3.

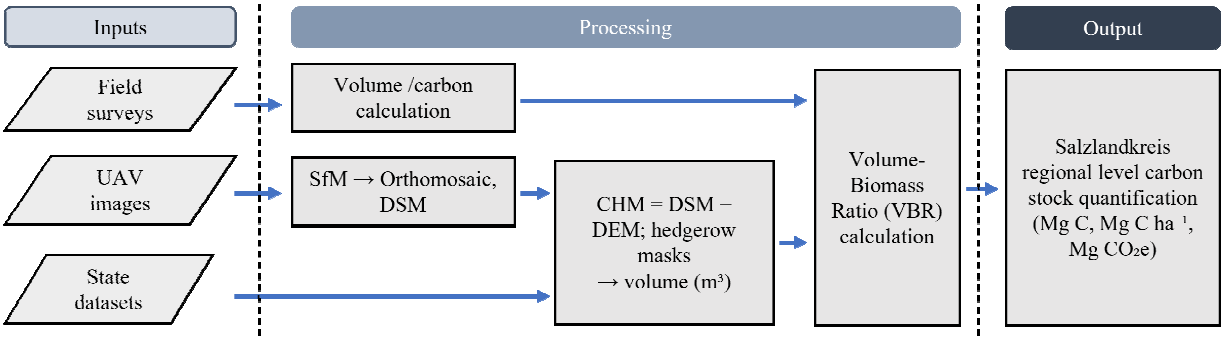

Fig. 1: Research workflow.

3.1 Study Area

The Salzlandkreis (Salzland district; total area: 1,427 km²) is located in central Saxony-Anhalt, Germany, and is characterized by an agricultural landscape typical of the North German Lowlands, representing

intensive agricultural landscapes in this region. In this study, researchers initially identified six locations with a high density of hedgerows within the Salzlandkreis through the application of ArcGIS Pro's Density analysis tools. Subsequently, through site visits, researchers ultimately selected three sample research area (1.5km x 1.5km/each) from those six candidate study sites (see figure 2 and 3).

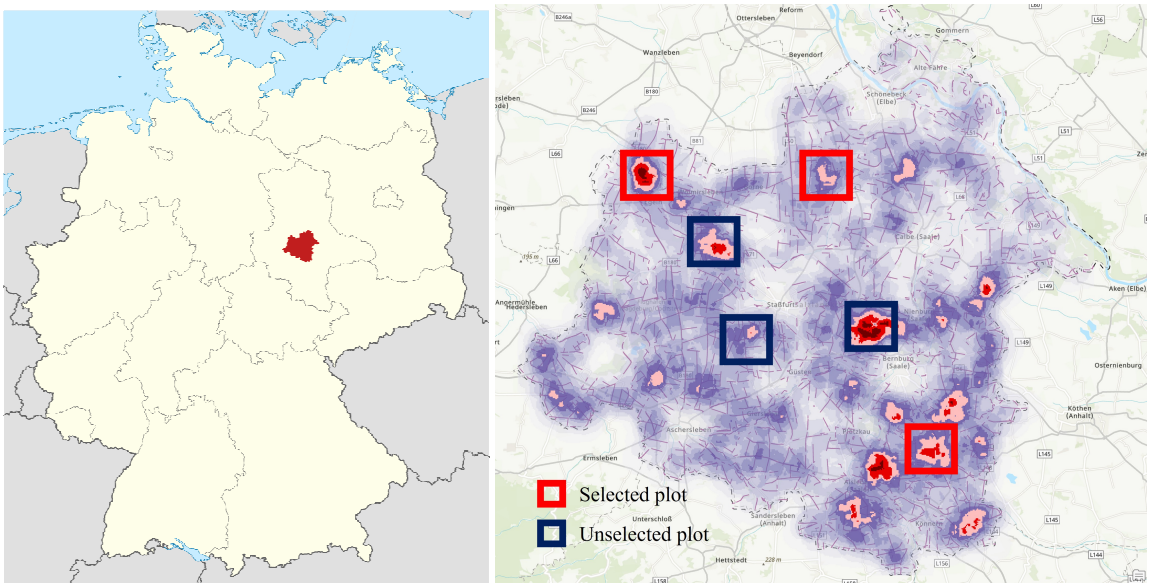

Fig. 2: Location of Salzlandkreis in Germany (left) and three selected research plots (red) in Salzlandkreis (right).

Fig. 3: The three selected research plots (located in Westeregeln, Unseburg, and Peissen from the top to bottom).

3.2 Methods

3.2.1 Field Survey and Biomass Measurement

At three research sites, tree-species-specific values for the calculation of CO_2 potential and standing biomass were recorded for 4,382 woody plants. For this, all woody plants (diameter > 3.5 cm) were measured using Nikon Forestry Pro rangefinder which is a tree height measuring device ranging of 7.5 to 1600 m and a

diameter tape measure. Relevant parameters such as tree species, tree height (h), diameter at breast height (DBH), and nature conservation-relevant characteristics were recorded in a mapping sheet. The calculations of the comparison values for carbon storage and gross carbon were carried out with the software I-Tree Eco (USDA forest service software suite), taking into account the characteristics measured in the field for each woody plant. The calculation of the tree volume was carried out using a form-factor-based volume estimation formula as applied in forest inventory. Only the stem volume without branches and roots is considered here (see Figure 4). The form factor (f) describes the deviation of the stem shape of a tree from a perfect cylinder. Depending on location and tree species, the form factor lies between 0.45–0.52. For the calculations, this was uniformly set to 0.5. The individual tree volume was calculated as follows:

$$V\,[m^3] = \left(\frac{DBH\,[cm]}{200}\right)^2 \cdot \pi \cdot h\,[m] \cdot f$$

where:

V = individual tree volume without branches and roots

DBH = diameter at breast height (1.3 m above ground)

h = tree height

f = form factor (species-dependent correction value)

For the calculation of biomass B [kg], the individual tree volume V [m³] is multiplied by the species-specific basic density WD [kg/m³] for each tree species (see Table 1), according to the following formula:

$$B\,[kg] = V\,[m^3] \cdot WD\,[kg/m^3]$$

where:

B = biomass

V = individual tree volume

WD = wood density

Species	Wood Density (kg/m³) at 12-15% Moisture Content
Populus x canadensis	410
Fraxinus excelsior	650
Tilia platyphyllos	490
Acer platanoides	590

Table 1: Examples of average raw densities of selected wood species (Source: Grabner, 2017; Steuer, 1985; Kollmann, 1982).

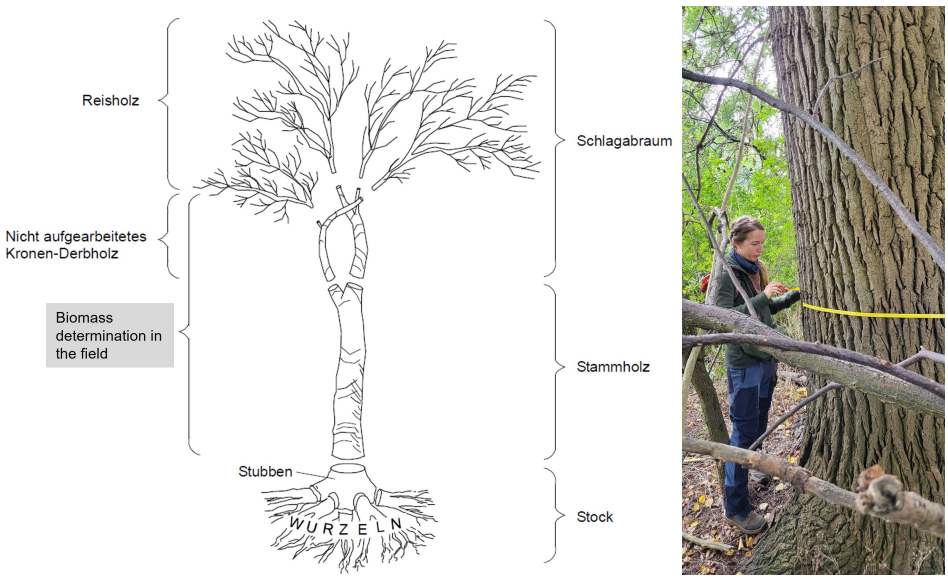

Fig. 4: Field survey and biomass measurement (the figure on the left source: Englert, H et al., 2009).

3.2.2 Remote Sensing Data Acquisition and Processing

High-resolution aerial imagery was acquired at three research sites using a DJI Mavic 3 Enterprise RTK (Real Time Kinematic) drone with a 20M pixels RGB sensor. Flights were conducted at 50 m above ground level (AGL) from multiple viewing angles with 75% forward and 75% side overlap to support 3D reconstruction. Structure-from-Motion (SfM) photogrammetry was applied to generate a 6 cm/pixel resolution digital surface model (DSM) and a 3 cm/pixel resolution orthomosaic. These products enabled precise measurement of hedgerow structural attributes. Official state aerial datasets were used: DSM1 (1 m resolution) and iDSM20 (0.2 m resolution), provided by the State Office for Surveying and Geoinformation of Saxony-Anhalt (Landesamt für Vermessung und Geoinformation Sachsen-Anhalt, LVermGeo). The DSM1 was provided as GeoTIFF to be used directly and the iDSM20 was provided as compressed point clouds (LAZ). Those were converted to LAS format. They were then rasterized to GeoTIFF for analysis. These multi-resolution datasets (DSM1, iDSM) were jointly used to derive hedgerow volumes at scale, with UAV dataset calibrating and validating volume–biomass relationships for regional application.

3.2.3 Calculation of Volume-Biomass Ratio (VBR)

The use of line features provided by the State and manually added in the creation of hedgerow mapping areas that were extended with 20 m radius buffer in order to identify the analysis zones. The canopy height model (CHM) was made through the CHM = DSM – DTM equation (see Fig. 5). The threshold was increased from 1.2 meters to 2.2 meters because of adjacent tall crop fields (such as sunflower fields) that are unrelated to hedgerow vegetation. Hedgerow volumes were obtained by calculating the canopy height over pixels multiplied by pixel area, using zonal statistics in ArcGIS Pro Raster Calculator according to:

$$V_i = \sum_{j=1}^{n} (h_{ij} \times A_{\text{pixel}})$$

where:

V_i = total canopy volume of hedgerow i in Salzlandkreis (m³)

n = total number of pixels within the buffer zone where CHM ≥ 2.2 m

j=1 = no sub-divisions (the object consists of one element)

h_{ij} = canopy height at pixel (i, j) above 2.2 m threshold (m)

A_{pixel} = pixel area (1 m² for DSM1; 0.04 m² for iDSM20)

Biomass was calculated by multiplying the volume of each zone by the Volume-Biomass Ratios that derived from the three-test site analysis for each data.

Fig. 5: Canopy height model (CHM) at Westregeln study area using DSM1, iDSM20 and UAV data sets (from left). DSM1, DSM20, DTM source: State Office for Surveying and Geoinformation of Saxony-Anhalt (LVermGeo).

4 RESULTS

Using the methods discussed previously, conversion factors for converting remote sensing volume to biomass at a number of resolutions were developed. The conversion factors are summarized in Table 2 as both the volume-biomass ratio (VBR), and as biomass density (kg m^{-3}). Results indicated that the high-resolution UAV data set had the lowest Volume Biomass Ratio (0.6) and correspondingly the highest biomass density (1.66 kg m^{-3}).

	DSM1	iDSM20	UAV
Volume-Biomasse Ratio (VBR)	0.97	0.78	0.60
Woody Biomass (kg/m³) in Field Vegetation	1.03 kg m^{-3}	1.29 kg m^{-3}	1.66 kg m^{-3}

Table 2: Average values of the volume-biomass ratio (VBR) for DSM1 (1 m spatial resolution), iDSM20 (0.2 m spatial resolution), and UAV (0.06 m spatial resolution), and mean value, woody biomass in kg per 1 m³ of field vegetation.

Table 3 presents total aboveground hedgerow carbon stock estimates for the 1,427 km² Salzlandkreis area using both DSM1 (1m spatial resolution) and iDSM20 (0.2 m spatial resolution). Aboveground total carbon stock ranges were 96,538 – 104,341 Mg C (equivalent to 354,294 – 382,931 Mg CO_2e).

Category	DSM1 (1 m)	iDSM20 (0.2 m)	Unit
Salzlandkreis Area	1,427 km² = 142,700 ha		–
Hedgerow Area	1,690	1,484	ha
Total Hedgerow Volume (≥ 2.2 m)	187,452,364	161,768,729	m³
Total Hedgerow Biomass	193,076	208,682	Mg dry weight
Total Hedgerow Carbon Storage	96,538	104,341	Mg C
Total Carbon Sequestration Potential	354,294	382,931	Mg CO_2e
Carbon Density	57	70	Mg C ha^{-1}
Total Carbon Sequestration Density	210	258	Mg CO_2e ha^{-1}

Table 3: Total Salzlandkreis aboveground hedgerow carbon stock estimates.

On this basis, the carbon storage capacity (and corresponding CO_2 equivalents) of specific hedgerow structures can be determined and evaluated at specific areas. Beyond carbon, integrating these results with other ecosystem service metrics enables a holistic evaluation of individual structure for planning purposes. The derived volumetric estimates also provide a baseline for exploring hedgerow biomass as a potential resource; however, determining sustainable extraction levels would require additional research on growth rates, species composition, and ecosystem service impacts. Consequently, these carbon assessments would provide a foundation for enhancing nature conservation planning. In combination with agroforestry systems, sustainable regional utilization concepts for biomass can be developed and implemented.

5 CONCLUSION AND OUTLOOK

This research demonstrated a feasible and applicable approach for estimating hedgerow carbon content in the Salzlandkreis region using DSM with resolutions of 1 m and iDSM 20 cm, in combination with empirical biomass-volume relationships for calibrating biomass estimates from aerial data including UAV high resolution data.

Utilizing this process, estimated regional above ground carbon stock density for mapped hedgerows were found to be in the range of 96,538 – 104,341 Mg C (equivalent to 354,294 –382,931 Mg CO_2e). This corresponds to carbon densities of 57 to 70 Mg C ha^{-1} when normalized to the total hedgerow area in Salzlandkreis, representing a difference of approximately 23% deviation between the two difference types of data: iDSM20 and DSM1.

There are several limitations to the findings of the current study. For example, the estimates represent only the above-ground woody biomass of the hedgerows; therefore, the below-ground biomass and soil organic carbon (substantial components of mature central European hedgerows) have not been accounted for in the estimates. Additionally, the CHM threshold may need to be site-specifically calibrated based on other land

types and regions. Furthermore, the age and management of the hedgerows, which would both affect biomass and carbon stock estimates were not considered as part of the estimation using the remote sensing method. Finally, this study reveals how data resolution affects results: low-resolution data may smooth canopy features, which can lead to vegetation volume underestimation. Conversely, fine-scale data, including UAV data, can capture temporal seasonal changes, which would affect the regional aggregation of estimates.

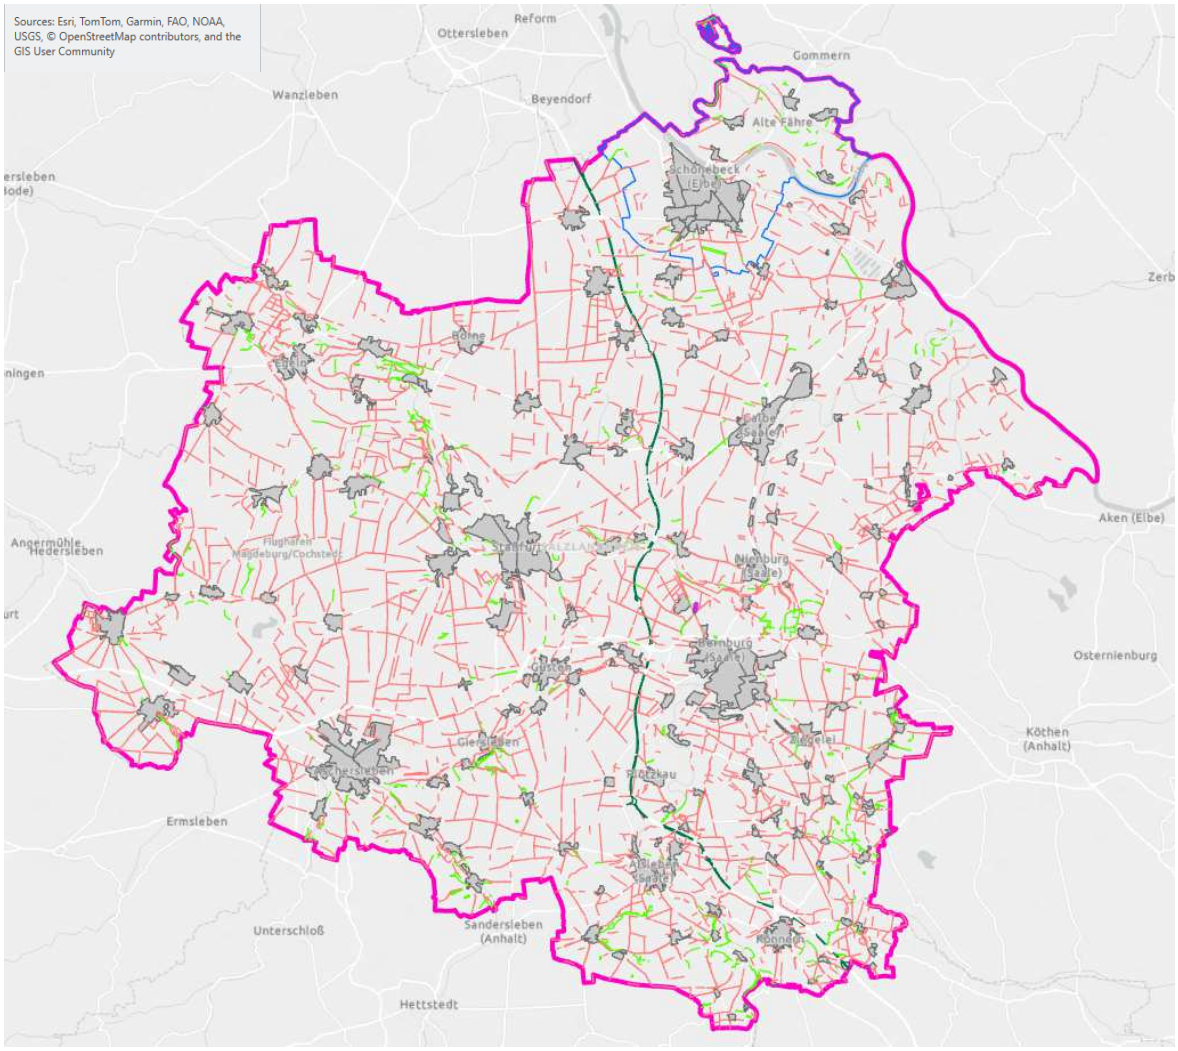

Fig. 6: Hedgerows in Salzlandkreis, Map base: ESRI. Data sources: basic-DLM, manual digitizing and administrative boundaries.

Future research should expand upon the current study by incorporating additional carbon pools (such as below-ground biomass and soils) into the framework to estimate the total carbon content of the hedgerows. The results of this study could also have a substantial impact on the spatial management of resources by providing high-resolution, decision-based information for identifying valuable regions for conservation purposes, allocating optimal use of land for agricultural and urban development, and creating hedgerow-based networks to assist with climate adaptation in rural areas. Additionally, future studies should focus on analyzing the temporal changes of these carbon stocks over time and comparing data across different vegetation zones and countries to establish standardized global baselines.

The spatial data generated in this study provide a foundation for evaluating a wide range of ecosystem services at the regional level, such as: hedgerow health mapping; assessing agroforestry potential; quantifying sustainable harvestable biomass; and creating multi-year carbon balances. Co-development of management and utilization concepts with agricultural and municipal stakeholders will facilitate the conversion of the hedgerow carbon stock estimates into practical mitigation strategies and regional bio-economy opportunities.

6 ACKNOWLEDGEMENTS

This research is a part of AgroPot project and funded by the European Union and the State of Saxony-Anhalt.

1 ABSTRACT

Despite significant progress in urban planning, smart city initiatives, and city branding, many cities still struggle to translate strategic goals into a sustainably experienced urban quality of life. Early work in urban sociology, environmental psychology, and governance research pointed to shortcomings regarding social cohesion, autonomy, trust, and integrated sustainability. Current research (2023–2026) confirms that these aspects remain inadequately addressed despite technological innovations, data-driven management approaches, and institutional reforms. This article revisits this persistent issue and conceptualizes cities as complex service and value creation systems. It systematizes four key areas of tension in urban development: efficiency versus experiential quality, governance versus autonomy, technology versus trust, and sustainability as an external service versus integrated urban logic and provides an integrated framework.

Keywords: Smart City, Urban Experience, Governance, Urban Planning, City Branding

2 THE LIMITS OF FUNCTIONAL URBAN EXCELLENCE

Cities today face the challenge of reconciling increasing demands for efficiency, sustainability, and competitiveness with their residents' expectations of quality of life and identification with their community. For several decades, research in urban sociology, environmental psychology, and governance has indicated that functional optimization and technological performance alone are insufficient to create vibrant and attractive cities in the long term (Jacobs, 1961; Lynch, 1960; Arnstein, 1969). Nevertheless, smart city strategies, data-driven governance approaches, and city branding concepts continue to shape the urban agenda. These instruments have undoubtedly contributed to efficiency gains and improved governance. However, recent reviews and case studies show that key aspects such as social connectedness, perceived agency, trust in institutions, and an integrated sustainability logic continue to be insufficiently addressed (Hollands, 2008; OECD, 2023; Rasoulzadeh Aghdam et al., 2025).

This discrepancy between functional performance and experienced urban reality points to a central question of this article: Why don't functionally optimized cities automatically become places where people like to live, get involved, and invest long-term? Hence, the described shortcomings are not new findings, but rather persistent problems that, despite years of theoretical grounding and numerous practical initiatives, have not yet been systematically translated into integrated implementation models. This article therefore aims to conceptually address this integration gap.

2.1 Research gap and knowledge contribution

Smart city research has expanded considerably in recent years, addressing key topics such as digitalization, efficiency improvements, and data-driven management of urban systems (Hollands, 2008; Datta, 2015). In parallel, city branding literature emphasizes the importance of identity, narratives, and the coherence of diverse stakeholder groups for the long-term attractiveness of cities (Kavaratzis & Hatch, 2013; Kaufmann and Durst, 2008).

Despite these conceptual advancements, recent reviews and empirical studies show that key challenges of urban development persist and are currently addressed only inadequately in an integrated manner (OECD, 2023; Rasoulzadeh Aghdam et al., 2025). This identified integration gap also provides a clear starting point for further academic research, particularly regarding conceptual modeling, empirical validation, and comparative analyses of urban implementation models. Three key shortcomings can be identified that mark a persistent research gap:

2.1.1 Fragmentation of Analysis Levels

Efficiency, participation, technology, and sustainability are often viewed as separate fields of action, even though they are systemically intertwined in everyday urban life. This sectoral perspective was identified

early on as a key weakness of urban governance (Bulkeley & Betsill, 2005). Current studies confirm that fragmented responsibilities, siloed programs, and a lack of horizontal integration continue to limit the effectiveness of integrated urban development strategies (Yu et al., 2023; European Parliament, 2025).

2.1.2 Lack of an Outcome-Oriented Perspective

Urban performance is still predominantly measured using functional, technical, and process-related indicators, while perceived quality of life, trust, identification, and a sense of responsibility are only marginally considered. This problem was already addressed in early work on perception and environmental psychology (Lynch, 1960; Evans & McCoy, 1998).

Current policy-oriented analyses confirm that outcome-oriented measurement and management approaches are still insufficiently established in urban development (OECD, 2023; Osei-Kyei & Ampratwum, 2025).

2.1.3 Lack of Integrated Implementation Models

While numerous strategic visions, target systems, and pilot projects for urban development exist, consistent models that systematically translate these objectives into everyday urban experiences are lacking. This gap has already been described in the context of New Public Governance (Osborne, 2006).

More recent studies show that living lab approaches and co-creative formats often remain project-based and are not sustainably embedded in overarching governance and value creation logics (Almeida et al., 2025; Sofronievska et al., 2025).

This article addresses these shortcomings and the resulting integration gap by conceptualizing cities as complex service and value creation systems. Building on this, four key areas of tension in urban development are identified, in which the shortcomings manifest themselves in the interplay of efficiency, governance, technology, and sustainability. In addition, an integrated implementation framework is proposed that combines outcome-oriented logic with living lab approaches and provides a starting point for further academic research as well as for empirical and comparative analyses of urban development approaches.

3 THEORETICAL FUNDAMENTS

3.1 Human experience, connectedness and scope for action

Neuroscience and motivational psychology research show that human well-being, learning ability, and engagement are significantly influenced by two factors: social connectedness and perceived self-efficacy or autonomy (Deci & Ryan, 2000; Hüther, 2015). When these elements are lacking, a demonstrable increase in the risk of withdrawal, aggression, and social disintegration (Evans & McCoy, 1998) occurs.

Current interdisciplinary studies confirm these correlations for the urban context as well and show that perceived social isolation, lack of influence, and lack of identification with one's living environment have negative effects on trust, sense of security, and social engagement (OECD, 2023; Rasoulzadeh Aghdam et al., 2025). Applied to cities, this means that urban design and administrative interaction should not only be functional, but rather relationship- and experience-oriented. Classic works in urban sociology point out that a lack of social integration, poor quality of life, and anonymous spaces can promote perceptions of insecurity and contribute to social fragmentation (Jacobs, 1961; Newman, 1972). Recent studies confirm that participatory design approaches, transparent administrative processes, and tangible participation sustainably strengthen perceptions of safety, belonging, and responsibility (Gjørtzvang et al., 2025).

3.2 The city as a service and value creation system

Service-dominant logic understands value creation not as the result of isolated service provision, but as the result of interaction and co-creation between actors within a system (Vargo & Lusch, 2004). Applied to cities, this means that urban quality is not created solely through planning, regulation, or infrastructure, but through the interaction of diverse stakeholders in everyday urban life. This perspective is supported by approaches of New Public Governance, which regard public organizations not primarily as rule-setters, but as coordinators of complex service ecosystems (Osborne, 2006). Current governance research confirms that cities are increasingly acting as platforms where public, private, and civil society actors jointly create value for different stakeholders (Almulhim, 2025; OECD, 2023). The key urban stakeholders include in particular:

- Citizens,

- Local businesses and employers,
- Visitors and commuters,
- Employees of the administration and municipal enterprises,
- Institutional and private partners.

Against this backdrop, results-oriented urban development requires clarity about which services are to be provided to which stakeholder groups and with what intended effect. Recent studies show that a lack of clarity of objectives and insufficient coordination between stakeholder groups can significantly impair the effectiveness of urban strategies (Shao et al., 2025).

4 FOUR KEY AREAS OF TENSION IN URBAN DEVELOPMENT

4.1 Efficiency versus experience quality

Increasing efficiency has long been considered a central goal of urban planning and administration. Smart city initiatives, digital administrative processes, and data-driven control systems primarily aim to optimize processes, use resources efficiently, and provide services in a scalable manner (Hollands, 2008; Datta, 2015). This perspective has undoubtedly led to measurable improvements in areas such as infrastructure management, mobility, and administrative processes. Additionally, studies on service experience show that perceived quality does not depend solely on functional performance but is significantly shaped by comprehensibility, relationship-building, and personal accessibility (Berry & Carbone, 2007). Early urban sociological studies already indicated that efficiency without a conscious design of interaction can lead to distance, loss of trust, and declining acceptance (Lynch, 1960; Jacobs, 1961).

Current research confirms these tensions and shows that digital solutions without accompanying consideration of user experience, quality of stay and social inclusion often cause acceptance problems and weaken trust in public institutions (OECD, 2023; Rasoulzadeh Aghdam et al., 2025).

4.2 Control versus scope for action

Urban development is largely shaped by governance logics. Planning, regulation, standards, and controlling form the basis for the reliability, legal certainty, and coordination of complex urban systems. Smart city approaches, in particular, increasingly rely on data-driven decision support and centralized control mechanisms to design urban processes efficiently and consistently (Datta, 2015; OECD, 2023). However, early work on participation already indicates that formal participation processes alone are insufficient to enable genuine co-creation and the assumption of responsibility. Arnstein (1969) demonstrated that many participation formats are largely symbolic and offer limited opportunities for real influence. Without a perceived sense of agency, identification with, engagement with, and trust in institutional actors decline.

Recent studies confirm these findings and show that while technology-based participation tools increase transparency and reach, they are often not linked to genuine decision-making authority or verifiable feedback (Gjørtzvang et al., 2025). In such situations, a discrepancy arises between formal participation and perceived effectiveness, which can lead to frustration, withdrawal, or political disengagement. At the same time, newer governance approaches indicate that cities become more resilient and effective where spaces for shaping the future are deliberately created and responsibility is shared. Co-creative processes, participatory decision-making formats, and transparent negotiation mechanisms not only strengthen the quality of decisions but also the sense of responsibility among the participating actors (OECD, 2023; Rasoulzadeh Aghdam et al., 2025).

4.3 Technology versus Trust

Digital technologies form a central basis for contemporary urban development. Sensors, data platforms, AI-supported analyses, and networked infrastructures promise more efficient processes, better decision-making, and new forms of urban services. Accordingly, technological solutions play a key role in smart city strategies (Datta, 2015; OECD, 2023). At the same time, social science and information systems studies have long shown that technological capability alone does not guarantee acceptance. Trust is not created by technology itself, but by transparency, traceability, and fair governance structures. If these prerequisites are lacking, digital systems are perceived as opaque, controlling, or externally controlled (Gefen et al., 2003).

Recent studies confirm that data-driven applications in urban areas in particular raise sensitive questions about data protection, algorithmic decision-making logic, and institutional responsibility. If these questions are not addressed openly, this can undermine trust in public institutions and have a lasting negative impact on the use of digital services (OECD, 2023; Almulhim, 2025). At the same time, studies show that transparent data practices, clear responsibilities, and understandable communication can significantly increase the acceptance of technological solutions (Rasoulzadeh Aghdam et al., 2025).

Against this backdrop, it becomes clear that technology and trust are in a state of mutual tension. Digital innovations only have an impact when they are embedded in trust-building governance structures and remain comprehensible to different stakeholder groups.

4.4 Sustainability: External services versus integrated urban logic

Sustainability has become a central guiding principle of urban development. Climate protection, resource efficiency, circular economy, and social sustainability shape strategies, programs, and funding logic at the municipal, national, and international levels. In practice, however, sustainability is often treated as a separate field of activity and implemented through specialized programs, external service providers, or project-related initiatives (Elkington, 1997; Bulkeley & Betsill, 2005). This outsourcing of sustainability-related tasks often leads to ecological and social goals being perceived as additional cost factors, existing alongside performance and efficiency logics. Current studies show that while sustainability measures can achieve short-term effects under such conditions, they lose their impact in the long term if they are not integrated into the core logic of urban value creation (OECD, 2023; Shao et al., 2025).

Recent governance and urban economics research indicates that sustainability is effective where it is understood as an integral component of urban service and value creation systems. Approaches to the urban circular economy, local energy and resource systems, and community-based service models demonstrate that ecological objectives are compatible with economic attractiveness when value creation is locally anchored and considered systemically (Almulhim, 2025; European Environment Agency, 2024).

Against this backdrop, a tension emerges between sustainability as an externally purchased service and sustainability as an integrated component of urban logic. Cities that understand sustainability not as an additional task, but as a structural principle of their service, investment, and governance models, unlock new potential for economic resilience, innovation, and long-term attractiveness as a business location. The four key areas of tension in urban development are summarized in Figure 1. The figure categorizes the four key areas of tension in urban development identified in this article. It demonstrates that urban quality and long-term attractiveness do not arise from optimizing individual dimensions, but rather from consciously balancing equally important, interwoven areas of tension at the organizational, governance-related, socio-technical, and structural-economic levels. Figure 2 illustrates the integrated implementation framework, which will be explained in more detail in the next chapter.

Figure 1: Key areas of tension in urban development: an overview.

The diagram illustrates the proposed integrated implementation framework, which combines outcome logic with living lab principles. The framework serves to operationalize the four identified areas of tension in real urban contexts by linking co-creation, iterative learning processes, and transparent governance with clear outcome dimensions.

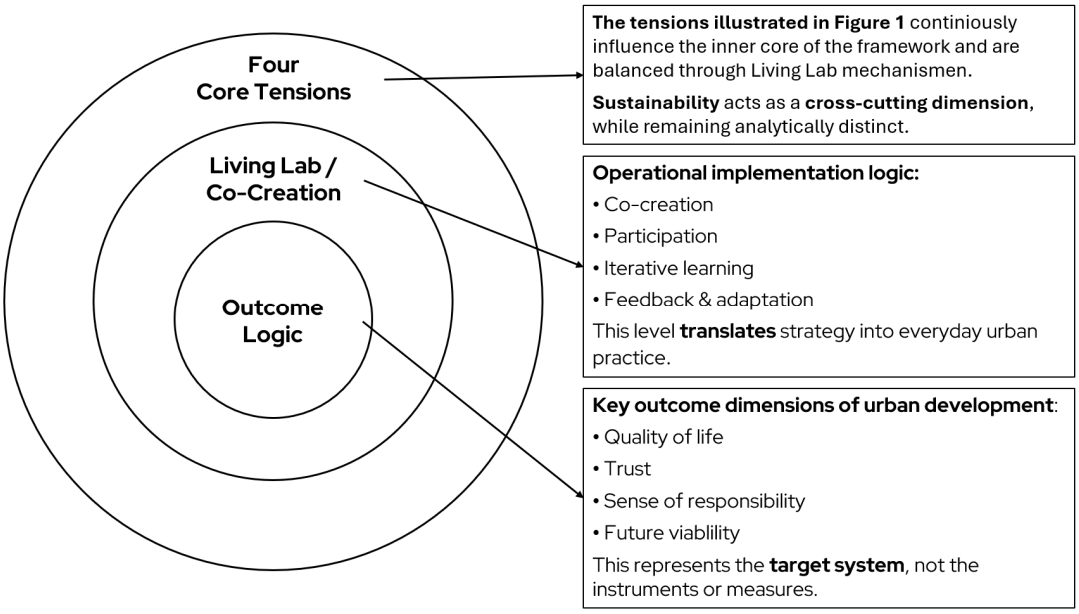

Figure 2: Integrated implementation framework for operationalizing urban tension areas

5 INTEGRATIVE IMPLEMENTATION FRAMEWORK: RESULTS LOGIC AND LIVING LABS

The implementation framework proposed here is based on a results-oriented perspective that evaluates urban development not primarily in terms of the instruments or measures used, but in terms of their intended and perceived effects. The focus is in particular on perceived quality of life, trust in institutions, sense of responsibility, and long-term identification with the urban environment. These outcome measures form the connecting reference point for the planning, implementation, and evaluation of urban development processes.

To operationalize this outcome logic, living lab approaches are a suitable option, and are discussed in current urban research as an effective bridge between strategy and everyday practice. Living labs make it possible to test new solutions under real-world conditions together with diverse stakeholders, to develop them iteratively, and to evaluate them systematically (Schuurman, 2016; OECD, 2023). They create a protected space in which efficiency, design options, technology use, and sustainability are not negotiated abstractly, but rather experienced and reflected upon concretely. Efficiency is linked to experiential quality, governance is connected to real design options, technological innovation is embedded in trust-building governance structures, and sustainability is understood as an integral component of urban value creation.

6 CONCLUSION AND OUTLOOK

This paper has shown that key challenges of urban development have been known for decades, yet persist despite technological advances, data-driven governance approaches, and diverse sustainability initiatives. The analysis clarifies that this persistence is less due to a lack of theoretical knowledge than to a failure to integrate this knowledge into consistent, results-oriented implementation logics. By conceptualizing cities as service and value creation systems and identifying four key areas of tension, an analytical framework is provided that systematically integrates functional, social, technological, and sustainability-related perspectives. The proposed integrated implementation framework connects this analysis with a results-oriented logic and living lab approaches, thus opening a path to translating strategic objectives into tangible urban practice. This article offers conceptual added value to smart city, governance, and city branding research by explicitly highlighting a hitherto insufficiently addressed integration gap and proposing a structured approach to addressing it. At the same time, it demonstrates that urban performance cannot be measured solely by efficiency or technological maturity, but is essentially manifested in experienced quality of life, trust, and long-term identification. Several starting points emerge for future research. These include the empirical validation of the identified areas of tension in different urban contexts, comparative analyses of outcome-oriented management approaches, and the further development of measurement and evaluation instruments that systematically capture experienced urban impacts. Furthermore, living lab formats offer a promising field for transdisciplinary research in which theoretical concepts can be further developed and tested under real-world conditions.

Gender-Inclusive School Architecture: An International Comparison

Carla Schwaderer

(DI Carla Schwaderer MA, TU Wien, Karlsplatz 13, 1040 Wien, carla.schwaderer@tuwien.ac.at)

1 ABSTRACT

Gender-inclusive school architecture seeks to design educational environments in which all genders – girls, boys, non-binary, trans and intersex people – are equally considered, feel safe and addressed, and have access to the same spatial opportunities. Drawing on a decolonial, queer and intersectional feminist perspective, this paper analyzes how architectural decisions and spatial configurations can either reinforce or challenge social power relations. Intersectionality provides the analytical lens to understand how discrimination based on gender, body norms, origin or social position operates simultaneously and interactively. This framework highlights the ongoing influence of historical, colonial and normative structures that continue to shape school architecture.

The study is grounded in a broad dataset collected between 2021 and 2024. Through qualitative methods such as interviews, drawings, questionnaires and participatory workshops, more than 460 children and adolescents aged 6 to 16 were included across school and extracurricular settings. This mixed-methods approach captures a wide range of spatial needs and experiences. From the analysis, four core dimensions of gender planning in school construction emerged: (1) safety, security and well-being; (2) movement spaces; (3) retreat spaces; and (4) toilets. These dimensions emphasize the tight interrelation between spatial design, participation, visibility, privacy and psychological safety.

A European comparison underscores Vienna's pioneering role in gender-inclusive planning. Building upon Carla Schwaderer's dissertation „Gender Planning in School Architecture", a comprehensive guide for gender-inclusive school architecture has been developed. Its principles are reflected in several Austrian best-practice projects, including the Konrad-Lorenz-Gymnasium in Gänserndorf, the NMS Mittelweiherburg in Hard and the Pestalozzi Education Centre in Leoben. Complementary examples from other European contexts broaden the analytical scope: Learning Landscapes in Basel, the Reggio School in Madrid and the TORNHØJ HALL in Aalborg Øst in Denmark.

Across Europe, cities and countries pursue different strategies, yet the comparative analysis reveals shared priorities: participatory planning processes, adaptable spatial structures, and safe, inclusive sanitary, movement and retreat areas. These elements form the basis of successful gender-inclusive school construction. The study concludes by reflecting on what can be learned from international examples for future European planning practices and how decolonial and queer-feminist perspectives can be embedded more systematically in architectural practice and educational policy.

Keywords: gender , inclusion, school architecture, intersectionality, planning

2 GENDER-INCLUSIVE SCHOOL ARCHITECTURE AS AN INTERDISCIPLINARY FIELD OF RESEARCH

2.1 Theoretical foundations and social relevance

Girls and young women, as well as other groups affected by discrimination (e.g., based on class, origin, etc.), have long been denied unrestricted access to education in Europe and have been systematically excluded at the institutional level (Jakobi, 2013; Kleinau & Opitz, 1996). Although this has improved in recent years, it is still noticeable in school buildings. Like all buildings, school buildings are mainly designed by male planners according to male needs, which means, among other things, that they are geared towards the "male" body (Criado-Perez, 2020), which differs from the average size, mass, and weight, and has different requirements, for example, in terms of room temperature (Chang & Kajackaite, 2019). The following section will outline the theoretical foundations of gender planning and its social relevance.

2.1.1 Gender, space, and education: A feminist-intersectional perspective

Gender-inclusive school construction refers to a planning and design-oriented approach that aims to design school buildings and spaces in such a way that students of all gender identities feel safe, respected, and included.

This approach takes into account not only binary gender categories, but also non-binary and other gender identities (such as inter, trans, etc.). The relevance of this approach stems from the central role that educational institutions play in the everyday lives of children and young people: Since they spend a significant amount of their time in schools, school spaces function not only as places of learning, but also as social living spaces with a significant influence on individual development processes (Friedrich, 2008, p. 24; Seydel, 2023, p. 19).

The topic of gender-inclusive school architecture is located at the intersection of gender studies, architecture, and education. While gender studies analyze social gender relations, power structures, and mechanisms of discrimination (Butler, 2025; Ahmed, 2024), architecture deals with the material and spatial organization and design of school environments (Kühn & ÖISS, 2025; Rieger-Ladich & Ricken, 2009, p. 197). Pedagogy, in turn, examines educational processes, social interactions, and the institutional framework of learning (Rosenberger 2023). Only through the intertwining of these three disciplines does it become apparent how spatial design, pedagogical practice, and gender attributions influence each other.

Schools are central social institutions in which all children and young people, regardless of their gender, should have access to safety, belonging, and support. Gender-inclusive architecture can help reduce experiences of discrimination, conflict, and insecurity, thereby supporting a supportive school climate. Furthermore, it enables more equitable learning and development opportunities by challenging stereotypical attributions of use, removing spatial barriers, strengthening user privacy, and designing flexible usage structures (Schwaderer, 2025b).

Gender-inclusive school architecture aims to create spatial conditions that ensure safety, well-being, and equal participation for all students. Key criteria here are accessibility, privacy protection, and multifunctional and adaptable spatial concepts. In this context, the term gender is understood as social gender and encompasses socially constructed role models, expectations, behaviors, and normative attributions associated with different gender identities. This is to be distinguished from biological sex, which refers to physical and physiological characteristics used to classify individuals at birth. Feminist spatial theories analyze the extent to which social norms and power relations structure the perception, appropriation, and use of spaces without using biological differences as an explanatory starting point.

The examination of gender-inclusive school architecture is approached from a decolonial, queer, and intersectional feminist perspective (Ahmed, 2024; Crenshaw, 1989). Decolonial approaches problematize historically grown power and knowledge orders that have emerged from colonial contexts and advocate for a pluralization of knowledge beyond Eurocentric norms (Roig, 2024). Intersectional perspectives analyze the interaction of various axes of discrimination – such as gender, origin, social class, disability, or sexual orientation – and reveal how they reinforce each other (hooks, 2000 [1984]; Lorde, 2007 [1984]; Lorde 2017). The feminist approach focuses in particular on structural inequalities and disadvantages faced by FLINTA* individuals and aims to eliminate them.

More than half of students in Austria can be assigned to at least one category of discrimination. Since spatial structures both promote and restrict social practices, the design of school buildings is of central importance.

Architectural decisions have a significant influence on whether experiences of discrimination are reproduced or reduced in the school context and thus contribute significantly to the creation or reduction of social inequalities in the educational space (Goffman, 2001 [1994]).

In addition, the discussion is based on inclusive and user-oriented research approaches that actively involve those groups that are often marginalized in planning and decision-making processes. These include people with disabilities, members of discriminated groups, and people with limited access to resources (Schwaderer, 2024). By systematically incorporating their perspectives as experts in their own lives, research and design processes are made participatory and oriented toward the actual needs, experiences, and everyday practices of the future users, i.e., the students, educators, teachers, and school administrators.

2.1.2 Research gap

Although there has been growing interest in issues of gender equality, inclusion, and diversity in the discourse on school construction in recent years, systematic engagement with gender-inclusive school architecture has remained fragmentary. While educational research often examines social dynamics, experiences of discrimination, and institutional conditions in everyday school life (Heinrich Böll Foundation

2022), architectural discourse increasingly focuses on accessibility, functional flexibility, or gender inclusivity in relation to the school's outdoor space (Diketmüller & Studer 2007; Hottenträger, 2005; Studer, 2002; Federal Ministry of Education, Science and Research, 2019; University of Vienna & tilia, 2007), there is a lack of integrative approaches that consistently combine spatial design, educational practice, and gender-theoretical perspectives.

In particular, there is a lack of empirically based studies that analyze the concrete impact of spatial design decisions on the use, perception, and appropriation of school spaces in relation to gender. Questions about how gender-inclusive planning approaches affect the sense of security, social participation, or well-being of different user groups in the long term have not yet been sufficiently researched.

Furthermore, there is a clear gap in the institutional and procedural anchoring of gender planning in school construction. In existing school construction guidelines, competition procedures, and planning processes, gender aspects are often only considered implicitly or selectively (MA56 – Schools, 2021; MA56 – Schools, 2023; ÖISS, 2021). There is a lack of binding guidelines for establishing clear responsibilities, for example in the form of gender coordinators within construction and planning projects, who would ensure the continuous integration of gender-related issues across all project phases.

Last but not least, there is a research gap regarding the political and legal embedding of gender-inclusive school architecture. Although there are equality, anti-discrimination, and inclusion laws at the national and international level, their spatial implications for school construction have hardly been analyzed and even less frequently translated into concrete building standards. The interactions between legal requirements, political objectives, and architectural practice thus remain largely underexposed.

2.1.3 Research relevance

Against this background, the scientific examination of gender-inclusive school architecture is of great social, political, and planning relevance. Schools are central places of socialization where spatial structures not only enable learning processes but can also reproduce or challenge social norms, power relations, and affiliations.

The study of school spaces from a gender, spatial, and educational theory perspective therefore makes a significant contribution to understanding structural inequalities in education.

This research is particularly relevant because it has the potential to establish gender planning as a binding component of school building guidelines. Such anchoring makes it possible to no longer treat gender equality as a voluntary additional service or individual commitment of individual actors, but to define it as a structural requirement in school architecture.

At the same time, the research provides a basis for argumentation for decision-makers in politics, administration, and planning to legitimize gender planning in school construction in a sustainable manner, secure it financially, and anchor it institutionally.

Overall, the examination of gender-inclusive school architecture closes a central research gap at the interface of gender studies, architecture, and education. It contributes to the further development of discrimination-sensitive, socially just, and sustainable educational construction and opens up new perspectives for planning practices that understand spatial design as an active component of gender equality policy.

2.1.4 Research question

Against this background, this paper takes a comparative international approach and addresses the following research question:

How do different cities and countries in Europe deal with gender-inclusive planning in school architecture, and what can be learned from their analysis for future innovative gender-inclusive school architecture?

2.2 Methods

The empirical data for this study was collected between January 26, 2022, and November 11, 2024, at public compulsory schools in Vienna. The focus of the study was on elementary and middle schools, as these represent a central stage in the socialization of children and young people and are therefore particularly relevant for the analysis of gender-related perceptions of space and experiences of use.

Data collection was primarily carried out in participatory workshops with children and young people. The aim of these workshops was to record subjective perceptions, experiences, and needs with regard to school spaces and to make these visible from the perspective of the actual users. The collected material comprises a total of 32 guided interviews with 53 students, 110 drawings, 111 completed task sheets, 145 written responses from workshop sequences, and 45 standardized questionnaires. The diversity of the survey formats enabled a multidimensional approach to the research field and helped to take into account the different forms of expression and communication of the participating children and young people (Vogl, 2015, p. 69).

All participating students were of compulsory school age at the time of the survey and were between 6 and 16 years old. The deliberate inclusion of this age group takes into account the fact that children and young people perceive and use school spaces differently and that gender-related attributions and spatial appropriation processes already take effect in early stages of life.

The data collected from the students as the central focus group of the study was supplemented by a total of 15 expert interviews. Experts from the fields of architecture, pedagogy, education and urban policy, city administration, and gender studies were interviewed. These interviews served to contextualize the institutional, planning, and political framework conditions of school construction and to triangulate the students' perspectives with expert assessments from various disciplines.

The interviews were recorded as audio files using mobile devices and then transcribed in full. The entire qualitative data material was evaluated using Mayring's summary qualitative content analysis (Mayring, 2015, p. 69-70). This evaluation method enabled a systematic reduction and structuring of the material as well as the identification of central thematic categories, patterns, and connections in relation to gender-inclusive spatial perception, experiences of use, and institutional conditions of school construction.

Research ethics principles were consistently taken into account when conducting the empirical survey, especially with regard to working with minors as a particularly vulnerable research group. Participation in the study was entirely voluntary. Before data collection began, both the legal guardians and the participating children and young people were informed in an age-appropriate manner about the aim, procedure, and content of the research. The consent of the legal guardians and the informed assent of the students were obtained prior to participation (Vogl, 2015, p. 88-89).

2.3 Four Core Dimensions

As already described, gender-inclusive school architecture aims to design spatial structures in such a way that they do not reproduce gender-related inequalities, but actively contribute to equal opportunities, participation, and social justice. The starting point is the recognition that spaces are not neutral, but can materialize and reinforce social norms, power relations, and role models. Gender-inclusive school architecture therefore takes into account the diverse needs, perceptions, and ways of appropriating space of students in all their diversity and avoids binary attributions or stereotypical space allocations (Schwaderer, 2023).

Key principles include the equality of all users, the flexibility and ambiguity of spaces, accessibility, transparency in planning decisions, and the institutional anchoring of gender competence in all phases of the design and planning process. Gender planning thus understands school architecture as an interdisciplinary task that integrates architectural, educational, and social science perspectives and views spatial design as an integral part of education and equality policy. Against this background, four core dimensions can be identified that are of particular importance for gender-inclusive school architecture.

2.3.1 Safety, security, and well-being

Safety, security, and subjective well-being are fundamental prerequisites for successful learning and social participation in the school context. Gender-inclusive school architecture takes into account not only objective safety aspects, but also, in particular, the subjective sense of safety of different user groups. Studies show that perceptions of insecurity can be strongly gender-dependent and that girls, non-binary, and gender-nonconforming students in particular are more likely to identify spaces that cause fear or insecurity (Schuster, 2012; Schwaderer, 2025b).

In this context, architecturally relevant features include clear spatial structures, easily visible traffic areas, clear orientation systems, and a balance between openness and protection. Dark, remote, or poorly visible

areas – such as long corridors, stairwells, or outdoor spaces – can increase feelings of insecurity and promote social exclusion mechanisms. Gender-inclusive planning therefore aims to minimize areas that cause fear and to create an atmosphere of transparency through design, lighting, and choice of materials, without placing the emphasis on surveillance or discipline.

Furthermore, well-being is closely linked to emotional and social security. School rooms should enable identification, make diversity visible, and give students the feeling that they are welcome. This can be supported by flexible furniture, age- and user-friendly design, and the opportunity to participate in the design process (Montag Stiftung Jugend und Gesellschaft, 2017, p. 191). Architecture that promotes security contributes significantly to reducing stress, withdrawal from everyday school life, and gender-specific exclusion.

2.3.2 Movement spaces

Movement spaces play a central role in everyday school life, as they not only enable physical activity, but also make social interactions, power dynamics, and gender-specific appropriation processes visible (Ostermann, 2009). In many schools, large-scale, competition-oriented exercise facilities – such as soccer fields or gyms – dominate, and these are often used more by certain groups, mostly boys. Other students are implicitly excluded or withdraw as a result (Schwaderer, 2025c).

Gender-inclusive school architecture challenges these one-sided spatial offerings and strives for a variety of movement spaces that enable different forms of movement, play, and physical expression. In addition to classic sports areas, this includes informal movement zones, small-scale offerings, multifunctional outdoor spaces, and transition zones that promote spontaneous, non-performance-oriented activities. It is crucial that no form of use is hierarchized or normatively evaluated (Women in Sport, 2022).

The design of movement spaces should also ensure social safety and accessibility. Clear zoning, flexible usability, and transparent rules can help enable all students to participate equally. From a gender-inclusive perspective, exercise spaces are therefore not only places for physical activity, but also central venues for social negotiation processes that can be specifically influenced by architecture (Derecik, 2015, p. 59).

2.3.3 Retreat areas

Retreat areas are an essential element of gender-inclusive school architecture, as they take into account the different needs for quiet, privacy, and emotional relief (Eichler, 2021). Everyday school life is often characterized by high social density, noise, and constant visibility, which can be particularly stressful for marginalized or more sensitive students. Gender-specific expectations regarding presence, assertiveness, or conformity further exacerbate this pressure.

Gender-inclusive planning recognizes retreat not as a deficit, but as a legitimate and necessary strategy for self-regulation. Retreat spaces can take various forms, such as small lounges, niches, reading corners, or sheltered outdoor areas. It is crucial that they are easily accessible, do not have a stigmatizing effect, and can be used by all students without having to justify or legitimize their use.

Architecturally relevant aspects include acoustic shielding, visual separation, flexible furniture, and a pleasant atmosphere. Retreat areas not only contribute to individual well-being, but also promote social sustainability by reducing potential for conflict and enabling self-determined use of space (Derecik, 2015). In gender-inclusive school concepts, they are therefore not an additional offering, but an integral part of the spatial program.

2.3.4 Toilets

Sanitary facilities are a particularly sensitive area of school architecture, as they are closely linked to issues of intimacy, physicality, gender, and social control (Schwaderer, 2025a; Schreiber, 2019). Traditionally binary school toilets can be a significant source of stress for trans*, non-binary, or gender-nonconforming students, leading to insecurity, avoidance, or discrimination. At the same time, toilets are often places of bullying, assault, or social exclusion.

Gender-inclusive school architecture aims to design toilet facilities in such a way that they guarantee safety, privacy, and dignity for all users. Key design principles include lockable individual cubicles, ceiling- and floor-to-ceiling partitions, clearly visible entrance areas, and a clear separation of washing and toilet areas.

Gender-neutral or all-gender toilets should be an important addition or alternative to binary options, provided they are integrated into the room concept in an equal, visible, and natural way (Schwaderer, 2025a).

In addition, the location of toilets in the school building is important. Good accessibility, social integration, and the avoidance of spaces that cause anxiety are crucial for reducing barriers to use. Toilet facilities are therefore not only functional infrastructure elements, but also key indicators of the extent to which a school recognizes and spatially supports gender diversity (ibid.).

3 EXAMPLES FROM PRACTICE

The aim of Carla Schwaderer's dissertation entitled "Gender Planning in School Construction. A Guide to Gender-Inclusive School Architecture" is to develop a guide that will be compiled in cooperation with the Austrian Institute for School and Sports Facility Construction (ÖISS) and published in spring 2026. Research conducted as part of the dissertation shows that, although there are specifications and guidelines for tenders and architectural competitions for school buildings in Vienna, some of these are binding and some are merely recommendations (Plattform schulUMbau, 2010; ÖISS, 2023; City of Vienna, 2023). However, these are mainly limited to general references to gender-inclusive planning, without providing specific instructions or design principles for gender-inclusive implementation. This gap is to be closed in the future by the guidelines developed as part of the dissertation.

An international comparison based on extensive research also shows that Vienna occupies a special position in the international context: Vienna is the only one of the regions studied that explicitly stipulates gender-equitable school spaces in its school building guidelines. In other countries – including Denmark, Sweden, Switzerland, Norway, Spain, Italy, Japan, the USA, and Canada – gender equity has not played a comparable role, at least at the level of guidelines, even though individual projects that have been implemented can certainly be classified as gender-inclusive – as we will discuss in chapter 3.2 International Examples.

3.1 Examples from Austria

With its early feminist urban planning, which was already influenced by Eva Kail (Kail, 2002) in the 1990s, Vienna has generally played a pioneering role in gender planning and can point to a long history of gender-sensitive planning (Knoll & Szalai, 2010; City of Vienna, 2007).

3.1.1 Konrad-Lorenz-Gymnasium, Gäserdorf

The Konrad-Lorenz-Gymnasium in Gänserndorf is a contemporary example of a school that goes beyond mere functional renovation and creates spatial qualities that take into account both the educational and social aspects of school. The building was completed in 2022 after the architectects Franz&Sue ZT GmbH won a Europe-wide competition for the renovation and expansion. The school serves as the main school location for around 1,000 students and integrates existing buildings with a new connecting structure to form an open, hierarchy-free ensemble (Franz&Sue, 2026; ZAB, 2026).

The architectural intervention responds to the structural deficits of the former, strongly linear and spatially segregated corridor school by focusing on central meeting and orientation spaces. The open auditorium in the middle of the building serves as an identity-forming center and connects different levels with wide seating steps. Floods of daylight, attractive seating areas, and a direct visual connection to neighboring open spaces enhance both the communicative use and social accessibility of the space. This communicative core supports an atmosphere in which different groups and social identities can overlap, thus contributing to a school environment that embraces diversity as a constructive element (Austria Architects, 2026).

The cluster structure of the classrooms around this central space creates manageable yet interconnected learning units that facilitate orientation and shorten distances. The deliberate structure promotes the self-organization of learning groups and minimizes areas of uncertainty, which can have different psychological effects on students, especially in larger building complexes (Kühn & Schwaderer, 2025). Color concepts and a visual guidance system also provide intuitive orientation that is not bound to traditional, strictly functional hierarchies, but opens up opportunities for identification through differentiated visual addresses.

Another feature is the integration of indoor and outdoor spaces, which allows views from the classroom into a variety of open areas. The schoolyards and school garden are designed so that they not only function as pure break areas, but also invite different forms of use – from exercise and informal encounters to quiet

retreat areas. This spatial diversity addresses key requirements of gender-inclusive school architecture, as it enables different forms of movement, lingering, and appropriation and promotes social participation among multiple user groups (ibid.).

The choice of materials and the design of the façade also reflect an approach to aesthetic identification and tactile quality: a delicate wooden slat façade lends the building liveliness and warmth, which, beyond functional requirements, can support a feeling of belonging and well-being.

Particularly noteworthy is the range of movement options in the intermediate zones of the school building, which can be considered exemplary for gender-inclusive school construction. Instead of a strict separation between learning, traffic, and movement areas, access areas, stairwells, and lounge areas are deliberately designed as informal spaces for movement and appropriation (Schwaderer, 2025c).

Seating steps, spacious staircases, and open transitions enable spontaneous, low-threshold forms of movement that are not performance-oriented and are not associated with any specific sports culture. This creates alternatives to classic, often gender-dominated exercise spaces such as gyms or sports fields. These informal movement opportunities promote diverse use by different groups of students, reduce mechanisms of exclusion, and support self-determined, gender-independent appropriation of the school space. The integration of movement into everyday routes and lounge areas thus contributes significantly to an inclusive, stress-reducing, and socially balanced school day (ibid.).

As a whole, the Konrad-Lorenz-Gymnasium shows how spatial structures beyond purely functional logic can enable social experiences, orientation, encounters, and identification. These qualities are central elements of gender-inclusive architecture, as they aim to allow for differentiated uses and to spatially accommodate heterogeneous realities of life in everyday school life. Through its combination of open communication spaces, differentiated learning clusters, designed outdoor areas, and an integrative color and orientation system, the building can be considered a model that supports spatial openness, social accessibility, and heterogeneous modes of appropriation in the spirit of contemporary school architecture.

3.1.2 NMS Mittelweiherburg, Hard

The Neue Mittelschule (NMS) Mittelweiherburg in Hard is an exemplary example of the contemporary approach to school interior design in the context of educational and social requirements. Originally opened in 1978, the school building underwent a comprehensive renovation, which was completed in April 2022, and was given a new focus in terms of content and space. The renovation was planned by the architects gruber locher architekten ZT GmbH from Bregenz, which was tasked with transforming the existing qualities of the school building while implementing modern standards of educational interior design (Daibau Magazine, 2026; gruber locher architekten, 2023).

As part of the renovation, the building was not only technically and energetically upgraded, but also structurally redesigned and given a new spatial logic. The aim was to transform the school building from a 1970s school typology often perceived as a “bunker” into an open, communicative, and flexible learning environment that allows for a variety of uses (Schlocker, 2023).

A central design element is the atrium at the intersection of the two wings of the building, which was designed as a vertical meeting zone and distribution area across all floors. This open hall serves not only as a spatial center, but also as a social mediator between formal teaching, informal encounters, and informal learning processes. The original solid steel railings have been replaced by transparent glass balustrades, significantly improving sightlines, permeability, and spatial orientation. This removes boundaries between the levels and allows spaces to be experienced as interconnected social places.

The cluster structure of the learning areas, in which three classrooms are grouped around a semi-open learning area, promotes communication, cooperation, and self-organization among the students. Such spatial constellations support heterogeneous forms of learning that have an integrative effect and enable different learning styles and social interactions. This flexibilisation of learning spaces is in line with gender-inclusive planning principles, as it breaks down stereotypical usage boundaries and creates learning environments that can be used and shaped equally by different groups (Nextroom, 2026).

Another aspect that sets the project apart in terms of gender-inclusive school construction is its use of materials, colors, and atmosphere. Whereas the school used to be characterized by brutal exposed concrete surfaces and garish colors, a coordinated material and color concept now creates a pleasant, diverse room

atmosphere that allows for both visual calm and acoustic differentiation. The use of wood, warm colors, and differentiated flooring materials contributes to the school's functional and emotional appeal, which supports the well-being and identification of all users, regardless of gender identity or personal preferences.

In addition, the renovation made the school barrier-free and equipped it with an elevator, which ensures physical accessibility and enables equal use of all school areas by students with different motor skills. This dimension of accessibility is a central component of gender-inclusive architecture, as it takes multiple differences into account and not only proclaims inclusive participation, but also realizes it spatially.

Finally, communal areas such as the auditorium, library, and modern lounge areas are an integral part of the spatial program, supporting both formal and informal uses. The combination of learning, lounge, and meeting areas promotes social interaction beyond formal teaching situations and fosters an atmosphere of openness that is important for diverse spaces of identity and experience.

As a whole, the NMS Mittelweiherburg shows how an existing school building can be transformed through careful but consistent pedagogically and socially oriented architecture. The combination of transparent spatial structure, flexible learning landscapes, differentiated materiality, and barrier-free access creates a spatial environment that not only tolerates diversity but enables it. This school building project thus makes an important contribution to an architecture of learning that follows gender-inclusive planning principles and translates them into concrete spatial qualities (Weber, 2025).

3.1.3 Pestalozzi Education Center, Leoben

The Pestalozzi Education Center in Leoben-Donawitz is considered one of the most innovative school construction projects in the country. The comprehensive renovation and reorganization of the existing Pestalozzi school complex was completed in 2016, after which the building was put into operation at the beginning of the 2016/17 school year. The Graz-based architectural office nonconform, in cooperation with schuleRAUMkultur/Michael Zinner from the University of Art and Design Linz, was responsible for the planning and implementation, jointly developing an integrative and participatory process management approach (Kühn, 2025).

The project brings together three different types of compulsory schools under one roof – elementary school, new middle school, and polytechnic school – and transforms the building into an open, shared educational center that serves as a model for other regions. The spatial reorganization aimed to break down barriers between traditional functional units and enable diverse forms of use. Participation processes with students, teachers, parents, and other user groups formed the basis for a spatial concept that is not characterized by rigid hierarchies, but focuses on social interaction, communication, and appropriation (nonconform, 2026).

An essential element of this gender-inclusive approach is the transparency and permeability of the spatial structure: classrooms open onto corridors and communal areas that serve as informal learning and meeting spaces. The spatial interaction between formal teaching and open communication spaces promotes heterogeneous modes of learning, facilitates social orientation, and minimizes isolating spatial forms. In this way, the architecture responds to the different needs of students and addresses differences in perception and use across genders, age groups, and learning preferences (ibid.).

Another characteristic feature of the education center is the integration of different age groups and school types into a common spatial logic. The resulting “interstitial spaces” between the units enable informal encounters that promote social exchange across institutional boundaries. Such intermediate zones offer a variety of opportunities for expression and movement: they serve as informal learning spaces, lounge areas, and informal meeting places that are not normatively defined for a specific use. This spatial openness supports a gender-inclusive appropriation of the school space by allowing for multiple identities and social practices equally, rather than reproducing traditional functional assignments.

In this context, the project's participatory planning strategy is relevant not only in terms of process but also in terms of architecture: the involvement of the school community in the design and appropriation phases has helped to ensure that spaces are not “imposed” but respond to actual everyday needs and can be flexibly developed. This form of participation – which goes beyond a mere survey of usage – strengthens the sense of shared responsibility and co-creation, which has a positive effect on subjective security, belonging, and well-being.

Finally, the importance of the Pestalozzi Education Center is also evident in the fact that it is perceived as a best-practice example of integrative school space design in both educational and architectural discourse. Professional recognition, participatory approaches, open spatial logic, and consciously promoted informal usage practices make the project a model that not only addresses gender-inclusive planning in school construction in theory, but also implements it in concrete spatial qualities.

3.2 International examples

This text focuses on Europe, as the regulations here are most comparable to our own context and to the guidelines in Austria; therefore, the learning effect is greater.

In a non-European context, gender planning in school architecture – for example in African countries – may instead emphasize aspects such as safe routes to school, sanitary facilities, and hygiene measures.

3.2.1 Learning landscapes at the St. Johann elementary school in Basel (Switzerland)

The learning landscapes at St. Johann Elementary School in Basel represent an exemplary approach in contemporary school construction, combining spatial qualities and educational requirements into an integrative spatial concept. The redesign of the school rooms was completed in 2019 and was carried out by the Basel-based architectural office ZMIK GmbH, which was able to develop new spatial structures in a participatory process with students and teachers (ZMIK, 2019).

Originally, the long corridors of the historic school building served merely as access zones for teaching purposes. In the context of the renovation, ZMIK transformed these linear spaces into multifunctional learning and recreation areas that combine informal learning, social interaction, and physical activity. The planning followed an intensive participatory process in which the perspectives of the actual users – especially the children – served as the conceptual basis, which promoted a high level of identification with the final spatial concept (ibid.).

Architecturally, the three main rooms of the school building are divided into three differently usable zones: cloakroom, learning landscape, and central movement and meeting area. This zonal structure not only enables functional differentiation, but also supports a variety of ways of using the space. Terraced and variably usable elements are arranged along the window side, serving both as work surfaces for individual or collaborative activities and as informal retreat and communication areas.

Particularly noteworthy is the hybrid character of the learning landscapes: instead of rigid classrooms or functional hallway structures, spatial niches such as “caves” and “hides” have been created that allow for different modes of use – concentrated work, playful discovery, retreat, or informal interaction. Elements such as slides, balance beams, and bouncing balls promote a concept of “active learning” that sees physical activity as an integral part of everyday school life (Schwaderer, 2025c).

From a gender-inclusive perspective, this project is exemplary because it breaks down traditional binary attributions of space and creates types of space that are not tied to specific roles, behaviors, or normative expectations of use. The learning landscapes thus promote the equal participation of all students – regardless of gender identity, learning style, or physical preferences – by offering different forms of access to learning and social interaction. The spatial structure allows for individual self-determination, supports cross-group communication, and creates a variety of opportunities for spending time together that are not evaluated hierarchically.

In addition, the integration of natural materials, differentiated acoustic solutions, and a graduated color palette has a psychosocially supportive effect: it promotes well-being and orientation, reduces stress factors, and creates an atmosphere that encourages positive social exchange. The proximity to the historic building and the acceptance of the existing building as a material basis underscore that gender-inclusive design can be effectively realized not only in new buildings, but also in the careful transformation of existing school buildings.

As a whole, the St. Johann elementary school shows how participatory planning, diverse spatial offerings, and flexible appropriation options can result in a school building that not only supports educational innovation but also creates a multi-layered, socially inclusive, and gender-inclusive learning and living space.

3.2.2 Reggio School in Madrid (Spain)

The Reggio School building in Madrid (El Encinar de los Reyes) was designed by architect Andrés Jaque and the Office for Political Innovation (OFFPOLINN) and completed at the end of 2022. The design is based on the educational principles of Reggio Emilia pedagogy, which views children as active designers of their own learning processes. This educational approach has a direct impact on the architectural concept and makes the school a remarkable example of gender-inclusive school construction (iqd, 2022).

Architecturally, the Reggio School is designed as a vertically organized, open ecosystem that deliberately avoids rigid functional divisions. The spatial organization follows the principle that the learning environment itself – alongside teachers and peers – acts as a "third educator" and thus actively participates in learning processes. Rooms are designed to allow for diverse, self-directed forms of acquisition and interaction. This diversity of possible uses is a central aspect of gender-inclusive planning, as it accommodates different learning styles, modes of expression, and physical needs without reproducing conventional attributions of use.

A striking example of this openness is the central, more than 8-meter-high common room, which serves as a multifunctional agora. This large, light-filled hall can be used as a space for movement, a meeting place, a teaching area, or a social gathering place, and is deliberately not zoned hierarchically. It functions as a social hub that promotes exchange across age groups, interests, and gender boundaries – a spatial counterpart to inclusive educational relationships.

The Reggio School largely dispenses with traditional corridors and instead creates flowing transitions between learning, play, and recreation rooms. These fluid transitions allow students to flexibly cross spatial boundaries and experience the school space in their own way, breaking down stereotypical patterns of use and enabling diverse forms of appropriation (Baunetzwissen, 2022).

Another important aspect is the design of the materials and space, which combines transparency, rawness, and ecological sensitivity. Visible technical systems, exposed pipes, and the consistent integration of natural elements such as courtyards and green spaces create a non-hierarchical, exploratory learning environment in which students of all genders are equally motivated to explore their surroundings and use them interactively.

The vertical staggering of the building – younger children on the lower levels, older children on the upper levels – supports age-differentiated but at the same time permeable use of space. This organization allows for the creation of autonomous spaces for experience without building social barriers, and creates spaces for experience that can be shared by heterogeneous groups (Metalocus & Dragoeva, 2022).

As a whole, the Reggio School combines architectural diversity, pedagogical openness, and ecological responsibility to create a spatial structure that implements gender-inclusive school construction not only as a normative goal, but as a concrete spatial practice. The school creates spaces that equally enable exploration, cooperation, social interaction, and self-directed learning, thus minimizing barriers between different users, age groups, and social identities, both thematically and spatially.

3.2.3 TORNHØJ HALL in Aalborg Øst (Denmark)

Completed in 2012, Tornhøj Hall is a motor skills-based extension of the sports hall at Tornhøjskolen in Aalborg Øst and was designed and built by the Danish architectural office Keingart (in collaboration with technical planning partner Kærsgaard & Andersen). The design responds to the conversion of an existing, traditionally organized hall structure and transforms it into an open, versatile environment for exercise and recreation (Keingart Space Activator, 2012).

Although it is not formally a classic new school building, the project is closely linked to the school context in terms of its functional and social impact: the hall is an integral part of Tornhøjskolen and is not only used for physical education, but also functions as a social, sporting, and interactive center for students of all ages, genders, and social backgrounds. This allows the hall to be seen as an example of gender-inclusive planning in the broader context of school interior design.

The basic architectural concept consists of opening up, connecting, and differentiating spaces for movement and interaction (Schwaderer, 2025c). The long, formerly dark sports hall has been made more permeable; corridors and access areas have been transformed into movement-promoting landscapes that spiral through the building and invite a variety of physical activities: from climbing and balancing facilities to free play and

movement zones to retreat and relaxation niches. This spatial openness and diversity of use promotes spontaneous, non-hierarchical forms of movement that are not bound by traditional performance or gender norms.

Particularly relevant in terms of gender-inclusive aspects is the integration of movement and social spaces: instead of a strict functional separation between sports and recreation areas, intermediate zones are created in which all students – regardless of gender, athletic ability, or physical characteristics – can move and interact independently. This corresponds to a planning concept that breaks down stereotypical patterns of use and offers space for diverse ways of appropriation. The small-scale nature of the facilities, in combination with the open spaces, creates a low-threshold participation structure in which different groups can participate on an equal footing (Keingart Space Activator, 2012).

Furthermore, opening up the hall to the school and the public space has created a strong connection between everyday school life and communal use. The newly created café and lounge areas function as social threshold spaces that enable informal encounters and exchanges before and after class or outside of organized sports activities. This spatial coupling promotes social cohesion and reduces barriers between user groups, which is a central concern of gender-inclusive planning.

The project is also notable for its understanding of physical activity not only as a cognitive or performance-related discipline, but as a social and everyday process of interaction. This perspective supports different forms of expression of movement and reduces normative attributions – an approach that, beyond its specific use, can serve as a reference for gender-inclusive school architecture by showing how spaces open up potential for movement, encounter, and appropriation for all users equally (ibid.).

4 CONCLUSION

The present analysis shows that gender-inclusive school architecture goes far beyond questions of individual room types or design details. It should be understood as an interdisciplinary field of action in which architecture, pedagogy, and gender studies jointly contribute to understanding school spaces as social, political, and pedagogical spheres of influence. School buildings are not neutral containers of learning, but rather materialize social norms, power relations, and ideas of belonging – and thus have the potential to either reproduce inequalities or actively dismantle them.

The theoretical approaches, empirical findings, and practical examples examined illustrate that gender-inclusive planning is effective when it is structurally, procedurally, and spatially anchored. Safety, opportunities for physical activity, places of retreat, and sanitary facilities prove to be central sites of negotiation for gender participation, where social dynamics manifest themselves particularly clearly. At the same time, international and national examples show that gender-inclusive school architecture is not a singular design model, but is characterized by flexible, context-related, and participatory solutions.

This makes it clear that gender planning in school architecture is not an optional addition, but a central prerequisite for sustainable educational architecture. Only when gender equality is understood as a cross-cutting issue in planning and is translated into binding guidelines, processes, and built spaces can schools become learning and living spaces that not only allow for diversity but actively support it.

1 ABSTRACT

The strategic significance of geological resources for sustainable development and the security of European societies is well established. Nevertheless, the subsurface resources are often not systematically assessed in spatial planning at the municipal level. In cities, there is a variety of increasing demands and land-use conflicts, but these issues are also relevant for smaller municipalities. The absence of strategic prioritisation results in suboptimal utilisation of subsurface resources. Accordingly, a multidisciplinary research project (UNDER) is developing novel methods to incorporate subsurface considerations into spatial planning. This work is being carried out in close collaboration with spatial planners at the City of Malmö (a medium-sized city) and at the municipality of Askersund (a small municipality) in Sweden.

The geosystem services concept has been put forward as a concept that could support the efficient use of subsurface resources and improve systematic planning of the subsurface (e.g., Lundin Frisk, 2025). Geosystem services, analogous to ecosystem services, describe goods and services delivering benefits to humans either derived from the subsurface (van Ree & van Beukering, 2016) or the geosphere (Gray, 2011), often referred to as abiotic nature in this context). Similar to the classification of ecosystem services, geosystem services are categorised into supporting, provisioning, regulating, and cultural services. For instance, groundwater as a supply resource constitutes a provisioning geosystem service, whereas water quality regulation is considered a regulating service. The service perspective is holistic in the sense that it takes into account potentially conflicting uses of the subsurface and highlights a broader range of services and goods than typically included in spatial planning. In order to operationalise the concept, an indicator-based framework for assessing different geosystem services has been developed (Lundin Frisk et al., 2025).

The City of Malmö in southern Sweden (≈370,000 inhabitants) is currently developing a climate resilience plan. To support this effort, the research project has developed seven thematic GIS maps of geosystem services, including stormwater infiltration and retention capacity and access to subsurface space (Lundin-Frisk et al., 2026). The municipality of Askersund (≈11,500 inhabitants) is simultaneously preparing its comprehensive plan. Within Askersund municipality, diverse subsurface resources, such as a zinc mine and mineral resources, groundwater reserves, and geological construction materials (gravel and sand) are present, alongside underground transport infrastructure. Five thematic GIS maps of geosystem services have been developed, including maps for erosion resistance and the access to bedrock with quality suitable for aggregate production (Gustafsson, in prep.).

The thematic maps were presented in workshops with urban planners in Malmö and Askersund. Workshop feedback supported the relevance of geosystem services in supporting planning decisions and suggested future development needs for such maps. In Malmö, maps on stormwater infiltration and geoenergy were viewed as particularly valuable. In Askersund, participants emphasised that geosystem services provide a useful framework for communicating with non-experts, including decision-makers.

Keywords: Subsurface planning, Geosystem services, Strategic planning, Case study, Resilience

2 ABSTRACT (DEUTSCH)

Die strategische Bedeutung geologischer Ressourcen für eine nachhaltige Entwicklung und für die Sicherheit europäischer Gesellschaften ist längst anerkannt. Trotzdem spielen unterirdische Verhältnisse eine

untergeordnete Rolle in der räumlichen Planung auf der kommunalen Ebene. In den größten Städten gibt es eine Vielfalt von steigenden Ansprüchen und Nutzungskonflikten, aber diese Fragen sind auch für kleinere

Gemeinden relevant. Das Fehlen einer strategischen Priorisierung führt zu einer suboptimalen Nutzung der unterirdischen Ressourcen. Deshalb entwickelt ein interdisziplinäres Forschungsprojekt neue Methoden, um unterirdische Fragestellungen in die Raumplanung einzubeziehen. Diese Arbeit wird in engem Austausch mit Malmö (mittelgroße Stadt) und Askersund (kleine Gemeinde) in Schweden betrieben.

Um unterirdische Ressourcen effizienter zu nutzen und die Planung des unterirdischen Raums zu verbessern, wird der Begriff Geosystemdienstleistungen entwickelt (z.B. Lundin Frisk, 2025). Geosystemdienstleistungen ähneln den Ökosystemdienstleistungen und beschreiben Vorteile für den Menschen, unterscheiden sich jedoch durch ihre Fokussierung auf unterirdische Ressourcen und dass sie potenziell konfliktierende Nutzungen berücksichtigt. Ein indikatorbasiertes System zur Bewertung verschiedener Geosystemdienstleistungen ist entwickelt worden (Lundin Frisk et al., 2025). Ähnlich wie Ökosystemdienstleistungen werden auch Geosystemdienstleistungen in unterstützende, bereitstellende, regulierende und kulturelle Dienste aufgeteilt.

Die mittelgroße Stadt im südlichen Schweden Malmö (etwa 370.000 Einwohner) arbeitet derzeit an der Entwicklung eines Klimaresilienzplans. Zur Unterstützung wurden im Forschungsprojekt verschiedene thematische Karten zu Geosystemdienstleistungen mit GIS entwickelt, z.B. für Kapazität des Bodens Regenwasserversickerung (Lundin-Frisk et al., 2026). Die kleine Gemeinde Askersund (etwa 11.000 Einwohner) entwickelt derzeit ihren Masterplan. Innerhalb der Gemeinde gibt es eine Vielfalt unterirdischer Ressourcen inkl. eine Zinkgrube, Grundwasserressourcen, Baustoffen (Kies und Sand), gleichzeitig gibt es auch unterirdische Transportinfrastruktur. Für Askersund wurden thematische Karten entwickelt, beispielsweise zur Erosionsbeständigkeit und zum Zugang zu Gebirgsarealen für Gesteinskörnungen (Gustafsson, 2026).

Die thematischen Karten wurden in verschiedenen Workshops mit Stadtplaner(innen) in Malmö und Askersund präsentiert. Die Rückmeldungen aus den Workshops unterstreichen, dass Geosystemdienstleistungen einen wesentlichen Beitrag zur planerischen Entscheidungsunterstützung leisten. Für Malmö wurden besonders die thematischen Karten zur Regenwasserversickerung und Geoenergie als wichtig beachtet. In den Workshops mit Askersund haben die Teilnehmenden zum Ausdruck gebracht, dass Geosystemdienstleistungen ein wichtiger Begriff in der Kommunikation mit Nicht-Fachleuten, z. B. Entscheidungsträgern, sein kann.

3 INTRODUCTION

This paper presents results from an ongoing research project aimed at investigating the role of geosystem services to support integration of the subsurface in spatial planning. The research is case study-driven, focusing on planning cases in the cities of Malmö and Gothenburg, and the rural municipality of Askersund. For Malmö and Askersund, a similar approach for the dialogue with municipal planning professionals was used, and this paper presents results from this process.

3.1 Background: Geosystem services and subsurface planning

The subsurface plays a significant yet often overlooked role in urban development by providing critical services – such as stormwater infiltration to mitigate flooding, geothermal energy, and groundwater resources (Erlström et al., 2016). However, its potential is frequently neglected in planning, primarily due to limited awareness and understanding of subsurface data and functions (Dick et al., 2017; Finesso & van Ree, 2022). The concept of geosystem services bridges this gap by framing geological information in terms of societal benefits, extending the ecosystem services framework to include the subsurface and abiotic nature (van Ree & van Beukering, 2016; Gray, 2011; Lundin-Frisk, 2025). Lundin-Frisk et al. (2025) identify 39 such services, some of which were applied in the two case studies presented in this paper.

Geosystem services are defined, in this paper, as the contributions provided by the subsurface to human wellbeing, although there are alternative definitions (e.g., Fox et al., 2020; Gray, 2011; Lundin-Frisk et al., 2022; van Ree & van Beukering, 2016). As a parallel to ecosystem services, geosystem services are divided into provisioning, regulating, supporting, and cultural services, and many identified services are presented in Figure 1 (Lundin-Frisk, 2025). For a systematic description, presentation, and analysis of different

geosystem services in a certain geophysical setting, indicators and capacity classes for assessing and visualise the potential for delivering different services have been developed (Lundin-Frisk et al., 2025).

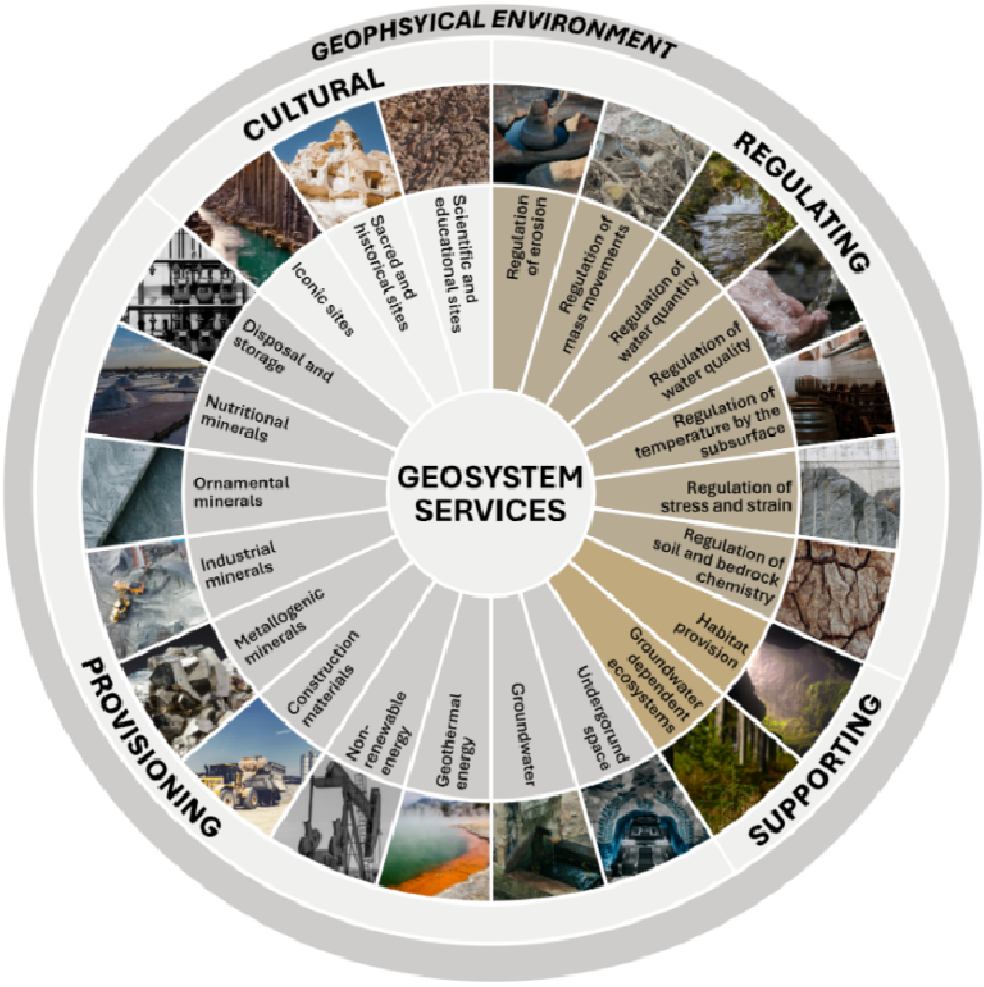

Fig. 1: Geosystem services are systematically divided into provisioning, supporting, cultural, and regulating services (from Lundin-Frisk, 2025)

Previously and in parallel with the ongoing development of the geosystem services concept, other related concepts and definitions – such as nature-based solutions (NBS), geodiversity, geoheritage, geodesign, and geoconservation – have been proposed or established. Steinitz (2012) introduced geodesign as an iterative, collaborative, and multidisciplinary approach applicable across scales, from landscape architecture to comprehensive planning. While geodesign may incorporate georesources and the underground, its primary focus remains on surface planning rather than the subsurface. NBS leverage natural processes and systems to address environmental and societal challenges, such as maintaining biodiversity, flood mitigation, and climate adaptation. Furthermore, NBS generally connects to ecosystem services, but already in its current useage extends to geosystem services such as regulation of water quantity (Kabisch et al., 2022). Previously established or proposed concepts insufficiently include the subsurface, and only ecosystem services have been successfully implemented in Sweden. Therefore, the inclusion of geosystem services in spatial planning is considered important.

3.2 Aim and objectives

This study is part of a collaborative effort of researchers from the UNDER-project, property developers, and civil servants from the Malmö municipality, as well as civil servants of the Askersund municipality, to explore the role of the subsurface in urban planning.

Primary Aim: To explore how geosystem services can enhance urban climate resilience planning in Malmö and for the development of an updated comprehensive plan for the municipality of Askersund. The two municipalities have been studied individually by Gustafsson (2026) and Lundin-Frisk et al. (2026), whereas this paper presents a combined discussion and joint conclusions of the two different studies.

4 CASE STUDIES

The two municipalities for the case studies, the city of Malmö and the municipality of Askersund, were selected because of the importance of the underground, ongoing planning processes, and their openness to exchange with the research project.

4.1 Case study 1: City of Malmö

Malmö is located in the south of Sweden and is the country's third-largest city, and currently has approximately 365,000 inhabitants. The city's rapid population growth, coupled with its coastal location, makes it vulnerable to the impacts of emerging climate change (Malmö stad, 2016; Persson et al., 2012; Sonesson et al., 2024). The surrounding areas comprise a flat landscape with a mixture of suburbs and agricultural land. The municipality is densely populated, considering its 334 km² area. Consequently, civil servants in Malmö are working to improve the city's climate resilience, particularly in response to four anticipated effects of climate change: (1) rising sea levels, (2) more frequent and intense rainfalls, (3) more frequent and severe heatwaves, and (4) more prolonged periods of drought.

4.2 Case Study 2: Municipality of Askersund

The municipality of Askersund has a population of about 11,500 and is located on the northern shore of Lake Vättern, about halfway between the two largest cities in Sweden: Gothenburg and Stockholm. The administrative centre is Askersund town, which has a small-town character. The municipality covers about 1,020 km², and approximately 4,700 inhabitants live in Askersund town, approx. 4,000 in smaller communities and 2,500 in rural areas. Demographic trends indicate a growing proportion of elderly citizens relative to the working-age population (Statistics Sweden, 2025).

Within the municipality of Askersund, there are important geosystem services that may be relevant for spatial planning. These include those assigned as national interest (for mineral resources), and there is an active underground mine, there is underground transport infrastructure with rail tunnels, groundwater resources, a planned drinking water tunnel, as well as areas prone to instability and erosion. A significant share of the coastal area along Lake Vättern is subject to environmental protection, whereas there is a preference to establish new housing in the vicinity of the lake.

5 METHODS

As a part of the UNDER-project, geosystem service maps were developed as presented in Lundin-Frisk et al. (2026) and in Gustafsson (2026). The process to select the geosystem services to be mapped was similar for the two cases, with feedback from the two different municipalities.

Repeated exchange between UNDER-project researchers, property developers, and Malmö municipality civil servants occurred (Lundin-Frisk et al., 2026). For the Askersund case, the exchange was limited to the UNDER-project and civil servants of the municipality (Gustafsson, 2026).

Methodological Steps:

- Exchange with stakeholders/municipality:
    - Malmö: Introduce the geosystem services concept at a workshop, investigate current subsurface use, and match uses with geosystem services. A discussion focusing on what services are assessed to be of the highest importance.
    - Askersund: Workshop/meeting/webinar with civil servants involved in spatial planning to discuss and select the most important geosystem services for the comprehensive plan.
- Map Development: This work with the development of thematic maps is presented in more detail in Lundin-Frisk et al. (2026) and Gustafsson (2026). A selection of geosystem services is presented in Table 1, and indicators are based on Lundin-Frisk et al. (2025).
    - Development of thematic maps based on geosystem services indicators (e.g., erosion regulation, temperature regulation, groundwater provisioning).
    - To further assess the accessibility of different and suitability of geosystem services, further aspects were included, such as depth, contamination, conflicts of interest, nature protection, etc.

- For Malmö and Askersund, seven resp. five thematic maps for geosystem services were developed.

- Stakeholder/municipality feedback:
  - Webinar and Workshop 1: Introduce the concept of geosystem services and their potential applications in spatial or climate resilience planning. In the Askersund case, a focused discussion was held to identify and prioritize the most relevant geosystem services..
  - Workshop 2: Two different workshops to test maps with urban planners and civil servants at the Askersund and Malmö municipalities, respectively, assess usefulness, and gather improvement suggestions.

Section	Geosystem service	Indicator [unit]
Regulating services	Regulation of erosion	Soil eroded kg, ml-2t-1]
		Landscape index [-]
		Soil erodibility [-] *
	Regulation of water quantity	Reduced flood risk area [m2, m2person-1]
		Storage and permeability capacity [-] *
		Quantity of water filtered [l3/t]
		Water Retention Index (WRI) composed of sub-indicators [-]
		Permeability index [-] *
	Regulation of water quality	Quantity of water filtered [l3/t]
		Biochemical degradation capacity [-]
Provisioning services	Construction materials	Thermal conductivity (λ) [W/(K m)]
	Groundwater for drinking	Groundwater level [m]
		Current groundwater extraction [l3/h]
		Number of springs [-]
		Potential extraction capacity [l3/h]
		Hydraulic conductivity in rocks [log10(K)]
		Number of wells [-];

Table 1: Examples of indicators for geosystem services based on Lundin-Frisk et al. (2025), the services were systematically divided into provisioning, supporting, cultural, and regulating services.

6 RESULTS AND DISCUSSION

The participants in the stakeholder/municipality exchange in the workshops with the city of Malmö and the municipality of Askersund both gave a positive response to the geosystem services concept. The positive response primarily underscored the geosystem services concept for its communicative value in planning dialogues and for fulfilling its purpose to highlight resources and conflicts of interest. They also pointed out that some of the services in the developed maps are already presented under different nomenclature in the current planning process.

6.1 Development of geosystem services potential maps

For the city of Malmö, seven thematic geosystem services maps were developed and included accessibility and suitability. Highlighting the role of the subsurface in providing beneficial services for climate resilience, the following thematic geosystem service potential maps were created, based on previously elaborated indicators for geosystem services (Lundin-Frisk et al., 2025): regulation of erosion, temperature by the subsurface, groundwater quantity and provisioning, underground space (deep and shallow), and construction material. Additionally, the maps were developed further to indicate accessibility of the services (how easily accessible it is due to, e.g. above-ground constructions or depth) and suitability (how suitable it is to make use of certain geosystem services due to, e.g. contamination), thus also providing information about potential conflicts of interest or areas where there is currently untapped potential (Lundin-Frisk, 2025).

For the municipality of Askersund, the selection of five prioritised geosystem services themes was influenced by municipal preferences, risk perspectives, data availability, and assessment by researchers. Despite limited prior experience with the geosystem services concept among participants, the webinar and workshop 2 confirmed the importance of four thematic areas: Bearing capacity, infiltration and retention of storm water, resistance to erosion, and provision of rock aggregate. Drinking water supply (provision of groundwater) was assessed as less important for the comprehensive plan by the municipality planners, but

Gustafsson (2026) emphasised the societal importance and potential risks from climate change. The outcomes reflect a balance between practical planning needs and broader research considerations. The resulting geosystem services potential map for provisioning of groundwater on a municipal scale is shown in Figure 2, and additional maps were delveloped for each selected theme (Gustafsson, 2026).

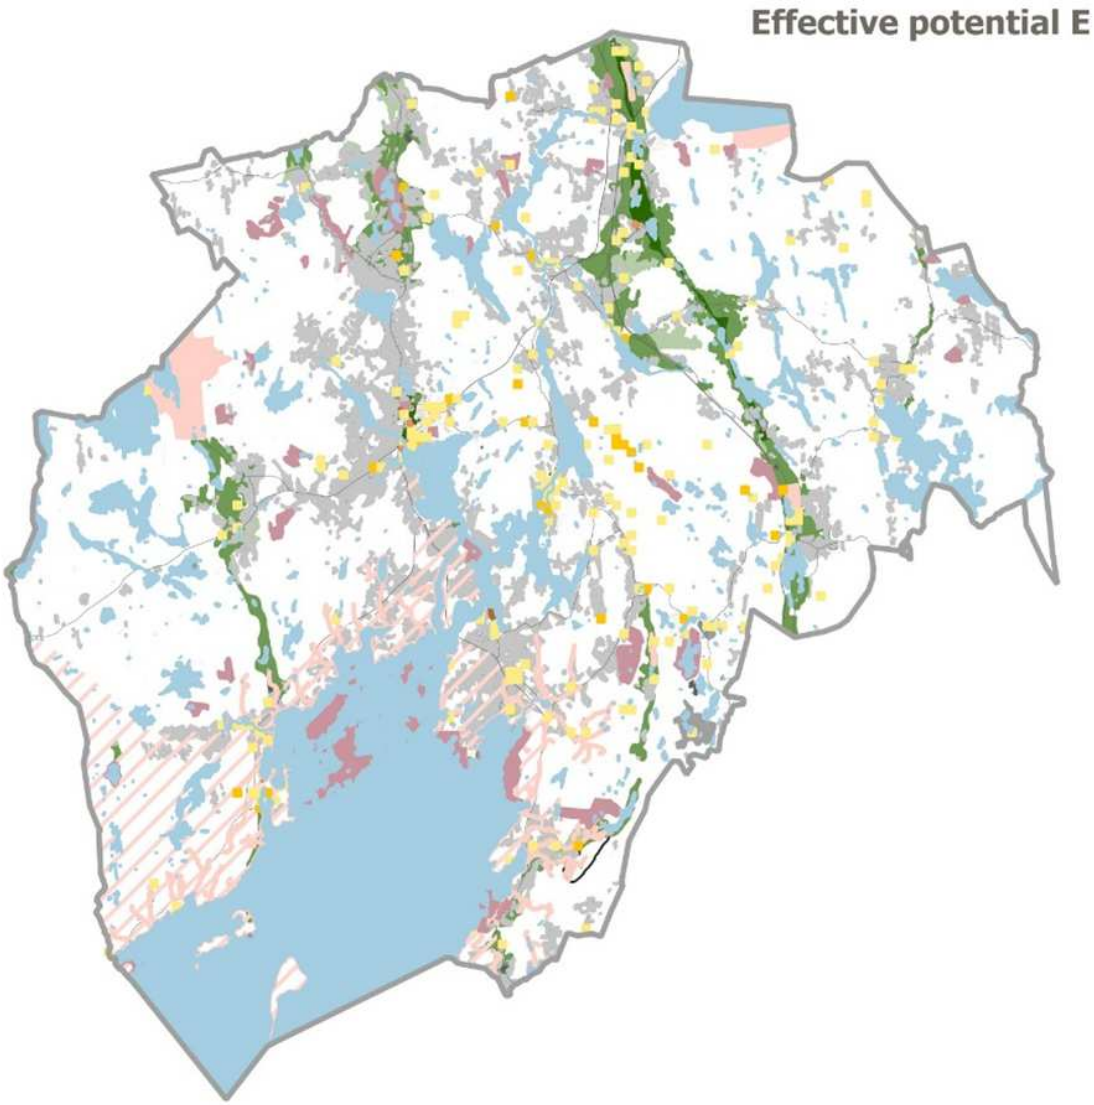

Fig. 2: Example map presenting a geosystem services potential map for groundwater provisioning on a municipal scale for Askersund (from Gustafsson, 2026).

6.2 Feedback from the municipalities and stakeholders

Preliminary results indicate that the city of Malmö is already considering the subsurface in its plans to some extent, for example, through stormwater parks that can delay and store incoming stormwater. Although the concept of geosystem services was new to workshop participants, it was positively received. It was recognised to potentially have a high communicative value for facilitating dialogue and improving the understanding of the contributions of the subsurface to enhance the city's climate resilience. The feedback from participants during the second workshop suggests that such maps may serve as a valuable basis for discussion in the early stages of planning, e.g. in the comprehensive planning process. The information provided by the maps can foster better collaboration among stakeholders from diverse backgrounds by offering a shared point of reference (Lunding-Frisk et al., 2026).

The webinar and the workshop gathered representatives from the municipality of Askersund, including a comprehensive planner, a GIS/map engineer, a land and development engineer, spatial planning architects, an environment inspector, and two relevant supervisors. As a first step, the group explored the relevance and practical application of nine pre-selected geosystem services for comprehensive planning. The discussion revealed that participants did not identify any missing aspects, though some, particularly those new to the

geosystem services concept, acknowledged the need for more time to fully assess its scope. Some of the services, such as groundwater provisioning, geological construction materials, and mineral resources, were deemed less relevant to current municipal planning. For mineral resources and construction material, this was related to the limited influence that the municipality exercises regarding these services and the permitting process. Participants also highlighted challenges in integrating complex map materials, preferring simplified, user-friendly formats. The most useful geosystem servicesand maps were those related to regulating erosion, infiltrating stormwater, and preventing harmful emissions, as these directly addressed pressing issues like buildability, stormwater management, and contamination (Gustafsson, 2026).

6.3 Discussion

The discussions in workshop 2 in both case studies highlighted the advantage of geosystem services maps to facilitate optimised subsurface use (e.g., geothermal energy, stormwater management) and resolving conflicts of interest. In the Malmö case, the workshop also facilitated stakeholder collaboration and innovative planning strategies. The scalability and applicability of geosystem services' potential maps to other urban contexts were also discussed and considered important in exchanges with both Askersund and Malmö.

During the workshop with the municipality of Askersund, data transparency, resolution, and scale stood out as key themes, especially regarding the stormwater infiltration and retention map, revealing that no single map can serve all users effectively. Too low a resolution of the maps developed within the project could miss critical details, while excessive detail may lead to overconfidence in uncertain data. Balancing these challenges requires aligning technical limitations (like data quality and availability) with user preferences. It was concluded that the purpose of each map must be defined and consistently communicated, from selecting geosystem services and through the development process.

The discussions at the Workshop 2 with the municipality of Askersund provided detailed comments on the five geosystem services potential maps, whereas the discussions at the Workshop 2 with Malmö held a more general character. The participants at the two Workshops (with Malmö and Askersund, respectively) had different backgrounds, and their overview may differ, with participants from Askersund likely working with a municipal-wide perspective. The workshops focusing on geosystem services maps were conducted earlier in Malmö than in Askersund, allowing insights and experiences from Malmö to be integrated into the Askersund case. Therefore, the maps for Askersund had been further developed at the time of the workshops and issues that were discussed in Malmö had been addressed.

The similarities between geosystem services and the established concept of ecosystem services facilitated communication with workshop participants. It is crucial to operationalize both ecosystem and geosystem services in spatial planning. While some geosystem services already align with Nature-based Solutions (NBS), more could be integrated – such as those vital for climate resilience. Expanding the scope of the NBS concept should also be considered as a potential path forward alongside the implementation of geosystem services in spatial planning.

7 CONCLUSIONS

The integration of geosystem services in spatial planning offers a promising concept for enhancing urban climate resilience as well as comprehensive planning. The use of maps in stakeholder engagement was deemed a critical instrument for effective planning. The exchange with the Askersund and Malmö municipalities indicates that the geosystem services potential maps should be further developed, as well as the indicators. Furthermore, there is a need for adaptivity for each mapping case regarding the indicators for geosystem services.

The study underscores that integrating the concept of geosystem services into spatial planning could enhance spatial planning, examplified by Malmö's climate change resilience plan and the comprehensive plan in Askersund. This can be achieved by

- enabling more effective planning and subsequently new or optimised uses of the subsurface, such as harnessing deep and shallow geo-energy for heating and cooling buildings, and improved utilisation of the subsurface for storing and delaying stormwater flow.

- improving the management of conflicts of interest, which is a key advantage of a more holistic perspective, as that provided by geosystem services.
- fostering better collaboration among various stakeholders in spatial planning processes, thus facilitating the implementation of innovative strategies that integrate the subsurface more effectively into climate resilience initiatives.
- A stronger connection between the concept of Nature-based solutions and the subsurface, and thereby geosystem services, should be considered for enhanced utilization of geosystem services.

1 ABSTRACT

European policy initiatives such as the Green Deal, the New European Bauhaus, and the "No Net Land Take" objective call for sustainable, inclusive, and climate-resilient urban development. Yet many cities, especially small and mid-sized ones, struggle to operationalise these ambitions due to fragmented governance, unclear investment pathways, and limited institutional capacity. Heritage-led regeneration projects face particularly governance challenges: layered approval processes involving multiple heritage authorities, ownership fragmentation across public and private actors, technical uncertainty regarding structural interventions and conservation standards, and persistent institutional silos between heritage protection, urban planning, and economic development mandates.

This paper presents findings from the NONA project (New gOvernance for NewspAces), funded under the Danube Region Programme, which developed and tested a governance framework for green and inclusive regeneration of degraded urban areas. At the centre of this approach is a six-phase investment lifecycle that supports cities in structuring regeneration processes, from initial diagnosis through to implementation and long-term monitoring. The lifecycle model addresses recurrent implementation failures in heritage-led regeneration by making dependencies and prerequisites visible at early stages, introducing staged feasibility checks, and clarifying institutional responsibilities before design lock-in occurs.

Applied across ten pilot cities in the Danube Region, including Stuttgart, Cluj-Napoca, Odessa, Chișinău, Gabrovo, Veszprém, Šabac, Cazin, Ravne naKoroškem, and Virovitica, the model enabled local actors to align diverse objectives (heritage reuse, climate adaptation, and public space inclusion) with actionable steps tailored to their specific governance and resource environments. The lifecycle approach functions as a coordination and risk-reduction mechanism, helping cities to translate strategic goals into feasible project pipelines through feasibility checks, stakeholder engagement routines, and explicit sequencing of regulatory, technical, and financial prerequisites.

The findings demonstrate how a structured, adaptable governance process can bridge the gap between EU policy aspirations and local implementation realities. The paper argues that embedding lifecycle thinking into urban regeneration practice offers a replicable pathway for aligning institutional responsibilities, reducing fragmentation, and mobilising investment across varied urban contexts.

Keywords: governance models, degraded areas, heritage led regeneration, inclusive public space, urban planning

2 INTRODUCTION

2.1 European policy drivers and the call for holistic local transformation

Across Europe, cities face rising pressure to revitalise degraded and underused areas while addressing climate risk, social needs, and heritage preservation. Policy priorities promote compact development, adaptive reuse, circular approaches, and the reduction of land take and soil sealing, complemented by place-based and people-centred agendas (European Commission, 2019; United Nations, 2016; Decoville and Feltgen, 2023; Marquard et al., 2020). Regeneration is increasingly framed as a cross-sector transformation that requires coordination across planning, heritage, environment, mobility, public services, and social inclusion, and often across multiple jurisdictions.

Degraded and underused areas are commonly addressed through brownfield and adaptive reuse agendas, yet implementation remains shaped by uncertainty, missing or fragmented evidence (e.g., ownership, constraints), and weak coordination between planning and investment preparation (CABERNET, 2006; Barborič et al., 2022; Černič et al., 2022). Heritage-led regeneration intensifies these challenges through layered approvals, more fragmented ownership and stewardship arrangements, and higher technical

uncertainty when reconciling conservation standards with contemporary performance requirements (Tweed and Sutherland, 2007; Pendlebury et al., 2009; Bullen and Love, 2011; Veldpaus and Pereira Roders, 2014).

Against this backdrop, this paper investigates how a structured lifecycle governance model can bridge the gap between strategic regeneration ambitions and operational delivery, particularly in heritage-led and resource-constrained contexts. The central research question is: How and under what conditions does lifecycle governance improve feasibility, coordination, and investment readiness in urban regeneration? Drawing on empirical insights from ten pilot cities in the Danube Region, this study critically assesses the applicability, limitations, and contextual dependencies of the NONA lifecycle approach. In doing so, it contributes to ongoing debates in urban studies and planning around implementation logics, governance innovation, and institutional capacity for place-based transformation.

2.2 The implementation gap

While policy frameworks provide direction, many local administrations face recurring obstacles when moving from ambition to delivery. Across the pilots, these obstacles clustered around (i) sequencing failure, where feasibility constraints (ownership, approvals, technical studies) emerge after design or political commitments; (ii) coordination failure, where fragmented mandates and weak interfaces prevent alignment; and (iii) investment-readiness failure, where risk profiles, governance arrangements, and delivery assumptions remain too unclear to mobilise funding or partners (Roberts and Sykes, 2000; Couch et al., 2011; Tallon, 2013).

2.3 From ambition to delivery

This paper argues that lifecycle governance offers a pragmatic response to implementation failures by introducing a process logic that aligns strategic ambition with staged feasibility validation. Within the NONA framework, progression through the investment lifecycle is conditional on resolving key prerequisites – such as ownership clarification, regulatory approvals, and technical assessments – and on maintaining structured engagement among public authorities, civil society, and knowledge actors. This sequencing reduces premature design lock-in and improves the planning–finance interface through clearer roles, decision gates, and investor-facing project packaging (Healey, 2006; Ansell and Gash, 2008; Morris, 2013; Weber et al., 2014).

Although iterative governance requires calendar time, addressing regulatory, technical, and ownership uncertainties early increases the durability of outcomes and prevents late-stage project failure. In this sense, lifecycle governance deliberately counters pressures for accelerated planning that often lead to premature commitments and implementation risks (Flyvbjerg, 2009). For similar reasons, investors are engaged later in the lifecycle sequence. Early investor involvement in contexts of unclear land ownership or planning conditions may reinforce speculative land-holding behaviour and distort project objectives (Adams and Tiesdell, 2013). By contrast, sequencing investor engagement after governance conditions and feasibility parameters have been clarified helps ensure that financial actors participate in shaping credible, implementable projects rather than driving premature development pressures.Placing investor engagement later in the lifecycle therefore serves a governance function: it allows public authorities and local stakeholders to stabilise spatial objectives, regulatory conditions, and ownership arrangements before capital commitments shape project trajectories.

3 NONA APPROACH

3.1 Project overview and objectives

NONA (New Governance for New spAces) is a transnational project funded under the Danube Transnational Programme (2021–2027) that focuses on mainstreaming green investments into the revitalisation of degraded areas through governance innovation and practical tools. The project developed a common structure to support cities in structuring regeneration processes, clarifying responsibilities, improving investment readiness, and strengthening stakeholder coordination.The structure was tested through pilot actions across ten territories, enabling comparative learning across different territorial scales and planning contexts. The ten pilot cities represent diverse governance and regeneration contexts:

Regional scale: Stuttgart (Germany): Metropolitan context with heritage-led regeneration of industrial sites, involving complex multi-level governance and stakeholder coordination. Cluj-Napoca (Romania): Big city addressing heritage reuse in historic neighbourhoods with ownership fragmentation and capacity constraints. Chișinău (Moldova): Capital city testing lifecycle governance under resource-constrained conditions and Odessa (Ukraine).

Mid-sized cities: Gabrovo (Bulgaria): Mid-sized city revitalising industrial heritage sites with limited market appetite and unclear business models. Veszprém (Hungary): Mid-sized city integrating cultural heritage with climate adaptation and public space inclusion, requiring cross-sectoral coordination. Šabac (Serbia): Mid-sized city addressing brownfield reuse with fragmented ownership and regulatory uncertainty. Cazin (Bosnia and Herzegovina): Mid-sized city with limited administrative capacity.

Small sized cities: Ravne naKoroškem (Slovenia): Small municipality addressing industrial heritage reuse in a weak market context and Virovitica (Croatia).

These pilots deliberately cover different territorial scales (metropolitan, mid-sized, micro-municipal), governance conditions (strong/weak institutional capacity, single/multi-level mandates), and regeneration challenges (heritage-led reuse, climate adaptation, industrial brownfields, inclusive public spaces). This diversity enabled comparative assessment of how lifecycle governance performs across contexts and under what conditions it is transferable.

3.2 Six-phase investment life cycle

A core component of the NONA methodology is a six-phase investment lifecycle designed as a cyclical process rather than a linear sequence. The lifecycle is inspired by Project Cycle Management frameworks used by the European Commission, World Bank, and OECD (European Commission, 2004; World Bank, 2020), but adapted specifically for urban regeneration contexts characterised by high uncertainty, fragmented governance, and complex stakeholder environments. Unlike standard PCM approaches, which assume relatively stable objectives and clear institutional mandates, the NONA lifecycle emphasises iterative feasibility validation, continuous stakeholder engagement, and staged risk reduction suited to heritage-led and brownfield regeneration challenges.

From an analytical perspective, the six-phase investment lifecycle can be understood as a governance response to recurrent implementation failures observed in urban regeneration processes. Across many European contexts, regeneration initiatives tend to fail not due to a lack of strategic vision, but because of weak sequencing, late identification of feasibility constraints, fragmented institutional mandates, and poorly structured interfaces between planning and investment decision-making (Couch et al., 2011; Tallon, 2013). Lifecycle governance addresses these failures by introducing an explicit process logic that aligns strategic ambition with staged feasibility checks, clarified responsibilities, and iterative decision gates. Rather than assuming linear progression from vision to delivery, the lifecycle framing makes dependencies and prerequisites visible at early stages, thereby reducing the risk of premature design lock-in and late-stage project blockage. In this sense, lifecycle governance operates less as a normative planning model and more as a pragmatic coordination and risk-reduction mechanism that structures how actors, evidence, and investments are progressively aligned over time.

The lifecycle supports cities in moving from identification of needs to planning, land and environmental regulation, implementation, usage, and monitoring and evaluation. Participation is embedded across phases to ensure that the investment logic remains aligned with local needs and that decisions are supported by stakeholder cooperation. The lifecycle is operationalised through structured routines as stakeholder mapping (identifying actors, interests, and mandates at each phase), evidence collection for the degraded area (ownership, contamination, heritage status, infrastructure, market conditions), feasibility checks (staged validation of regulatory, technical, financial, and governance prerequisites), milestone logic (decision gates where progression is conditional on resolving specific constraints), preparation of investor-oriented materials (structured project information packages clarifying constraints, sequencing, and long-term operational assumptions).

For heritage-led regeneration specifically, the lifecycle marks checkpoints: Phase 1 (Identification): Early heritage status assessment, preliminary ownership mapping, and identification of approval layers. Phase 2 (Planning): Structured consultation with heritage authorities, technical conservation assessments, and

alignment of heritage protection with urban planning and economic development objectives. Phase 3 (Land and Environmental Regulation): Resolution of ownership fragmentation, completion of required heritage impact assessments, and clarification of regulatory prerequisites before design lock-in. Phase 4 (Implementation): Staged implementation logic that sequences conservation interventions with contemporary adaptations, allowing for technical adjustments as uncertainties are resolved. Phase 5 (Usage): Long-term stewardship arrangements that clarify maintenance responsibilities under heritage protection regimes. Phase 6 (Monitoring and Evaluation): Feedback loops that assess whether heritage values are maintained and whether governance arrangements remain effective.

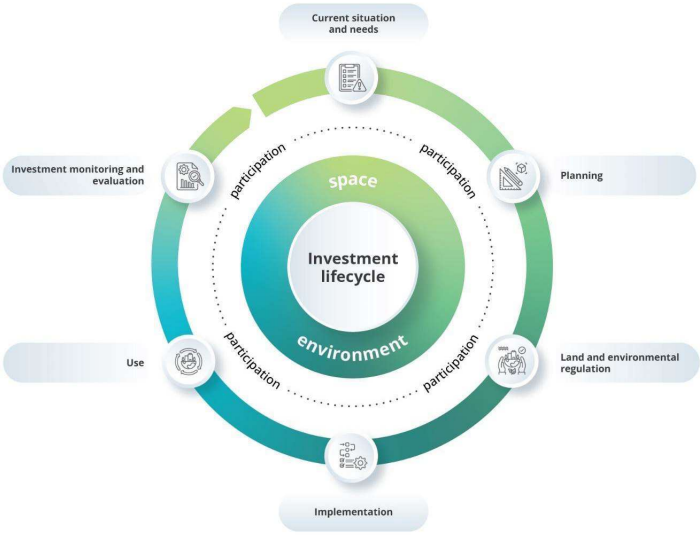

Fig. 1: Investment life cycle in the NONA methodology.

4 PILOT APPLICATION AND COMPARATIVE INSIGHTS

4.1 Methodology

This paper draws on qualitative, comparative analysis of ten pilot projects conducted under the NONA (New gOvernance for NewspAces) initiative between 2022 and 2025. The research is based on three primary data sources: (1) internal project documentation including feasibility reports, planning diagnostics, and stakeholder mappings; (2) records of participatory events and workshops held during each lifecycle phase; and (3) cross-pilot synthesis outputs produced collaboratively by local and transnational project teams.Analytical insights were generated through structured thematic coding of these materials, focusing on recurring governance challenges (e.g., sequencing failures, stakeholder fragmentation, unclear investment pathways) and lifecycle responses (e.g., feasibility checks, participation routines, decision gating). A matrix was used to compare how the lifecycle performed across different territorial scales (metropolitan, mid-sized, and micro municipalities) and regeneration types (heritage reuse, brownfield transformation, public space revitalisation). While the findings are grounded in real-world pilot implementation, they reflect early to mid-stage progress rather than completed projects. As such, the analysis emphasises process performance rather than long-term outcomes.

4.2 Pilot design and scope across territorial scales

The NONA methodology was tested across ten pilots deliberately selected to reflect different territorial scales, governance conditions, and regeneration challenges. This multi-scalar design enabled the project to assess whether a shared lifecycle governance approach can remain applicable across contexts ranging from complex metropolitan and functional urban rural settings to capacity-constrained mid-sized cities and border micro municipalities.

4.3 Pilot typologies and thematic alignment

This paper focuses on the pilot typologies that most directly inform the conference theme and the paper's argument, namely the implementation gap between European ambitions and local delivery, and the role of lifecycle governance in structuring green, inclusive, and heritage-sensitive revitalisation. Table 1 synthesises

the relevant pilot typologies by linking territorial scale to the implementation gap and to the specific governance functions supported by the NONA six-phase investment lifecycle. The typology groups are derived from cross-pilot synthesis (NONA, 2025) and reflect recurring patterns in governance challenges and lifecycle responses observed during pilot testing.

Methodological note: The pilots are grouped analytically by scale-related governance characteristics rather than by geographic location alone. Some pilots contribute to multiple typologies depending on the specific regeneration challenge addressed. For example, Stuttgart and Cluj-Napoca are classified under "functional urban and metropolitan contexts" due to multi-level governance complexity but also exhibit heritage-led regeneration characteristics. The grouping serves to highlight scale-sensitive governance patterns.

Pilot scale group	**Pilot typology (theme)**	**Pilots**	**Where the "implementation gap" shows up**	**What the NONA lifecycle supports**
Functional urban and metropolitan contexts	Multi-level regeneration and shared assets (water, land)	Stuttgart, Cluj-Napoca,	Fragmented mandates, cross-jurisdiction coordination, and uneven stakeholder urgency	Sequencing responsibilities, cooperation routines, and investor-facing clarity
Functional urban and metropolitan contexts	Heritage-led regeneration prerequisites	Cluj-Napoca, Chișinău	Approvals, technical studies, ownership, and financing uncertainty	Early-stage readiness pathway, staged risk reduction, clearer investment narrative
Mid-sized cities	Reuse of industrial assets and cultural-social infrastructure	Gabrovo, Šabac,Veszprém,	Weak project pipelines, and community acceptance issues	Structured pipeline building, participatory validation, prioritisation, and staging
Mid-sized cities	Inclusive public space revitalisation	Veszprém, Šabac, Cazin	Operational governance unclear, long-term stewardship risks	Roles for maintenance/use, co-creation across phases, monitoring, and iteration
Border micro municipalities	Industrial heritage or brownfield reuse in weak markets	Virovitica, Ravne naKoroškem	Business model uncertainty, limited investor visibility, and funding gaps	Decision-gating, phased implementation logic, investment packaging, and communication

Table 1: Scale-related constraints and added value of lifecycle governance.

4.4 Comparative findings from pilot testing

Across pilot typologies, several key insights emerged regarding how lifecycle governance functions in practice and how it addresses implementation failures. These findings are illustrated with short examples from pilot cities.

4.4.1. Integrated Governance and Cross-Sectoral Coordination

Pilot evidence confirms that sector-based planning is insufficient for complex green and heritage projects where responsibilities, externalities, and beneficiaries span administrative and sectoral boundaries. In Stuttgart, water was established as a binding spatial reference, enabling catchment-based planning that linked land use, hydrological interdependencies, and responsibilities across municipalities and institutions; this increased transparency over "impact chains" (retention–infiltration–runoff) and created early coordination points before project definition. In Cazin, a cross-sectoral coordination model between urban planning, municipal utilities, and development administration reframed a conventional public-space upgrade as a multifunctional green system (stormwater management, alternative materials, tree planting), improving feasibility through clearer sequencing and technical documentation aligned with permitting. In Virovitica, internal project teams improved inter-departmental coordination (planning–property management) and exposed the absence of city-wide integrated planning as a shared constraint, illustrating how lifecycle governance can function as a diagnostic device for fragmentation before it becomes a delivery risk.

4.4.1 From consultation to co-creation

Across pilots, the shift from one-off consultation to iterative co-creation emerged as a key mechanism for stabilising expectations and strengthening implementation capacity. In Šabac, the Local Action Group

(LAG) provided a shared governance interface that reduced fragmentation between city departments, public institutions, and external actors; co-creation outputs were progressively translated into implementation narratives through the Regional Investment Forum. In Gabrovo, the NONA Civil Society Bootcamp moved local actors from consultation to co-production and contributed to an integrated roadmap that positioned culture, ecology, and social inclusion as mutually reinforcing drivers of riverfront regeneration. In Veszprém, a stakeholder and population-survey methodology – supported by a redesigned communication strategy to counter rumors and increase willingness to engage – helped re-centre decision-making on residents' needs while keeping strategic flexibility for future investment choices.

4.4.2 Investment structuring and readiness

Pilots provide convergent evidence that investment readiness depends on timing: credible investor engagement generally requires early public de-risking, while premature 'capital seeking' without documentation can undermine credibility. In Cluj-Napoca, early involvement of financial actors (e.g., banks and EIB-linked expertise) as mentors – paired with ESG and EU Taxonomy alignments supported clearer bankability criteria and a shared "investment language", although fragmented ownership and lengthy permitting remain binding constraints. In Gabrovo, an operational phased concept (temporary–seasonal–permanent) strengthened municipal readiness by enabling testing and risk management before long-term capital commitments. In Chișinău, the lifecycle process clarified that structural assessments, heritage compliance pathways, and an operational model for phased activation are prerequisites for investor appetite in protected sites. In Veszprém, strong market interest in residential development was tempered by the pending comprehensive spatial plan, demonstrating how regulatory sequencing can delay investable packaging even where demand exists.

5 NONA ADDED VALUE AND TRANSFERABILITY

The comparative pilot testing indicates that the main contribution of NONA is not a single thematic intervention, but a repeatable governance routine that helps cities translate regeneration ambitions into implementable pathways. The six-phase investment life cycle provides a shared process logic that connects planning intent with feasibility, delivery, and long-term stewardship, reducing the risk that projects remain atthe concept level or become blocked when constraints emerge too late (NONA, 2025).

A first element of added value lies in clarifying sequencing and decision gates. By structuring regeneration as an investment life cycle, cities are supported in identifying prerequisites early, such as land and regulatory constraints, required studies, institutional roles, and realistic delivery assumptions. This improves the quality of project pipelines by making dependencies visible and by encouraging staged progression rather than one-step conceptual planning. The pilot examples (Stuttgart, Chișinău) demonstrate how this sequencing logic prevented premature design lock-in and late-stage regulatory blockage by making prerequisites explicit early.

A second element lies in strengthening cooperation through embedded co-creation. NONA treats participation as a continuous task across phases, supporting repeated moments of alignment among public actors, civil society, knowledge institutions, and private stakeholders. This helps reduce fragmentation not by institutional redesign alone, but by providing a shared process structure that clarifies when engagement is needed and what decisions it should inform. For projects involving heritage reuse, inclusive public space, and contested urban transformation, this sequencing of engagement is essential for legitimacy and long-term sustainability. The pilot examples (Veszprém, Gabrovo) demonstrate how structured stakeholder engagement across phases reduced late-stage opposition, improved long-term stewardship arrangements, and co-constructed feasible pathways that balanced community aspirations with technical and financial constraints.

A third element concerns investment readiness and risk reduction. Pilots showed that the ability to communicate a project credibly to potential funders, investors, and partners depends on clear information about constraints, governance readiness, sequencing, and long-term operation. The NONA approach supports this through structured investment packages and investor-facing communication, which helps cities present projects as staged, feasible propositions rather than isolated design ideas. Even in weaker markets or capacity-constrained administrations, this improves the basis for funding applications, blended financing, and partnership building.

Transferability, however, is conditional. The pilots also reveal persistent constraints linked to political continuity, administrative capacity, and market appetite. In metropolitan and functional urban contexts, the

main challenge is aligning multiple institutions and interests over time. In mid-sized and micro municipalities, the main challenge is maintaining continuous capacity for feasibility work, stakeholder engagement, and implementation preparation.

6 DISCUSSION: LIMITATIONS AND CONDITIONS FOR TRANSFERABILITY

6.1 Evidence-based and analytical approach

This paper is based on a qualitative comparative synthesis of NONA pilot applications. The analysis draws on pilot documentation and cross-pilot comparison materials produced during methodology testing, focusing on how governance bottlenecks and investment readiness barriers appear across different territorial scales and pilot typologies.

6.2 Interpreting the core contribution: lifecycle governance as a bridge between planning and investment readiness

A key insight emerging from the pilots is that the main barrier to implementation is often not a lack of ideas, but the absence of a shared process logic for moving from ambition to delivery.This is especially relevant in contexts where ownership issues, regulatory steps, required studies, or environmental burdens can halt a project once it is already politically and publicly announced. In such cases, the governance value lies in clarifying what must be resolved first, what evidence is required, and what institutional roles need to be formalised to reduce uncertainty.

For heritage-led regeneration specifically, the lifecycle logic addresses governance challenges that are particularly acute in these contexts layered approval processes (sequencing heritage authority consultations and technical assessments), ownership fragmentation (identifying ownership prerequisites early and staging negotiations), technical uncertainty (requiring conservation expertise and structural assessments at appropriate phases), institutional silos (creating formal coordination routines between heritage, planning, economic development, and environmental actors).

The pilots further suggest that regeneration becomes more credible when participation is embedded across phases. Stakeholder engagement that is sequenced and linked to concrete decisions can reduce fragmentation by stabilising expectations, building legitimacy, and improving coordination among public actors, civil society, knowledge institutions, and private stakeholders. This does not eliminate conflict, but it improves the capacity to negotiate trade-offs and to keep projects progressing through realistic decision gates rather than through ad hoc negotiation or late-stage opposition.

Table 2 provides the typology-oriented framing used to interpret patterns across contexts. Extracting generalisable insights from these patterns clarifies what aspects of the lifecycle approach remain stable across scales and which are more sensitive to administrative capacity or governance complexity.

These patterns suggest that lifecycle governance is transferable across scales, but requires adaptive implementation that respects local capacity, governance complexity, and market conditions. The core logic remains stable, but tools, engagement strategies, and support mechanisms must be tailored.

6.3 Critical Reflections and Transferability Conditions

While pilot applications suggest that lifecycle governance offers a promising response to implementation failures, effectiveness is conditional on enabling factors that vary by scale and institutional setting. Political continuity and administrative capacity are preconditions for sustaining feasibility work and decision-gating: in capacity-constrained contexts, early phases can stall when diagnostics, technical documentation, or mandate clarity cannot be produced at the required pace (Pritchett et al., 2013). NONA's contribution was therefore strongest where cities could institutionalise a minimum coordination nucleus (e.g., inter-departmental teams or a LAG) that persisted beyond individual events.

Market conditions and investor behaviour shaped the planning–finance interface across pilots. In stronger markets (e.g., Cluj-Napoca), early dialogue with finance actors supported bankability criteria and ESG-ready packaging, yet investors remained conditional on regulatory de-risking and predictable delivery assumptions. In weaker markets (e.g., Ravne naKoroškem; parts of Gabrovo), the lifecycle improved the credibility of grant applications and partnership building but could not substitute for systemic demand constraints; here,

"investment readiness" took the form of phased, low-regret interventions and capacity-building before larger capital commitments.

Category	Aspect	Metropolitan Contexts	Mid-sized Cities	Micro Municipalities	Cross-scale Notes
Stable across scales	Lifecycle logic	Applicable	Applicable	Applicable	Core sequencing, decision gates, feasibility checks, and engagement routines remain consistent.
Stable across scales	Prerequisites	High complexity	Moderate complexity	Lower complexity	Ownership, regulatory, technical, and financial prerequisites apply universally; complexity varies by scale and asset type.
Scale-sensitive	Coordination complexity	High (multi-level)	Medium	Lower actor number, capacity-intensive	Metropolitan settings need formal cooperation routines; smaller cities need lightweight but persistent coordination.
Scale-sensitive	Fragile phases	Phase 3 (land/regulation)	Phases 2–4 (planning→delivery)	Phases 1–2 (diagnosis/planning)	Vulnerability shifts with regulatory layers vs. internal capacity and evidence production.
Scale-sensitive	Market conditions	Stronger private appetite	Mixed	Weaker demand	Funding mixes differ: metropolitan areas can test blended finance; smaller cities rely more on public programmes and partnerships.
Scale-sensitive	Investment packaging value	High for institutional investors	High for mixed funding	High for grants/partners	Investor-facing clarity improves credibility across contexts, even where private capital is limited.

Table 2: Patterns of lifecycle governance across scales.

Finally, regulatory and procedural environments often conflicted with iterative regeneration logics. Heritage protection procedures (e.g., Chișinău) and slow plan revision cycles (e.g., Veszprém) illustrate how sequential approvals can delay even well-coordinated processes, shifting fragility to Phase 3 (land and regulation) or creating "dead time" between planning and investment packaging. Transferability therefore depends on adapting tools to local capacity (simplified checklists, external technical support) and on creating lawful pathways for temporary, reversible interventions that enable learning-by-doing without undermining conservation and accountability.

These findings align with broader urban governance literature emphasizing the importance of adaptive capacity, institutional learning, and phased implementation in managing complex urban transformations (Pritchett et al., 2013; Hodgson &Cicmil, 2006). Lifecycle governance is not a panacea, but a structured negotiation device whose success depends on its institutional embedding, technical support, and ability to adapt to local realities.

7 CONCLUSION

This paper has presented a comparative, multi-scalar analysis of the NONA project's lifecycle governance framework, designed to support the revitalisation of degraded urban areas through green and heritage-sensitive investments. Situated within the broader context of European policy ambitions – such as the Green Deal, the New European Bauhaus, and the "No Net Land Take" objective (European Commission, 2019; 2021) – the findings reinforce the persistent challenge of operationalising high-level policy objectives within fragmented, resource-constrained, and institutionally complex local governance systems (Couch et al., 2011; Pendlebury, 2013).

Drawing on pilot applications across ten Danube Region cities, the study demonstrates that a structured, iterative investment lifecycle – unlike traditional integrated planning models (Healey, 2006) or project management frameworks assuming linearity and institutional clarity (European Commission, 2004; World Bank, 2020), can serve as a pragmatic bridge between strategic ambition and implementation. Lifecycle governance addresses common failures identified in the literature, including sequencing gaps (Morris, 2013), coordination breakdowns (Ansell & Gash, 2008), and investment readiness constraints (Weber et al., 2014), by embedding decision gates, participatory routines, and feasibility logic into all stages of the process.

In heritage-led regeneration in particular, the NONA lifecycle adds distinct value by sequencing engagement with heritage authorities and technical assessments (Pendlebury et al., 2009), addressing ownership fragmentation (Tweed & Sutherland, 2007), and managing technical uncertainty (Bullen & Love, 2011). These are challenges that are generally under-served by conventional planning frameworks, which often lack mechanisms for continuous cross-sectoral coordination and early feasibility validation (Veldpaus& Pereira Roders, 2014; Hodgson &Cicmil, 2006).

Pilot findings confirm that the approach is applicable across scales, but that transferability depends on adaptive implementation aligned with local capacity and market context. As summarised in Table 2, while the core sequencing logic remains stable, capacity constraints and complexity levels shift vulnerability across phases (Pritchett et al., 2013). The pilots also echo insights from urban regeneration literature that successful delivery hinges less on having visionary plans and more on having structured processes to manage risk, negotiate trade-offs, and progressively align actors over time (Couch et al., 2011; Roberts & Sykes, 2000).

From a practical perspective, the main recommendation is to treat regeneration not as isolated planning exercises but as investment-ready, lifecycle-governed processes, where early outputs include clarified mandates, stakeholder roles, and feasibility evidence, not just design concepts. From a research perspective, further longitudinal studies are needed to track how later lifecycle phases, particularly implementation, usage, and monitoring, contribute to sustained outcomes in heritage conservation, social inclusion, and environmental performance.

Ultimately, the NONA lifecycle framework offers a replicable yet adaptable governance routine that helps cities move from fragmented ambition to feasible delivery, thereby advancing the EU's integrated, green, and inclusive urban agenda (European Commission, 2019; Decoville& Feltgen, 2023). As shown in diverse urban contexts, from Stuttgart to Ravne naKoroškem, the governance innovation lies not only in strategic alignment, but in operationalising complexity through structured decision-making and context-sensitive risk management.

8 ACKNOWLEDGEMENTS

The research presented in this paper was developed within the framework of the NONA – New gOvernance for NewspAces project, funded by the Interreg Danube Region Programme 2021–2027 under the European Union Cohesion Policy. The project aims to support cities and regions in mainstreaming green investments and innovative governance approaches for the revitalisation of degraded urban areas.

The authors would like to acknowledge the valuable contributions of the project partners and pilot cities involved in the NONA consortium, whose practical experiences, stakeholder engagement processes, and pilot activities provided the empirical basis for this research. In particular, the collaboration of local administrations, civil society organisations, research institutions, and regional development actors across the Danube Region made it possible to test and refine the lifecycle governance methodology presented in this paper.

The authors also thank the local stakeholders and participants involved in workshops, Local Action Groups, and pilot activities across the participating territories for their insights and engagement throughout the project implementation.

The content of this publication reflects the authors' views only, and the programme authorities cannot be held responsible for any use that may be made of the information contained therein.

1 ABSTRACT

The transition to climate neutrality, which attempts to accelerate renewable energy generation, requires trade-offs due to the diverse demands on land use. As a consequence, early consideration of potential conflicts and transparency on the selection of type and location of energy generation, storage and distribution is key. Due to our poly-crises, we urgently need to reflect not only the necessity to orientate towards climate-neutrality but also the need to promote species and biodiversity conservation at the same time. Particularly, relevant aspects for biodiversity such as the connectivity can only be sufficiently treated at supra-local planning levels, while other indicators deserve a detailed consideration at local level (tiering).

The relevance to consider trade-offs and alternatives based on sufficient data and information by stakeholders becomes particularly evident at the regional level. The Austrian federal state Burgenland is often listed as a role model for energy transition at regional level and excellence in balancing trade-offs at earlier planning stages. Before starting with the first wind turbines in 1997, the regional self-supply share for electricity was at 1,5 %. Only 16 years later, in 2013 there was more electricity generated than used on an annual basis, evolving to up to 239 % in 2024. For 2030, the goal is to generate more clean energy (including energy for heat and mobility) than is used on an annual basis. This transition process is guided by a constantly evolving planning approach starting in 2002 which is strongly based on integrating diverse perspectives from multiple actors involved in planning.

This paper aims to describe the formal and informal involvement of stakeholders together with the planning approach as well implications for the consideration of biodiversity and landscape aspects. As a preliminary study, it examines the extent to which the planning approach affects the quality of the basis for decision-making and conflict minimisation with focus on biodiversity and landscape. In this context we investigated whether this iterative and collaborative planning approach with direct interlinking of SEA with zoning planning leads to a more comprehensive consideration of decision-relevant data bases and also to greater acceptance of local decision makers and citizens. Based on case study research and document analysis, the paper highlights achievements of this planning approach and outlines points for improvement. Our investigations serve as a pre-study for the Biodiversa+ project BIOGAIN, which deals with transformation towards biodiversity net-gain in strategic spatial planning for renewable energy development through a strongly transdisciplinary research approach and investigating the role of novel AI supported data collection and analysis in diverse planning contexts.

Keywords: Collaborative Planning, Green Energy Transition, Biodiversity Net Gain, Regional Governance, Urban Planning

2 INTRODUCTION

To tackle the challenges of decarbonisation and – as an important part of it – the transformation of the energy system is one of the most challenging tasks we face at present. Challenges refer to conflicting objectives regarding land uses leading to implications on e.g. biodiversity, human health, recreation or food security. The role of spatial planning is amongst others to provide land for energy generation facilities like wind park and PV installations and balancing trade-offs at the same time. The few experiences and fast technical development of wind turbines and PV-systems make this task challenging with the need to create a 'learning process' that can improve over time. Particulary, interrelationships between diverse types of renewable energy developments and consequences for biodiversity are still underresearched.

With experience in strategic planning for renewable energy systems since 2002, Burgenland is Austria's pioneer state in this field of spatial planning. It was the first federal state in Austria, where wind power

development took place at large scale and where spatial effects were addressed in a systematic way. Due to its rapid growth and expected land use related conflicts, the development of the energy sector became a spatial planning issue.

In Burgenland the energy transition claims a huge amount of space (3.000 ha zones for PV, 9.500 ha zones for wind parks), which is not directly comparable to any other spatial planning tasks with a comparable demand of land before. Impacts on biodiversity have become particularly relevant with regard to connectivity, particullarly when energy production meets linear infrastructure such as railway or highway infrastructure. Sandfort et al. (2025) demonstrated that renewable energy developments affect established animal corridors as they provide the reliable distance from settlements. This is particularly relevant as suitable spaces are challenging to find in case of extensive renewable energy expansion. Both the installation of power plants as well as the mitigation and compensation of negative impacts has required intensive amounts of land. In order to coordinate this, site selection processes and facilitate them with the appropriate data a large number of actors has been involved. Consequently, knowledge transfer and acceptance became crucial elements of the planning processes.

Considering the multiple pressures on land and the decline of biodiversity at the same time, a knowledge-based decision-making based on sound biodiversity data as well as learning from monitoring processes becomes key (Diaz et al., 2019). Net-gain policies, introduced by the EU legislation, will even more require a coordinated, strategic planning approach based on usable data and well-organized data sharing processes. Particuluarly then when we target biodiversity net-gain planning, the transparency between the rational ground for decision making and the value-tradeoffs becomes essential.

Based on the analysis of the strategic spatial planning process for renewable energy development in Burgenland so far, this paper reflects the formal and especially the informal involvement of diverse groups of actors in the integrated planning approach with SEA in light of their contribution to biodiversity data sharing as well as knowledge transfer. Against the background of planning theories – the collaborative planning approach (Healey, 1997) and the rational-collaborative planning model (Stoeglehner, 2010) – we discuss the implications of the integration of actors and their role and knowledge contribution.

Core research questions are i) which actors are involved throughout the strategic spatial planning process for renewable energy development in Burgenland so far and ii) how far their involvement influences the data sharing and knowledge transfer in the field of biodiversity and landscape. Finally, we want to discuss as a preliminary study, how far the experiences from Burgenland can provide a basis for learning in a transformative planning approach which focuses not only on compensation but also on the advancement of biodiversity in light of a net-gain planning approach.

Based on case study research including observations of one author and reflexive dialogue with the other authors, combined with document analysis, the paper highlights achievements of the planning approach taken in Burgenland and outlines relevant needs for improvement. Finally, we discuss entry points for additional data deriving from novel sources such as AI supported automated data collection. Our investigations serve as a pre-study for the EU-Biodiversa project BIOGAIN, which deals with transformation towards biodiversity net-gain in integrated spatial and energy planning through a strongly transdisciplinary research approach and investigating the role of novel AI supported data collection and analysis in diverse planning contexts.

3 BACKGROUND – THEORETICAL CONCEPTS OF PLANNING APPROACHES IN LIGHT OF GREEN ENERGY TRANSITION

Integrated spatial and energy planning has been a highly dynamic planning field with different approaches in all Austrian federal states. To discuss the contribution of formal and informal involvement of different groups of actors we introduce two theoretical planning concepts:

Dating back to the nineties of the previous century Healey (1997) explored planning as a collaborative governance process. According to her approach, planning should be organized as an inclusive, deliberative process that enables collective action across public agencies, private actors, and civil society. In this context, several authors discussed therewith how planning can be reframed away from top-down technocratic control towards communicative, dialogic practice grounded in public reasoning (Gunton and Day, 2003; Linnenluecke et al., 2017).

The concept after Healey (1997) includes the following key points:

- Communicative rationality: legitimacy and quality of decisions depend on open, inclusive discourse and reason-giving among stakeholders
- Institutional capacity: comprising knowledge resources, relational resources (trust, networks), and mobilization capacity
- Place and path dependency: effective planning engages local narratives and path dependencies to co-produce context-sensitive strategies.
- Strategy-making as iterative: Emphasis on iterative, reflexive 'strategy making' rather than fixed master plans, with experimentation, feedback, and learning.
- Power and inclusion: Process design must recognize power asymmetries and broaden inclusion so marginalized groups can influence outcomes.
- Governance focus: Planning is embedded in multi-actor governance networks; the task is to create arenas and interfaces for negotiation and coordination across sectors.

Several authors discussed the collaborative planning approach over the past three decades and developed it further in different thematic fields and planning contexts (e.g., Van Dijk, 2021 or Conzales and Connell, 2022). Already fifteen years ago, Stoeglehner (2010) introduced the rational-collaborative planning model, which combined the rational (facts, analysis) "level of facts" and collaborative (values, participation) strengths "level of value" as two essential components of planning. This approach outlines the importance of a sound information basis, and transparent aggregation rules to link values and facts (Stoeglehner, 2010).

More recent publications such as Jiricka-Pürrer and Stöglehner (2025) discuss the relevance and challenges of recognizing trade-offs with a focus on strategic planning contexts like integrated spatial and energy planning. In this context, the importance of a sound information basis as well as the risk of unperceived biases related to trade-offs becomes even more evident. Applying a rational–collaborative planning paradigm targets to increase transparency on values, and foster traceable aggregation rules for judging environmental significance.

In the field of impact assessment, a variety of scholars such as Cashmore and Richardson (2013) or Hansen et al. (2013) dealt with power relationships related to collaboration and actors' involvement. Partidario et al. (2023) elaborated further the discussion how decision-makers connect values and facts, influenced by power relation and actor constellations in an environmental assessment.

4 METHODOLOGICAL APPROACH

Our approach focuses on case study research (Yin, 2018), combining observations of one author with document analysis and reflective discurse with the co-authors against the background of planning theory. In the following we explain first our methodological approach for this preliminary study and then summarize the case study area's development in strategic spatial planning for renewable energy development.

4.1 Case study research

Due to his longterm experience in strategic spatial planning for renewable energy development, the first author had the ability to reflect from its personal experience and participation, the development of strategic spatial planning for renewable energy development over more than a decade. His involvement comprised the regional framework concepts as well as detailled examination for wind energy zones as expert reports from 2011 to 2021 as well as the following planning and assessment processes for the ordinance on wind energy zones with its amendments including the respective SEAs. For solar power development he contributed to both the generel guidelines for ground-mounted PV systems including the drafting of the criteria-set for planning and assessment of the zones. Furthermore he was involved in the planning and assessment processes for the ordinance on solar energy zones with its amendments including the respective SEAs.

With his background in spatial planning and a professional experience in environmental assessments, he contributed to the analysis of data sharing related to the procedural involvement of different groups of actors. Advances of strategic spatial planning for renewable energy development through careful site selection under the consideration of diverse needs and land use demands, is part of his PhD.

In this study his research focuses on the integration of biodiversity data. Due to his past responsibilities in developing environmental reports for the zoning planning in Burgenland for both wind and solar energy, he has the ability to not only reflect the documented outcome (see also 4.2) but also the procedural data collection processes as well as the involvement of different groups of actors.

The last author served as an independent counterpart for reflection with an extensive experience in environmental assessment both from research and practice in other fields of EA, providing structured feedback for the analysis of the planning process in order to question the related stakeholder involvement against the conceptional literature background of power dynamics and decision making in environmental assessments. Both developed this contribution – together with input from the third author – in an iterative, discursive process against the literature background on planning theory as well as literature on power dynamics related to stakeholder involvement.

4.2 Literature-supported analysis of planning documents

As a basis for discussion, the planning documents on strategic spatial planning for energy development in Burgenland have been taken into account.

For wind energy, zoning there are seven regional framework concept dating from 2002 to 2020 with 35 detailed examinations on municipal level, all conducted as expert report. Since the setting of a legal basis in 2022, there is an ordinance with currently 2 amendments and the corresponding environmental reports:

- Festlegung von Windkraft-Eignungszonen 2022. Integrierter Umweltbericht und Erläuterungsbericht. 2022
- Änderung der Verordnung, mit der Windkraft-Eignungszonen festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2023
- Änderung der Verordnung, mit der Windkraft-Eignungszonen festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2023
- For solar-PV zoning, there is an ordinance with currently four amendments in power and one in public consultation. The corresponding environmental reports were analyzed for this study:
- Verordnung mit der Eignungszonen für die Errichtung von Photovoltaik-Freiflächenanlagen im Burgenland festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2021
- Verordnung mit der Eignungszonen für die Errichtung von Photovoltaik-Freiflächenanlagen im Burgenland festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2022
- Änderung der Verordnung, mit der Eignungszonen für die Errichtung von Photovoltaik-Freiflächenanlagen im Burgenland festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2023
- Änderung der Verordnung, mit der Eignungszonen für PV-Freiflächenanlagen festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2023
- Änderung der Verordnung, mit der Eignungszonen für PV-Freiflächenanlagen festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2024
- Änderung der Verordnung, mit der Eignungszonen für PV-Freiflächenanlagen festgelegt werden. Integrierter Umweltbericht und Erläuterungsbericht. 2026

Additionally, all the insights out of action research and scanning of the planning documents were double-checked with the corresponding entries in the Austrian Spatial Planning Reports (ÖROK, 2005; ÖROK, 2008; ÖROK, 2012; ÖROK, 2015; ÖROK, 2018; ÖROK, 2021; ÖROK 2024).

4.3 Description of the case study area – evolution of regional concepts for energy development in Burgenland

Historically, the federal state of Burgenland was the only region in Austria without any substantial generation of electricity. Until 1997 the share of regional self-supply was constantly below 2 % (STATISTIK AUSTRIA, 2025a), whereas even the Austrian capital Vienna, which is a federal state on his own, accounts 75 % in average from 1988-2024 (STATISTIK AUSTRIA, 2025b). It is therefore not

surprising that the provincial government seized the opportunity to take advantage of the technical and economic development of wind power together with the exceptionally good wind potential in the sparsley populated areas of Northern Burgenland and promoted the first-time-possible generation of electricity in a larger scale within state's borders. Soon after the construction of the first turbines, it became clear, that the dynamic development of wind power needs to be managed on a strategic level (ÖROK, 2005).

4.3.1 Wind power development

In 2002, the first regional framework concept for wind power development ('Regionales Rahmenkonzept für das Nördliche Burgenland') was elaborated. This concept presented general strategies and evaluation criteria as a basis for further approval processes of future wind parks. Furthermore, the area of 13 municipalities was investigated and six suitability zones as well as exclusion zones were designated. (ÖIR, 2002). Soon after the first concept, in 2004 a spatial extension to another nine municipalities was added (Regionales Rahmenkonzept für Windenergieanlagen Im Mittelburgenland und um Eisenstadt, 2004), resulting in then zones for 190 wind turbines (ÖROK, 2005). Both of them had the status of an expert report, without legally binding effect, but served as a technical decision basis in the approval processes (ÖROK, 2008). Since then, a number of revisions and extensions were elaborated.

A major revision and extension of the regional framework concepts for wind power development was elaborated in 2010 (ÖIR, 2010a; ÖROK, 2012). Not only, the evaluation criteria was adjusted to technical wind turbine development, but also a voluntary strategic environmental assessment was carried out, taking into account the cumulative effects of the planned development and serving as a basis of information for the neighbouring countries Hungary and Slovakia (ÖIR, 2010b). Reflecting one decade of strategic regional framework concepts for wind power development, two insights became clear: i) an assessment of individual turbines needs the broader regional context to be considered, and ii) for a comprehensive assessent of such a major intervention as wind parks, a sound regional basis involving all specialist departments and experts is necessary (ÖROK, 2012). In 2015, the first strategic concept for repowering of wind parks was elaborated, regulating the renewal of old wind turbines (ÖIR, 2015).

From 2002 until 2022, a total area of approximately 8.000 ha was designated as suitability zones for wind power, of which appr. 7.500 ha are to be counted as used. All of them based on the status of an expert report without legally binding effect. It took until 2022 until legal regulation of wind power development in the federal state of Burgenland was passed (Burgenländisches Erneuerbaren-Beschleunigungsgesetz - Bgld. EbBG, LGBl. Nr. 42/2022). Since then, suitability zones as well es exclusion zones for wind power development are continuously assessed in a legally binding process.

As of February 2026, 9 zones with a total amount of appr. 1.500 ha is designated by ordinance, all of which either already have wind turbines installed or are at least in the approval process. Additionally, appr. 8.000 ha of zones based on expert reports still host 415 wind turbines.

4.3.2 Large scale PV development

In the light of strong development pressure regarding ground-mounted PV-installations in the early 2010s, the federal state of Burgenland elaborated a general guideline for PV in 2013, called 'Photovoltaikanlagen auf Freiflächen. Rahmenrichtlinien für das Burgenland' (ÖIR, 2013). The aim of this guideline was to coordinate the spatial requirements of the PV expansion – especially with nature conservation – and thus raise the acceptance of installing ground-mounted PV-systems (ÖROK, 2015). Nevertheless, due to legal and economic development – subsidies for ground-mounted PV had been cancelled and feed-in tariffs had fallen sharply – the expected development did not take place.

In 2020, the guidelines have been evaluated and updated in line with current energy and climate targets and technical innovations. The 'Rahmenrichtlinie Photovoltaikanlagen auf Freiflächen für das Burgenland 2020' (ÖIR, 2020) provided a framework for the process and assessment criteria for zoning, planning, and construction of ground-mounted PV-systems and served as a basis for administrative proceedings in land-use planning and plant approval (ÖROK, 2021).

Based on the guidelines as a technical basis, an amendment of the provincial spatial planning act (Bgld. RPG 2019), announced as Burgenländisches Erneuerbaren-Beschleunigungsgesetz – Bgld. EbBG, LGBl. Nr. 42/2022, set a legally binding basis for further zoning for ground-mounted PV on provincial level. Since then, a number of changes and refinements were set in the spatial planning act. For instance, special rules

were elaborated for the direct supply of public infrastructure or industrial facilities, and for large.scale zones, there is no administrative procedure for changes in land-use plan needed on municipal level. Furthermore, since the amendment LGBl.Nr. 107/2024, the regulation also applies to thermal-solar facilities. As of February 2026, 80 zones with a total amount of appr. 3.000 ha is designated by ordinance, of which 2.600 ha are to be counted as used. Currently (February 2026), the fifth expansion of the ordinance is published as a draft bill for consultation and appraisal.

5 IN-DEPTH ANALYIS OF THE PLANNING APPROACH IN BURGENLAND

5.1 Status-quo of the planning and assessment process and analysis of actors involved

Strategic spatial planning for renewable energy development has a long history in Burgenland as sketched in section 4.1. From first informal concepts (ÖIR, 2002) to legally binding zones, the process has undergone a lot of changes, be it in its formal status, its spatial scope or the depth of planning. But still, some key principles remained the same from the beginning.

The process of defining criteria for assessment, examining only certain areas of interest instead of the whole federal state, setting mitigation measures and formulating recommendations for zoning always included relatively broad stakeholder involvement, an extensive discussion and negotiation process, the use of replicable assessment criteria and case-by-case determination of mitigation measures for each zone.

As the whole process started out of a recognized pressure and need, but without a solution already present, a lot of stakeholders from different sides were involved from the beginning.

Although the state's planning department has ever since been the owner of the process, the state environmental attorney turned out as a key player in the whole communication and negotiation process. The major challenge was to coordinate the different requirements and needs from different groups of stakeholders, thus a continuous and trustful communication with the state's nature conservation department as well as with NGOs in the field of nature conservation (like BirdLife or WWF) was crucial.

The political goal for the whole process always has been to foster renewable energy development while keeping acceptance of citizens very high. For rising local support, the municipalities in which the examination zones were located have been involved via their mayors and administrative bodies invited to planning workshops.

The developers of wind energy projects and their respective planners also have been involved in an early stage of the zoning process. What seems odd at first sight had the goal to bring in the technical perspective and also some understanding of the economic feasibility of this new kind of large-scale energy projects.

Another important principle has been, that not the whole federal state is the planning scope, but only certain parts of it, with specific interest of realizing projects. Thus, a more detailed planning procedure was possible and also the learnings could be implemented more easily in following processes.

Over the years, the process was evolving and became more and more standardized. After 20 years of strategic spatial planning for renewable energy development, finally in 2022 the legal basis was set for compulsory zoning as a prerequisite for further implementation of wind energy and ground-mounted PV-installations (Burgenländisches Erneuerbaren-Beschleunigungsgesetz – Bgld. EbBG, LGBl. Nr. 42/2022). This marked a big caesura in the development of the planning process, which which led to the current design, which is based on the following nine principles (own compilation based on ÖIR, 2025).

- The federal state's energy strategy is the basis for the whole process
- Planning is limited to specified examination zones with specific project interest
- Involvement of experts (nature conservation, legal processes, water management, cultural heritage, etc.) from administration as well as NGOs
- Early involvement of municipalities, consensus with municipalities
- Coordination of mitigation measures during zoning process with experts, municipalities and project developers
- Interconnection of zonal planning and Strategic Environmental Assessment: Consideration for protected goods already while determination of mitigation measures

- Workshops with municipalities (political and/or administrative representatives) to present and discuss zoning plans
- Zoning plans and environmental report available for public with opportunity to express their opinion before coming into force
- Determination of zoning via ordinance by the federal state (legal requirement for plant approval)

In the zoning process for the use of renewable energy, four phases can be identified: The starting phase to set the scope of the process and identify the examination zones. The planning phase for the detailed examination of all the zones including the coordination and negotiation with all relevant stakeholders. The legislative phase containing the finalisation of the environmental report, the public consultation as well as the required legal processes for the ordinance to come into force. The implementation phase, where the energy plant is approved and constructed with implementation of mitigation measures and monitoring of effects and impacts.

For a better understanding of which actors are involved to what extent in which phase, the following illustration (Fig. 1) gives an overview over the phases and stakeholder involved.

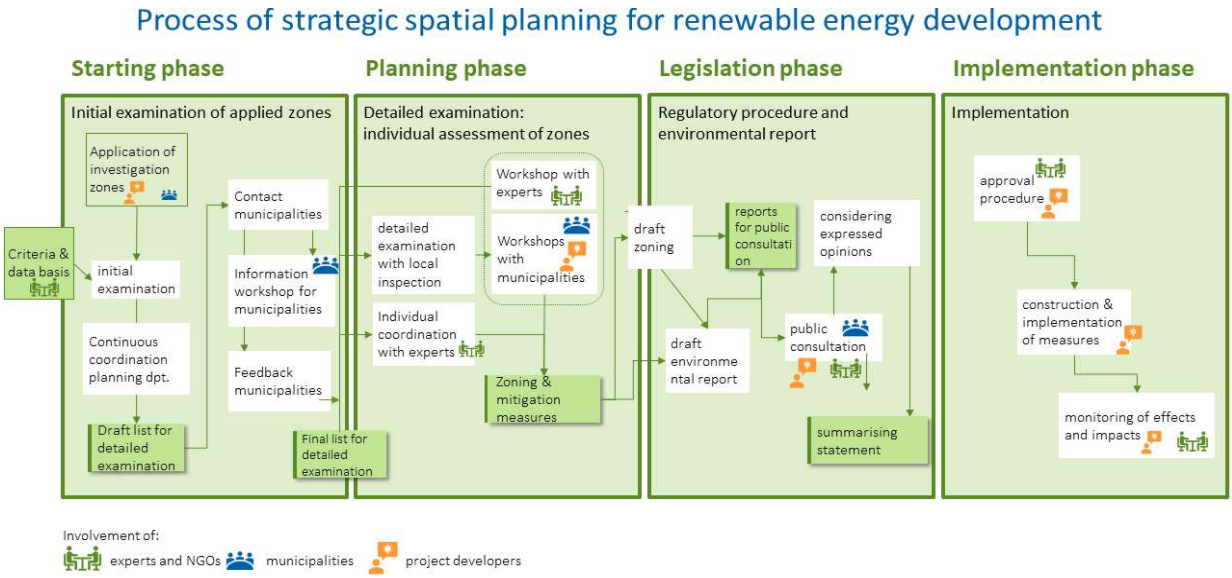

Fig. 1: Phases of the planning process and stakeholder involvement (own illustration based on ÖIR, 2025).

5.2 Reflection in light of the rational-collaborative planning model

According to the rational-collaborative planning model, there are three key aspects which have to be addressed: the 'level of facts', which stands for a well-established information base, the 'level of values' which represents a clear and agreed value system, and transparent rules about how to aggregate these two levels (Stoeglehner, 2010). In the following we reflect on the formal and particularly the informal integration of stakeholders of different groups of actors involved in the strategic spatial planning process for renewable energy development in Burgenland and implications for the consideration of biodivesity and landscape protection goals.

Against this background, two aspects will be reflected on in detail: data sharing and knowledge transfer as a contribution to the 'level of facts' as well as the systematic and transparent management of trade-offs related to conflicting interests in terms of laying the ground to the 'level of values'.

5.2.1 Analysis of data sharing and knowledge transfer in the processes with focus on biodiversity and species as well as their habitats (planning and accompanying SEA)

When coming to data, the zoning process faced two major challenges: First, and this was a special challenge in the early days, it was the fundamental question on what effects and impacts can occur when implementing large-scale renewable energy projects, and thus what data is needed for assessments of environmental impacts. Especially in the beginning, technology was new and developing very fast. Consequently, the list of relevant data and assessment criteria was elaborated step by step.

The second challenge referred to the existence and availability of data linked to these likely impacts. For the known possible effects and impacts, very little data existed ready-to-use, that could have been provided by provincial administration. For example, no state-wide biotope mapping existed. Thus, mutual learning together with institutional and stakeholder-related information, which stakeholders brought in during the process, was even more important in order to enable a corresponding factual and technical data basis. The process design with its broad involvement of stakeholders and different actors was very helpful for this. Thereby, it turned out, that not only the presence in the process is sufficient, but mutual trust is and belief in the process is crucial, otherwise there is a risk, that informal data is not provided. Transparent communication at the beginning of each zoning process and a mutual understanding of each actor's role and contribution possibilities created this confidence in the process.

Although the department of nature conservation in Burgenland had little comprehensive data on biodiversity-related topics, the individual experts have contributed a wealth of personal knowledge and experience on certain sites and special habitats that they contributed to the expert workshops. Sharing of such existing but rather general data often resulted in first assumptions which proved to be useful for further detailed non-site investigation by the planning team and cumulated to the 'zoning data base'. Examples are historical breeding sites or rarely used wildlife corridors.

BirdLife Austria, an NGO working in the field of bird protection, has been involved from the very beginning of the first development concepts, and the planning process can draw on an existing and continuously maintained database of bird observations. In addition, specific studies are being carried out as part of the zoning investigation, in which the existing data is being reviewed and supplemented. In northern Burgenland, where there is a very good existing database, high-quality results regarding birds and their habitats can thus be achieved very quickly. In central Burgenland, this broad database is lacking, meaning that the investigation process is much more complex and the results are nevertheless not as comprehensive as in the north, with many years of records. The results of the specific studies are fed back into the BirdLife-database. While different levels of citizens science and NGO data became evident across the planning scope, birds are overall still very well researched and monitored in contrast to other avian animals where less data derives from public sources and citizen science. While bird protection proved to be very important in the responsible designation of suitable areas for wind farms right from the start, it took 15 years for bat protection to be considered equally important. Bats are now the second most important species group to be included in the detailed studies.

Another important source of information were the workshops with the mayors of the respective municipalities. They knew their area best and had the opportunity to contribute their perceptions and experiences. Although most of them have not been experts in the field of biodiversity or nature conservation, they knew the history of the places and often provided important clues on specific habitats, which fostered transdisciplinary knowledge transfer that helped to put the right focus on the detailed investigations.

By involving project developers at an early stage of zoning planning and establishing good relations with them, helped to view and consider their research data e.g., deriving from monitoring of earlier energy projects or which they collect during preliminary studies for detailed plant planning and submission for approval. Although often being very detailed. nevertheless, it was crucial to check the developers' data for reliability and validity.

To sum up, the situation and handling of data in the zoning planning process in Burgenland has been highly heterogenous: General comprehensive mapping of habitats and biotopes was initially missing and planners profited strongly from informal expert knowledge queried during the workshops. Yet. a systematic structure to collect and process this information was missing. Data on bird protection was – at least for some parts of the federal state – existing in a comprehensive database maintained by the NGO BirdLife. This information was used as a baseline. As the planning and environmental assessments investigated further data during the planning process, a loop existed when this data was fed back into the database. For bats, no comparable database or continuous monitoring has existed. In this case the planning process benefited even more from, informal networks during the collaborative and iterative planning process. Data on connectivity like wildlife corridors was initially spread across different provincial and federal agencies and therefore sometimes difficult to access. Thus, data management and sharing became as relevant as the data collection itself. Based

on previous experience in the zoning process, first attempts have been made to continuously build up a database containing this information.

5.2.2 Systematic and transparent management of trade-offs

Strategic spatial planning for renewable energy development has from its beginning faced two, partly controversal objectives. On the one hand the generation of renewable energy as a contribution to achieving climate change migitation goals has been in the public interest. At the same time, Burgenland needed to safeguard nature conservation interests, which are particularly relevant due to highly valuable bird habitats like in the national park Neusiedlersee and European legal requirements linked to the habitat and bird directives across the country. Thus keeping a balance beteween all the differing, often competing claims on the use of space has been an intrinsic challenge throughout the planning process.

In order to minimize conflicts and trade-offs in zoning planning, the impact asssessment experts and planners therefore needed to select carefully the criteria needed based on the known impact chains at the planning time/stage and the available data. While the rational basis was set according to the data and its rational interpretation, the weihging of thecriteria was part of the collaborative negotiation process.

While there existed legally binding standards in some thematic fields, such as the prohibition of killing in species protection or the prohibition of deterioration in Natura 2000 habitats, stakeholders could discuss acceptable trade-offs for other topics such as the landscape appearance or the impairment of the landscape's recreational function only during the planning process. In these context the importance of the rational basis became even more evident.

Because the perception of changes to the landscape is an important factor in the acceptance of wind farms and utility-scale PV-installations (Schauppenlehner et al., 2024), particular attention has been paid to their assessment from the outset. It has proven important to make the necessary information available to the stakeholders involved in a transparent and comprehensible manner, and to design and communicate the assessment schemes in a comprehensible way. In the early stages of wind zoning, the visual impact of wind turbines was determined using dominance analyses (ÖIR, 2010). This is a method in which the proportion of the vertical field of vision occupied by the structures is used as a measure of their dominance. Only, by comparing the ratios of different wind park scenarios, the evaluation could be made understandable for all involved stakeholders.

With the onset of a certain habituation effect on wind power and the technical advancement of wind turbines, this method with its rigid measurements took a back seat and was replaced by qualitative evaluation of 3D visualizations (ÖIR, 2025). This also takes into account the significant development of rotor diameters, as it is now possible to consider not only the absolute height but also the appearance of the entire rotor. By presenting different scenarios and an expert assessment by the planning team, workshop participants (both experts and municipality representatives) could experience and discuss the different appearances. This has proven to be particularly valuable in repowering processes.

For particularly sensitive cases, such as the potential impact on the World Heritage Site Fertö – Neusiedler See, additional independent expertise was sought from BOKU university, which created a 4D-model of the study area in a landscape lab and enabled workshop participants to immerse themselves even more deeply in the modeled scenarios using VR glasses (Bittner et al., 2024). This gave even non-experts a good approximation of a changed landscape and, based on this, enabled them to weigh up the pros and cons.

By far the most frequently mentioned trade-off with PV systems is the large-scale restriction of agricultural usability of the land taken. This issue has been addressed via the conflict criterion 'use of high-quality agricultural land' and corresponding mitigation measures as the restriction to Agri-PV-systems. To gain municipalities' acceptance, it proved crucial to show the possibilities of combined land-use in the planning workshops with the municipality and convince stakeholders about its effectiveness. As agriculture and food sovereignity are important topics, there have been several cases, where municipalities first opposed against a PV-zone but where convicted as they got to know about the possibility of mandatory Agri-PV.

Zones for ground-mounted PV systems occupy large areas and therefore have the potential to cut off important migration corridors for wild animals. This kind of potential conflicts was especially difficult to assess, as the reactions, especially avoidance behaviour, were hard to predict without prior experiences with installations at this large scale. As a first mitigation measure to reduce fragmentation, most of the zones for

solar energy use only allow construction without fences. But still, discussions in workshops and with additional experts did not lead to a clear consent on how large the necessary distances should be. As a consequence, discussed examination zones nearby the internationally significant Alps-Carpathians Corridor have been deferred, and for corridors with minor significance, assumed distances have been set with the requirement of monitoring in order to gain important insights for future zones.

These examples show that knowledge about the impacts and also about the effectiveness of mitigation measures is not only essential in order to anticipate trade-offs or negative impacts, but also for a transparent, collaborative process that can be conducted on an equal footing in order to lead to a consensual value judgement of all involved stakeholders. This is where the data bases outlined in section 5.1.1 in combination with transparent assessment criteria and a proven set of mitigation measures proofed to be essential. For this reason, information workshops were held with municipalities. However, the focus of these workshops was on the process and opportunities for municipal participation, rather than on impacts in general. Often questions came up in the forefront about financial benefits for municipalities for hosting suitability zones or about opportunities for renewable energy communities.

6 DISCUSSION

The process for strategic spatial planning for renewable energy development in Burgenland has undergone many changes since its start almost 25 years ago. Starting with an idea but no specific experience and a high level of uncertainty in the field of biodiversity and landscape a broad stakeholder involvement was one of the first steps, mainly to gather information about the different needs and concerns. This was necessary, as there was no approved criteria set and comprehensive data base for assessment, which would be the precondition for a rational planning process based on objective facts (Stoeglehner, 2010).

Although, the composition of the involved stakeholders has changed over time, and knowledge on impacts and data related to renewable energy development went from individual contributors to the common process, it is still a strong element in the whole process, which not only safeguarded the consideration of different perspectives, but also has served as a strong source for information and data. The process in Burgenland shows that institutional capacity building has been able to develop shared knowledge like pointed out by Healey (1997) and foster confidence in collaboration and relationships. Our research confirmes studies such as Hansen et al. (2013) on the value of informal communication between actors at the micro-power dynamics level in the decision-making process related to the environmental assesssment. Moreover it showcases the organizational arrangements which have allowed mutual learning as in the case of the animal data reintegrated into public data bases.

One of the main characteristics of the zoning process in Burgenland was the timing of an early involvement of different kinds of stakeholders, in order to address general concerns and either resolve them or cancel planning in this area. Similar as pointed out by Partidario and Sheate (2013) multidirectional knowledge transfers among stakeholders at an early time increased the effectiveness of planning and integrated SEA. An important puzzle piece was the transparent communication at the beginning of each zoning process, so that all invited actors knew their possibilites to contribute to the process.

Planning and environmental assessments were set up as a set of incremental and iteraritve processes, concentrated on certain scopes (assessment areas) with specific project interests rather than the whole federal state. This approach triggered activity by stakeholders as the chance of implementation in the near future has been much higher than in case of a general planning concept for the whole federal state and sparked their interest in participation Furthermore, this approach provided the opportunity to deepen the planning into a more detailed level and implement learnings in the following zoning reviews.

The possbility for the municpalities to be involved, to opt out at the beginning of the process and to contribute in developing mitigation measures, together with a recognizable added value for the municipalities, led to highly accepted proecess with hardly any objections or citizens' inititives against individual projects and with wind power as part of the identity of northern Burgenland.

Nevertheless, some of the key concepts of the collaborative planning approach were missing or seem to be only partly implemented, compared to the theoretical framework. Although there is a broad stakeholder involvement, citizens were directly involved only in the legislation phase by having the possibility to express their opinion during the public consultation. Any earlier involvement of the public has been subject to

decision of the municpalities representatives Furthermore, the rather informally agreed process of participation involved the risk, that not all relevant stakeholders were involved or some got marginalized.

Overall, a rational-collaborative planning paradigm has been applied with institutionalized formats to exchange information and produce new data as a basis for planning and assessment. With regard to the rational-collaborative planning model (Stoeglehner, 2010) we see the following interesting aspects in the case of Burgenland's integrated spatial and energy planning processes become evident: The SEA was considered a meaningful and integrated part of the whole process due to its integrated nature which led to streangthening the 'level of facts' in combination with the involvment of stakeholders. No discussions which questioned the necessity of an SEA arised. The environmental objectives and respective mitigation measures could be developed and discussed throughout the planning process to meet examination criteria and to optimize the zones.

In terms of planning alternatives, via the integration of assessment in planning, the iterative process of planning and SEA targeted the development of most environmentally friendly alternatives. The planning process, however, did not allow room to consider system alternatives, as the focused zoning model did not question the clear planning task it pursued.

The incremental and iterative approach of assessing only certain zones with specific project interest thus bears the possibility, that the overarching goal of the zoning process could fade into the background. Moreover, in addition to all the advantages, the close integration of planning and assessment carries the risk of diluting the objectives of the SEA, namely minimzing impacts on biodiversity and landscape considering the whole territory. In this context, again the stakeholder involvement provided a 'corrective' in several circumstances. In the case of Burgenland the power dynamics (Partzsch, 2016) allowed actors, such as the nature conservation department of the federal government, to reiterate the importance of protected species and their habitats.

Finally, for the SEA applied at this scope, the question remained how far species that are currently less endangered will be considered with regard to interelationships between different types of energy generation (in the future). Approaching these questions, however, would prerequisite a diverse governance structure with new planning instruments.

7 CONCLUSIONS

Rational–collaborative approaches that integrate environmental objectives early and require environmentally friendly benchmark alternatives can raise environmental standards in planning. In our study we surveyed the informal integration of stakeholders in light of a rational-collaborative planning approach. Strategic spatial planning for renewable energy development in Burgenland was particularly interesting as it involves strategic long-term development with extensive demand of land with a high potential for conflicts. At the same time energy planning in Burgenland started more than two decades ago with a level of high uncertainty and little existing data particularly in the field of biodiversity and landscape.

Our contribution discussed the strategic spatial planning approach for renewable energy development in Burgenland with regard to the 'level of facts' and the 'level of values' as specified by the rational-collaborative planning model. The examples provided in the field of biodiversity and landscape illustrate the relevance of multi-face stakeholder involvement, which has contributed to both levels and allowed partly even learning of time. It points out advantages of the focus on clearly defined planning scopes but outlines at the same time its limitations.

Taking into account the implementation rate and the perceived acceptance in public, the process for strategic spatial planning for renewable energy development in Burgenland can be accounted successful so far. The informal involvement of different groups of actors lead to improvements in the field of biodiversity and landscape as illustrated in this article. Future research within the Biodiversa+ project BIOGAIN will continue to analyse the perception of these contributions to the planning process by the diverse actors themselves as well as limitations and expectations for improvement including the new abilities to foster data collection and analysis by support of artificial intelligence.

Above all, the reflection on the 'Burgenland model' can provide inspiration but cannot be applied 1:1 to other regions in Austria or internationally. Too different are the prerequisites, on the hand in terms of spatial conditions and energy potential, but even more in terms of institutional capacities and planning traditions.

This connects to challenges of case study research observed in other contexts, when testing of the first outcomes is recommended in other contexts (Yin, 2018). The transferability analysis in combination with additional empirical data collection will be part of the ongoing research in the Biodiversa+ project to identify levers for transformation towards biodiversity net-gain. Thorough analysis of data flows and prerequesits for biodiversity-net gain in combination with governance in strategic spatial planning of renewable energy development will continue this preliminary study presented herewith.

8 ACKNOWLEDGEMENTS

The lead author thanks all the actors involved in the planning process in Burgenland for their valuable contributions to the planning process and confidence over the past decades.

1 ABSTRACT

Decarbonisation of the building sector is a vital task to cut greenhouse gas emissions and reach Europe's climate targets. This paper presents a novel refurbishment concept which allows the substitution of a fossil-fuelled heating system with a heat pump solution via the addition of a retrofitted thermal activation of the façade for buildings dating from the 1950s and 1960s that can be implemented in full operation of the building. Furthermore, monitoring data from the heating season 2024/25 is used to establish the temporal behaviour of the heat generation system (air-to-water heat pumps), to describe the energy fluxes between various components of the heating system (heat generation, distribution and release), and to evaluate the efficiency of the heating system. The monitoring data used consists of temperature measurement data of the indoor and outdoor environment as well as the heating water flow and return temperatures and façade core temperatures. Additionally, heat meter data for various points in the heating system is used as well as electricity meter data of the heat pumps. Calculated values for amounts of heat generated are cross-validated using heat meter data where available. Results show that in comparison to the available heat meter data, the modelling approach for the thermal power quantification of the heat pumps results in overestimation which would need to be fixed by obtaining more data on the heat pumps' actual efficiency behaviour (COP) for various operating parameters. Finally, the SPF of the heat pumps was established for an observation period of approximately three weeks in January/February 2025 and was found to amount to 3.9.

Keywords: air-to-water heat pump, refurbishment, radiant systems, TABS, efficiency

2 INTRODUCTION

Heating systems using fossil fuels are responsible for approximately 17 % of Austria's greenhouse gas (GHG) emissions [BMK, 2023]. Especially older buildings in their original condition display high heating demands resulting in a higher energy consumption for heating purposes. Thermal refurbishment along with a switch to low-carbon heat generation systems and, if necessary, an adaptation of the heat dissipation systems are therefore key measures to increase the energy efficiency of a building. Especially the extension of existing heat dissipation systems poses a challenge in apartment blocks as access to the flats must be given to conduct the necessary plumbing and building work.

This paper presents a refurbishment concept for apartment blocks with a centralised heating system (one heat generation system for the entire building) that can be executed in full operation of the building and without requiring access to the residents' flats. This refurbishment concept is currently being tested in the course of a dedicated research project (*Sani60ies*, FFG project number 889521) in various test case properties, of which the pilot building located in Große Neugasse (Vienna,IV.) has been in operation and under observation via the monitoring system installed for sufficient time to provide the required data for analysis and evaluation of the heating system's behaviour and efficiency.The refurbishment concept comprises the installation of a hydronic heat dissipation system integrated into the façade from the outside, the thermal refurbishment of the building (thermal insulation applied to the cellar ceiling as well as the attic and the exterior walls) and the substitution of the existing fossil heating system with heat pumps. Details concerning the structure of the façade heating are given in the material and methods section. The measurement data used for the evaluations in this paper was collected during the winter of 2024/2025, during which time the heat generation system consisted of two air-to-water heat pumps at the stated test case building.

In this paper, the behaviour of the heat generation system is analysed by quantifying the amounts of heat produced by the heat pumps as well as the efficiency of the heat pumps in terms of their modelled *COP* and their *SPF* based on measurement data. Additionally, the monitored electrical power data of the heat pumps, the heat meter data as well as the indoor and outdoor air temperatures and the façade core temperature is

used to draw up a heat flow diagram (Sankey diagram) visualising the heat fluxes between the various components in the heating system for a selected time period.

This paper builds on preliminary work prepared for a conference paper for the 2026 IEA Heat Pump Conference (abstract no. 27) which is currently in the submission phase.

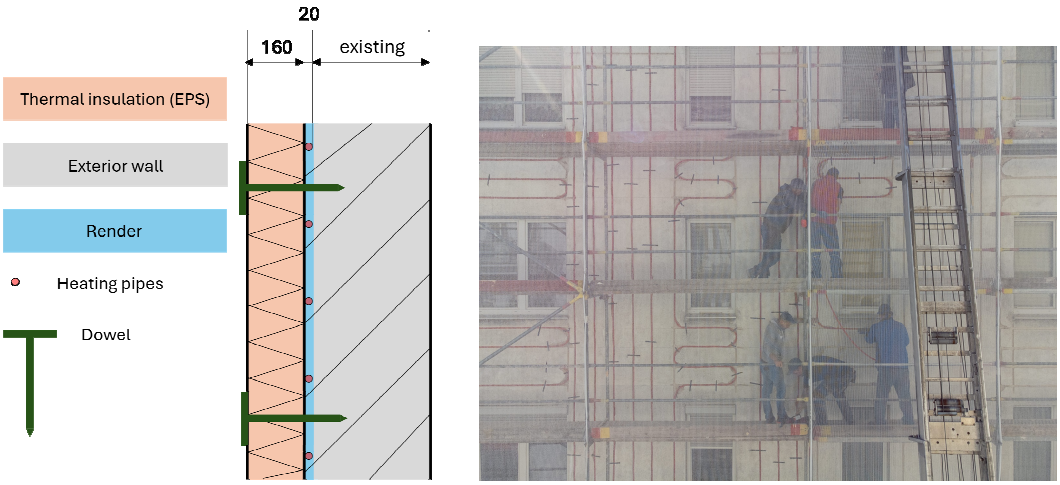
3 MATERIAL AND METHODS

The refurbishment concept and, in particular, the design of the façade heating is based on preliminary workespecially by SCHMIDT et al. [2017] and HINTERSEER et al. [2019] who suggest the retrofit of building façades either with capillary mats or multifunctional façade modules containing heating pipes. Further relevant research into radiant systems on a simulation or lab testing basis was conducted by GROß and SCHMIDT [2020], JUNASOVÁ et al. [2022], KRAJČÍK and ŠIKULA [2020], LECIEJ-PIRCZEWSKA and SZAFLIK [2024] and ZOU et al. [2025].

In this section, the case study building and the monitoring system are described and the calculations for the system analysis and evaluation are elucidated.

3.1 Case study building

The case study building is a multi-apartment block dating from 1968 and owned by the social housing association *Sozialbau AG*. It is located in Große Neugasse in Vienna's 4th district and features 2 shops and 20 flats on a conditioned floor area of 1,002 m^2. The building fabric of the external walls consists of *Durisol* bricks which are a mineralised wood wool casing filled with concrete [LEIER, 2024]. The external walls were thermally refurbished and furnished with heating pipes to form an additional heat dissipation system of the building in order to compensate for lowered heating water flow temperatures. These become necessary to ensure an efficient operation of the newly installed heat pumps substituting the old gas boiler. Fig. 1, left shows the structure of the external walls: the heating pipes (raised-temperature-resistant polyethylene pipes) are laid into channels cut into the 2 cm thick exterior render, on top of which the thermal insulation (expanded polystyrene (EPS)) is applied using dowels for fixing. The pipe gap is 30 cm (not to scale in figure). The process of the heating pipes installation is shown in Fig. 1 on the right. In total, the U-value of the exterior walls could be reduced to 0.2 W/m^{2}K instead of 0.93 W/m^{2}K before refurbishment.



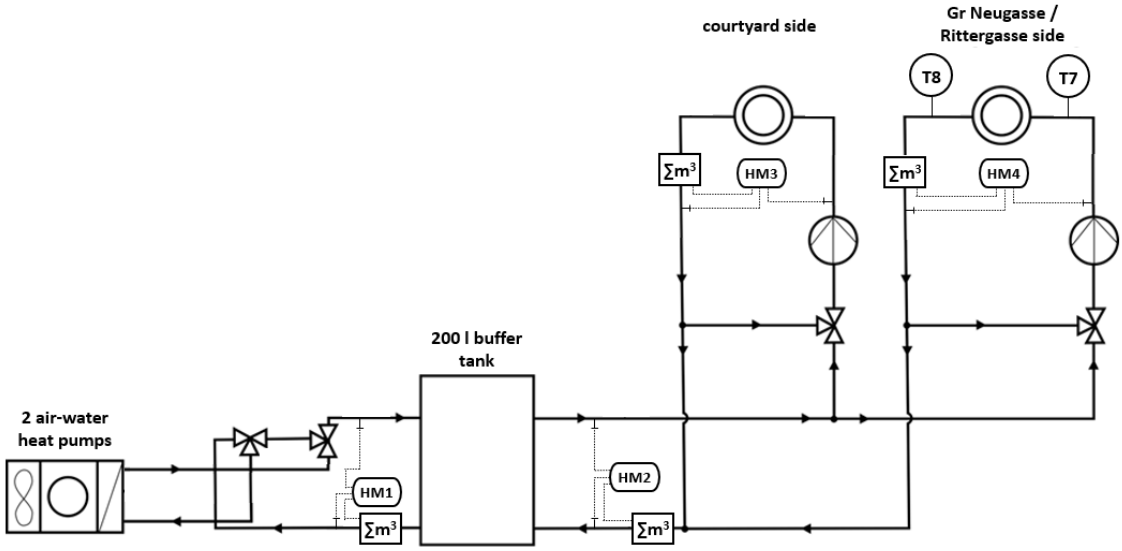


Fig.1: Structure of the external walls after refurbishment (left) and process of installing the heating pipes in the render of the façade before applying the thermal insulation (right).

The heat generation system consists of two *Stiebel Eltron* WPL-A 05 HK 230 Premium air-to-water heat pumps with an EN 14511 rated power of 5 kW at A-7/W35. These supply a buffer tank with 200 l capacity which, in turn, supplies the manifold splitting the heating water to the street and courtyard side heating loops. As indicated above, the façade heating supplements the existing radiator dissipation system. These radiators were still supplied using the gas boiler in the winter 2024/2025 and in operation throughout the heating season.

3.2 Monitoring system

To allow the detailed observation and evaluation of the installed heating system, an elaborate monitoring system was installed measuring the following parameters (all are relevant for the evaluations of this paper with the exception of the heating water flow or return temperature of each heating loop):

- Electrical power of the heat pumps
- Amount of heat transported from the heat pumps to the buffer tank, from the buffer tank to the manifold splitting the heating water into the street and courtyard side supply pipes, amount of heat transported to the street side heating loops and amount of heat transported to the courtyard side heating loops
- Heating water flow and return temperatures between the various system components in the plant room
- Heating water flow or return temperature of each heating loop to supervise presence of a water flow
- Façade core temperature at 5 locations
- Outdoor air temperature
- Indoor air temperature and humidity in one test flat

- Fig.2: Position of the heat meters HM1-4 and the PT100 temperature sensors T7 and T8 for the heating water flow and return temperature.

In particular, the electrical power $P_{el,i,j}$of the heat pumps was measured as 5 s mean values using two *Fluke* 1734 three-phase electrical power measurement loggers, the amount of heat transported between heat pumps, buffer tank and manifolds was metered using four *ista* heat meters with ultrasonic transducers and external temperature sensors and the heating water temperatures in the plant room as well as the outdoor air temperature were measured as 15 min mean values using PT100 temperature sensors.The heat meters were read locally at intervals of usually roughly one month. The electrical power loggers provide data for the period from 28th November until 6th December 2024, after which a logging gap due to technical issues with the loggers occurred which lasted until 18th December 2024. From 18th December, the issue was resolved and measurement data was again available until 17th March 2025 which is when the maximum local data storage capacity was reached.At this point, the heating season was, however, practically over due to rising outdoor temperatures. Moreover, as the datalogger collecting the 15 min mean values from the PT100 sensors had some technical issues until 22nd January 2025 resulting in logging gaps, outdoor air temperature data available as 10-minute mean values from *Geosphere Austria* [GEOSPHERE AUSTRIA, 2026] for the weather station "Wien Innere Stadt", ID: 5925 (ca. 600 m linear distance to the test case building) was used for the observation period before the indicated date. Furthermore, the only relevant measurements in the plant room for this paper are the flow and return temperature of the heating water supplied to the façade heating loops. These were only available for the street side heating loops for the winter 2024/2025 as the

sensors used for the courtyard side heating loops were relocated to measure the supply and return temperature of the radiator heating water. For the calculations described below, the heating water flow and return temperature was assumed to be the same for the entire system as both sides are operated to run on the same temperature levels (pumping and mixing units operated accordingly). The position of the heat meters and the temperature sensors measuring the flow and return temperature of the heating water of the street side is shown in Fig. 2.

The façade core temperature is measured using five PT100 temperature sensors which also log 15 minute mean values. Their location in the building façade is shown in Fig. 3.

Fig.3: Position of the façade core temperature sensors (T2-T6, green dots) on the façade in Rittergasse (left) and GroßeNeugasse (right). T1 had to be disconnected to allow the installation of the heating water flow supervision system. The red lines show the heating circuit piping.

The indoor air temperature was measured in one test flat using an *Efento* IoT data logger with a PT1000 temperature sensor. The flat is located on the top floor and looks out on to *Rittergasse* (two top left windows in Fig. 3).

3.3 Calculations

This section details the calculation methods used to establish the *COP* and heat generation of the heat pumps and visualise the heat flow in the heating system for a selected time period using the collected measurement data. Finally, the calculation method for the *SPF* quantification is presented.

3.3.1 Heat generation of the air-to-water heat pumps and COP

The momentary thermal power $\dot{Q}_{th,i,j}$per heat pump*i*per time step *j*was calculated based on their measured electrical power $P_{el,i,j}$and a calculated *COP* depending on the measured heat source (outdoor air) and heat sink (heating water) temperature $T_{source} = T_{out}$and T_{sink}:

$$\dot{Q}_{th,i,j} = P_{el,i,j} \cdot COP \quad [W] \tag{1}$$

Specifically, the*COP*for various heat source and sink conditions was calculated from the information given in the heat pumps' data sheet [STIEBEL ELTRON, s. a.] for the EN 14511 testing points. This was done by establishing the Carnot efficiency $COP_{Carnot}$for each of the three testing points A7/W35, A2/W35 and A-7/W35and then calculating the efficiency factor ζ from the COP_{Carnot} and the stated *COP* in the datasheet per test point by rearranging the following equation to give ζ:

$$COP = COP_{Carnot} \cdot \zeta = \frac{T_{sink}}{T_{sink} - T_{source}} \cdot \zeta \quad [-] \tag{2}$$

where T_{source} is the measured outdoor air temperature (+7, +2 and -7 °C for the test points) and T_{sink} is the setpoint flow temperature of the heating water (35 °C for the test points). The resulting ζ amounted to between 0.47 and 0.49 for the three given test points. Based on this, the *COP* of the heat pumps for other occurring heat sink temperatures was establishedaccording to eq. (2) by calculating the COP_{Carnot} for the three T_{source} of +7, +2 and -7 °C and assumingζ to be constant at 0.47 for all heat sink and source conditions as a worst case scenario. The other occurring setpoint flow temperatureswere determined from the heat pumps' online operation protocol (logbook) logging every change in the heat pumps' setpoints. This was used rather than temperature measurement data from the plant room due to the abovementioned logging gaps of the datalogger used. Fig. 4 shows T_{source} (*Geosphere Austria* data until 23rdJanuary 2025 00:00h and own data since then) and T_{sink} for the period of 1st December 2024 until 31st March 2026.

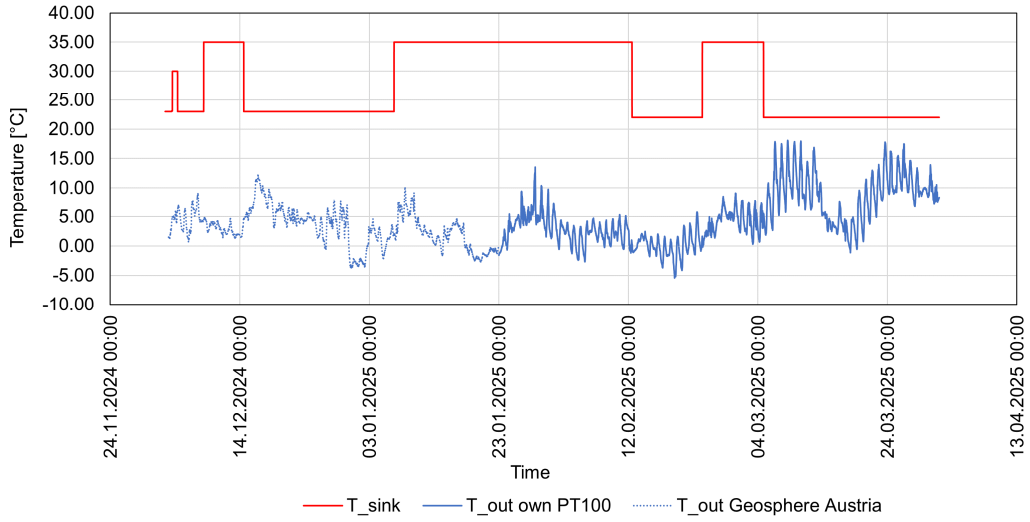

Fig.4: T_{source} (T_{out}) and T_{sink} (heating water setpoint temperature) for the time period from 1st December 2024 until 31st March 2025.

According to the heat pumps' operation protocol and as can largely be seen in Fig. 4, the occurring setpoint flow temperaturesT_{sink} amount to either 35, 30, 23.1, 23 or 22 °C. For every T_{sink}, a polynomial trend function was calculated to describe the *COP* depending on T_{source}= T_{out} (cf. alsoFig. 5 for a visualisation of the trend functions):

$$COP_{35} = 0.0026 \cdot T_{out}^{\ 2} + 0.1407 \cdot T_{out} + 4.3082 \ [-] \quad (3)$$

$$COP_{30} = 0.006 \cdot T_{out}^{\ 2} + 0.1675 \cdot T_{out} + 4.7321 \ [-] \quad (4)$$

$$COP_{23.1} = 0.0136 \cdot T_{out}^{\ 2} + 0.2875 \cdot T_{out} + 5.9727 \ [-] \quad (5)$$

$$COP_{23} = 0.0138 \cdot T_{out}^{\ 2} + 0.2901 \cdot T_{out} + 5.9958 \ [-] \quad (6)$$

$$COP_{22} = 0.016 \cdot T_{out}^{\ 2} + 0.3191 \cdot T_{out} + 6.2374 \ [-] \quad (7)$$

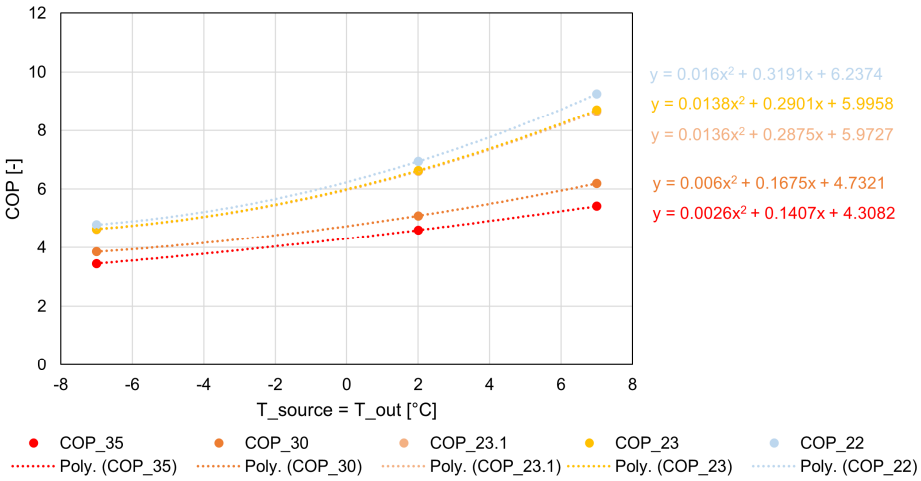

Fig.5: Trend functions of the *COP* for the various heating water flow temperatures T_{sink}.

Thus, for every time step in the evaluated period, the thermal power per heat pump $\dot{Q}_{th,i,j}$ is calculated via eq. (1) using the measured electrical power $P_{el,i,j}$ and the corresponding *COP* function taking in T_{out} according to eqs. (3-7). The amount of heat generated $Q_{th,i,j}$ per heat pump *i* and time step *j*is consequently calculated as:

$$Q_{th,i,j} = \frac{\dot{Q}_{th,i,j} \cdot \Delta t}{3{,}600{,}000} \quad [kWh] \tag{8}$$

where Δt refers to the measuring interval of 5 s. The total amount of heat generated per heat pump *i* is:

$$Q_{th,i,total} = \sum_{j=1}^{n} Q_{th,i,j} \quad [kWh] \tag{9}$$

Thus, the total amount of heat generated by heat pumps 1 and 2 is:

$$Q_{th,total} = Q_{th,1,total} + Q_{th,2,total} \quad [kWh] \tag{10}$$

The calculation of the heat pumps' thermal power and heat generation was conducted for the time period from 6th December 2024 until 17th March 2025. The start date corresponds to the date of the start of the heating mode of the heat pumps and the end date corresponds to the day where the maximum local data storage capacity of the electrical power meters was reached. Due to rising outdoor air temperatures, the heating season was, however, de facto over and the façade heating was operated at very low temperatures (22 °C) until 24th June 2025 which was the day on which the cooling mode for the summer was started. For the calculations of this section, the measurement data not given in 5 s intervals (temperature measurement data) was restructured to match the 5 s intervals of the electrical power measurement data.

3.3.2 Amount of heat transported between the various heating system components

For this, an observation period from 22nd January until 4th February 2025 was chosen as this is a period where all necessary data was available. For the amount of heat generated by the heat pumps, see section 3.3.1. The amount of heat transported to the buffer tank was read from heat meter HM1, see Fig. 2. The difference between the heat generated by the heat pumps and the heat meter data was put down as losses as well as imprecision of the model used to calculate the thermal power of the heat pumps. Furthermore, the heat losses of the buffer tank were calculated as the difference between the amounts of heat measured by the two heat meters on the generation (HM1) and dissipation side (HM2) of the buffer tank. The amount of heat transported to the manifold was calculated as the sum of the amount of heat read from the heat meter metering the courtyard side (HM3) and the amount of heat read from the meter metering the street side (HM4) of the heating circuits. The losses between the buffer tank and the manifold were calculated as the difference in amounts of heat between the buffer tank dissipation side heat meter (HM2) and the manifold (HM3 + HM4). For the last stage in the flow chart, the amount of heat transported to the indoor and outdoor environment ($Q_{facade,in}$and $Q_{facade,out}$) was calculated based on the method employed by SCHNEIDER [2025] for the cooling mode which was adapted here for the heating mode. This method establishes the heat fluxes from the façade heating into the indoor and outdoor environment ($\dot{Q}_{facade,in}$and $\dot{Q}_{facade,out}$) as follows:

$$\dot{Q}_{facade,in} = U_{in} \cdot A_{facade} \cdot \left(\bar{T}_{sys} - T_{in}\right) \quad [W] \tag{11}$$

$$\dot{Q}_{facade,out} = U_{out} \cdot A_{facade} \cdot \left(\bar{T}_{sys} - T_{out}\right) \quad [W] \tag{12}$$

where U_{in} and U_{out} refer to the U-value of the wall layers between façade heating pipes and indoor or outdoor environment of 0.97 W/m^{2}K and 0.25 W/m^{2}K, respectively.A_{facade} refers to the activated façade area of 569.6 m^2, T_{in} and T_{out} to the indoor and outdoor air temperature and $\bar{T}_{sys}$ to the mean system temperature of the façade heating which was calculated as:

$$\bar{T}_{sys} = \frac{T_{flow,GrNeu} + T_{return,GrNeu} + \bar{T}_{facade}}{3} \quad [°C] \tag{13}$$

where $T_{flow,GrNeu}$and $T_{return,GrNeu}$ refer to the flow and return temperature of the façade heating measured by T7 and T8 in Fig. 2 and $\bar{T}_{facade}$ to the mean façade core temperature calculated as the arithmetic mean of the temperature measured by the five PT100 sensors shown in Fig. 3:

$$\bar{T}_{facade} = \frac{\sum_{i=1}^{n} T_{facade,i}}{n} \quad [°C] \tag{14}$$

Where $T_{facade,i}$ is the temperature measured by the sensor i and n is the total number of sensors = 5. The amount of heat transported was calculated from the heat fluxes $\dot{Q}_{facade,in}$and $\dot{Q}_{facade,out}$ similarly to eq. (8):

$$Q_{facade,in} = \frac{\dot{Q}_{facade,in} \cdot \Delta t}{3{,}600{,}000} \quad [kWh] \tag{15}$$

$$Q_{facade,out} = \frac{\dot{Q}_{facade,out} \cdot \Delta t}{3{,}600{,}000} \quad [kWh] \tag{16}$$

with Δt as the time step of 15 minutes, i.e. 900 s. Finally, the difference between the heat metered by HM3 + HM4 in comparison to $Q_{facade,in}$ + $Q_{facade,out}$ was put down as losses as well as inaccuracies of the heat dissipation modelling.

3.3.3 SPF calculation

The *SPF* was established for the time period of 10th January until 4th February 2025. This is the longest heat meter reading interval with full availability of electrical power measurement data. The best available measured heat data for the heat pumps' thermal production is that logged by HM1 between the heat pump and the buffer tank inlet. The *SPF* was thus calculated as follows:

$$SPF = \frac{heat\ \text{transported}\ measured\ by\ heat\ meter\ \text{HM1}}{E_{el,total}} \quad [-] \tag{17}$$

where $E_{el,total}$ refers to the total electricity consumption of heat pumps 1 and 2:

$$E_{el,total} = E_{el,1,total} + E_{el,2,total} \quad [kWh] \tag{18}$$

which, in turn, are calculated as:

$$E_{el,i,total} = \sum_{j=1}^{n} E_{el,i,j} \quad [kWh] \tag{19}$$

Finally, the electrical power consumption per heat pump i and time step j is calculated as:

$$E_{el,i,j} = \frac{P_{el,i,j} \cdot \Delta t}{3{,}600{,}000} \quad [kWh] \tag{20}$$

With $P_{el,i,j}$as the mean power consumption of heat pump i in the time step j and Δt as the logging interval of 5 s.

4 RESULTS AND DISCUSSION

First, the results for the heat pumps' thermal power as well as heat production are presented along with the trajectory of their momentary *COP*. Then, the results of the heat flow analysis for the time period from 22nd January until 4th February are elucidated. Finally, the *SPF* resulting for the time period of 10th January until 4th February 2025 is presented.

4.1 Heat generation of the air-to-water heat pumps andCOP

The momentary thermal power$\dot{Q}_{th,i,j}$ as well as the cumulative heat produced $Q_{th,i,total}$per heat pump are shown in Fig. 6.

As can be observed, the thermal power of the heat pumps is reduced during periods of lower heating water setpoint temperatures, such as from 14th December 2024 until 6th January 2025 or from 12th until 23rd February 2025 where the setpoint temperature amounted to 23 and 22 °C, respectively. Furthermore, the prioritisation of heat pump 2 can be observed from the data in that heat pump 1 remains inactive during periods with lower demand. The prominent spikes in the momentary thermal power especially evident from 4th March 2025 are due to the reduction of the setpoint flow temperature to 22 °C at that date together with outdoor air temperatures rising to levels permanently above 5 °C and reaching upto 18 °C, resulting in a very high *COP*; see Fig. 7. The total calculated amount of heat generated during the entire observed timespan $Q_{th,total}$amounts to 15,028 kWh. Comparing this roughly to the amount of heat metered by the heat meter located between heat pumps and buffer tank (HM1) during the period of 6th December 2024 until 25th March

2025 of 13,543 kWh, a not inconsiderable discrepancy emerges, especially taking into account the logging gaps of the electrical power meters which, if filled, would result in even higher calculated amounts of heat.

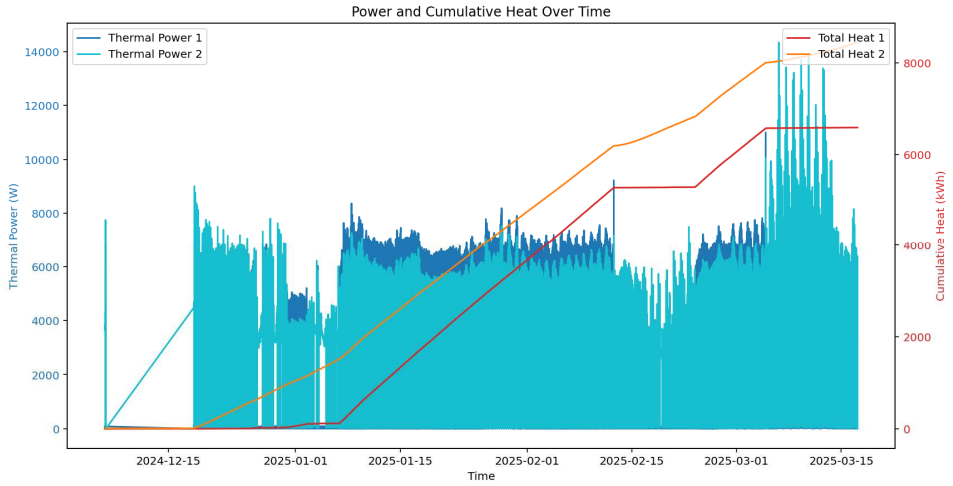

Fig.6: The thermal power provided $Q_{th,i,j}$ and cumulative heat generated $Q_{th,i,total}$ per heat pump for the timespan from 6th December 2024 until 17th March 2025.

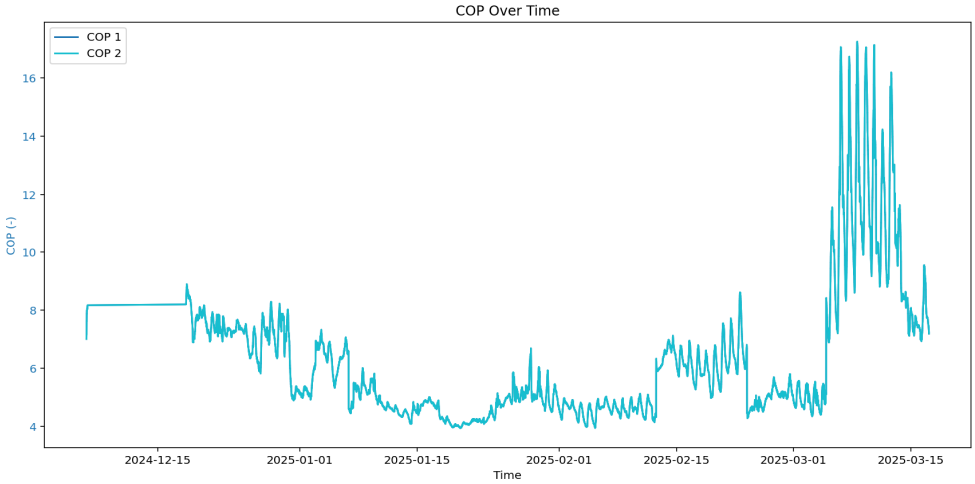

Fig. 7: The *COP* of the heat pumps for the time period from 6th December 2024 until 17th March 2025.

To give a clearer picture, a shorter time period according to a heat reading interval with full availability of electrical power data was selected and the amount of heat generated calculated. This is the period from 22nd January until 4th February 2025. The results are shown in Fig. 8.

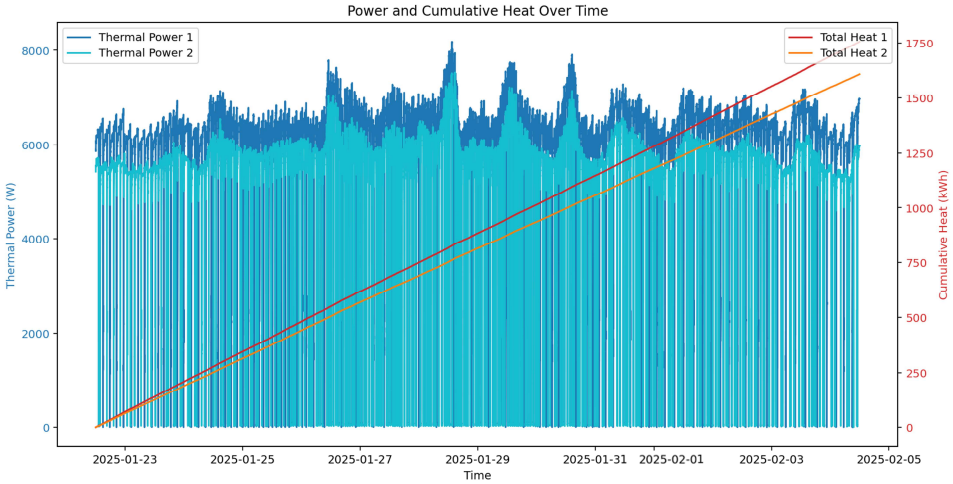

Fig.8: The thermal power provided $Q_{th,i,j}$ and cumulative heat generated $Q_{th,i,total}$ per heat pump for the timespan from 22nd January until 4th February 2025.

During this period, the heating water setpoint temperature amounted to 35 °C and the outdoor air temperature fluctuated between -2 °C and +13 °C.The *COP* fluctuated between 4 and 6.7, see Fig. 9.

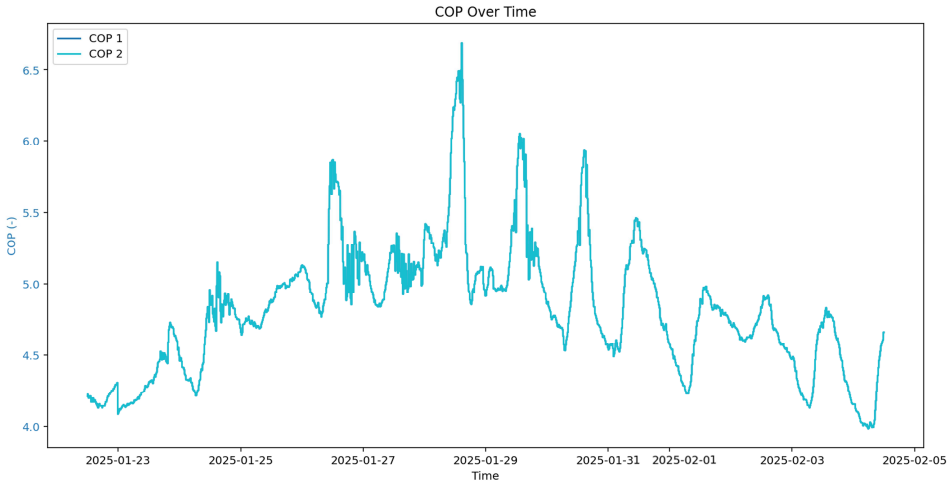

Fig. 9: The *COP* of the heat pumps for the time period from 22nd January until 4th February 2025.

During this period, the total amount of calculated heat amounts to 3,365 kWh and the amount of heat metered between heat pumps and buffer tank by HM1 to 3,142 kWh. Naturally, a certain amount of heat will be lost during transport from the heat pumps to HM1; however, as will be shown in the following section, heat losses in the buffer tank and piping are quite low for other components. A certain inaccuracy of the model must therefore be inferred.

4.2 Amount of heat transported between the various heating system components

To give a clearer picture of the amount of heat transported in the heating system, the timespan from 22nd January until 4th February 2025 with full monitoring data availability (temperature logging, heat metering and electrical power logging) was selected to visualise the observed and calculated energy fluxes. The results are shown in Fig. 10.

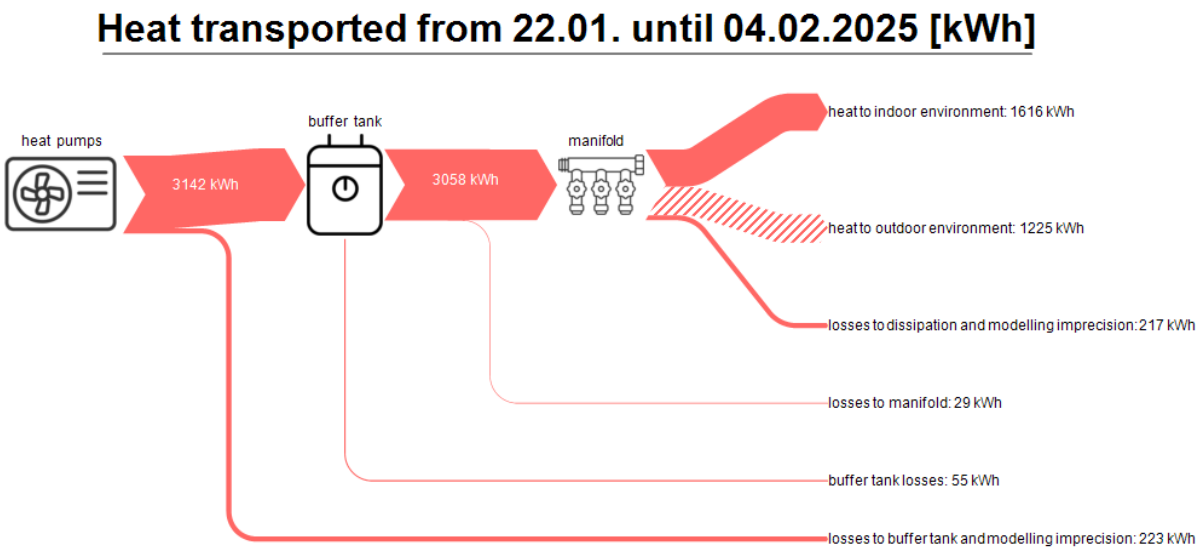

Fig. 10: Flow chart showing the measured and calculated amounts of heat transported between the various heating system components for the timespan from 22nd January until 4th February 2025.

This shows that of the 3,365 kWh produced by the heat pumps, 1,616 kWh (48 %) are supplied directly to the indoor environment and 1,225 kWh (36 %) are lost to the outdoor environment. However, the total amount of heat released via the façade activation of 2,841 kWh (84 %) contributes to the formation of a thermal barrier between indoor and outdoor environment and thus inhibits a potential heat flux from the indoor environment to the outdoor environment as long as the façade core temperature is higher than or close to the indoor air temperature. Thus, the heat flux from the façade to the outdoor environment is the price we pay for the formation of the thermal barrier. The heat losses of the buffer tank as well as of the piping

between buffer tank and manifold are relatively low which implies that the losses observed between the heat pumps and buffer tank as well as the manifold and the heat dissipation system (façade activation) are not entirely due to real losses in the piping, but also to inaccuracies of the models used to calculate the heat pumps' heat production as well as the heat release by the façade. The larger portion of the discrepancy at the heat generation end is very likely due to model inaccuracies as the pipe length between heat pumps and heat meter is rather short; however, the discrepancy at the dissipation end could indeed be mainly due to losses in the piping as the heating water travels some distance from the manifold in the plant room to the supply string at the bottom of the façade from which the individual heating circuits branch off. Various factors are likely to contribute to inaccuracies in the models used: apart from measurement errors, the assumptions made for the calculations are a source of inaccuracy. For the heat pumps' thermal power modelling, the estimation of the *COP* via the Carnot efficiency and an assumed constant ζ is, of course, a less accurate method than measured *COP* data for a larger number of testing points. Pertaining to this, also the assumption of a polynomial relationship between *COP* and heat source temperature could be questioned. For the façade heating's heat release calculation, the assumption of a uniform indoor air temperature in the entire building based on the measurement data for the only available indoor air temperature measurement device may not be representative for the entire building. Similarly, the assumption of the applicability of the heating water flow and return temperatures of the street side heating circuits to the courtyard side heating circuits must be borne in mind when interpreting the results. Overall, the largest source of inaccuracy seems to be the calculated *COP* which results in an overestimation of the thermal production of the heat pumps. This could best be rectified by establishing the behaviour of the heat pumps' efficiency via dedicated measurements.

4.3 SPF calculation

For the period of 10th January until 4th February 2025, a total amount of electricity consumed of 1,437 kWh in comparison to a measured amount of heat of 5,657 kWh was observed, resulting in a *SPF* of 3.9. This seems an acceptable *SPF* for the given heat source and heat sink conditions [ŠIMKO et al., 2024]. A slight inaccuracy in this calculation is caused by the positioning of the heat meter measuring the amount of generated heat (HM1). This is situated on the supply side of the buffer tank. Heat losses occurring in the piping between the heat pumps and the heat meter are therefore expected to result in slightly smaller amounts of measured heat than that produced by the heat pumps. However, these losses are expected to be small and bear a small significance to the *SPF* calculated.

5 CONCLUSION

In conclusion, the calculated *COP* fluctuates largely between 4 and 9 between 6th December 2024 and 17th March 2025 (with the exception of the outliers towards the end of the observation period with values of up to 17). The calculated total amount of heat generated amounts to 15,028 kWh, however, a comparison of this value to the heat meter data implies that the model overestimates the thermal power and heat production of the heat pumps. A more limited time period from 22nd January until 4th February 2025 with full availability of measurement data is chosen to evaluate the modelling approaches more closely and visualise the heat fluxes occurring between the various heating system components. It is found that the chosen modelling approach indeed overestimates the heat production of the heat pumps. The approach employed for the quantification of the heat fluxes directed from the façade heating to the indoor and outdoor environment appears to be more accurate. To counteract the thermal power overestimation, more information concerning the actual *COP* behaviour of the heat pumps would be necessary. In terms of the useful energy transported in the heating system, 48 % of the heat generated is released to the indoor environment and 36 % of the heat is lost to the outdoor environment. In terms of the total efficiency of the heat generation system, the *SPF* of the heat pumps amounts to 3.9for the period from 10th January until 4th February 2025.

1 ABSTRACT

This paper examines the emergence of hijacked residential buildings in affluent suburbs as a new form of urban informality, using a qualitative case study of Bryanston in Johannesburg. Drawing on secondary data and informed by theories of informality as a mode of urbanisation, grey space and the Right to the City, the study shows that suburban hijackings are not isolated criminal incidents but structural outcomes of housing exclusion, weak governance of vacant property and housing financialisation. The findings reveal how informal rentalisation of high-value suburban properties provides precarious access to well-located urban space while reproducing vulnerability and exploitation. The paper argues that the suburbanisation of informality challenges spatially bounded planning imaginaries and enforcement-led responses and calls for metropolitan-wide, justice-oriented planning approaches that address vacancy, regulate informal rental markets and expand access to affordable housing in well-located areas.

Keywords: Hijacked buildings, Urban informality, Spatial justice, Housing inequality, Urban governance

2 INTRODUCTION AND BACKGROUND

Urban informality is a defining feature of contemporary cities and is increasingly understood not as a peripheral or temporary condition, but as a structural outcome of how cities are planned and governed. Critical urban scholarship argues that informality is produced through selective regulation, uneven governance, and exclusion from formal urban systems rather than through the absence of planning (Roy, 2005; Roy & AlSayyad, 2004). While informality has historically taken forms such as informal settlements and backyard dwellings, growing attention is being paid to the informal occupation of buildings. Vacant or underutilised properties, often linked to speculation, absentee ownership, or legal disputes, are increasingly repurposed as informal housing, creating concealed and hybrid spaces that blur the boundaries between formality and illegality and are sustained by fragmented governance and weak oversight (Lees et al., 2018; Yiftachel, 2009). In South Africa, urban informality is rooted in apartheid spatial planning, which excluded the majority of the population from well-located urban land and continues to shape contemporary inequality. Despite post-apartheid commitments to spatial justice, cities face persistent housing backlogs, rising costs, and limited access to affordable, well-located accommodation (Harrison & Todes, 2015; Turok & Visagie, 2018). Informality has therefore remained a structural feature of urban life, historically concentrated in informal settlements and backyard dwellings within townships (Lemanski, 2009). More recently, however, informality has begun to emerge within affluent suburban areas. In Johannesburg, hijacked buildings, once associated with inner-city decline, are increasingly appearing in well-located suburbs such as Bryanston, involving the illegal modification of high-value homes and unlawful service connections. These concealed practices challenge planning assumptions that equate informality with peripheral or deteriorated areas. This study uses a qualitative case study of hijacked residential properties in Bryanston to examine the dynamics of suburban informality and their implications for housing exclusion, governance failure, and spatial justice in South African cities.

2.1 Literature review and theoretical framework

Urban informality has been extensively examined within urban studies, particularly in relation to housing exclusion, governance failure, and spatial inequality. Early conceptualisations framed informality as a residual or transitional condition associated with poverty, rapid urbanisation, and weak state capacity. More recent scholarship has challenged this understanding, arguing that informality is not external to planning systems but is actively produced through them. Roy's (2005) conceptualisation of informality as a mode of urbanisation has been particularly influential in reframing informality as the outcome of selective regulation, uneven enforcement, and state inaction. From this perspective, informality emerges not where planning is absent, but where legality is unevenly applied across urban space. This reconceptualisation has been critical

in shifting attention away from informal settlements alone toward a broader range of informal practices embedded within formally planned environments. Informality is increasingly understood as a continuum rather than a binary, blurring distinctions between legality and illegality, and between formality and informality (Yiftachel, 2009). The concept of grey space further illuminates how certain urban practices remain tolerated, ignored, or intermittently enforced, producing spaces that are neither fully legal nor fully illegal. This theoretical framing is particularly relevant for understanding informal housing practices that occur within existing building stock, often concealed within formal neighbourhoods. A growing body of international literature examines the informal occupation of buildings as a response to housing shortages, rising costs, and speculative property markets. In cities across the Global North, including London, Berlin, Barcelona, and Athens, high levels of residential and commercial vacancy coexist with acute housing unaffordability. Scholars document how vacant or underutilised buildings, frequently held as speculative assets or entangled in legal disputes, have been informally occupied by low-income households, migrants, and homeless populations seeking access to well-located urban space (Aalbers, 2016; Lees et al., 2018). These cases demonstrate how informality can emerge even within strong regulatory contexts when housing is treated primarily as an investment rather than a social good. While some building occupations in these contexts are politically organised and linked to housing movements, others operate as informal rental arrangements mediated by unregulated landlords or intermediaries, blurring the line between resistance and exploitation (Pruijt, 2013). This distinction is important, as it complicates normative readings of informal occupation as inherently rights-based. Drawing on the Right to the City framework (Lefebvre, 1968; Harvey, 2008), scholars argue that informal occupation often reflects claims to urban space based on use and need rather than ownership. However, such claims are frequently distorted by unequal power relations and market pressures, resulting in precarious and exploitative living arrangements rather than substantive urban rights (Marcuse et al., 2009).

In the Global South, informal building occupation has long been observed alongside informal settlements, yet scholarship increasingly highlights its expansion beyond inner-city or visibly marginal areas. In São Paulo, centrally located office and residential buildings have been occupied by low-income households seeking proximity to employment and services, often governed through informal systems that regulate access, rent, and internal order (Caldeira, 2017). Similarly, in Mexico City, abandoned or partially completed apartment blocks have been informally occupied in contexts of weak enforcement, fragmented ownership, and post-disaster abandonment (Duhau & Giglia, 2008). In Indian cities such as Mumbai, informal subdivision of older buildings has intensified as formal housing becomes increasingly inaccessible, producing dense and unsafe living conditions within formally zoned urban areas (Bhan, 2016). Across both Global North and Global South contexts, several common themes emerge. Informal building occupation is closely linked to vacancy and underutilisation, particularly where housing is financialised and disconnected from social need. These forms of informality are often spatially concealed, embedded within formal neighbourhoods, and sustained through fragmented governance. Moreover, informal building occupations frequently operate as informal rental markets, where access to shelter is mediated by intermediaries who extract rent, reinforcing vulnerability rather than alleviating it. These patterns underscore Roy's argument that informality is a governance outcome rather than a spatial deviation.

Within South Africa, scholarship on informal housing has historically focused on informal settlements and backyard dwellings, particularly within townships. Backyard shacks have been widely documented as a coping strategy that enables households to generate income while accommodating those excluded from state-subsidised housing and formal rental markets (Lemanski, 2009). Planning and policy responses have largely treated such informality as spatially bounded, reinforcing the assumption that informality belongs in marginalised spaces. This framing aligns with critiques from spatial justice scholars, who argue that planning systems often reproduce inequality by normalising informality in some areas while criminalising it in others (Soja, 2010). Research on hijacked buildings in South Africa has primarily concentrated on inner-city Johannesburg, linking their emergence to deindustrialisation, white flight, property disinvestment, and the collapse of formal property management during the late apartheid and early post-apartheid periods (Beall et al., 2002; Huchzermeyer, 2011). These studies document how unlawfully occupied buildings are governed through informal and often criminal systems that regulate access and extract rent in the absence of effective state intervention. More recent evidence suggests that hijacked buildings are no longer confined to inner-city areas but are increasingly appearing in well-located suburban contexts, reflecting broader housing

affordability pressures and governance gaps. Despite these insights, there remains limited empirical work examining suburban hijacked buildings in South Africa through a theoretical lens that connects informality, governance, and spatial justice. Existing literature has yet to fully engage with how informality is shifting spatially into suburbs and what this reveals about the limits of current planning frameworks. By drawing on theories of informality as a mode of urbanisation, the Right to the City, and grey space, and situating suburban hijacked buildings alongside international experiences of informal building occupation, this study seeks to contribute to a more nuanced understanding of urban informality as a metropolitan-wide phenomenon shaped by structural inequality, vacancy, and governance failure.

3 RESEARCH METHODOLOGY

This study uses a qualitative case study approach to examine hijacked residential buildings in affluent suburban contexts, focusing on Bryanston in the City of Johannesburg as a critical and illustrative case. The study is exploratory and aims to unpack how hijacked buildings operate in suburban environments and what they reveal about housing exclusion, governance dynamics, and planning failure. Bryanston was selected due to the emergence of multiple high-profile hijacked luxury properties, which challenge assumptions that building hijackings are confined to inner-city or marginalised areas, and because sufficient public information exists to support robust analysis. The study draws on secondary qualitative data from investigative journalism, municipal documents, policy frameworks, and academic literature, which were analysed using thematic qualitative analysis combining deductive and inductive coding (Braun & Clarke, 2006). Theoretical lenses informed the initial coding, while cross-source triangulation was used to enhance analytical credibility.

4 FINDINGS AND DICUSSION

4.1 Suburban informality and the limits of planning imaginaries

A key finding of the study is the emergence of informality within affluent suburban contexts, which unsettles entrenched planning imaginaries that equate suburbs with formality, legality, and effective governance. Planning scholarship has long shown that the "suburb" is not merely a residential form but a normative project, built around assumptions of order, controlled density, private property protection and regulated access to urban services (Fishman, 1987; Knox, 2008). In many contexts, suburbs are governed through a combination of municipal regulation and privatised systems of control (e.g., security regimes, homeowners' associations, managed infrastructure), producing what some scholars describe as splintered or uneven urbanism, where services, rights, and protections are distributed unequally across space (Graham & Marvin, 2001). Within this frame, the appearance of hijacked luxury homes in Bryanston is not simply "informality in the wrong place"; it exposes the fragility and selective nature of suburban governance arrangements and the extent to which suburban order relies on assumptions of predictable ownership and continuous management. The Bryanston case also challenges the spatially bounded way in which informality is typically anticipated in planning practice. Much of the planning and housing literature, especially in South Africa, has treated informality as a phenomenon expected in townships, informal settlements, and inner-city areas shaped by disinvestment and marginality (Huchzermeyer, 2011). This has produced what Watson (2009) critiques as a persistent "informality–formality" binary in planning, where informality is handled through containment, upgrading, or enforcement in already marginalised zones, while suburban spaces are protected as sites of "proper" urbanism. The suburbanisation of informality destabilises this logic by showing that informality can be produced within formal planning regimes, not merely outside them.

Roy's (2005) theorisation is particularly useful here because it reframes informality as a mode of urbanisation and a product of governance rather than a location or sector. Seen through this lens, suburban hijackings are not anomalous but symptomatic of how urban legality is unevenly produced. Roy argues that states do not simply regulate informality; they actively construct it through selective enforcement and the normalisation of exceptions. This resonates with Yiftachel's (2009) "grey space" thesis, which emphasises that urban spaces often exist between legality and illegality, sustained by delayed enforcement, institutional ambiguity, and political calculation. The Bryanston case illustrates how suburban spaces can also become grey: properties can remain effectively "unseen" by governance systems when vacancy, absentee ownership, or weak monitoring create regulatory blind spots, until a crisis triggers sudden and forceful intervention. At the same time, the suburbanisation of informality must be read within the political economy of housing and

land. International debates on housing financialisation show how property is increasingly treated as an asset class rather than shelter, generating vacancy, absentee ownership, and disconnection between housing supply and housing need (Aalbers, 2016). When affordability crises intensify, the literature shows that informal and precarious habitation can appear in unexpected places, including within high-value neighbourhoods because access to well-located space is increasingly restricted through market mechanisms (Lees et al., 2018). In this sense, the Bryanston case is part of a broader urban contradiction: high-value suburbs may simultaneously embody wealth and become sites of concealed housing precarity when vacant properties are repurposed through informal occupation.

Critically, the visibility and politicisation of suburban informality also reveals the classed and racialised moral geographies of "acceptable" informality. Scholarship on "advanced marginality" and territorial stigma demonstrates how certain spaces become socially coded as legitimate sites for poverty and informality, while others are protected from it through intensified surveillance and boundary-making (Wacquant, 2008). In South African cities, this is amplified by apartheid's spatial legacy, where townships and informal settlements are often treated as the expected reservoirs of urban crisis, while suburbs are framed as spaces of entitlement and security. When informality appears in suburbs, it is more likely to be narrated as invasion, disorder, or criminality, rather than as a housing system failure, thereby legitimising enforcement-heavy responses and reinforcing spatial exclusion (Huchzermeyer, 2011; Watson, 2009). The suburbanisation of informality therefore exposes not only housing failure but also the limits of planning's dominant spatial imagination. It suggests that planning has often operated through a dual logic: normalising informality as a manageable condition in historically marginalised areas while treating its emergence in affluent areas as an exceptional threat. This dualism is increasingly untenable as metropolitan housing pressures intensify and as informal housing markets adapt to new spatial opportunities. The Bryanston case thus foregrounds a critical planning challenge: to move beyond spatial containment and moralised framings of informality, and to recognise suburban informality as a metropolitan-scale governance and housing question shaped by market exclusion, vacancy, and uneven regulation.

4.2 Vacancy, informal rentalisation and the production of grey urban space

The Bryanston case reveals how vacancy and informal rentalisation intersect to produce suburban grey space, transforming high-value private properties into sites of concealed informality. Vacant and underutilised homes often linked to absentee ownership, unresolved legal status, speculative holding, or long-term service disconnections, emerge as critical entry points through which informal occupation takes root. Importantly, this process is rarely abrupt. Instead, it unfolds incrementally as weak monitoring and the absence of proactive municipal intervention allow properties to be quietly subdivided, informally retrofitted, and reconnected to services over time. What initially appears as temporary or marginal illegality gradually solidifies into a stable, though informal, housing arrangement. This dynamic aligns closely with Yiftachel's (2009) concept of grey space, where urban practices exist between legality and illegality and are sustained through institutional ambiguity and selective enforcement. In suburban contexts such as Bryanston, properties are neither immediately sanctioned nor regularised; rather, they persist through tacit tolerance, delayed intervention, and fragmented governance. Suburbs are often assumed to be self-regulating through private ownership, security regimes, and zoning controls, resulting in limited proactive oversight by planning authorities. Responsibility for intervention is dispersed across departments concerned with housing, utilities, by-law enforcement, and public safety, allowing illegality to normalise until it becomes visible through infrastructural strain, safety risks, or financial loss. At that point, enforcement is intensified, often abruptly and punitively. However, the production of grey space in Bryanston is not solely a function of regulatory failure; it is also deeply tied to the informal rentalisation of vacant property. The findings indicate that hijacked suburban buildings operate primarily as informal rental housing rather than spontaneous squatting. Occupants reportedly paid rent to intermediaries who controlled access, subdivided internal space, and managed utilities, revealing a commodified form of informality embedded within private property regimes. This reflects broader debates on housing financialisation, where housing is treated as an asset rather than shelter, generating vacancy alongside acute housing need (Aalbers, 2016). In this context, informality becomes a market response to exclusion, filling the gap between unaffordable formal housing and unmet demand for well-located accommodation.

From a Right to the City perspective, these informal rental arrangements represent distorted claims to urban space. Residents seek proximity to employment, services, and infrastructure that affluent suburbs offer, yet access is mediated through precarious, marketised arrangements rather than rights-based inclusion (Lefebvre, 1968; Harvey, 2008). The right to inhabit the city is effectively reduced to the ability to pay informal rent to unregulated intermediaries, stripping it of its collective and political dimensions. Rather than democratizing access to urban opportunity, suburban informality reproduces exclusion through new spatial forms, where vulnerability is intensified by unsafe living conditions, lack of tenure security, and exposure to sudden displacement. Critically, this merged dynamic exposes a profound contradiction in planning governance. While planning frameworks emphasise spatial justice, efficiency, and sustainable land use, they offer limited mechanisms for regulating vacancy and informal rental markets within private property systems. Planning silence around speculation, absentee ownership, and the social obligations of property ownership enables the very conditions under which suburban informality emerges. Hijacked suburban buildings are therefore not simply governance failures or criminal deviations; they are products of a planning regime that tightly regulates land use while largely ignoring how property is held, left vacant, or informally commodified.

An instructive analogy is to view suburban hijacked buildings as the "backyard shacks of the affluent city"not in form, but in function. Just as backyard dwellings in townships absorb housing pressure through informal rentalisation on private plots, hijacked suburban properties absorb metropolitan housing demand through concealed subdivision and informal rent extraction within high-value homes. In both cases, informality is tolerated as long as it remains spatially and socially contained. When it breaches the moral and spatial boundaries of privilege, it is reframed as crisis, prompting enforcement rather than structural reform. This analogy underscores that suburban informality does not represent a breakdown of the urban system, but rather its adaptation, revealing how housing exclusion, vacancy, and uneven governance are redistributed across space rather than resolved. By foregrounding vacancy and informal rentalisation as central mechanisms, the Bryanston case demonstrates that suburban hijacked buildings are a critical lens through which to interrogate the limits of planning frameworks that separate land-use control from housing justice. Addressing such phenomena therefore requires moving beyond reactive enforcement toward metropolitan-scale interventions that confront vacancy, regulate informal rental markets, and expand access to affordable, well-located housing, before grey spaces harden into entrenched urban conditions.

4.3 Implications for planning, spatial justice and urban futures

Taken together, the findings reveal that suburban hijacked buildings are not anomalies but warning signals of deeper structural contradictions in South African cities. They expose the failure of planning systems to reconcile property regimes with housing justice, and the inadequacy of spatially bounded approaches to informality. For urban planning, this demands a shift from reactive enforcement toward metropolitan-wide strategies that address vacancy, affordability and access to well-located housing. This includes proactive monitoring of underutilised properties, stronger regulation of vacancy, and the expansion of transitional and affordable housing options in suburban and central locations. Without such interventions, informality will continue to adapt and reappear in new forms, further blurring the boundaries between formal and informal urban space. As a result, the suburbanisation of informality forces planners to confront uncomfortable questions about who the city is planned for, whose informality is tolerated, and whose is criminalised. Addressing hijacked buildings therefore requires not only technical solutions, but a reorientation of planning practice toward spatial justice and substantive urban inclusion.

5 CONCLUSION AND RECCOMENDATIONS

This paper has examined the emergence of hijacked residential buildings in affluent suburban contexts through a case study of Bryanston in the City of Johannesburg. Drawing on theories of informality as a mode of urbanisation, grey space, and the Right to the City, the study demonstrates that suburban hijackings are not isolated criminal anomalies but structural outcomes of housing exclusion, uneven planning regulation, weak governance of vacant property, and the financialisation of housing in deeply unequal cities. The findings reveal a significant spatial shift in informality, challenging entrenched planning imaginaries that confine informality to townships or inner-city areas. Vacant and underutilised suburban properties become grey spaces where illegality is normalised through institutional ambiguity and delayed intervention, while informal rentalisation offers precarious and exploitative access to well-located urban space. The Bryanston case exposes a central contradiction in South African urban planning: although policy frameworks emphasise

spatial justice and integration, planning practice continues to rely on spatial containment and enforcement-led responses to informality. Such approaches restore formal order temporarily but fail to address the structural drivers of suburban informality, leading to cyclical displacement and the reproduction of vulnerability across the metropolitan region. As housing pressures intensify, informality is likely to continue adapting and reappearing in new spatial forms unless these underlying conditions are addressed. In response, this paper argues for a shift toward proactive and justice-oriented urban governance. Municipalities should strengthen the monitoring and regulation of vacant and underutilised properties, including mechanisms that discourage prolonged vacancy and speculative holding. Planning and housing strategies must expand transitional, social, and affordable rental housing options in well-located suburban and central areas, including the adaptive reuse of suitable properties. Responses to hijacked buildings should be integrated across planning, housing, social development, and enforcement functions, moving beyond fragmented and punitive interventions. Finally, planners must rethink spatially bounded assumptions about informality and recognise it as a metropolitan-wide phenomenon shaped by structural inequality rather than a localised deviation. Addressing suburban hijackings effectively therefore requires not only improved regulation, but a reorientation of planning practice toward spatial justice and substantive urban inclusion.

How can the Transformative Research Methodology be Applied to Regional Governance?

Jörg Knieling, Franziska Ulrich

(Prof. Dr. Jörg Knieling, HafenCity University Hamburg; Hamburg, DE; joerg.knieling@hcu-hamburg.de)
(Franziska Ulrich, MSc, HafenCity University Hamburg; Hamburg, DE; franziska.ulrich@hcu-hamburg.de)

1 ABSTRACT

The transformative research methodology has become a widely recognised approach to increasing the impact of research on sustainability transitions. Methods such as real-world laboratories, experiments and interventions enable scientists, stakeholders and citizens to collaborate. However, this methodology has mostly been applied at a local level or to specific spatial issues in neighbourhoods or selected sites. This raises the question of how far the transformative research methodology could also be useful at more abstract scales, such as regions or metropolitan areas, and what adaptations or modifications would be required to contribute to regional or metropolitan governance.

In the case of the Metropolitan Region of Nuremberg, this question was addressed in the 'Climate Pact 2030 Plus' research project on the energy transition (BMFTR, 2023–2027). The Climate Pact provides an ambitious vision for regional climate policy and has set up Real World Labs in the fields of energy provision and building renovation to explore different approaches to stakeholder collaboration. Experiments and pilot projects were chosen for implementation, aiming at typological solutions that can be transferred to the metropolitan region. In addition, a monitoring and reporting tool enables reflection and evaluation.

Against the backdrop of its theoretical framework, the paper outlines the methodological approach adopted for the case study and details the experiences of its implementation during the initial phase of the project. Building on this, it considers to what extent sustainable transitions in metropolitan regions can benefit from transformative research, and which restrictions and methodological adaptations need to be taken into account to integrate it into transformative regional governance.

2 STUDY AREA: EUROPEAN METROPOLITAN REGION OF NUREMBERG

With its Climate Pact, the European Metropolitan Region of Nuremberg/Germany (EMN) has set itself the goal of promoting the energy transition and pursuing ambitious climate protection targets. The Klimapakt2030plus research project aims to develop a strategic transformation path and suitable governance and cooperation structures for energy transition and climate protection in the EMN.

The EMN was founded in 2005. In the EMN charter, the founding members laid down the rules and objectives of cooperation. The Council of the Metropolitan Region comprises eight cities and twelve districts (Standecker 2007). The development of the EMN is based on the already close interconnection of central urban axes, in particular the Nuremberg-Fürth-Erlangen chain of cities. These functional relationships, complemented by joint transport and infrastructure networks such as the Greater Nuremberg Transport Association, were important driving forces behind the growth of a polycentric metropolitan region in which Nuremberg is also the dominant centre. Since its foundation, the EMN has gradually expanded as other cities and districts have joined on a voluntary basis.

The governance structure of the EMN consists of several key elements:

- Metropolitan Region Council: This is the political decision-making body of the founding members and sets the strategic goals.
- Charter and Rules of Procedure: These define the institutional rules for cooperation, decision-making and financing.
- Specialist forums: Thematic working committees on the economy and infrastructure, science, transport and planning, culture, sport, heritage and leisure, marketing, climate protection and sustainable development. The forums are supported by initiative groups.
- Funding: The work of the EMN is made possible by contributions from local authorities, corporate donations and project funding.

The EMN is not a hierarchical governing body, but primarily functions as a network and cooperation platform. The governance of the EMN is based on voluntary participation, the principle of subsidiarity and cooperative network structures. This means that decisions are made at the local level wherever possible, while the metropolitan region itself primarily acts in an enabling and supportive capacity. It sees itself as a catalyst, moderator and supporter of regional self-organisation processes, without having any sovereign powers. Its role is to connect stakeholders, exchange experiences and facilitate joint strategies, such as in the 'Climate Pact 2030 Plus' project (Standecker 2007; European Metropolitan Region of Nuremberg 2023).

3 REQUIREMENTS FOR TRANSFORMATIVE RESEARCH AT CLIMATE PACT 2030PLUS

The research project 'Climate Pact 2030plus – Energy Transition in the Nuremberg Metropolitan Region' uses transformative research methods to support the energy transition. The project will run for five years (2023–2027) and is being carried out by a transdisciplinary research network comprising practitioners and scientists. The practitioners involved include the Nuremberg Metropolitan Region and the Nuremberg Energy Region, while the scientists include universities from the region and HafenCity University Hamburg as a partner for accompanying socio-ecological research and governance analysis. The project is funded by the Federal Ministry of Education and Research as part of its research for sustainability programme. From the ministry's perspective, Climate Pact 2030plus is a pilot project for the metropolitan region's level of action.

In view of the special spatial constellation of a metropolitan region, a number of specific conditions and requirements arise for transformative research:

- Multi-level governance: The energy transition in a metropolitan region is embedded in multi-level structures, from the municipal and district level to the metropolitan region level to state and federal policy, European guidelines and global contexts. Transformative research must therefore be designed to capture interactions and contexts at the various levels of governance. A multi-level-oriented understanding helps to uncover coordination problems between the levels and identify potential for improvement in the management of the energy transition.
- Urban-rural interdependencies: The Nuremberg metropolitan region encompasses urban centres and rural areas. Solutions in densely populated areas may differ from those in rural areas. For example, rural areas play an important role in the generation of renewable energy (wind farms, solar fields) due to their large open spaces, while urban areas are centres of consumption and innovation. Transformative research should therefore aim to highlight interactions (e.g. with regard to energy, resources, knowledge transfer) between cities and their surrounding areas.
- Implementation barriers and obstacles to transformation: Climate Pact 2030plus examines the governance of the energy transition at regional level. Barriers to implementation can be institutional (lack of responsibilities, silo thinking between sectors), socio-cultural (acceptance problems, conflicting values), economic (financing issues, distribution disputes) or technical/infrastructural. In addition, the research maps the roles of important key players (local administrations, political decision-makers, networks, industry/energy suppliers, etc.) and their power resources and interests.
- Transformative methods: As part of Climate Pact 2030plus, tests are being conducted to determine how transformative research methodology can be applied at the metropolitan regional level. This involves the use of transformation arenas, real-world laboratories and real-world experiments, among other things. The climate pact process culminates in a collective narrative for a shared future of regional development aimed at climate neutrality.

4 THEORETICAL FRAMEWORK: TRANSFORMATIVE GOVERNANCE

4.1 Fundamentals of transformation research

Transformation research deals with social change processes and the conditions under which they arise, stabilise or accelerate. In the Climate Pact 2030plus project, it serves to scientifically analyse the energy transition in the EMN and to make governance structures visible. The aim is to support decision-makers and actors in advancing the energy transition by examining ongoing processes and testing transformative control elements (WBGU 2016; Schneidewind and Singer-Brodowski 2014; Radtke and Canzler 2019). A

distinction is made between two complementary approaches. While transformation research aims to derive general system knowledge from the observation of real transformation processes, transformative research actively accompanies these processes in order to provide targeted support and gain a better understanding of them. In this understanding, transformations are enabled by social, economic and technical innovations. (WBGU 2016, pp. 20–33, also Hofmeister et al. 2021)

4.2 Role of transformation research in the Climate Pact 2030plus project

In the Climate Pact 2030plus project, overarching transformation research analyses the governance structures of the EMN in order to understand how political, economic and civil society actors interact with each other and which institutional paths promote or hinder the energy transition. At the same time, it pursues an explicitly transformative approach in the real-world laboratories: it plays a formative, cooperative and process-supporting role, without directly intervening in the governance structure of the EMN (Parodi et al. 2016). This results in a dual approach: analysis of the existing system on the one hand and experimental testing of new forms of control and transformation on the other.

The energy transition can be understood as a socio-technical transformation process that encompasses both technological and societal changes. Socio-technical systems consist of closely interwoven social and technical components that can only be changed together (Geels and Schot 2011). The transformation of a socio-technical system requires technical innovations as well as their embedding in social structures, market mechanisms and institutional frameworks.

4.3 Fundamentals of governance research

Governance research has its roots in various social science disciplines (van Kersbergen and van Waarden 2004), which makes it difficult to arrive at a uniform definition (Benz and Dose 2010). While ‘government’ refers to the system of government of a political entity, governance encompasses all processes that take place between state, private sector and civil society actors and aim to organise collective affairs (Benz and Dose 2010; WBGU 2016). Governance is thus understood as an umbrella term for the forms and mechanisms used to coordinate the interdependent actions of various actors. This includes both formal institutions, such as legal regulations and state administrative structures, and informal arrangements, such as cooperative networks (Benz and Kilper 2018, WBGU 2016, 544, 102). Governance is not understood as opposed to state action, but as an analytical framework that systematically encompasses different modes of governance, including state hierarchy, market mechanisms and civil society self-organisation. The focus is particularly on coordination and cooperation, as political control in complex fields such as the energy transition is hardly possible through hierarchical control alone (Benz and Kilper 2018).

4.4 Role of governance research in the Climate Pact 2030plus project

The accompanying research in the Climate Pact 2030plus project is based on an understanding of governance that encompasses both hierarchical governance and the participation of social and economic actors in decision-making processes. The analysis focuses on the applicable regulatory systems, institutional configurations and forms of interaction that shape the field of climate protection in the European Metropolitan Region of Nuremberg (Benz and Kilper 2018). The project distinguishes between five types of governance instruments: (1) regulatory instruments, (2) financial assistance, (3) market participation, (4) organisational instruments and (5) informal instruments.

4.5 Metropolitan regions as governance areas

Metropolitan regions develop from socio-economic interdependencies that increasingly overlap existing municipal and administrative boundaries. Due to urbanisation, changing commuter flows and economic networks, the political and administrative boundaries of many cities and counties no longer correspond to the actual functional areas. Metropolitan regions are responding to this change by forming broader territorial boundaries that better represent and organise current social, economic and infrastructural interdependencies (Yan and Growe 2022). This presents the challenge that governance cannot be focused exclusively on urban centres, but must actively integrate the surrounding peripheral areas in order to avoid regional imbalances. Concepts such as ‘communities of responsibility’ are intended to promote a new ‘spatial awareness’ that strengthens cooperation and solidarity within the region (Miosga 2007).

The governance of metropolitan regions is generally voluntary and characterised by the principle of subsidiarity. Decisions should be made as locally as possible, while the metropolitan region itself primarily assumes a coordinating role: it acts as a catalyst and moderator for regional self-organisation processes. By networking actors and exchanging experiences, it strengthens regional capacity for action, but generally without having any sovereign powers of its own (Standecker 2007; European Metropolitan Region of Nuremberg 2023). Overall, metropolitan regions are emerging as governance spaces that are characterised less by formal hierarchies than by cooperative networks. Their special quality lies in their ability to connect regional actors, enable collective problem-solving and coordinate long-term transformation processes (such as the energy transition) across institutional boundaries.

4.6 Metropolitan regional transformative climate governance

Metropolitan regional transformative climate governance can be understood as a form of governance that aims to achieve the sustainable transformation of socio-technical systems (in the Climate Pact, this refers in particular to the energy system and building stock) within polycentrically organised metropolitan areas or regions. It combines knowledge of profound social transformation processes (WBGU 2011; Schneidewind and Singer-Brodowski 2014; Radtke and Canzler 2019) with an understanding of governance that encompasses intentional forms of coordination between governmental, economic and civil society actors (Benz and Dose 2010; WBGU 2016; Benz and Kilper 2018). This form of climate governance is transformative because it aims to integrate technical, economic, social and political-administrative knowledge in order to shape knowledge-intensive processes such as the energy transition (Dewald et al. 2019). At the same time, it offers an analytical approach that takes into account institutional frameworks, stakeholder landscapes, forms of cooperation and path dependencies typical of long-term transformation processes (Czada and Radtke 2018). It is metropolitan-regional because it takes place in a space characterised by close socio-economic interdependencies, functional urban-rural relationships and the overlapping of municipal boundaries (Yan and Growe 2022; Miosga 2007).

In the Climate Pact 2030plus project, metropolitan regional transformative climate governance forms the theoretical framework for analysing and shaping the energy and climate transformation.

5 TRANSFORMATIVE METHODS

The methods of transformative research focus on various levels of action within the complex multi-level structure of the EMN.

- Steering committee. A select group of decision-makers from the metropolitan region ensures that the work of Climate Pact 2030plus is linked to real-world processes. The steering committee also acts as an interface between the Metropolitan Region Council and the expert forums, enabling the transfer of results and the adoption of the necessary resolutions.
- Transformation arenas. At the metropolitan region level, annual transformation and climate pact conferences have established transformation arenas that facilitate exchange, networking and information sharing among the stakeholders involved. They create spaces for knowledge exchange and enable discussion of implementation approaches. Participatory and co-creative working methods aim to promote interaction and activate participants.
- Transformation agenda. At the start of the project, the EMN already had a target document, the Climate Pact. This was revised in the first few years of cooperation in a collaborative working process. The Climate Pact is a joint strategy paper in which the members of the metropolitan region voluntarily commit themselves to actively promoting climate protection and the energy transition. The Climate Pact creates a common framework, formulates strategic goals and bundles the political commitments of the participating municipalities and districts. However, these are kept open enough to allow sufficient room for creativity and adaptation to changing conditions during the implementation process.
- Real-world laboratories. Two real-world laboratories, ‘Energy Supply Transformation’ and ‘Building Stock Transformation,’ were also set up at the metropolitan region level. They deal with the topics of energy and heat supply as well as building renovation. Real-world laboratories are research infrastructures in which experiments are carried out under real-world conditions (Beecroft

et al. 2018; Parodi et al. 2016). As cooperation platforms, they bring together a wide variety of actors from the respective subject areas, who jointly develop and test strategies and measures for implementing the Climate Pact. The collaboration aims to generate various forms of knowledge that contribute to transformation processes (Beecroft et al. 2018, Benz and Dose 2010): system knowledge, target knowledge and transformation knowledge. The design of the real-world laboratories provides for a variety of working methods, such as workshops, excursions and individual consultations, in order to achieve the highest possible level of transformation activity in the region.

- Experiments and experimental spaces. The implementation processes of the real-world laboratories are organised in a variety of ways and are geared towards the needs of the respective measure. This has led to the creation of sub-regional energy supply companies organised as inter-municipal cooperatives. In the field of building renovation, region-wide training events, for example for homeowners or property managers, offer solutions and attempts are being made to identify and overcome obstacles in the renovation sector. This can then be done on a small scale as a pilot project.
- Monitoring and reporting: As part of Climate Pact 2030plus, a monitoring system has been developed to track progress in climate protection and the energy transition. In addition to presenting numerical values, the monitoring system also includes reporting that showcases successful projects and measures. This is intended to encourage others to follow suit and recognise the respective project sponsors. The monitoring system differentiates between districts and independent cities, thereby helping to highlight pioneers and encouraging laggards to become more involved in climate protection and the energy transition. (Ulrich et al. 2026)

6 CONCLUSION

The Climate Pact serve as central platforms for supporting and disseminating the regional transformation processes initiated by Climate Pact 2030plus. They are key building blocks for bringing project results to the region while at the same time incorporating new ideas from practice and involving regional actors in the transformation process.

For sustainable spatial development, transformative research offers a repertoire of methods that supports co-creative processes and provides a space to move from the idea to experimental testing. Until now, these approaches have been used predominantly in small-scale contexts, such as at the neighbourhood level (e.g. Oltmann et al. 2022). The Climate Pact 2030plus research project attempts to scale these experiences to the metropolitan regional level.

The metropolitan region offers both advantages and challenges for transformative research approaches. On the one hand, the abundance of diverse actors available simply due to the size of the area is an advantage. They make it possible to identify sufficient transformation pioneers and forge innovation alliances. On the other hand, the large size of the area makes it difficult to establish the proximity and trust that are prerequisites for successful cooperation. Consequently, it is necessary to respond to the complex multi-level structure of the metropolitan region with a multi-level methodology of transformative research. Large-scale real-world laboratories play with the different levels of action, applying formats for the entire region as well as smaller-scale experiments, with the selection depending on the respective topics.

Furthermore, there are special requirements for the integration of transformation processes into metropolitan regional governance. The EMN's steering committees are also the key decision-making structures for the implementation of transformative experiments and other results of the cooperation process. This requires system knowledge in order to make use of the necessary access points and negotiation forums.

These requirements also give rise to further research questions, such as how transformative research processes can be integrated into existing multi-level structures, how urban-rural specifics affect transformation, both in terms of potential and possible restrictions, or whether the specific spatial structure of a metropolitan region – for example, centralised or polycentric – gives rise to special requirements for transformative research. And, of course, the question arises for a metropolitan region as to what extent the instruments of transformative research can permanently supplement the repertoire of regional development,

i.e. can experimental forms of governance in the context of real-world laboratories increase stakeholder cooperation and innovation dynamics selectively or even permanently?

1 ABSTRACT

Cities are increasingly confronted with rising temperatures and more frequent heatwaves, posing significant challenges for urban resilience and spatial planning. In this study, we investigate heat exposure and its interaction with social vulnerability in the cities of Augsburg, Zwickau and Hamm, Germany, based on remotely sensed, geo- andcensus data as well as citizen science air temperature data. A comprehensive 2.5D urban model was developed, integrating 30 different parameters such as vegetation shares, impervious surfaces, and building parameters like density or floor area ratio, as well as spectral characteristics like Normalised Difference Vegetation Index (NDVI) or satellite-based Land Surface Temperature (LST). In combination with citizen science (‘gathered by the public’) air temperature data measurements, it enabled 100m resolution modelling of heatwave peaks. Machine-learning techniques (Random Forest, RF) and multivariate techniques, particularly Partial Least Squares (PLS) regression, performed convincingly in handling the uncertainties inherent in citizen-science air temperature loggers and ensured robust, area-wide heat wave exposure predictions.

In parallel to modelling heatwave exposure, social vulnerability was assessed using the 2022 census data in Germany. Age structure serves as the core vulnerability indicator, with residents above 65 identified as particularly sensitive, and younger cohorts considered moderately vulnerable compared to the remainder of the population. Merging the information on social vulnerability with the modelled heat exposure, an exposure weigheted Heat Vulnerability Index (HVI) was created at the grid level, revealing spatial patterns of heat risk across the three cities.TheHVI highlights the most heat-endangered urban areas where residents are most likely to suffer from heat.

The findings provide a robust evidence base for municipal adaptation strategies and risk-sensitive planning. The study underscores that meaningful heat-risk assessment is only possible throughintegration of social vulnerability, and that its spatial granularity is crucial for designing effective, locally adapted measures to enhance urban resilience.

Keywords: Heatrisk, Social Vulnerability, Heat Exposure, Population, Heat Vulnerability Index

2 INTRODUCTION

Worldwide, many cities experience extreme heat and rising exposures are projected for the future (Friesen & Taubenböck, 2025, IPCC, 2022). It has become one of the most critical climate-related hazards in urban areas, with increasing morbidity and mortality. The combined influence of global climate change and therefore an increase in the number and severity of heatwaves on the one hand and urban heat island (UHI) effects on the other hand disproportionately affect temperature conditions in cities (Ramachandra et al., 2025, Dodman et al., 2022, Gilabert et al., 2021). The UHI is the product of dense built-up structures, impervious surfaces, limited vegetation,anthropogenic emissions from air conditioning, industries and vehicles, as well as limited airflow. In this process, urban areas experience significantly higher temperatures than their rural surroundings (Ramachandra et al., 2025, Liu et al., 2024). At the same time, ongoing climate

change is leading to an increase inboththe frequency and intensity of heatwaves. In combination with rapid urbanization (Taubenböck et al., 2024) this leads to thermal stress in urban agglomerations and and inceased risk for human health, infrastructure, and urban livability (Dodman et al., 2022, Gilabert et al., 2021).

Remote sensing has become a cornerstone of urban heat analysis and modelling. Its ability to provide information for spatially continuous and temporally consistent observations of land surface temperature (LST) as well as related surface characteristics over large areas stands out (Li et al., 2013, Weng, 2009, Voogt & Oke, 2003). Multiple sensors like Landsat, MODIS, or Sentinel are widely used to identify urban heat hotspots, to quantify the surface UHI (SUHI), and examine the influence of land cover on surface temperatures (e.g. Zargari et al., 2024, Aslan & Koc-San, 2016). However, satellite-derived LST only approximates near-surface air temperature. In complex urban environments, such as street canyons and residential neighbourhoods, LST often fails to capture spatial variability in air temperatures (Li et al., 2013, Voogt & Oke, 2003). Moreover, the heat that people actually experience is defined by air temperature, together with humidity, radiation, and wind (Oke et al., 2017).

To overcome limitations, citizen science (CS) air temperature measurements are increasingly used as input data for urban heat modelling (e.g. Leichtle et al., 2023 a & b). The data are collected via personal, CS weather stations, and stored in publicly accessible servers, providing alternative and low-cost input air temperature data(Meier et al., 2017).Combined with remote sensing data, CS observations improve the spatial resolution of temperature estimates compared to LST data and enable more realistic representations of thermal conditions experienced by urban populations (Fenner et al., 2021, Zumwald et al., 2021).

However, heat-related impacts are not determined by temperature alone. Risk emerges from the combination of thermal exposure and social vulnerability of exposed inhabitants. The latter varies across urban neighbourhoods due to differences in age structure, health status, socioeconomic conditions, housing quality, or access to cooling resources (Weigand et al., 2023, Dodman et al., 2022, Dong et al., 2020).Elderly individuals, young children, people with chronic illnesses, and socioeconomically disadvantaged groups are particularly susceptible to heat stress, often experiencing disproportionate health burdens during extreme heat events (Dodman et al., 2022, Harlan et al., 2013). Integrating vulnerability indicators with remote sensing-based heat metrics is therefore essential to move from heat exposure mapping towards a risk-oriented perspective that better reflects real-world impacts (Dodman et al., 2022; Chen et al., 2018).

Therefore, this study aims to identify urban heat hotspots by jointly considering heat exposure during heatwave conditions and spatially explicit age-related vulnerability. By combining heatwave models based on remotely-sensed landcover and spectral information like Land Surface Temperature, as well as CS air temperature, with socio-demographic vulnerability factors, this paper establishes a Heat Vulnerability Index (HVI) locating the areas within cities posing the greatest risk to human populations. Such an integrated approach aims at a more comprehensive understanding of urban heat risk and aims to support targeted adaptation strategies, informing urban planning, public health interventions, and climate adaptation efforts in cities.

3 MATERIAL AND METHODS

This section introduces the study area, describes the datasets used and their pre-processing steps, and outlines the methodology applied for the heatwave models as well as the HVI.

3.1 Study area

The study was conducted in three mid-sized German cities: Augsburg, Hamm, and Zwickau, each representing distinct urban contexts in terms of geography, demographic structure, and local climate. Their location within Germany is shown in Fig.2, top left.

Augsburg, located in the state of Bavaria in southern Germany, has a population of approximately 308,000 inhabtitants within an area of about 147km² (Stadt Augsburg a, 2026, Amt für Statistik und Stadtforschung der Stadt Augsburg, 2026). The city experiences a warm temperate climate with relatively high precipitation throughout the year (Köppen-Geiger classification Cfb). The summers are warm and the winters cool (Climate-Data.org a, 2026, Beck et al., 2018).

Hamm is situated in the federal state of North Rhine-Westphalia in western Germany and has an estimated population of around 180,500 inhabitants across approximately 226km² (Stadt Hamm a, 2026, Statistisches

Bundesamtd, 2026). The city's climate is also classified as warm temperate with mean annual temperatures of 10,3°C and relatively even precipitation throughout the year, accompanied by warm summers and cool winters often near or slightly below freezing (Köppen-Geiger classification Cfb; Climate-Data.org b, 2026, Beck et al., 2018).

Zwickau, located in the state of Saxony in eastern Germany, is the fourth largest city in Saxony with about 87,000 inhabitants and covers roughly 102km² (Stadt Zwickau a & b, 2026). The local climate is similarly temperate with warm summers and cold winters typical of Central Europe, reflecting the Cfb climate regime by Köppen-Geiger with average temperatures of 9,1°C and high precipitation numbers throughout the year (Climate-Data.org c, 2026, Beck et al., 2018). Zwickau's location in the Mulde river valley and its surrounding topography influence local microclimatic conditions. The position in the valley causes a traffic jam of warm air within the heavily overheated districts, especially during summery, windless weather conditions (Stadt Zwickau c, 2026).

Collectively, these three cities represent a range of urban settings in Germany with temperate climates, all of which are increasingly affected by heat stress during summer as a consequence of climate change and the rising frequencyand intensity of heatwaves (Stadt Augsburg b, 2026, Stadt Zwickau c, 2026, Stadt Hamm b, 2026).

3.2 Data

This section presents the datasets used for heatwave modelling (see Section 3.3.1 for a detailed methodological description) and for the identification of age-related population vulnerability. Both datasets serve as input variables for the construction of the HVI, which is described in detail in Section 3.3.2 and is used to spatially assess heat risk across the three test cities.

3.2.1 Input Data for HeatwaveModelling

Citizen Science air temperature data

CStemperature data form one part of the heatwave modelling input for the three test cities. Observations were sourced from two CS sensor networks: Netatmo Citizen Weather Stations and Sensor.Community (formerly Luftdaten.info). Previous studies show that crowdsourced air temperature data are statistically comparable to official meteorological observations, supporting their use in urban climate and heatwave analyses (Leichtle et al., 2023b).

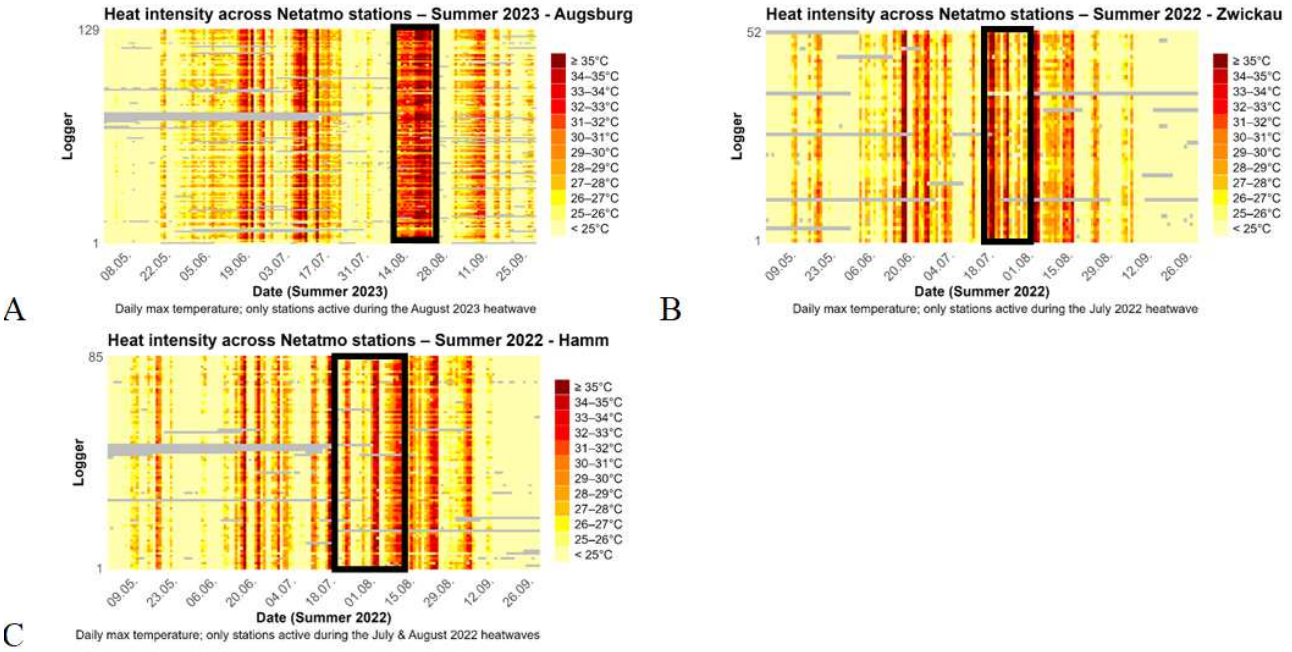

Figure 1: Heat intensity across Netamto stations during summer 2023 for Augsburg (A) and summer 2022 for Zwickau (B), and Hamm (C). In each case, the black box highlights the time period from which the data used in this study were derived.

Netatmo Citizen Weather Stations are commercial devices produced by the French company Netatmo. The outdoor module measures air temperature and relative humidity at a temporal resolution of five minutes.

Data are transmitted automatically and wirelessly to Netatmo serversand, if users consent, are made publicly available and can be collected from the Netatmo network (https://weathermap.netatmo.com/) via the Netatmo Application Programming Interface (API, https://dev.netatmo.com/). For this study, Netatmo data were retrieved for the period August 2023 for Augsburg (13.08.-26.08.2023, 129 loggers, Fig.1A), July 2022 for Zwickau (18.07.-31.07.2022, 52 loggers, Fig.1B) and July and August of 2022 for Hamm (18.07.-12.08.2022, 85 loggers, Fig.1C), representing real time heatwaves visible in the data (Fenner et al., 2021).

The second data source, Sensor.Community, provides environmental data from an open-source sensor network. Data were accessed via the Open Sensor Web platform (now operating under the name Sensoto), which aggregates measurements from multiple open environmental sensor networks (PIKOBYTES GmbH, 2026). Sensor.Community data were also downloaded via an API for the same periods as Netatmo (Hamm: twologgers; Augsburg: eightloggers; Zwickau: twologgers). The sensors are assembled by users themselves and were originally designed for fine dust measurements rather than meteorological observations. The recording resolution is two and a half minutes. The spatial distribution of the loggers from both CS networks is shown in Fig.2.

Figure 2: Spatial distribution of the Netatmo (orange) and Sensor.Community (pink) loggers throughout the test cities Augsburg (A), Zwickau (B), and Hamm (C). In Augsburg 129 Netatmo and eight Sensor.Community loggers, in Zwickau 52 Netatmo and two Sensor.Community loggers, and in Hamm 85 Netatmo and two Sensor.Community loggers were applied. In the background, impervious surfaces can be seen.

In contrast to official meteorological stations, data from both CS networks are not subject to formal verification procedures and may exhibit various sources of error. These include issues related to sensor installation, station design (e.g. insufficient ventilation), sensor calibration, and data transmission problems (Fenner et al., 2021). To address these uncertainties, in a first quality-control step, the CS temperature data were adjusted using the CrowdQC+ R package (Fenner et al., 2023), which applies statistical methods to detect and correct measurement biases (Bechtel et al., 2024).

To prepare the data for modelling, daily maximum air temperature values were derived for each CS logger and used as model input. After aggregation, all stations were manually re-evaluated regarding the plausibility of their maximum temperatures. This screening showed that some loggers recorded unusually high temperatures in predominantly vegetated areas, while others showed unexpectedly low values in densely built-up structures, contradicting expected land - temperature relationships (Leichtle et al., 2023a). These inconsistencies were particularly evident in Hamm and Zwickau, where the number of sensors was limited and not all Local Climate Zones (LCZs; Stewart and Oke, 2012) were sufficiently represented (e.g. only one sensor representing industrial areas). As these anomalies were likely related to station design (e.g., insufficient radiation shielding) and only became apparent in relation to surrounding land cover, they were not detected by the standard CrowdQC+ quality control.

As a consequence, for Zwickau and Hamm, a limited number of daily maximum air temperature values were slightly manually adjusted to improve the physical plausibility and representativeness of the temperature input data used for model development.In Hamm, four stations were adjusted: three near vegetated areas

were slightly lowered to align with comparable sensors within the test city, while one inner-city station was slightly increased.In Zwickau, one station was slightly lowered, as it recorded one of the highest temperatures citywide despite being located in a green area next to a large water body, where lower readings would typically be expected.

Landcover data

In addition to meteorological data, landuse landcover (LULC) information was used to model heat exposure during heatwave events. For this purpose, LULC classifications derived from very high-resolution (VHR) satellite imagery were employed. The datasets include WorldView-3 imagery for Augsburg acquired on 19th of July 2018 (30 cm spatial resolution), WorldView-2 imagery for Zwickau acquired on 25th of July 2022 (50 cm), and GeoEye imagery for Hamm acquired in 2020, consisting of two images from 27th of April and 8th of May 2020 (40 cm). All three images were obtained from European Space Imaging, EUSI (https://www.euspaceimaging.com/).

Image classification was conducted using the software eCognition. For the VHR WorldView datasets, knowledge-based approaches relying on spectral image characteristics were applied, while the GeoEye dataset was classified using a Convolutional Neural Network (CNN; Montensinos López et al., 2022, Geiß et al., 2022)followed by a knowledge-based post-classification refinement. The final LULC products provide detailed information on vegetation (including height attributes), water bodies, and impervious surfaces, including buildings. Overall accuracies rank from 87% in Zwickau to 94% in Hamm.

The classified land cover data were aggregated to a regular 100 m × 100 m INSPIRE-compliant grid (European Comission, 2013) covering the entire extent of each test city for model application. In addition, a separate 100 m × 100 m grid was generated for the surroundings of the temperature sensor locations to establish relationships between air temperature and land cover characteristics.

Based on the LULC classifications and supplementary geospatial datasets, including normalised digital surface models (nDSMs) and Open Street Map data, a range of additional parameters were derived at the grid-cell level. These include shadow cast at noon and dawn, green volume, climate effective vegetation (cooling effect extending beyond the local site, green spaces ≥ 0.5 hectar, Aram et al., 2019), sky view factor, distance to the city centre, and building-related metrics such as building density, building volume, and floor area ratio.

Furthermore, spectral information from the VHR imagery and additional Landsat-8 data (30 m spatial resolution, retrieved through the Google Earth Engine) were integrated into the grid framework. For each city, Landsat-8 acquisition periods were selected to closely match the acquisition dates of the respective VHR images. Accordingly, Landsat-8 data from April to August 2022 were used for Zwickau, from April to August 2020 for Hamm, and from April to August 2018 for Augsburg. The spectral variables include the Normalized Difference Vegetation Index (NDVI) and surface albedo. Furthermore, Land Surface Temperature (LST) was incorporated as a climatological metric, computed as the mean summer LST over the period 2013-2024 based on all available Landsat-8 data for the summer periods for each respective city.

The final output consists of a spatially comprehensive 100 m × 100 m grid for each test city and an additional grid centered at the locations of the CS temperature measurements, also with a 100m x 100m resolution. Each grid cell contains the full set of derived land cover, structural, and spectral parameters used for heat exposure modeling. An overview over included parameters is shown in Table 1.

Building parameters	Landcover parameters	Describing parameters	Spectral parameters
• Volume • Density • Floor area ratio	• Imperviousness • Water • Vegetation *(all, green volume, climate effective, ≤2m, 2m - ≤10m, 10m - ≤20m, > 20m)*	• Distance to centre • Shadow • Sky View Factor	• NDVI • Albedo • LST

Table 1: Overview of the parameters included in the areawide grid cells covering the test cities and in the grid cells surrounding the logger locations.

3.2.2 Social Vulnerability

Data from the German Census 2022, provided on a nationwide 100 m × 100 m grid and accessible via the Zensus database (Statistisches Bundesamt a & b, 2022), served as the primary source. Two census datasets

were employed:population counts disaggregated into 10-year age groups (<10 years to >80 years; Alter in 10er-Jahresgruppen in Gitterzellen (A), Statistisches Bundesamt a, 2022), andpopulation counts disaggregated into five age classes (<18 years, 18–29 years, 30–49 years, 50–64 years, and ≥65 years; Alter in 5 Altersklassen in Gitterzellen (B), Statistisches Bundesamt b, 2022).Each grid cell stores the number of residents belonging to the respective age group. Grid cells corresponding to the study areas were extracted from these nationwide datasets. As land cover information is available on an INSPIRE-compliant 100 m grid (see Section 3.2.1), the census grids align precisely with the land cover grids within the test cities.

Previous studies have shown that residents aged 65 years and older areparticularly vulnerable to heat stress, while young children and infants also face elevated heat-related risks (e.g. Azan et al., 2015, Arsad et al., 2022, United Nations Children's Fund, 2023, Hajat et al., 2007). Accordingly, these age groups constituted the primary focus of the present analysis. To do so, three data preprocessing steps were carried out. Initially, datasets (A) & (B) were combined into one grid layer. The new grid contains all columns from both data sets. Secondly, to enable a fine-scale assessment of age-specific heat exposure below four years of age, the population below 10 years of age was even further refined using the GENESIS database (Bevölkerung: Kreise, Stichtag, Geschlecht, Altersgruppen, Statistisches Bundesamt c, 2026), which provides city-level relative age-group shares. For the cities of Hamm and Augsburg, the relative shares of children aged <3 years, 3–5 years, and 6–10 years are available. Proportions of these sub-age groups within the total population under 10 years of age were calculated and applied to the 100m census grid cells, resulting in a refined spatial representation of children's age groups. For Zwickau, no city-specific sub-age-group information for children under 10 years was available. In this case, the mean proportions derived from Hamm and Augsburg were used to disaggregate the population under 10 years of age into the same three sub-age groups, ensuring methodological consistency across all study areas. In a third preprocessing step, both census information age intervals were combined. Up until age group 50-59 years, the present paper uses the information from dataset (A), including the newly defined sub-age groups below 10 years of age. Above 60 years of age, based on previous publications, the threshold 65 years and older should be used (e.g. Kohon et al., 2024, Reid et al., 2012). Therefore, this age group from dataset (B) had to be combined with the age classes 60-69 years, 70-79 years and above 80 years from datset (A)to derive the age group 60-64 yearsin order to generate consistent age coverage while using the age group 65 years + from dataset (B) for the analysis. This was achieved by summing the age classes 60–69, 70–79, and ≥ 80 years from (A) and subtracting the 65+ population from (B). As both datasets are stored within the same grid structure, this operation was performed directly at the grid-cell level.

The final age categories used in the analysis are: < 3 years, 3–5 years, 6–9 years, 10-19 years, 20-29 years, 30-39 years, 40-49 years, 50-59 years, 60–64 years, and ≥ 65 years.

3.3 Methodology

3.3.1 Heatwave Modelling with Partial Least Squares Regression or Random Forest and Validation

Partial Least Squares Regression (PLS) and Random Forest (RF) were applied to model maximum air temperature patterns under heatwave conditions in the three test cities Augsburg, Zwickau, and Hamm, using in-situ observations from the CS networks Netatmo and Sensor.Community. PLS was selected as the primary approach because it performs well with limited observations and strong multicollinearity among predictors (Pirouz, 2006), both of which characterise the dataset (e.g., correlations between impervious surfaces, bare soil, and vegetation-related variables). Given the restricted number of CS temperature measurements, this robustness was particularly relevant. For comparison, RF was additionally implemented. As a non-parametric, non-linear method (Breiman, 2001), RF can capture complex relationships between land cover patterns and air temperature and is generally robust to multicollinearity, often outperforming conventional regression approaches, although predictions remain limited to the value range represented in the training data (He et al., 2025; Oukawa et al., 2022; Breiman, 2001).

The model input consisted of daily maximum CS temperature measurements per logger and a set of land cover and spectral variables extracted from grid cells surrounding the sensor locations. Based on these data, both models established statistical relationships between air temperature and land cover as well as spectral parameters (see section 3.2.1).For each city, both modelling techniques were developed, and the better-

performing modelwas subsequently applied to the complete spatial grids covering the test cities to generate spatially continuous temperature estimates for heatwave conditions to analyse heat exposure.

The results were validated using the statistical error measuresMean Absolute Error (MAE) and Root Mean Squared Error (RMSE), based on a 10-fold cross-validation procedure in which the dataset was repeatedly split into training and test subsets and the performance metrics were averaged across all sections.Both metrics are widely used to measure model performance (Chai & Draxler, 2014), and provide information about the average model-prediction error, in this study expressed in degree Celsius. Compared to MAE, RMSE gives more weight to outliers (Willmott & Matsuura, 2005). Moreover, two heat-specific validation metrics were applied to assess the model's performance under extreme heat conditions. Heat-days are defined as days with maximum air temperatures of at least 30°C (EEA, 2021). This is particularly important because a model may show low overall MAE or RMSE while still misrepresenting extreme temperatures during heatwave situations. The first metric is theProbability of Detection (POD) adjusted to heat-days, defined as the fraction of observed heat-daysthat were correctly classified by the model. POD ranges from 0 to 1, with values close to 1 indicating a high ability to detect heat events (NOAA a, 2026, Mohapatra et al., 2025, Developmental Testbed Center, 2009). In the context of this study (modelling heatwave extreme scenarios), POD therefore evaluates the spatial consistency between observed and modelled heat-day locations. High values indicate that the model correctly identified those locations that experienced extreme heat during the observed heatwave.In addition, the Mean Error onhot days (also referred to as hot-day Bias) is used as a fourth evaluation metric. It quantifies the difference between the mean of predicted heat-day temperaturesand the mean of observedheat-day temperatures (maximum temperature ≥ 30°C), giving information about over- or underestimation of extreme heat.Values close to zero indicate a minimal bias(Stanski et al., 1989, NOAA a, 2026, NOAA b, 2026).Together, these two heat-specific metrics allow the assessment of model performance under extreme heat conditions. POD assesses the spatial agreement in the identification of heat-affected areas, while the hot-day bias evaluates the accuracy of the modelled heat intensity within these areas.

3.3.2 Development of theHeat Vulnerability Index

Building on existing studies that link population vulnerability to thermal exposure, a HVI was developed to integrate both heat exposure and population susceptibility at the grid-cell level (e.g.Rupp et al., 2026, Zhang et al., 2019, Johnson et al, 2012). Heat exposure is represented by spatially modelled daily maximum air temperatures during heatwave conditions, while population vulnerability is approximated using age-specific population groups, following established findings in the literature.Based on evidence indicating increased heat-related health risks, population groups aged 65+ years were classified as highly vulnerable, whilechildren below 3 years of age as vulnerable (e.g. United Nations Children's Fund, 2023, Arsad et al., 2022,Azan et al., 2015,Hajat et al., 2007). Children under three years were considered slightly less vulnerable (weighting factor 0.3) than the 65+ age group (weighting factor 0.4), as epidemiological studies show that heat-related mortalityis higher among older adults (e.g. An der Heiden et al., 2020, Linares & Díaz, 2008).All remaining age groups were considered to exhibit comparatively low heat-related vulnerability (weighting factor 0.1).

Prior to index construction, all input variables were z-standardised, resulting in a mean of zero and a standard deviation of one for each indicator. This standardisation ensures comparability among variables measured on different scales and enables their weighted combination(e.g. Ko et al., 2021, Guo et al., 2019).

The social component of the index was calculated as a weighted linear combination of the standardised age-group indicators, representing social heat vulnerability (0.4 for age groups above 65 and 0.3 for age groups below three). To account for heat exposure, this social vulnerability component was subsequently multiplied by the standardisedmodelled maximum air temperature per grid cell. The resulting exposure-weighted HVI thus highlights locations where high population vulnerability coincides with elevated heat exposure.Finally, the continuous HVI values were classified into three relative vulnerability classes (Low, Medium, High) using the 33rd and 66th percentiles as class thresholds. This quantile-based classification facilitates a relative comparison of heat vulnerability patterns within each test city.

4 RESULTS

This section explains the results of the heatwave modellingapproaches and the results of the calculation of the HVI for all three test cities.

4.1 Heatwave Models

The results of the heatwave models, portraying the spatial distribution of maximum air temperatures observed during a real heatwave period, are shownin Fig. 3, with the corresponding statistical metrics summarisedin Table 2. For Augsburg, PLS performed best with an RMSE of 2.73°C, a MAE of 2.23°C, a hot-day Bias of -2.59°C, and a POD of 1. The relatively high RMSE indicates that the model occasionally produces larger errors, particularly on the hottest days, as this metric gives more weight to outliers (here, maximum temperatures). The MAE is slightly lower, as it is less sensitive to extreme values, reflecting that the model performs well on average. Nevertheless, the mean error remains around 2°C. The hot-day Bias reveals a systematic underestimation of heat intensity at the loggers' locations. Despite this, all heat-day locations (POD = 1) were correctly captured, demonstrating strong spatial agreement during the heatwave scenario. In Hamm, PLS was also used to model the areawide heatwave situation. With an RMSE of 2.89°C, Hamm exhibits the highest overall deviations among the three test cities, indicating the presence of potentialtemperature outliers. The MAE of 2.32°C indicates generally accurate predictions despite these deviations. Thehot-day Bias is the smallest among the three test cities at -0.24°C, reflecting only a minor underestimation of extreme heat intensities. Similar to Augsburg, all heat-day locationswerecaptured correctly (POD = 1), indicating excellent spatial detection at the sensor locations. In Zwickau, RF outperformed PLS, particularly in visual comparison (not shown). The heatwave model achieves the best statistical validation metrics, with anRMSE of 1.57°C and a MAE of 0.96°C, indicating very low deviations and high accuracy. The hot-day Bias shows a small underestimation (-0.59°C), while POD = 1 confirms that all heat-day locations were correctly identified at the logger sites.

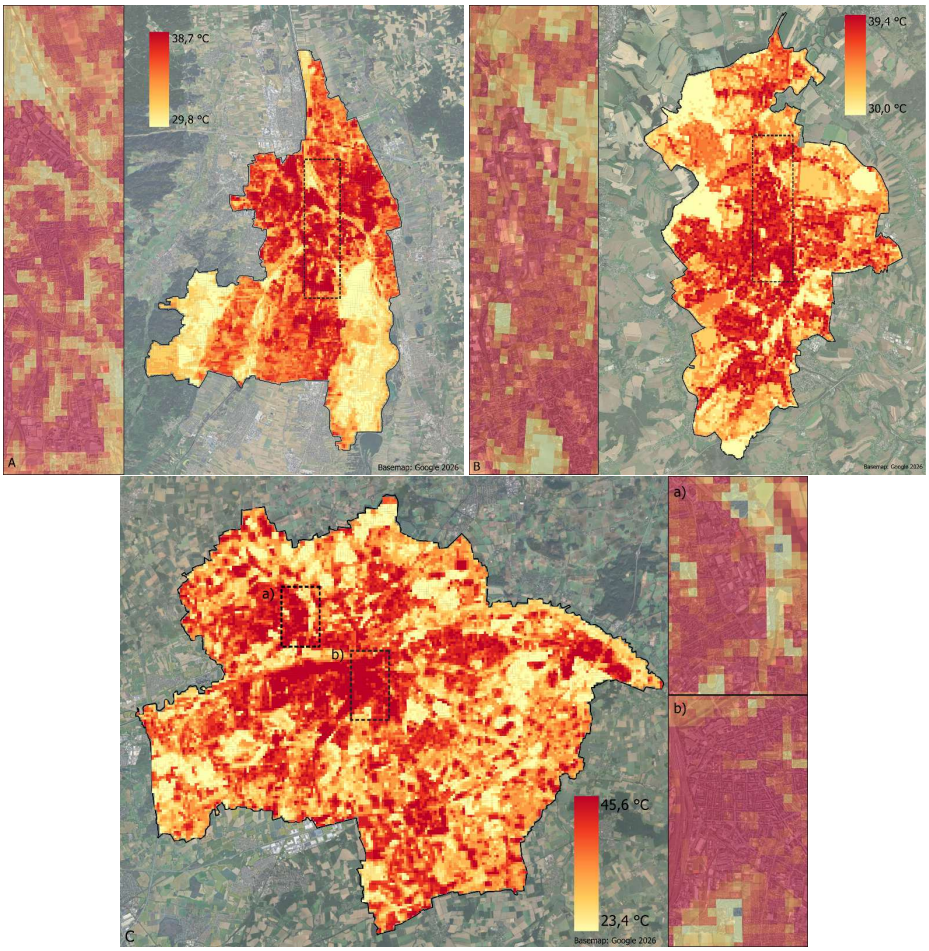

Figure 3: Heatwave model results for Augsburg (A), Zwickau (B), and Hamm (C).

In the cartographic representation (Fig.3), the hottest locations are generally located in the inner-city districts and industrial areas (dark red), whereas forested zones remain comparatively cool (light yellow). In Augsburg (A) the zoomed-in area shows the inner city of Augsburg, along with the surrounding northern and southern districts. Maximum temperatures reach nearly 39 °C in the city centre and industrial zones, while areas along the rivers and water structures as well as more forested areas, remain the coolest. In Zwickau (B), the close-up view shows the inner city in the south extending northward into industrial areas, with temperatures reaching nearly 40 °C. Cooler areas are observed around the inner-city water body and a park. For Hamm (C), two zoomed-in areas are presented: Zoom a) highlights an industrial area with high temperatures, surrounded by cooler forested zones, while Zoom b) shows the city centre with maximum temperatures reaching up to 45°C.

	Model	RMSE[°C]	MAE[°C]	Hot-day Bias [°C]	POD
Augsburg	PLS	2.73	2.23	-2.59	1
Zwickau	RF	1.57	0.96	-0.59	1
Hamm	PLS	2.89	2.32	-0.24	1

Table 2: Validation metrics results for the three test cities Augsburg, Zwickau, and Hamm.

4.1.1 Heat Vulnerability Index

The results ofthe exposure weighted HVI are presented in in Fig.4, with the heatwave models shown beneath with transparency. The HVI is only displayed for areas where the census data provide population information. Therefore, non-built-up areas and industrial zonesare excluded (dark red areas in the background, where heat intensity is also high during heatwaves).

For all three cities, locations within the inner-city districts (zoomed excerpts) exhibit predominantly high HVI values, indicating that these areas experience both elevated heat exposure and a comparatively large population of residents above 65 years of age or below 3 years of age. However, cells with a high HVI are not confined to the inner-city districts. As Fig. 4 illustrates, high HVI values are distributed across the urban areas, highlighting locations where extreme heat exposure coincides with a high age-related social vulnerability regarding heat related health risks. Medium and low HVI zones are predominantly scattered throughout suburban and less densely built-up areas, even though also present in the inner-city areas.

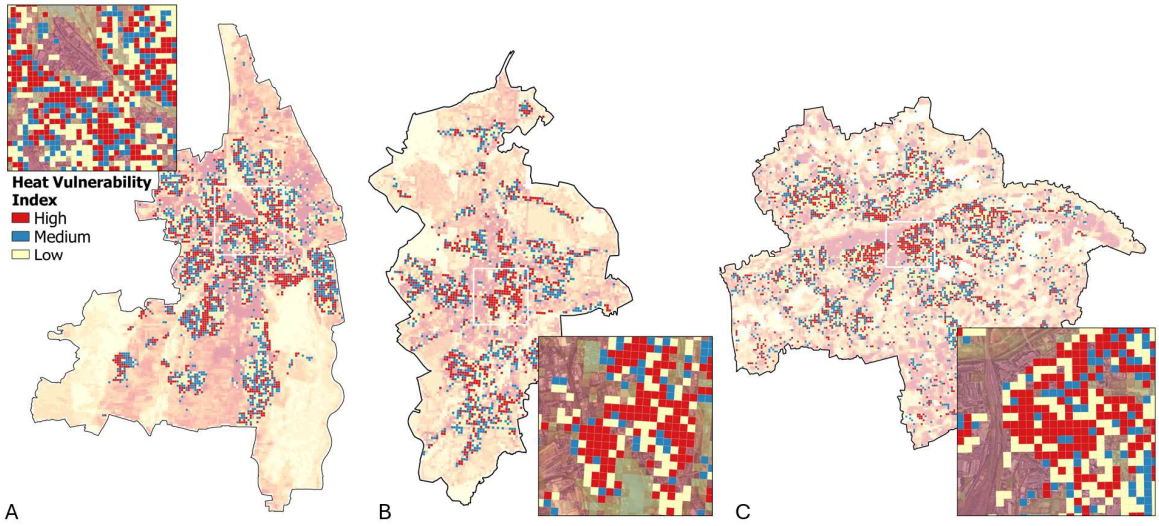

Figure 4: Heat Vulnerability Index for Augsburg (A), Zwickau (B), and Hamm (C).

5 DISCUSSION

In general, this study demonstrates that the proposed approach –combining multisensor remote sensing data, machine learning techniques, CS air temperature measurements, and census data–enables the robust identification of urban heat hotspots. Importantly, the analysis goes beyond the assessment of heat exposure alone by explicitly incorporating social vulnerability, thereby capturing not only where the hottest locations are, but also where vulnerable populations are most affected.

This integrated perspective is particularly valuable for the development of targeted heat adaptation strategies, as it highlights neighbourhoods where elevated heat exposure coincides with a high proportion of vulnerable age groups. The identification of these hotspots provides a critical basis for urban planning, public health

interventions, and resource allocation, supporting more effective mitigation ofheat-related health impacts during heatwave events.

Despite the overall validity and usefulness of the results, several methodological limitations, uncertainties within the CS data (e.g. bias due to logger design or missing validation with an official networkas part of this study) and potential improvementsshould be acknowledged. Concerning the heatwave temperature models, the results indicate that a systematically transferable temperature model across cities is not yet achievable. Instead, city-specific adaptation of temperature data is required, particularly when the available data volume is limited.As demonstrated in the case of Hamm and Zwickau, in comparison with Augsburg, where there are many more data loggers available, insufficient data coverage may not adequately compensate for local biases. Furthermore, if the data pool does not sufficiently represent all LCZ, e.g. only one sensor representing industrial areas in Hamm or only one sensor representing open green space and near water areas in Zwickau, model performance can be reduced, and therefore, the input CS temperature data had to be adapted manually beforehand. In addition, the statistical metrics did not always indicate optimal model performance. However, this limitation is of secondary importance for the primary objective of this study, which focuses on identifying the relative spatial distribution of the most heat-exposed areas, rather than exact temperature values. Systematic over- or underestimation of absolute temperature does not substantially affect the identification of relative heat hotspots within the urban context. Moreover, model experiments during the modelling process revealed that very good statistical performance can sometimes coincide with visually unrealistic spatial patterns, e.g. predicting industrial or densely built-up areas as cooler than adjacent largervegetated areas, highlighting the importance of combining quantitative validation with qualitative, visual evaluation within the framework of using CS data.

It is also important to acknowledge that air temperature measurements obtained through CS approaches represent a valuable data source; however, they capture only near-surface air temperature and not the heat stress actually experienced by people, which results from a combination of air temperature, humidity, radiation, and wind (Oke et al., 2017).

Beyond these methodological aspects, the assessment of social vulnerability could be further refined in future research. In the present study, vulnerability related to age structure was considered based on existing studies and the thresholds used; however, evidence from studies suggests that heat-related health risks increase substantially with advancing age (e.g. Arsad et al., 2022, Benmarhnia et al., 2015). Differentiating weighting factors within the elderly population, for example,higher vulnerability for age groups above 75 years, could therefore potentially improve the representation of heat susceptibility. In addition, further vulnerability indicators such as income level or housing conditions could be incorporated to better reflect adaptive capacity, which was not explicitly accounted for in this analysis (e.g. Rupp et al., 2026,Kohon et al., 2024). Including such socioeconomic variables would allow for a more comprehensive characterisation of population vulnerability and resilience to extreme heat events. Wilson et al. (2024) recently demonstrated that heat related health risks seem to be strongly dependent on external circumstances.

Moreover, the current vulnerability assessment is temporally static and does not account for variations in population exposure over the course of the day or between weekdays and weekends. However, people's spatial distribution and activity patterns differ between daytime and nighttime, as well as between working days and weekends. A time-dependent analysis could therefore provide more realistic insights into heat exposure and associated risks, particularly by capturing commuting patterns and daily mobility. Related to this, industrial and commercial areas were excluded from the vulnerability analysis due to the absence of census data. Nevertheless, these areas can host large numbers of workers during daytime hours on weekdays and may thus represent significant, yet currently unaccounted-for, zones of heat exposure. Incorporating daytime population data or workplace-related exposure estimates would further enhance the realism and applicability of the vulnerability assessment, especially for occupational heat risk management.

6 CONCLUSION

Overall, this study provides a robust and transferable methodological framework for the identification of urban heat risk by integrating temperature exposure during heatwave conditions with social vulnerability indicators. Despite existing limitations, the results offer valuable insights for heat risk management and demonstrate the added value of combining environmental exposure with demographic vulnerability. The

proposed approach therefore represents a meaningful contribution to urban climate research and offers a solid foundation for future refinements and practical applications in heat adaptation planning.

7 ACKNOWLEDGEMENTS

This research was funded by the Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection as part of the funding programme for measures to adapt to the impacts of climate change (DAS), grant number 67DAS255, HEATS – Urban heat risk management. Project period: 01/06/2023 – 30/11/2025.

Additionally, we kindly thank all owners of Citizen Weather Stations, CWS, who shared their data and this way, made the analysis possible, as well as Jonas Kittner and collegues from Ruhr-Universität Bochum for providing the data within the HEATS framework.

1 ABSTRACT

The Global South is undergoing unparalleled urbanisation rates, alongside profound consequences for infrastructure demand and supply. This paper examines the relationship between the political economy and infrastructure planning in the global south cities. A particularly disturbing trend in Global South development is the explosion of large-scale, internationally-financed infrastructure developments that serve exclusive interests while abandoning the everyday necessities of majority populations. Drawing on literature from diverse geographic contexts, we explore the political economy of urban planning in understanding complexity as essential. The paper identifies key mechanisms linking the intersection of climate vulnerability with factors such as sociopolitical issues, poor governance, and limited technological capability, further declining infrastructure resilience. Infrastructure discrepancies in informal settlements echo deliberate poor policy choices and planning failures, isolating these areas. Additionally, we examine evidence on KwaZulu-Natal, South Africa, a particularly valuable empirical context for understanding planning's role in infrastructure improvement, disaster response, and resilience. Evidence shows that climate-induced disasters associated with risk and vulnerability are aggravated by socioeconomic issues, including housing deficiencies, compelling people to construct settlements in flood-prone zones. Finally, we propose several key pathways that emerge from this analysis for advancing more effective, equitable planning in Global South cities. The paper concludes that addressing institutionalized participatory planning as standard practice, integrating planning across sectors and governance levels, adopting explicit equity frameworks in planning, investing in municipal capacity building, decolonizing planning knowledge and practice and address the political economy of infrastructure would shape local institutional capability and encourage adaptive learning as opposed to continued dependence on external finance expertise.

Keywords: Global south, cities, urban planning, infrastructure, political economy

2 INTRODUCTION

The Global South encompasses previously marginalized countries across Latin America, Africa, Asia, Oceania and the Caribbean (Al hothaufi et al.,2025). Studies on global south cities indicate that planning's complexity and political nature can operate as both a hurdle and a passageway to infrastructure quality. Political instrumentalization (Sajjad and Javed, 2022), governance fragmentation (Schoulund et al., 2021), economic constraints (Sajjad and Javed, 2022) and social inequalities (Tiznado-Aitken, 2022) create multilayered problems to infrastructure development. However, effective interventions influence these complexities, for example, integrated planning developments transformed institutional fragmentation into viable interdisciplinary cooperation in Argentina, obtaining increased spatial quality at minimal extra costs (Schoulund et al., 2021). This literature review answers the following research question: How can planning and political nature influence quality infrastructure in the Global South cities ? To answer this question, we outline below the literature review, methodology, survey these phenomena, and discuss how these influences affect the quality of infrastructure in the Global South cities.

3 METHODOLOGY

The literature review was conducted using PRISMA protocols (Moher et al., 2016) Scopus is the main used database for research in bibliometric analysis. The search of the literature was specifically on publications between 2021 and 2026. The database search in Scopus was done and categorised using the following keywords.

- "Urban planning" AND "Global South"

- "Quality infrastructure" AND "Politics" AND "Complex"
- "Infrastructure quality" AND "Approach" AND "Developing countries"

The inclusion criteria were all articles published between 2021--2026 in the field of urban planning to improve quality infrastructure in Global South cities (Table 1).

Inclusion Criteria	Exclusion Criteria
Articles with topics relating to planning in Global South cities	Outside urban planning scope
Articles with topics relating to infrastructure development	Unpublished disserations and thesis
Articles with topics related to the complexity of politics and planning	Non-English Language

Table 1: Inclusion and Exlusion criteria for the data extracted

The search in the literature was directed by screening titles and abstracts for each article to confirm eligibility. The in-depth information on the selection process is presented in Fig. 1 as guided by the PRISMA protocols. The review identified 527 studies in Scopus, of which 9 were duplicates and consequently removed. 30 were used for this paper.

A key outcome from KwaZulu-Natal study is that though policy outlines exist, severe governance gaps hinder effective implementation. Cities have distaster management policies and land-use plans, yet management failures and feeble institutional capacity weaken effectiveness (Alam and Bhat, 2025). Moreover, government has not been able to satisfactorily involve vulnerable societies in policy formulation and implementation. The fiasco to reinforce and promote public participation abandons vulnerable societies powerless against disasters (Oreta, 2025). Recommendations evolving from KwaZulu-Natal study emphasise to institutionalise noteworthy community engagements and participation in all spheres of planning and implementation, establish robust intergovernmental coordination, and increase resource allotment to address disaster risk mitigation (Oreta, 2025).

4 FINDINGS

4.1 The Global South Urban Crisis: Context and Challenges

In urban settings, the Global South is challenged with fragmented governance, institutional constraints and informal development requiring green infrastructure approaches aligned to the context to improve equitable city regeneration and climate resilience (Al hothaufi et al.,2025).). In Menoni (2025) it was found out that the relationship between climate vulnerability and factors such as limited technological ability sociopolitical issues, and governance further deteriorates infrastructure resilience. Flooding in urban areas has become progressively severe in several Global South metropolises, with severe occurrences documented across Africa, China, Latin America, Southeast and South Asia. The impacts are disturbing, with numerous metropolises experiencing repetitive flooding incidences that reveal human vulnerability and infrastructure weaknesses.

A particularly disturbing characteristic in urbanization in Global South cities is the explosion of large-scale, internationally financed infrastructure developments that serve exclusive interests while abandoning the everyday necessities of majority populations. Countries in the Global South constantly invest in comprehensive, vanity infrastructure developments, which do not benefit the majority citizens (Shatkin, 2022). An example is Walter et al (2025) on the effect of spatial planning on the development of export-oriented green-hydrogen projects. The researchers analysed how spatial planning impacted the development of export-oriented green-hydrogen projects in South Africa, Namibia and Chile. The study revealed that, South Africa, Namibia and Chile have developed dissimilar planning approaches for export-oriented green-hydrogen projects. South Africa pursued a facilitative approach, Namibia a restrictive approach, whilst Chile is transitioning from a market-centred towards a restrictive approach. The different approaches indicate different stakeholder interests and political priorities and suggest diverse outcomes on the expansion of export-oriented green-hydrogen projects in terms of their size, number, shared infrastructure, acceptance and socio-environmental effect. The study underscored the need for properly designed high-quality spatial planning outlines.

Al hothaufi et al. (2025) emphasized the urgency to repurpose underutilized spaces into multifunctional green infrastructure. The study explored case studies in Latin America, Asia, and Africa, mainly focused on underutilized public spaces, brownfields and vacant lots. Analysis revealed four thematic groups: spatial analysis (site identification), (2) community-led and participatory planning, (3) policy and governance

mechanisms, and (4) multifunctionality in green infrastructure strategies. Key gaps incorporate limited integration of spatial, procedural, and social justice into green infrastructure planning. Reliance on outdated datasets that disregard altering vacancy patterns and informal land use. Cities in India exemplify this problem, for instance, a scrutiny in the transportation infrastructure development in Mumbai Municipal Region has failed to meet the demand for infrastructure, as a result, excessive delays, traffic jams, and an absence of inclusive and integrated transportation systems (Shaban and Sattar, 2023). The infrastructure shortage is not merely a financial or technical problem but depicts political choices on which needs are prioritised and resource allocation. Increased urbanisation throughout the Global South remains to be embedded by poorly managed and unplanned expansion, aggravating services deficiencies and ecological stress (Zhou et al., 2022). SV

In Adom et al. (2025) the South African context is surveyed and echoes the country has formulated an in-depth climate change adaptation framework reinforced by substantial legislative milestones, comprising the National Climate Adaptation Strategy, the landmark Climate Change Act, and the ground-breaking Coastal Adaptation Response Plan. Even so, evidence shows existing leadership gaps, including industry influence, lack of political will, complexity, short-term focus, international collaboration challenges, inadequate skills and understanding significantly delay the implementation of an in-depth climate change adaptation framework in the country.

4.2 The Political Economy of Urban Planning: Understaning Complexity as Essential

Urban planning is characteristically political and contains decisions about resource distribution, land allocation, and which voices have substance in shaping cities. It is imperative to understand planning as political and not perceive planning as a weakness to defeat. The structural ferocity of spatial conversion in Global South metropolises reflects socio-spatial reform in hybrid neoliberal governments, resulting in momentous harm to marginalised and poor groups (Burte and Kamath, 2023). Studies similar to Prasad et al., (2023) explored informality glitches to smart urban planning in Indian metropolises and proved how informality – an essential distinguishing factor of Global South metropolises – remains largely unseen in smart urban planning frameworks. These frameworks show significant disregard of informality at the cost of socio-spatial division, creating a fundamental challenge for smart city development claiming to serve all residents. The implication is clear planning that ignores the political dimensions of infrastructure -whose needs are served, what values guide planning, how power shapes decisions – inevitably reproduces existing inequalities. This is not an accidental outcome but rather a structural feature of planning systems that have not been fundamentally reformed to address equity concerns.

George-Williams et al (2026) further explored Sierra Leone's water sector, an investigation on stakeholder relationships and governance dynamics. The study identified key actors and their interests, roles, interdependencies and influence, while also investigating systemic barriers in political, economic, social, technical, and environmental dimensions. The findings revealed an extremely fragmented governance ecosystem, categorised by donor dependency, weak enforcement, overlapping mandates, and the side-lining of community voices. Though current reforms comprising donor-financed infrastructure projects, new regulatory institutes, and community-based projects illustrate improvement, they remain mostly insufficient, reactive, and piecemeal to address rooted structural deficiencies.

Das (2025) confirmed the difficulty of planning in cities in the Global South spreads beyond political contention to deep institutional disintegration. Amplified urbanization has moulded situations where particular agencies manage separate infrastructure systems energy, transport, water, waste without proper coordination, as a result, creates duplicated investments, inefficient resource allotment, and inconsistent interventions. Studies on infrastructure planning problems in developing cities illustrate how insufficient governance structures, poor shareholder coordination, and resource constraints destabilise integrated planning and execution. Critical limitations in city infrastructure development encompass resource constraints, poor shareholder coordination, inadequate urban drainage, insufficient governance, fractured solid waste management, insufficient sewerage, and improper transportation systems (Caldern-Ramrez et al., 2025).An essential intricacy in urban planning in the Global South is the occurrence of informal economies and informal settlements. Research has shown informal settlements are rapidly expanding but continue to be excluded from formal urban planning frameworks and official data platforms. In South Africa,

approximately one in four urban people reside in informal dwellings, however their realities are often ignored in urban development planning (Mangara and Dorasamy, 2025).

4.3 Evidence in KwaZulu Natal: Planning Contexts and Imperatives

Understanding socioeconomic vulnerability and risk to disasters induced by climate change requires the assimilation of geographic information systems, spatial techniques, socioeconomic vulnerability and risk mapping, and hazard exposure mapping (Menoni, 2025). Studies directly related to the South African setting reveals that disaster risk and vulnerability focuses on informal dwellings where environmental hazards, infrastructure deficits, and housing inadequacy converge, aggravated by socioeconomic influences such as housing shortages convincing individuals to build settlements in flood-prone zones (Alam and Bhat, 2025).

The KwaZulu Natal (KZN) province is renowned for occasionally suffering natural disasters (Aiseng and Gamede, 2023). In KZN, the city of eThekwini is one district that is well-known to have been gravely affected by devastating floods, with distressing effects on its extensive informal settlements (Dlamini et al, 2024). The city of eThekwini is an example of a colonial city in South Africa, designed to be unable to accommodate a population over the city limits. As a result, several township settlements were developed using the apartheid settlement approach contained by a fifty kilometre radius of the metropolis (Thinane et al. 2023). The legacy of the apartheid regime and its spatial planning, old and dilapidated infrastructure, governance challenges, rapid sprawling of informal settlements and lack of visible early warning communication to the destitute living on high-risk areas contribute to the distressing flood effects (Ngcamu,2023). A report by the Moses Kotane Institute documented that the harm inflicted by the disastrous floods in eThekwini were intensified by inadequate infrastructure, poor urban planning, and houses constructed on hilly areas (Ngcamu,2022). The absence of housing is a major challenge confronting government, and it forces the marginalized people to build informal houses on land unauthorized for human settlements, precisely floodplains and slopy land (Dlamini et al. 2024).

Nonetheless, findings illustrated that response interventions in flood disaster in KZN were rapid and efficient; however, several gaps existed in pre-disaster and post-disaster management (Olanrewaju and Reddy, 2025). Accordingly, the increase in knowledge in the connection of climate hazards and inadequate infrastructure exposes planning as a key factor in disaster risk mitigation, making it important to conduct a comprehensive literature review to identify approaches to reconceptualise planning for cities in the Global South. This paper aims to use Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) to document the knowledge of quality infrastructure in Global South cities, identify emergin themes and new approcahes in the literature. Following this introduction, we discuss the methodological PRISMA method concentrating on how the data was gathered and analysed for this paper. The subsequent section presents findings obtained from the systematic analysis. Following, a discussion on findings and and a conclusion.

5 CONCLUSION

The failures of planning visible across Global South cities are not inherent failures of planning itself but rather failures of planning systems that have not been fundamentally reformed to address equity, democracy, and sustainability concerns. These systems continue to reflect colonial legacies, top-down imposition, elite capture, and exclusion of marginalised communities. They persist in treating infrastructure as a technical problem amenable to engineering solutions while ignoring the social, political, and economic dimensions of infrastructure access and quality. They continue to prioritise vanity projects serving elite populations while infrastructure essential to the majority's survival deteriorates.

The idea of transformative planning would fundamentally look different. The concept begins with clear commitments to equity, democracy, and social justice. It would encourage participatory procedures, to ensure authentic public voice in decisions impacting the futures and lives of the public (Terdoo, 2024). Transformative planning would connect multiple aims – disaster resilience, housing, environmental protection, service delivery, and employment – within clear frameworks instead of continuing sectoral, fragmented approaches (Hakiman and Sheely, 2023). It would acknowledge and work with infrastructure heterogeneity rather than imposing standardised, externally-designed solutions. It would build local institutional capacity and support adaptive learning rather than perpetuating dependence on external expertise and financing (Wieszczeczynska et al., 2024).

In conclusion, planning is not a failed endeavour or an impediment to development in Global South cities. Rather, planning, when fundamentally reconceptualised to prioritise equity, democracy, and social justice, represents an essential tool for addressing the interconnected crises of urbanisation, infrastructure inadequacy, climate vulnerability, and spatial inequality. The evidence presented throughout this paper, drawn from diverse contexts across the Global South, demonstrates that effective, inclusive, participatory planning can mitigate disasters, promote sustainable development, and advance social justice (Menoni, 2025; Terdoo, 2024). The task ahead is not to abandon planning but to transform it – to create planning systems that genuinely serve the needs of majority populations, that integrate multiple objectives through coherent frameworks, that build local capacity and knowledge systems, and that confront power inequalities perpetuating urban inequality and injustice.

1 ABSTRACT

Semantically rich 3D models at the building scale have long been established through Building Information Modelling (BIM), which has become a standard in interdisciplinary planning practice. By contrast, City Information Modelling (CIM) at the urban scale has yet to reach comparable consolidation or widespread use. Existing frameworks vary in focus and integrate a multitude of different datasets, yet they typically operate at similar scales: large urban areas or even entire cities. Consequently, these models often support only low levels of detail, with buildings represented as simple volumes and public space reduced to terrain surfaces.

Between the building and urban scales lies a critical but underrepresented level: the street or neighbourhood scale. The spatial characteristics of streets are central to urban quality of life, shaping potential uses, social interaction, mobility, and environmental performance. It is therefore crucial to understand and capture the built environment at this level. Detailed modelling of streetscapes offers a unique opportunity to represent fine-grained physical and perceptual characteristics, enabling digital environments that more authentically reflect human experience. Such models facilitate comprehensive analyses and the identification of potentials within street spaces – factors that are increasingly vital in the context of climate change, where street-level morphology and materiality directly affect heat exposure, shading, ventilation, and overall resilience.

This paper provides a review of the existing CIM frameworks and presents the implementation of a City Information Model on a micro-urban scale using the SSSEIC method as a framework for qualitative (and quantitative) streetscape analysis. The method provides a systematic approach to describing and evaluating the spatial configuration and perceptual attributes of streets, bridging the gap between CIM and BIM to form a consistent modelling logic at the street scale. It includes street uses and surfaces, underground installations (pipes and cables), facades of the adjacent buildings and organisation of the ground floor area including uses, all objects in public space (street furniture), and ecological aspects which inlcude all plants and green spaces. Through this comprehensive structure, the SSSEIC method supports the creation of a semantically rich micro-urban CIM that serves both as an analytical tool and as a foundation for future design processes.

2 INTRODUCTION

Over the past few decades, new planning methods and tools have emerged in the conceptualisation, planning and construction of the built environment. Individual 2D drawings were replaced by 3D models and the

resulting plan views. The digital models were gradually provided with more and more data that went far beyond purely geometric information.

At the building scale Building Information Modelling (BIM) has established itself as the semantically enriched successor to 2D and 3D CAD drawings and has long since become the standard, particularly in interdisciplinary planning processes. In contrast, urban planning continues to rely predominantly on GIS-based tools. Semantically enriched 3D models on the city scale, so called City Information Models (CIM) also are available and used, but they are far from having the same standardisation or prevalence as those at the building scale. Although existing frameworks differ in their focus and integrate various data sets, they generally operate at the level of large urban areas or even entire cities. Consequently, these models frequently support only a rudimentary level of detail, with edifices commonly depicted as elementary volumes and public spaces simplified to terrain surfaces.

Meanwhile, an all-important level remains largely unexplored by widespread new modelling approaches: the streetscape. Whilst the relevance of street space features (adjacent buildings, the ground floor zone and its use, street furniture, the presence and arrangement of vegetation and the like) for the perception of public space, social participation and, in general, the quality of urban life has long been established (Jacobs 1961, Rudofsky 1969, Gehl 1971, Anderson 1978, Jacobs, Whyte 1980, Appleyard/Gerson/Lintell 1981, Jacobs 1993) and urban designers increasingly advocate for design on a human scale, placemaking and highlight the importance of livable cities (Stojanovski et al. 2020) outdated technologies are still used for its analysis, planning and potential assessment.

2.1 A Model for Streets

Detailed modelling of streetscapes can represent a powerful approach for capturing the physical, spatial and perceptual nuances of urban environments in one place. It can enable the creation of digital representations that more accurately reflect how streets are experienced by people. By incorporating elements like geometries of the street and surrounding buildings, materials, functions and vegetation these models can offer a richer, more nuanced understanding of street spaces than traditional representations using 2D plans. Consequently, they can facilitate an in-depth analysis of a variety of aspect like environmental or traffic performance, spatial comfort, and social functionality, while also supporting the identification of existing and potential street uses within the urban fabric.

Beyond the involvement of planners and municipal actors, there is a wide range of other stakeholders like entrepreneurs, residents, and passers-by within the streetspace. Given this number of actors, the organization of participation and influence within public street space becomes a critical question. In current practice, opportunities for multidisciplinary collaboration and co-creative processes remain limited, as responsibilities are typically divided into discrete segments of the street and addressed in a largely sequential manner. (Tobisch/Löschenbrand/Psenner 2025A) Various aspects of interdisciplinary collaboration can be addressed with the help of street space modelling. Firstly, connections and interrelationships between different disciplines and their areas of influence can be visualised. Furthermore, the use of a model that provides all participants with real-time access enables direct collaboration without the need to exchange plans from different programmes in various data formats.

The importance of such detailed representation and interdisciplinary methods is ever growing in the face of rapid climate change. Street-level morphology, material characteristics as well as the presence and placement of vegetation play a critical role in shaping microclimatic conditions, directly influencing heat accumulation, solar exposure, shading patterns, airflow and as a result thermal comfort of street users and residents. Accurate streetscape models therefore provide an essential foundation for evaluating climate resilience and informing design strategies aimed at mitigating heat stress, improving ventilation, and enhancing overall environmental performance. In this context, detailed streetscape modelling becomes not only an analytical tool for assessing current circumstances and potentials, but also a key instrument for supporting more adaptive, resilient, and human-centred urban design. This is particularly relevant because municipalities have limited time and financial resources, yet time is of the essence when it comes to maintaining quality of life in cities amid changing conditions. The number of streets that can be adressed at any given time is limited, so in addition to quickly implementable and inexpensive interventions using tactical urbanism, the targeted use of resources for permanent redesign is crucial. Priority should be given to those street spaces that, on the one hand, have a high need for intervention, but on the other hand also have the most potential and promise the

greatest impact. Through the accurate presentation and processing of systemic information, both the suitable street spaces and the most sensible interventions can be selected in a targeted fashion.

2.2 Relevant Aspects

In order to enable analysis and comparison of different streets, including those with very different basic conditions, it is crucial to enable both qualitative and quantitative assessments. But before the issue of a suitable framework of consideration and modelling approach can be addressed, the relevant aspects within the streetspace have to be identified. The focus here is on all those aspects that constitute the real-life qualities street spaces as perceived by its users. For the identification of these qualities, interviews with experts from different disciplines were conducted and a workshop was held.[1] The resulting findings were complemented and refined by additional literature analysis and together form the basis for the qualities to be considered in the modelling. This quite extensive is by no means considered exhaustive and will be expanded further in the future. Nevertheless, it provides a useful overview of the range of topics and will therefore be used as a starting point for an initial examination of the subject. In this process, over 250 qualities or parameters of the street space have been identified (Tobisch/Löschenbrand/Psenner 2025A). Since most qualities can be viewed from different perspectives, it is not possible to separate them into distinct categories. Nevertheless, for the purpose of illustrating the range of aspects, the following broad thematic groups could be identified: relevant geographical information (i.e. street orientation and topography), the public space itself and its uses (i.e. surfaces, furniture, distribution of space and traffic volume), the adjacent buildings (i.e. facades, ground floor zone and uses), the urban infrastructure (i.e. underground installations, lighting), ecological topics (i.e. vegetation, microclimate, wind, sun exposure and shadows), matters related to perception (i.e. visual relationships, noise, temperature) and sociological factors (user groups, frequencies as well as quality of stay).

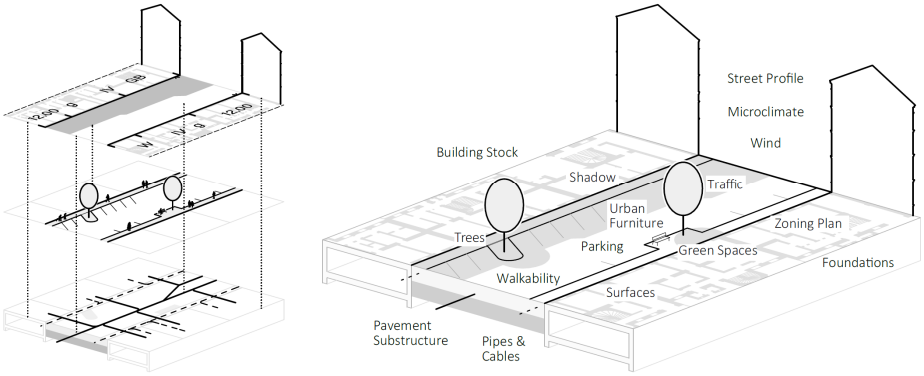

Fig. 2: A wide range of different aspects are represented in the street space, which a framework for a qualitative street space model is required to reflect. © Löschenbrand, Tobisch, Psenner

It is important to highlight that a combination of physical and non-physical aspect was identified. For the first category, the depiction within a 3D model and an underlying object-oriented database is straightforward, while the latter requires an alternative approach of consideration. Thus, a framework suitable for qualitative and quantitative street space analysis needs to be able provide a structure for both cases.

2.3 Research Questions and Methods

This paper aims to explore street space modelling by addressing questions that appear straightforward but, when examined in depth, reveal the underlying complexity of the topic:

What modelling frameworks and tools are currently available (BIM, CIM, etc.), what are their capabilities and limitations in relation representing street spaces on a micro-urban scale? What are the challenges with regard to methods, technical feasibility, data availability and workflow when modeling street spaces? How can a suitable framework for semantic street space modelling be conceptualised, and which components are required to support qualitative and quantitative analysis?

[1] A comprehensive discussion of the interviews conducted (the fields of expertise covered, the questionnaire and the survey results) and a description of the setting and results of the workshop was already published. (Tobisch/Löschenbrand/Psenner 2025A)

The methodological approach of this paper is exploratory and iterative in nature, combining a review of existing modelling concepts with the development and testing of a conceptual framework for street space modelling. The first step, existing concepts and tools for modelling the built environment are analysed with regard aspects relevant to street space considerations, including examination scale, representational accuracy, and the ability to capture semantic information. Based on the limitations identified, the methodological, technical, and organisational challenges associated with detailed street space modelling are subsequently examined. In a second step, questions of data availability, data quality, and data handling are explored using the case study of Vienna. The case study serves as test field for assessing the feasibility, limitations, and practical implications of implementing a detailed, semantically enriched street space model under real-world conditions. The findings from the review of existing frameworks and from the case study are then brought together to develop a proposed method for street space modelling. The resulting framework is subsequently applied in the construction of micro-urban CIM models for selected streets, allowing its internal logic, representational capacity, and analytical capabilities to be tested and reflected upon. In this way, the modelling process itself becomes an integral part of the methodological inquiry, informing both the refinement of the framework and the discussion of its potentials and limitations.

3 RESULTS

3.1 Review of Existing Frameworks

3.1.1 Building Models

Building Information Modeling (BIM) is a digital methodology for the integrated representation, management, and exchange of information related to the physical and functional characteristics buildings. (Xue et al. 2021) Unlike traditional CAD programmes, where elements are represented by blocks (composed of geometric elements), BIM programmes are based on architectural elements that can be placed freely from a prefabricated library. This object-oriented approach also reveals the roots of this approach, which can be traced back to the manufactoring industry (Eastman et al., 2011). For each of these elements, a range of information is stored in a database, which provides the model with its semantic properties. Today, BIM software for 3D modelling, such as Graphisofts ArchiCAD and Autodesks Revit, is more widely used than traditional CAD software, with the BIM standard having long been established in practice. IFC (industry foundation classes) define the corresponding standards for the both the structural framework and the file exchange format. They are structured hierarchically according to the requirements of building modelling (project, site, building, storey, element) and depict the relationships between elements and contain their underlying information. This allows data to be exchanged between different actors or even joint models to be operated. BIM thus functions not only as a three-dimensional modelling approach, but as an information management framework that supports process integration and data interoperability within the built environment. While BIM enables highly detailed representations, its structure is geared towards building production and management, and therefore does not offer modelling logic that goes far beyond the property scale, making it difficult to depict spaces that extend beyond that.

3.1.2 Urban Models

City Information Modeling (CIM) was introduced by Lachmi Khemlani in 2007 as an urban-scale counterpart to Building Information Modeling (BIM). Since its emergence, the concept has become increasingly prominent in academic urban research and has also gradually been adopted in urban design and planning practice (Souza/Bueno 2022, Xue et al. 2021). The initial approaches to CIM were strongly influenced by existing frameworks and combined Building Information Modelling (BIM) and Geographic Information Systems (GIS) data environment concepts (Xu et al., 2014). While often framed as a purely technical modelling approach, CIM can also been understood more broadly as a conceptual lens through which theories, methods, and tools from multiple disciplines can be integrated and examined on an urban scale analogues to BIM on the building scale (Stojanovski, 2013). It is described as three-dimensional model on an urban scale, that is based on city information data and has a multidisciplinary framework for collaboration (Xu et al. 2001).

Recent studies have a broader technical scope and emphasize advances in data acquisition and processing, including laser scanning, point clouds, artificial intelligence, and visual programming languages (La Russa et

al. 2023), as well as the role of CIM in smart city initiatives and urban digital twins (Cureton/Hartley 2023). By now, CIM is also understood as a means of covering and illustrating a wide range of other topics. Omrany et al. (2023) made an effort to identify all topics within this increasingly broad field and have compiled the most important areas of application for CIM: natural disaster management, urban building energy modelling, urban facility and infrastructure management, land administration systems, urban microclimate improvement, smart cities and digital twins, improvement of social engagement, and urban landscaping design. However, the main applications remain often supporting urban planners in designing sustainable cities and enabling the technically informed governace of cities (Souza/Bueno 2022).

Despite this growing body of work, a clear and universally accepted definition of CIM has remained elusive. CIM can therefore be understood less as a single, well-defined methodology and more as an umbrella term encompassing a range of intelligent city modelling approaches. What all of them seem to have in common is a three-dimensional representation and the inclusion of other, not necessarily spatial data in a semantic database of some kind. Nevertheless, some standards are also gaining ground here, arguably the most commonly used standard for CIM is CityGML (Ohori et al. 2018) developed by the Open Geospatial Consortium (OGC). Similar to IFC it is an application independent framework and exchange format. A particular interesting feature in CityGML is its Level of Detail (LoD) concept, which describes the level of detail for different objects (such as buildings, vegetation and terrain). Starting with LoD0 (footprint and roof edge), through LoD1 (block representations), LoD2 (roof models), LoD3 (detailed models), levels of representation accuracy are classified using the example of a built structure (OGP 2021). With all LoD being able to represent indoor information as well.[2] While very different degrees of accuracy can be classified here, the high levels of detail in particular are rarely found in large scale applications. Therefore, an example for one of the various limitations in CityGML with regard for the modelling of street spaces is the missing representation of elements above the street surfaces i.e. objects in public space (Beil 2025).

Other terms for urban models, which are becoming increasingly popular, usually refer to similar concepts that cover partially the same subject areas, but differ in their scope or focus. One example is the term (urban) digital twin (UDT), which also describes a semantic 3D model of urban dimensions. However, digital twins generally represent the current state of a city, while CIM has no restrictions of this kind and therefore enables also representations of the past and simulations of the future. At the same time, UDTs usually represent a structure for the dynamic monitoring, management or development of urban space and are therefore anove all to be understood as a governance tool. However, as Cureton & Hartley (2023) emphasise, good CIM is a prerequisite for making the transition from static (GeoBIM) models to dynamic UDTs.

3.1.3 Street Models

In addition to BIM and CIM, which are both semantic 3D models, there are already several different approaches to representing street spaces using various methods, levels of detail and amount of information, which are examind in the following.

Street View Imagery (SVI) is the most commonly used representation od streets and readily available on a multitude of platforms.[3] It is deployed for a number of different uses, most prominently for the creation and mainteinance of spatial data infrastructure, but also for the extraction of greenery, urban morphology analyses, transportation and mobility analyses, urban perception and more (Biljecki/Ito 2021). As it contains detailed visual information, it is also suitable for for reviewing the built environment (Kelly et al. 2013). However, due to the manner in which SVI is recorded (georeferenced photos are stitched together to form panoramas) they do not inherently contain explicit geometrical data and can therefore not be classified as street models.

One step beyond this are representations that are constructed with (textured) 3D meshes – often created combining surveying methods like photogrammetry or LiDar scans – which makes them visually detailed and geometrically accurate. While these models feature a relatively high level of detail (that still seems to be

[2] The original LoD4 class, which referred to interior models, was dropped in CityGML 3.0, as was the linking of semantic information with the level of detail in the modelling.

[3] The most widely used platforms are undoubtedly Google Street View and Apple Look Around, but Mapillary, which is based solely on images captured by users, also offers extensive coverage. Additionally, many municipalities conduct their own data collection, like the Kappazunder program by the City of Vienna (which simultaneously captures other data sets, such as 3D point clouds)

lacking in the case of objects in public space accoring to Golombek/Marshall 2021) that makes them appealing for examining individual street spaces, they are missing a sense of depth that can be perceived in the street space (i.e. through the windows of adjacent buildings) and are usually lacking all semantic information. While a lot of information is discernable from these meshes (the human eye can differentiate between a tree and a house and is able to identify the permeable parts of facades from closed walls) this information cannot be automatically processed and analysed without performing additional processing steps (Babahajiani et al. 2017). In this regard, there are also efforts to develop a method for a pipeline from point clouds to the semi-automated creation of object-based 3D models using AI. (La Roussa et al. 2023) However, the focus here is on buildings and building blocks; modelling of public spaces is not (yet) included.

In comparison, the semantic road model as described by Beil (2025:81) and based on CityGML in fact contains solid three-dimensional elements instead of surface meshes. In addition to the street surface, various objects in public space, like street signs and traffic lights are represented, as well as the adjacent buildings as simple volumes. In this case, the term semantic refers mainly to information concerning transport infrastructure, such as the hierarchies of functions when two streets meet. This approach does not include the detailed modelling of adjacent buildings, ground floor zones or the space underneath the surface. Vegetation, however, is included, but only visual factors are taken into account here; the underlying ecological data is not recorded.

The procedural modelling of street spaces is another approach, that enables the creation of detailed 3D models using 2D map data and a set of rules to generate a model for example using 3D-GIS aplications like Esri CityEngine (Badwi/Elliaty/Youssef 2022) or using OpenStreetMap data and Houdini (Gao/Gao/Yu 2022). These necessary parameters and variables can relate to the design of the street space itself (lanes, sidewalks) as well as the design of the adjacent buildings (building age, style, façade elements) and elements in public space (street lighting and furniture). This approach is generally also able to produce solid 3D elements equipped with semantic information. Although these models can sometimes be highly detailed they remain a generated approximation of reality and do not represent the actual qualities of the real location (Kelly 2021).

There are a number of other modelling approaches on a similar scale, worth mentioning here is the Neighbourhood Information Model (NIM) by Cookes (2025) and the Settlement Information Model (SIM) concept described by Sattler (2024). The aim in both approaches is to model entire neighbourhoods of settlements (in the latter case post-war housing estates), including their buildings, the associated open spaces and street spaces using a BIM-based method. In addition, Sattler aims to incorporate social aspects and parameters relevant to quality of life. While both these approaches still appears to be very much in the conceptual phase (with the authors mainly reflecting on existing tools and frameworks themselves), they also reflects the desire to create a semantic model on a similar scale that achieves a high level of detail and combines several domains (buildings, open spaces, streets) that are traditionally treated separately as well as non-physical aspects.

Outside of the field of modelling the built environment for research and design purposes, there is other use cases for highly sophisticated visual models of street spaces, most notably the gaming sector.[4] Procedural modelling using a set of rules or predesigned module libraries is in this case employed to generate realistic representations (in terms of geometries and surfaces) of spaces without any reference to real-life locations (whereby not only the street itself, but the entire city's street network is created). While in this context, the richness of detail serves as a backdrop for the gameplay only, but it does, in fact, reveal how these spaces need to be modelled in order to be representative to how public spaces are actually perceived – in great detail.

Due to the absence of a clear definition for CIM, there is also a lack of distinction from street space models. At the same time, approaches for street models often often use the same modelling logic as either building-related or city-wide models, and the limiting factor in applying detailed road space models to entire cities seems to be mainly computing power. At the same time, modelling concepts for settlements (Sattler 2024) or building blocks (La Roussa et al. 2023) are also being considered in a similar scale and level of detail (in

[4] Impressive examples of this can be found particulary on media platforms: e.g. https://80.lv/articles/001agt-006sdf-procedural-brooklyn-in-houdini

CityGML terms this corresponds to LoD3). Therefore, street space models are described here as CIM on a micro-urban scale in order to also incorporate similar concepts within this superordinate terminology.

While the existing frameworks analysed cover various aspects that are relevant to a qualitative street space model, there does not appear to be a comprehensive compilation of these in a single framework to date. The various authors identify numerous difficulties and limitations of their respective methods. While none of these frameworks were developed with the intention of creating a qualitative street space model, some of the limitations mentioned above also apply in this context. Further challenges anticipated the creation of a detailed, semantically rich 3D street model are highlighted in the following section.

3.2 Challenges

The challenges involved in creating a new framework are manifold. This section will address those that have already emerged from the analysis of existing frameworks. Others that only arose during the course of the process can be found in the subsequent chapters.

3.2.1 Depicting non-physical aspects

Arguably the greatest challenge for a framework for the analysis of street spaces from a qualitative perspective is that of integrating non-object-related or non-physical aspects. The aim of any semantic model is to attach all relevant aspects to modelling objects. These modelling objects do not necessarily have to be real-life physical objects – examples include the road centre lines frequently used in GIS analyses or the representation of uses as spatial volumes in BIM applications – but spatially precise delimitation is still a prerequisite for the representation as a modelling object.

Therefore all the identified relevant aspects were examined with regard to their representability. Different groups were identified: those aspects that can be represented in 3D objects, groups of 3D objects or can be calculated from them, those for which non-physical modelling objects can be created, and those that cannot be represented at all on a street segment basis. As will be outlined below in 3.3.2 all these aspects are covered in the theoretical framework, but the latter group had to be left out of the modelling logic for the time being. The information relating to these aspects cannot therefore be processed and evaluated directly in the model and must still be covered in another form.

3.2.2 Data availability and handling

One challenge concerning street space modelling is the data, since an accurate model on that scale requires a rather large amount of highly detailed data. Many of the methods examined use only specially created data sets (i.e. LiDar scans). These are often technically demanding, expensive or time-consuming to produce. Therefore, the present study strives to acquire as much data as possible from existing and publicly available data sets, only when no data is available, additional data is collected. Since data availability can vary greatly from municipality to municipality, making it difficult to draw general conclusions, this study focuses on the case of Vienna. A total of three research streets was investigated, and all data-related challenges that arose in the process are outlined here, including availability, compilation, handling, processing and collection.

The data review was carried out in the following steps. First, the digital data sets that are publicly available as open government data (OGD) on the platform data.gv.at were examined, starting with the 3D data sets and continuing with the 2D datasets. Then, analogue data sets from archives were consulted. Finally, any missing data was supplemented by manual collection on site.

The identified relevant 3D datasets are the terrain model (Geländemodell Dreiecksvermaschung) and, because the building model only has a low level of detail, the roof model (Generalisiertes Dachmodell LOD2.1).[5] However, neither of these two data sets can be imported directly into the street space model, as they are surface meshes (instead of solids) and do not provide the desired level of detail. For example, the terrain model is only a rough approximation that does not show any height differences within the street space (such as kerb edges). Similarly, although the roof model shows the volume and approximate shape of the buildings (sometimes even including bay window), it does not provide any further information (balconies,

façade design, entrances etc are missing). Therefore, both data sets can only be used as crude basis for modelling. Some of this missing information can directly be supplemented from 2D data sets. For example, the 2D city map (Mehrzweckkarte)[6] contains additional elevation points that enable more accurate modelling of the road surface, but even here the exact difference in height at the kerb is not specified. However, this map does indicate the division of the street space itself, i.e. the location of the kerb, the existing green areas, the arrangement of some elements in the street space (such as meter boxes or lampposts), and the building plots, footprints and position of the entrances and is therefore one of the key sources of data. Aerial photographs[7] were also used to obtain additional information about the street space, such as the number and type of parking spaces, the location of garage entries and additional objects in public space that are not already covered by the 2D city map (such as traffic signs, rubbish bins or benches). The records of cables and pipes (Zentrales Leitungskataster&Digitales Kanalinformationssystem)[8] provide information about underground infrastructure in the street space. These data sets are also only provided in 2D, and the availability of information for modelling (dimensions, height information) varies greatly. Since this data cannot be corrected manually, some assumptions have to be made in order to approximate the real situation. For more detailed information about the existing trees, beyond that provided by the 2D city map, such as tree species, tree height and age, the tree cadastre[9] was consulted. The City of Vienna maintains its own non-public application for image and Lidar data (Kappazunder[10]), where the surveys from 2020 are also available as OGD, but since the data is outdated and requires intensive pre-processing due to the large data volume, it was not used in this case. The spatial OGD datasets are generally available as dxf and, in some cases, as shp, allowing them to be opened and edited using standard CAD or GIS programmes, the aerial photos are available as jpeg. Some data can also be read directly via a web application (i.e. kanis) although this has to be done manually, it is the simplest method for manageable research areas.

In addition to digital data sets, analogue sources were consulted. Plans of all buildings adjacent to the streets, which can be accessed in the archives of the Building Department (Baupolizei – MA37), enable the three-dimensional construction of the façades and, on the ground floor, the spatial structures behind them. Since these building plans are sometimes very old, there are often discrepancies to other datasets that become apparent when combining them. A common example is the representation of floor plans on a perfectly rectangular plot of land, even though in reality the lengths of the plot sides and angles of the corners vary. In these cases, abstraction and approximation of the information is necessary.

All data necessary for a qualitative analysis that has not been mentioned above was collected on site. This includes photographic documentation of the façades, which allows for the precise reconstruction of detailed structures such as placement and appearance of doors, windows, balconies and mouldings. In addition, all furniture in the public space was recorded and the use of the ground floor zone as perceived from the street was documented. For more accurate modelling of the street surface, kerbs and other height differences were also measured. The remaining data was checked against reality and corrected where necessary.

3.3 Towards a Street Space Model

Based on the information obtained from the review and with the results of the investigation of the challenges in mind, a framework for a semantically rich street space model was developed.

3.3.1 Spatial and Conceptual scope

Since street spaces are in some cases highly specialised for specific purposes and the relationships between different streets in the network lead to diverse dependencies, restrictions have been set for the area under consideration. Given that the analysis is aiming to focus on the individual street itself, all streets whose use and design is primarily guided by higher-level systemic considerations, such as transport axes or shopping streets, are therefore excluded for the time being. Thus, the framework was limited to the consideration of secondary streets that mainly reflect local needs and conditions.

[10] Description of the Kappazunder application (https://digitales.wien.gv.at/projekt/kappazunder/)

The smallest possible area of consideration that allows for the desired qualitative analysis and is therefore sufficient for the creation of the framework was determined in the next step. In order to perform the analysis, at least one street segment (i.e. from intersection to intersection) is needed to be able to identify the qualities present and their interrelationships. As corner situations hold a distinctive position within the urban fabric – historically significant functions were often situated on the ground floors of corner buildings. (Psenner 2023) Information regarding the hierarchies between different user groups can also be found at this intersection of different streets. It is essential that these intersections are also included in a 3D street model. The street segments to be examined therefore need to have intersections at both ends that creates a corner situation on both sides of the street (meaning T-intersections are not suitable end points). Since, in addition to the façades, the connections and relationships with the ground floor zone and its uses are particularly relevant to the quality, functionality and design of the street space (Tobisch/Psenner 2021, Psenner 2023), they are modelled in their entirety and their uses are also documented.

To ensure that the framework and modelling logic are able to represent a wide range of conditions, research streets from different eras of construction were selected (Gründerzeit, interwar period and present day).

3.3.2 Introducing the SSSEIC Method

The SSSEIC method framework structure makes use of various components from other concepts (such as BIM and CIM) and introduces new logic wherever no suitable elements exist. All of the aspects collected were divided into three categories: those that can be modelled within the area under consideration, those that apply to the entire street segment, and those that extend far beyond the spatial scope and must therefore be considered in a higher-level analysis. For clear identification, those groups were named modelling parameters, meta parameters and evaluation parameters.

The group of modelling parameters is further subdivided and structured hierarchically. While in building-related projects the IFC nested structure goes from project to site to building to storey to element, a different spatial organisation must be considered for the street space. For this purpose, the street space is divided into five different spheres: The street level itself (the surfaces of the street space and all its uses), the street furnishing (all objects that are located in the public space above the surface: lighting, traffic lights, signs, benches, etc.), the underground (everything below the streetlevel i.e. the pipes and cables), the building level (the facades and the ground floor zones including the uses), and ecology (all vegetation). These five groups were chosen on the one hand based purely on spatial considerations (e.g. separation of public space and its enclosing elements), and on the other hand because they represent the typical (main) areas of consideration for different experts, thus providing a logical basis for interdisciplinary collaboration. Also for this reason, ecology has been highlighted separately – it sometimes extends into several spatial spheres, but is addressed by one field and therefore forms its own unit.

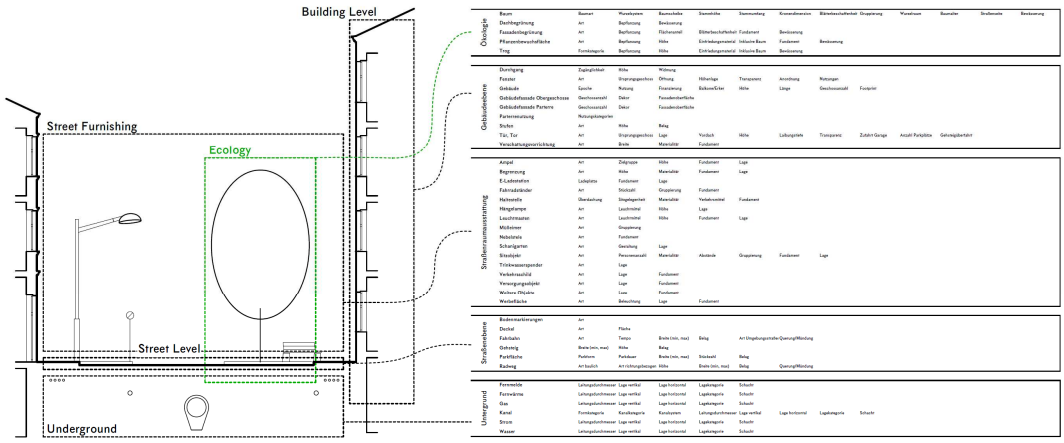

Fig. 3: The street is divided into different spheres within the framework. © Löschenbrand, Tobisch, Psenner

Within these spheres, there are sometimes further distinctions (individual buildings within the building level) followed by the individual modelling objects. These objects are equipped with a range of properties relating to the object type, dimensions, surface and context (there can always be several properties per category). Within the context category in particular, relevant information for qualitative analysis can be recorded that

relates not just to individual objects but rather to the relationships between them (e.g. a bench is situated under a tree)

With this SSSEIC framework, streets could already be accurately and comprehensively described. In the next step, this framework was therefore be put to the test to determine its applicability for the construction of a CIM on a micro-urban scale.

3.3.3 Modelling Programme

Currently, since there is no framework specifically tailored to semantic 3D modelling of streets, there is also no suitable programme available on the market. Therefore, in some of the cases already described (see 3.1.3), as well as in the present study, programmes that were originally intended for a different use were adapted for this purpose. This of course introduces its own set of problems and challenges, one of the most complex of which is circumventing the modelling logic built into the programmes.

After an initial test of CAD and GIS programmes to identify their respective limitations, CAD programmes were given preference over GIS programmes due to their capability to produce detailed representations. Since the lack of detailed and semantically rich street space models was the initial motivation for this study, the focus was ultimately placed on this aspect of modelling over others. A detailed representation usually leads to a restriction of the manageable research area, but this was not a concern for the initial three research streets and was therefore tolerated as a limitation for the time being. Therefore, all programmes that enable fine-scale representation were selected for closer consideration.

The input of GIS data was of minimal benefit due to the high proportion of manual work required and was therefore not a decisive criterion, which is why Vectorworks (a CAD programme with GIS data embedding) did not have an advantage over other CAD programmes. Ultimately, ArchiCAD was selected because its semantic database structure, based on freely selectable ‘properties’, allowed for a relatively high degree of customisation to create a proprietary framework. Nevertheless, there were certain limitations, which will be described in more detail below.

3.3.4 From Framework to Model

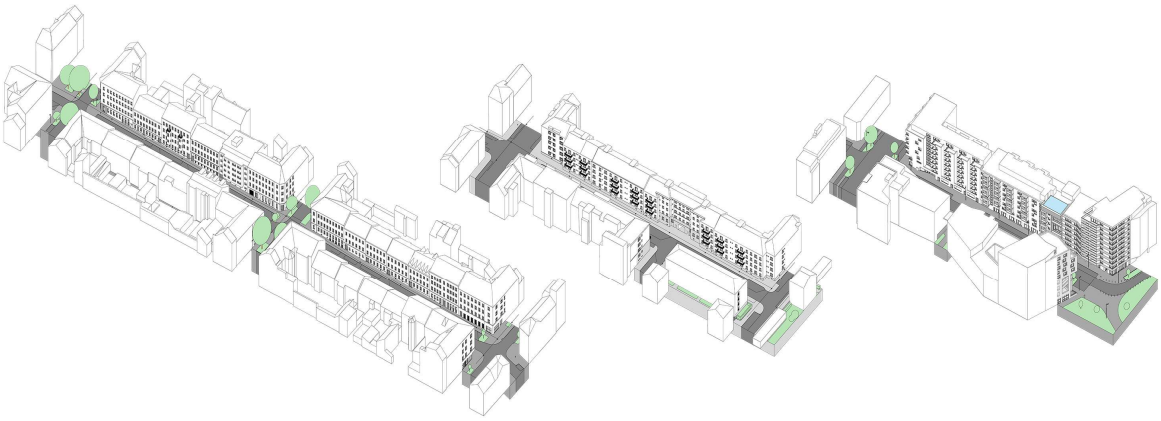

Fig. 4: Models of the three Viennese research streets © Tobisch, Löschenbrand, Psenner

For modelling purposes, ArchiCADs built-in logic, which is based on ifc standards was omitted as far as possible, therefore the parameters of the framework were established as properties. All modelled objects were assigned the properties, wherever the were known. For quantitative evaluation, apart from numerical values resulting from the geometry, only these properties were consulted. In addition, layers were used to display and hide elements during the modelling process, these were also based on the framework and are partially overlapping with the properties. In addition, layers were also used, which were also based on the framework and are partially congruent with the properties. They were mainly used to be able to show and hide elements, thus achieving a good view on the one hand, but also faster editability on the other. However, this revealed the first insurmountable issues with the logic inherent in the programme, as the layers cannot be freely selected for all elements. For example, doors and windows are designed as part of the wall and are therefore always located on the same layer. Similar challenges also arose with individual geometries, one example of which is the floor-by-floor structure of the model in the programme, which prevents openings that span several floors from properly displayed. To counter this problem, the façades above the ground floor

were no longer modelled floor by floor, but in their entirety with wall elements spanning multiple floors. Since the same applies to the placement of windows and doors in wall bends, workarounds that are also common for BIM models were used for the ground floor zone itself, for example, placing a second, empty opening in the adjacent wall. Another difficulty was the mesh tool, which is intended for modelling terrain. Here, the triangulation of the surfaces seems completely arbitrary, and the surface can only be clicked on at elevation points but not elsewhere on the surface. As already mentioned, the entire model had to be built manually. Since ArchiCAD is a building oriented software, the workflow was, as expected, easiest for architectural elements that are mainly horizontal or vertical, while other elements that are angled or curved, such as underground pipes and cables that are aligned with the eleveation of the street were tedious to create. Ultimately, the morph tool was frequently used, as it allows for free modelling with only minimal restrictions.. This was particularly useful for decorative elements on the façade and for furniture in public spaces. Initially, the amount of work involved is considerable because objects first have to be modelled, but the elements can be stored in the object library and used repeatedly, even across different files.
